Transient synovitis of the hip (TS) is a common childhood condition. While typically benign, it's crucial to be distinguished from more severe causes of acute hip pain in children. The aim of this study is to assess the level of knowledge of future rheumatologists on TS.
Material and Methods:
We conducted a cross-sectional descriptive study among Tunisian young rheumatologists. Participants were invited to answer an anonymous web-based questionnaire. The data were analyzed with descriptive statistics using the SPSS statistical package.
Results:
A total of 28 residents with a mean age of 28.9 [26-35] years, responded to the questionnaire. The sex ratio (M/F) was 0.12. Overall, 85.7% (n=24) of participants reported encountering less than five cases of TS during their medical training, while 14.3% (n=4) encountered between five and ten cases. Regarding the definition of TS, 85.7% (n=24) of residents picked the correct answer. Twenty-two participants (78.6%) correctly identified the age range associated with TS, while 24 participants (85.7%) indicated that this condition is more common in boys. Participants identified the following etiological factors of TS: recent infection (n=26), seasonal variation (n=16) and history of trauma (n=2).
According to 78.6% (n=22) of rheumatologists, this affection is considered a diagnosis of exclusion. Most of them (64.3%) acknowledged that the diagnosis is based on ultrasound findings, particularly the presence of hip effusion. Participants recognized the following conditions as potential differential diagnoses of TS: septic arthritis and osteomyelitis (n=28), slipped capital femoral epiphysis (n=21), fracture (n=13), and Legg-Calvé-Perthes disease (n=9). Most of rheumatologists (n=27) acknowledged rest and non-steroidal anti-Inflammatory drugs as effective treatments, while 14.3% of them (n=4) considered traction as a part of the therapeutic management for TS.
Conclusion:
Our study suggests that future rheumatologists have a good knowledge of TS. Therefore, implanting practical and motivational training methods appears essential to optimize their management of this paediatric condition.

P559

ARTIFICIAL INTELLIGENCE IN OSTEOPOROSIS MANAGEMENT: REVOLUTION OR ILLUSION?

C. Ben Ammar[1], H. Bettaieb[1], M. Boudokhane[1], M. H. Douggui[1], S. Bellakhel[1]

[1]Department of internal medicine , Internal Security Forces Hospital, Tunis, Tunisia

Objective:
Artificial intelligence (AI) is transforming medicine, including rheumatology. However, its application in osteoporosis (OP) management remains limited and poorly understood by practitioners. This study aims to explore rheumatologists' perceptions regarding the use of AI in OP management.
Material and Methods:
A cross-sectional descriptive study, with an anonymous questionnaire composed of 17 questions, designed with the Google Forms software, was sent to Tunisian rheumatologists. The data were analyzed with descriptive statistics using the SPSS statistical package.
Results:
A total of 62 participants responded to the questionnaire (56 women and 6 men). The mean age was 36.5 [25-70] years. Participants were as follows: 43.5% (n=27) residents, 46.7% (n=29) rheumatologists in the public sector and 9.7% (n=6) rheumatologists in the private sector. About 54.8% (n=34) of participants had already used AI in their clinical or research practice and 24.2% (n=15) of them had received training in it. Only 19.4% (n=12) of rheumatologists were familiar with AI applications in rheumatology.
According to participants, AI could improve the diagnosis of OP (77.4% of responses), the screening of OP (90.3% of responses) and patients 'monitoring (83.9% of responses). Moreover, 78.2% of rheumatologists believe that AI could identify at-risk patients through computerized records that consider risk factors and medical history. For management and monitoring, 74.2% of participants thought that AI could improve these aspects through smart mobile applications dedicated to patients.
Rheumatologists' expectations also include time-saving (72.6%), improved personalized follow-up (69.4%) and early detection of complications (64.5%). However, the challenges of using IA in OP are, in their opinion: professional resistance (61.3%), lack of training (59.7%), technology reliability (56.5%) and ethical and legal issues (53.2%).
Overall, 74.2% of rheumatologists believed AI could transform the management of OP in the next five years, while 25.8% remained skeptical. Furthermore, 93.5% of participants expressed interest in additional information on AI advancements applied to OP and wished to receive dedicated training.
Conclusion:
AI is seen as having significant potential for OP management, but efforts in training and awareness are needed to overcome the identified obstacles.

P560

CALCIUM AND VITAMIN D DISTURBANCES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

H. Bettaieb[1], E. Chemkhi[2], M. Ayari[3], C. Ben Ammar[1], M. Boudokhane[1], S. Ben Azouz[2], S. Bellakhel[1], M. H. Douggui[2], T. Jomni[3]

[1]Department of internal medicine , Internal Security Forces Hospital, Tunis, Tunisia, [2]Department of gastroenterology, internal Security Forces Hospital, Tunis, Tunisia, [3]Department of gastroenterology,internal Security Forces Hospital, Tunis, Tunisia

Objective:
During inflammatory bowel diseases (IBD), chronic inflammation can lead to poor absorption of calcium and vitamin D (VD). Moreover, variants of VD receptors were reported to contribute to susceptibility to IBD. The objective of our study was to assess calcium and VD metabolism in patients with IBD and establish their relationship with disease activity.

Material and methods:
A retrospective study was conducted, including patients with Crohn's disease (CD) and ulcerative colitis (UC). Clinical and biological data were collected: body mass index (BMI), hemoglobin (Hb), C-reactive protein (CRP) and bone profile. The severity of IBD flare-ups was assessed using Harvey-Bradshaw index (HBI) for CD and Mayo score for UC. Statistical analysis was carried out using SPSS software, with a significance threshold set at $p<0.05$.

Results:
Sixty patients (48 men and 12 women), with a mean age of 44 ± 15.9 years, were included. Median disease duration was 9.2[1-31] years. For CD patients, 37% of patients had the stenosing phenotype and 62% had ileocolic involvement. UC Phenotypes were as follows: pancolitis (15%), left-sided ulcerative colitis (13%) and distal ulcerative colitis (11%). IBD was associated with spondyloarthritis in 18.3% of cases. Mean HBI and Mayo scores were 2.8 ± 1.3 and 4.1 ±1.8 respectively.
Median Hb and CRP levels were 12[9-16]g/dl and 12[1-97]mg/dl respectively. Median serum calcium and phosphate levels were 2.29 [2.0-2.58] mmol/l and 0.78[0.67 -1.60] mmol/l respectively. Overall, 11% of patients had hypocalcemia. VD serum, measured in 25 patients, was abnormal in all patients: insufficiency (48%) and deficiency (52%).
Significant correlations were identified: a positive correlation between serum calcium and Hb (r=0.281 p=0,039), VD levels with BMI (r=0.469; p=0,024) and VD with Hb (r=0.5; p =0,019). Negative correlations were found between VD and respectively: HBI score (r=-0.536;p=0.039) and CRP(r=-0.38;p=0.05).

Conclusion:
Our study showed that anemia, inflammation and the severity of CD flare-ups are associated with VD deficiency. These findings emphasize the need for regular monitoring and early management of calcium and VD disturbances in patients with IBD.

P561

ADHERENCE TO ALLOPURINOL AND ASSOCIATED FACTORS AMONG TUNISIAN PATIENTS WITH GOUT

H. Bettaieb[1], A. Ben Amou[1], M. Boudokhane[1], I. Oueslati[1], R. Bourguiba[1], W. Helali[1], M. H. Douggui[1], S. Bellakhel[1]

[1]Department of internal medicine , Internal Security Forces Hospital, Tunis, Tunisia

Objective:
Gouty arthritis is a metabolic arthropathy caused by the deposition of monosodium urate crystals within joint spaces. Long-term urate-lowering treatment is essential to control serum uric acid levels (SUA) and prevent severe complications. This study aimed to assess allopurinol adherence among patients with gouty arthritis and identify the factors influencing this adherence.

Material and methods:
A cross-sectional study was carried out including patients with gout *(ACR/EULAR 2015 criteria)*. Treatment adherence was assessed using the "5-item Compliance Questionnaire for Rheumatology (CQR-5)." The questionnaire consists of five items measuring patients' perceptions of their treatment, with four response options on a four-point scale ranging from "Strongly disagree" (1) to "Strongly agree" (4). Patients were considered "good adherents" if their total score was greater than 8. Factors associated with good adherence were also studied. Statistical analysis was performed using SPSS software, with a significance threshold set at $p<0.05$.

Results:
Overall, 51 patients (34 men and 17 women) were included. The mean age of patients was 60.3 ± 10.9 years. Among patients, 37.3% (n= 19) were smokers and 27.5% (n=14) consumed alcohol. Comorbidities were as follows: 60.8% (n= 31) dyslipidemia, 52.9% (n=27) hypertension, and 47.1% (n=24) diabetes. Allopurinol was taken by 68.6% (n=35) of patients, with a mean dose of 155.7 ± 70.5 mg. Seven patients (13.7%) presented with kidney stones. The mean SUA was 468.1 ± 123.3 µmol/L. Among patients, 45.1% were classified as "poor adherents" and 54.9% as "good adherents." Good adherence was associated with non-diabetic patients ($p = 0.004$) and lower SUA ($p = 0.003$). No association was found between good adherence and the following parameters: age, gender, smoking, alcohol consumption and disease duration.

Conclusion:
Adherence to Allopurinol continues to be a significant challenge for patients with gouty arthritis, with a considerable number showing poor adherence. Providing proper therapeutic education is crucial to enhance adherence. The CQR-5 questionnaire might be an effective and useful tool for evaluating this adherence.

PODIATRIC MANIFESTATIONS OF RHEUMATOID ARTHRITIS: A STATUS REPORT IN A TUNISIAN POPULATION

H. Bettaieb[1], M. Dhifallah[2], S. Boussaid[2], S. Rahmouni[2], M. Boudokhane[1], K. Zouaoui[2], M. Abbes[2], S. Rekik[2], H. Sahli[2]

[1]Internal medicine, Internal Security Forces Hospital, La Marsa, Tunisia, [2]Rhumatology department, La Rabta Hospital, Tunis, Tunisia

Introduction:
Rheumatoid foot is a common manifestation of rheumatoid arthritis (RA) that can significantly impair quality of life. This study aims to evaluate the clinical and podiatric characteristics of this condition in a Tunisian population.
Methods:
This descriptive study included patients diagnosed with RA according to the 2010 ACR/EULAR criteria. Demographic, clinical, and podiatric data were collected.
Results:
The study included 40 patients with a mean age of 58.45 ± 10.85 years [range 31–83], and a female-to-male sex ratio of 5.6. The mean age at RA onset was 45.15 ± 10.9 years, and the mean disease duration was 13.33 ± 7.8 years. The mean DAS28 (CRP) score was 4.06 ± 1.38, the mean HAQ score was 1.44 ± 0.73, and the mean walking distance (MWD) was 386 meters. Twenty-seven patients (67.5%) had an MWD of <500 meters.
Foot pain, assessed using a visual analog scale (VAS), had a mean score of 6.17 ± 1.5. The most frequently affected areas were the forefoot (42.5%), ankle (35%), hindfoot (27.5%), and midfoot (20%). Deformities were present in 80% of patients, primarily hallux valgus (55%), claw toes (45%), and quintus varus (17.5%).
Podoscopic examination revealed plantar footprint abnormalities in 60% of patients: flat feet (40%), high-arched feet (20%), hindfoot valgus (22.5%), or hindfoot varus (12.5%). Excessive plantar pressure was observed in 52.5% of cases, and areas of insufficient pressure at the toes were noted in 47.5% of cases.
Conclusion:
The rheumatoid foot is characterized by pain, deformities, and podiatric abnormalities that significantly affect function and mobility. These findings highlight the importance of early and multidisciplinary management to mitigate these disabling conditions.

P563

POLYACRYLAMIDE HYDROGEL FOR KNEE OSTEOARTHRITIS: 5-YEAR RESULTS FROM A PROSPECTIVE STUDY

H. Bliddal[1], J. Beier[2], A. Hartkopp[3], P. Conaghan[4], M. Henriksen[1]

[1]The Parker Institute, Copenhagen University Hospital Frederiksberg, Copenhagen, Denmark, [2]Reumatolog Odense, Odense, Denmark, [3]A2 Rheumatology and Sports Medicine, Holte, Denmark, [4]University of Leeds & NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

Introduction
Polyacrylamide hydrogel (iPAAG), is CE marked for treating symptomatic knee osteoarthritis (OA), meeting the need for an effective, long-lasting, and safe non-surgical option. This study evaluates the efficacy and safety of a single 6 ml intra-articular injection of iPAAG in participants with moderate to severe knee OA over a 5-year post-treatment period.
Methodology
This prospective multicentre study (3 sites in Denmark) involved 49 participants (31 females) with an average age of 70 (range 44 – 86 years). They received a single 6 mL iPAAG injection. All participants provided informed consent and re-consented to continue after 1 year. The study followed GCP principles and was approved by Danish health authorities and local Health Research Ethics committees. One of the sites closed after the first year, while twenty-seven participants from the other sites completed the 5-year follow-up.
The study evaluated WOMAC pain, stiffness, function, and Patient Global Assessment (PGA) of disease impact. Changes from baseline were analysed using a mixed model for repeated measurement (MMRM). Sensitivity analyses were applied on the extension data, where the MMRM analysis was repeated only including patients in the extension phase and an ANCOVA model was used, replacing missing values at 5-years with baseline values (BOCF).
Results
The originally planned MMRM analysis including all available data from the 49 treated participants showed a statistically significant decrease in WOMAC pain scores (-14.6; 95% CI: -21.4; -7.7) from baseline to 5 years. The analysis only using data from the extension phase participants (n=27) showed similar results (-15.6; 95% CI: -22.3; -8.9). The BOCF analysis also showed a clinically relevant and statistically significant decrease in the WOMAC pain subscale from baseline (-9.1 units).
Seven new adverse events were reported between the 4-year and 5-year visits, with two reported as serious (acute myocardial infarction and femoral neck fracture). None of these seven events were related to the treatment.
Conclusions
This study shows that single injections of 6 ml intra-articular iPAAG were well tolerated and continued to provide clinically important effectiveness at 5-years after treatment.
Acknowledgements
The study was sponsored by Contura International A/S.

IMPACT OF ISLAMIC PRAYER PRACTICE ON KNEE OSTEOARTHRITIS

H. Boussaa[1], M. Ben Messaoud[1], S. Miladi[1], Y. Makhlouf[1], K. Ben Abdelghani[1], A. Fazaa[1], A. Laatar[1]

[1]Mongi Slim Hospital, Tunis, Tunisia

Introduction :
The relationship between religious practices and health has

gained increasing interest in recent years, highlighting the potential impact of beliefs on the physical and psychological well-being of patients. Studying the influence of Islamic prayer on degenerative rheumatic conditions holds particular significance.
The objective of this study was to evaluate the impact of daily Islamic prayer practice on knee osteoarthritis.

Methods :

This was a cross-sectional study including patients diagnosed with knee osteoarthritis according to the ACR 1986 criteria. Parameters related to knee osteoarthritis were collected, including disease duration, pain assessment using the visual analog scale (VAS), walking distance, Lequesne index, and radiological classification. Participants were also surveyed about the modalities of their religious practices. Statistical significance was set at $p<0.05$.

Results :

A total of 47 female patients were included. The mean age was 61 years [40–80], and the average body mass index (BMI) was 29 kg/m² [21–36]. Forty percent of participants were unemployed. Occupations involving prolonged standing were noted in 27% of cases, prolonged sitting in 12%, and sustained physical activity in 14%.
Twelve percent of patients engaged in regular physical activity. Twenty-nine percent were diabetic, 42% hypertensive, and 23% had dyslipidemia.
The mean pain VAS was 3/10 [0–9], with an average walking distance of 864 m [100–2000]. The mean Lequesne index was 7 [0–19]. According to the Kellgren-Lawrence classification, 44% of participants were at stage 2, 32% at stage 3, 15% at stage 1, and 9% at stage 4. Analgesics were prescribed in 89% of cases and NSAIDs in 27%. Corticosteroid injections and viscosupplementation were prescribed in 10% and 8% of cases, respectively. No patient had undergone total knee replacement.
All participants practiced Islamic prayer. The mean age at the onset of prayer practice was 36 years [12–66], with an average duration of 26 years [2–50]. On average, participants performed 9 prayers [5–20] per day.
No correlation was found between the duration of prayer practice and either pain VAS or Lequesne index. However, a significant correlation was observed between the duration of prayer practice and walking distance ($p<0.001$), as well as the radiological stage of osteoarthritis ($p<0.001$). The number of prayers was positively correlated with pain VAS ($r=0.1$, $p<0.001$), Lequesne index ($r=0.1$, $p<0.001$), and radiological stage ($p<0.001$).

Conclusion :

This study underscores the need for an integrated and holistic approach to health that considers individuals' physical, cultural, and religious dimensions. Targeted interventions aimed at adapting prayer postures to alleviate pain may contribute to improving the quality of life and well-being of individuals within the Muslim community.

P566

ASSOCIATION OF RISK FACTORS WITH FALLS IN MIDDLE-AGED PARTICIPANTS: A CROSS-SECTIONAL STUDY

H. Chi-Di[1], Y. Chen-Cheng[2]

[1]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung City, Taiwan, [2]Department of Occupational Medicine, Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University, Kaohsiung City, Taiwan

Objectives
We aim to explore the association between demographic, behavioral, physical performance, and self-reported factors and falls in middle-aged outpatients at an urban hospital.
Material and Methods
This cross-sectional study was conducted at a single urban hospital, involving 179 participants aged 45–65 years. Data on demographics, fall history, and behavioral factors were collected using structured questionnaires. Physical performance was assessed using the Timed Up and Go test. Statistical analyses, including independent t-tests and logistic regression, were performed to examine associations between these factors and self-reported falls in the past year.
Results
Among the 179 participants, 13.4% reported at least one fall in the past year. Logistic regression analysis identified female gender as significantly associated with increased fall risk (Odds Ratio [OR] = 5.05, 95% Confidence Interval [CI]: 1.11–22.96, p = 0.036). Longer Timed Up and Go test completion times were significantly associated with a higher risk of falls (OR = 2.83, 95% CI: 1.18–6.81, p = 0.019). Other variables, such as age and self-reported health conditions, showed no significant associations with falls.
Conclusions
Female gender and longer Timed Up and Go test completion times are significantly associated with falls in middle-aged outpatients. Improving physical performance, particularly among women, could help reduce fall risks. Further research is warranted to validate these findings and refine prevention strategies.
Disclosures: All authors declare no conflict of interests.

BENEFITS OF A DEMINERALIZED BONE MATRIX IN OSTEOPOROTIC INTERTROCHANTERIC FEMORAL FRACTURE PATIENTS

H. Cho[1], W. Chung[2], E. Choi[2]

[1]Department of Orthopedic Surgery, Gwangju Veterans Hospital, Gwangju, South Korea, [2]Department of Orthopedic Surgery, St Garollo Hospital, Suncheon, South Korea

Objective: Osteoporosis causes various fixation failures in patients with intertrochanteric fractures. This study aimed to investigate the effect of a demineralized bone matrix (DBM) for

cancellous or cortical bone defects on internal fixation in older osteoporotic patients with intertrochanteric fractures.
Materials and Methods: Among patients with intertrochanteric fractures who underwent surgical treatment from January 2019 to December 2023 at a facility, 171 patients were AO/OTA type 31-A1 and type 2 fractures which are considered relatively stable. The patients were grouped based on DBM use (Group A: DBM use, Group B: DBM non-use), and their clinical and radiology results were analyzed retrospectively. The patients were then subdivided into Group A-a and -b after removing factors that could cause treatment failures, such as the reduction status and location of the helical blade, and then further subdivided (Group A-a-1/2/3/4 and Group B-b-1/2/3/4) according to cancellous or cortical bone defects that could accompany intertrochanteric fractures. The time to full weight-bearing (FWB) and Harris hip score (HSS) 3 months after surgery in these subgroups were investigated.
Results: There was no significant difference in the clinical radiology results and complications between Group A and Group B. However, the time to FWB (p<0.001) and HSS (p=0.029) were significantly superior in Group A. In Group A-a with DBM use, after removing the risk factors for intertrochanteric fracture failure, the time to FWB (p=0.055) was close to the significance level, and HSS (p=0.036) was significantly superior. In Group A-a-1 (cancellous defect only) and Group A-a-3 (cancellous and cortical defect), the time to FWB (p=0.088, 0.052) was close to the significance level, and the HSS (p=0.039, 0.018) was significantly superior when DBM was used.
Conclusion: In patients with intertrochanteric fractures of AO/OTA type 31-A2.3 or less, if stable reduc tion and firm fixation are achieved, selective DBM use may help early recovery after surgery.

P568

RISK FACTORS ASSOCIATED WITH THE INCIDENCE OF FRACTURES IN GLUCOCORTICOID TREATED PATIENTS

H. Florez[1], K. Cajiao[1], J. L. Carrasco[2], J. Hernández-Rodríguez[3], A. Muxi[4], S. Prieto-González[3], M. C. Cid[3], A. Mocritcaia[1], A. Monegal[1], N. Guañabens[1], P. Peris[1]

[1]Metabolic Bone Diseases Unit. Department of Rheumatology. Hospital Clinic, University of Barcelona., Barcelona, Spain, [2]Biostatistics, Department of Basic Clinical Practice, University of Barcelona, Barcelona, Spain., Barcelona, Spain, [3]Vasculitis Research Unit, Department of Autoimmune Diseases, Hospital Clínic, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain., Barcelona, Spain, [4]Department of Nuclear Medicine. Hospital Clinic, University of Barcelona., Barcelona, Spain

Objective
Our group has previously reported the prevalence and risk factors associated with the development of osteoporosis (OP) and fractures (fxs) due to chronic glucocorticoid (GC) treatment in a cohort of 127 patients with autoimmune diseases[1]. After clinical assessment, antiosteoporotic treatment (AOT) was prescribed according to clinical practice guideline recommendations.
We aimed to analyze the incidence of new fxs in this cohort at 5 years of follow-up, adherence to the AOT and identify risk factors related to the development of new fragility fxs (FF).
Material and Methods
The cohort of 127 patients was re-evaluated after 5 years of follow-up. The clinical data collected included: incidence and location of new and previous FF (vertebral fractures [VF]+peripheral fxs), dose and GC-treatment duration and/or time since discontinuation, anthropometric data, adherence to AOT, bone mineral density BMD analysis (DXA; defining OP as a T-score ≤-2.5), trabecular bone score (TBS) (defining degraded microarchitecture [DMA] as <1.230), dorsolumbar X-ray (assessing VF) and baseline FRAX risk (GC-adjusted), among others.
Results
Of the 127 patients in the initial study, 109 (18 deaths) were re-evaluated, 66.1% being women. The mean age was 65.4±18.3 years and they were treated with a median GC dose of 2.5 [0-5] mg/day (25.7% ³5mg/day) for 76 months; 48 (44%) patients had discontinued GC treatment 31 [8.88-49.2] months before evaluation.
AOT was prescribed to 81 patients in the baseline assessment, with 38.27% (31/81) of the patients currently continuing this treatment.
During follow-up, 13/109 patients (11.9%) presented fragility fxs (FF), 9/13 were VF and 7/13 were peripheral. Patients with new VF were older (88 vs.67 years, p=0.006), with higher baseline FRAX risk (3.6 vs.2.3, p=0.037 and 12.7 vs.7, p=0.017 for hip and FMOP, respectively), with a longer AOT discontinuation period (p=0.03), higher frequency of previous VF (OR 4.83; 95%CI 1.04-21.3, p=0.039) and hip fx in parents (OR 9.63; 95%CI 1.79-56.7, p=0.003). Similar results were found when analyzing the FF, except for the FRAX risk; the number of falls in the previous year were associated with an increased risk of peripheral fxs (OR 2.03; 95%CI 0.99-4.18, p=0.034), especially ≥2 falls (OR 10.4; 95%CI 1.18-94.3, p=0.044). Neither BMD nor TBS values were related to the development of new FF.
Conclusions
Age, history of previous VF, family history of hip Fx and falls in the previous year were the main risk factors related to incident fxs during the follow-up. In addition, a higher baseline FRAX risk and longer AOT discontinuation period were also associated with fx development, indicating the importance of evaluating these factors in these patients.

UTILITY OF VERTEBRAL FRACTURE ASSESSMENT (VFA) FOR THE IDENTIFICATION OF VERTEBRAL FRACTURES IN GLUCOCORTICOID-INDUCED OSTEOPOROSIS

H. Florez[1], A. Muxi[2], J. Hernández-Rodríguez[3], J. L. Carrasco[4], S. Prieto-González[3], A. Mocritcaia[1], M. C. Cid[3], A. Monegal[1], N. Guañabens[1], P. Peris[1]

[1]Metabolic Bone Diseases Unit. Department of Rheumatology. Hospital Clinic, University of Barcelona., Barcelona, Spain, [2]Department of Nuclear Medicine. Hospital Clinic, University of Barcelona, Barcelona, Spain, [3]Vasculitis Research Unit, Department of Autoimmune Diseases, Hospital Clínic, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain., Barcelona, Spain, [4]Biostatistics, Department of Basic Clinical Practice, University of Barcelona, Barcelona, Spain., Barcelona, Spain

Objective

Glucocorticoid-induced osteoporosis (GIOP) is one of the most common forms of secondary osteoporosis (OP) and up to 50% of the patients may develop fractures (Fx), vertebral Fx (VF) being the most common. X-ray is the gold-standard diagnostic test, although VF can be identified by VFA using DXA when bone mass is measured, making it particularly useful for assessing GIOP.

We aimed to analyse the usefulness of VFA in identifying VF in patients treated with glucocorticoids (GCs) versus X-ray.

Material and Methods

127 patients on chronic GC treatment (≥5mg/day) were included (mean age 62±18 years, 63% women) in this cross-sectional study. All patients underwent dorsolumbar X-ray to assess VF (using Genant criteria[1]) and DXA (Lunar Prodigy) to analyse VFA from T4 to L4. Concordance between the two techniques was analysed with the kappa index: a value ≥0.41 was considered moderate, ≥0.61 substantial and ≥0.81 almost perfect. The sensitivity and specificity of VFA compared with X-ray were also assessed. Discordant cases were re-evaluated and consensus was achieved by two independent observers, also analysing the reasons for discordance.

Results

Of the 127 patients, X-ray showed at least one VF in 21 (16.6%) patients with a total of 39 VF. The Table shows the concordance results for VFA compared to X-ray for each vertebra, including the true positive (T+ [VFA+ and X-ray+]), false negative (F- [VFA- and X-ray+]), false positive (F+ [VFA+ and X-ray-] and true negative (T- [VFA- and X-ray-]) values.

Vertebra	T+	F-	F+	T-	Kappa
T4	0	1	2	124	-0.011
T5	1	3	3	120	0.226
T6	1	0	1	125	0.663
T7	1	1	2	123	0.388
T8	0	2	2	123	-0.016
T9	0	1	2	124	-0.011
T10	3	0	2	122	0.742
T11	5	4	1	117	0.647
T12	2	4	2	119	0.376
L1	5	1	0	121	0.905
L2	0	2	0	125	0.000
L3	0	1	3	123	-0.012
L4	0	1	1	125	-0.008

Concordance was poor for most of the vertebrae analysed, with high kappa index variability. Similarly, concordance by vertebral segments was moderate at T9-T12 and L1-L2 (k= 0.536 and 0.513 respectively) and low at T4-T8 (k= 0.245). Overall concordance was low (k= 0.444) with a low sensitivity (46%) but high specificity (99%). The main causes of discordance were vertebral deformities due to degenerative changes and scoliosis, and definition problems in the upper thoracic vertebrae (T4-T8).

Conclusions

VFA has a low sensitivity for identifying VF in GC-treated patients. However, its high specificity allows correct identification of subjects with VF and thus those who require anti-osteoporotic treatment. Nevertheless, concomitant performance of a radiological study is recommended in these patients.

THE EFFECTIVENESS OF OSTEOPOROSIS SELF-MANAGEMENT COURSE TO PROMOTE LONG TERM HEALTH BEHAVIOR

H. Ilkanheimo[1], T. Rikkonen[2], S. Nukarinen[3], A. Selkama[1], J. Lohikivi[1], A. Holm[1]

[1]Finnish Osteoporosis Association, Helsinki, Finland, [2]Kuopio Musculoskeletal Research Unit, Institute of Clinical Medicine, University of Eastern Finland, Kuopio, Finland, [3]Tampere University, Tampere, Finland

Objective

Around 336,000 people have osteoporosis in Finland. Annually, 45,000 osteoporotic fractures with nearly 9,000 hip fractures cause a significant economic burden and impair quality of life.

Finnish Osteoporosis Association organizes courses which aim to strengthen self-management of osteoporosis by promoting knowledge, motivation and health among the participants. The course consists of five three-hour group sessions over a 10–14-week period.

The aim of the study was to examine the effectiveness of Osteoporosis Self-Management Courses in Finland. A post-course survey was conducted for the participants regarding their initial health behavior changes and their persistence for 3 to 6 months after the course ended.

Material and Methods

The results are based on cross-sectional survey data between

January 2021 to July 2024. The data consisted of 397 course participants, with 390 women and 7 men, with the mean age of 69.4 years. A total of 316 individuals responded to the post-course survey. The survey included 15 questions consisting of self-management of osteoporosis, resources, perceived physical function, motivation and commitment to self-management of osteoporosis.

Results

Altogether, 96% of the responders reported at least one change in their health behavior during the self-management course. The results were persistent in the follow-up surveys. Most significant changes were seen in increased protein intake (74%) and physical exercise (69%). The least changes were observed in the responders' meal patterns (28%). The responders reported increased knowledge (+36%), skills (+32%), and resources in osteoporosis management (+14%) and perceived physical function (+14 %). In addition, motivation and commitment to self-management of osteoporosis increased during the course, either somewhat or significantly (100%).

Conclusion

The Osteoporosis Self-Management Course can be considered an effective tool to achieve better management of the disease and persistent changes to health behavior among the participants.

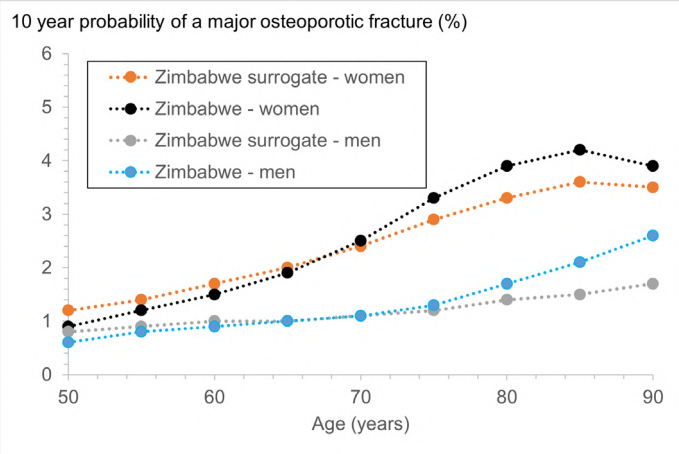
Objective Zimbabwe has previously relied on a surrogate FRAX® model for fracture risk assessment, using fracture incidence from South Africa. Data on the incidence of hip fracture have recently become available for Zimbabwe. Our aim was to develop a corresponding country-specific FRAX® tool from these data and compare fracture probabilities with the previous surrogate model.

Methods Numbers of hip fractures (ICD 10: S72.0, S72.1, S72.2) were retrieved from seven hospitals in Harare Province in Zimbabwe for two years (October 2021 – October 2023). These data were used to derive age- and sex-specific incidence of hip fracture in Zimbabwe residents and, combined with national mortality rates (United Nations (UN), 2020-2024), were used to create a FRAX® model for Zimbabwe. The 10-year probability of a major osteoporotic fracture (MOF) was used to compare the Zimbabwe model and the previous surrogate FRAX model for Zimbabwe. Examples are given for individuals with no clinical risk factors, body mass index (BMI) 25 kg/m^2, and unknown bone mineral density (BMD). The hip fracture incidence and UN population data were used to calculate the estimated number of fractures nationally in 2020 and 2050.

Results In total 243 hip fractures were identified (133[54.7%] female). The Zimbabwe model gave similar 10-year fracture probabilities for men and women compared to the previous surrogate model for Zimbabwe (figure). There were very close correlations (r=0.99) in fracture probabilities between the surrogate and authentic models, so that the use of the authentic Zimbabwe model had little impact on the rank order of risk. When the fracture incidence from Harare was applied to the population of Zimbabwe, it was estimated that 1030 hip fractures arose in 2020 in individuals over the age of 50 years, with a predicted increase by approximately 3.1 times to 3283 in 2050.

Conclusion The FRAX model should enhance the accuracy of determining fracture probability among the Zimbabwe population and help guide treatment decisions.

Figure The 10-year probability of a major osteoporotic fracture (%) for an individual with no clinical risk factors, BMI 25 kg/m^2, and BMD unknown.



P573

ASSESSMENT OF A MACHINE LEARNING MODEL FOR EARLY FRACTURE RISK PREDICTION IN CANCER PATIENTS RECEIVING OSTEOPOROSIS CARE

H. Koyanagi[1], S. Tsujino[2], C. Sawamura[3], T. Gokita[3]

[1]Department of Rehabilitation/ Saitama Cancer Center, Saitama, Japan, [2]Institute of Science Tokyo/ Orthopaedic department, Tokyo, Japan, [3]Department of Orthopaedic/ Saitama Cancer Center, Saitama, Japan

Background: Cancer patients undergoing treatments like chemotherapy, hormone therapy, and corticosteroids, or experiencing decreased physical function, face a higher risk of osteoporosis and related fractures. Fractures in these patients can disrupt treatment and negatively impact quality of life, making early risk prediction and preventive measures critical. In this study, we utilized data from our cancer osteoporosis outpatient clinic to develop and validate a machine learning model with PredictionOne® to assess fracture risk.

Methods: The study included 279 cancer patients who attended our osteoporosis clinic from 2021 to 2023. Data was divided into a training set (189 patients) and a validation set (90 patients). Using PredictionOne® (Sony Network Communications Inc.), we developed a model based on patient demographics and clinical information, including age, gender, cancer type, previous fractures, height, weight, BMI, hip YAM score, TBS score, dental visit history, post-visit dental collaboration, follow-up duration, and cancer-related mortality. Fracture outcomes in the validation group were used to assess model accuracy.

Results: The model showed a weak positive correlation (correlation coefficient: 0.38) between predicted and actual fracture occurrences. Sensitivity and specificity were recorded at 1.0 and 0.89, respectively, indicating the model's effectiveness in identifying fracture risks with some limitations.

Discussion: Although the model showed promise in identifying fracture risk among cancer patients, the weak correlation and risk of false positives highlight the need for improved accuracy. Additional clinical features and refined feature selection may enhance predictive performance in future applications.

Conclusion: The PredictionOne®-based machine learning model demonstrated potential as a predictive tool for fracture risk in cancer patients. However, further refinement and larger datasets are essential to improve its clinical utility.

P574

GARRÉ OSTEOMYELITIS: AN ATYPICAL NEW REPORT

H. Lassoued[1], S. Cherix[2], G.-R. Gonzalez-Rodriguez

[1]rheumatology department, Lausanne, Switzerland, [2]orthopedics department, Lausanne, Switzerland

Background

Garré sclerosing osteomyelitis is a rare condition with limited cases reported in the literature. It predominantly affects children and young adults, with the mandible being the most involved site. The diagnosis of Garré osteomyelitis is one of exclusion, as its imaging findings overlap with those of bone osteosarcoma and other aggressive conditions, including osteoid osteoma, Ewing sarcoma, and eosinophilic granuloma.

This report describes a novel case of Garré osteomyelitis involving the iliac crest, successfully treated with bisphosphonates.

Abstract

A 24-year-old patient presented with complaints of persistent pain in the right iliac crest region, without an identifiable triggering factor. Her medical history was notable for familial Leber's disease, left-sided hypoacusis due to tympanic membrane perforation at age three, a pineal brain cyst monitored by neurosurgery since 2019, and chronic migraines since 2017.

The pain originated six years earlier with an inconsistent pattern, transitioning from minimally symptomatic phases to persistent pain, exacerbated particularly at night. She also reported hyperalgesia phases where even light contact on the iliac crest was intolerable. Notably, she experienced significant weight loss of 25 kg over two months in 2016. A recent career change coincided with worsening pain in the iliac crest and hip region.

Clinical examination revealed a limp, but Trendelenburg sign was negative. Palpation of the right iliac crest elicited excruciating pain, while the left side was painless. Both hips had full and preserved mobility. Imaging studies, including a pelvic CT scan, lumbar and pelvic MRI, and whole-body MRI, showed hyperostosis lesions in both iliac wings. The inflammatory marks were normal. Histopathological analysis showed hyperostosis with thickened bony trabeculae, focal chronic and acute inflammation, and remodeling of the medullary stroma with edema. Immunohistochemistry using CD138 confirmed the presence of plasma cells, leading to a diagnosis consistent with Garré osteomyelitis.

Based on a literature review, treatment with bisphosphonates was initiated. The patient experienced complete pain relief after the first injection of Bonviva (ibandronate) 3 mg.

Conclusion

This case highlights the importance of histopathological findings and the exclusion of common differential diagnoses in establishing the diagnosis of Garré osteomyelitis. Bisphosphonates proved to be a promising therapeutic option, demonstrating efficacy in alleviating pain in this patient. Further studies are warranted to explore the broader applicability of bisphosphonates in similar cases.

P575

HEREDITARY MULTIPLE EXOSTOSES: CLINICAL FEATURES AND COMPLICATIONS IN AN ADULT COHORT

H. Lassoued[1], A. Bregou[2], S. Cherix[3], G.-R. Gonzalez-Rodriguez[1]

[1]rheumatology department, Lausanne, Switzerland, [2]pediatric orthopedisc department, Lausanne, Switzerland, [3]orthopedics department, Lausanne, Switzerland

Background.
Hereditary multiple exostoses (HME) is one of the most common benign musculoskeletal disorders. It is caused by genetic disorder with an autosomal dominant pattern of inheritance, characterized by the presence of at least two osteochondroma bony outgrowths. While it is generally considered as benign disorder, complications can significantly impact the disease outcome. These complications include nerve entrapment, compression, and malignant transformation into chondrosarcoma.
The objective of our study was to describe the clinical features of patients with HME and to determine the frequency of associated complications in this condition.
Methodology.
We conducted a retrospective study including adult patients with HME. Data recorded included sociodemographic features and disease characteristics (clinical manifestation, complication, involved sites). Radiographic data were also collected.
Results:
We included 21 patients with HME comprising 7 women and 14 men. The median age of the cohort was 43 years (range: 18–84), and the median age of diagnosis was 6 years (range: 2–14).
Most patients underwent surgical ablation of osteochondromas during childhood, with several interventions ranging from 0 to 9. Notably, 43% of patients inherited the mutation from their maternal family.
Seven patients were asymptomatic, and 14 reported clinical manifestations including arthralgia, articular limitation, and legs discrepancy (7, 14 and 4 patients, respectively).
The radiological findings showed the Madelung deformity in 6 patients (28.5%) and bilateral coxa vara in all patients.
Whole-body MRI revealed a peripheral distribution of osteochondromas in all patients. Axial involvement was identified in 13 patients, distributed as follows: pelvic involvement: 10 cases (47.6%), costal : 7 cases (33.3%) and rachis involvement: 2 cases (9.5%)
Regarding the HME complications, low-grade chondrosarcoma was diagnosed in 2 patients. Fibular nerve compression occurred in 1 case. Costal involvement was complicated by local respiratory dysfunction in one patient and local compression in another.
Conclusion:
The variability of the clinical patterns and the frequency of complications have been previously described in the literature. Our cohort underscores the need for close monitoring to prevent complications.

P576

ASSOCIATION BETWEEN PHYSICAL ACTIVITY AND SKELETAL MUSCLE MASS AND FUNCTION IN PATIENTS UNDERGOING PERITONEAL DIALYSIS : BASED ON THE ISOCHRONOUS SUBSTITUTION MODEL

H. Li[1], Y. Zhang[1], Y. Xiong[2], X. Zhang[2], Y. Zheng[3], X. Sun[4]

[1]School of Nursing, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Jiangxi Medical College, Nanchang University, Nanchang, China, [3]Peritoneal Dialysis Center, The First Affiliated Hospital, Nanchang University, Nanchang, China, [4]School of Nursing, Jiangxi Medical College, Nanchang University, Nanchang, China

Objective: This study aimed to explore the association between physical activity (PA) and skeletal muscle mass and function in patients undergoing peritoneal dialysis (PD) based on the isochronous substitution model (ISM).
Methods: From March 2023 to February 2024, a cross-sectional survey was conducted among 643 PD patients from two hospitals in China. Based on AWGS 2019, skeletal muscle index (SMI), handgrip strength (HGS), 5-times sit-to-stand test (5-STS) were performed to assess skeletal muscle mass and function respectively . The Chinese version of the Low-physical activity Questionnaire (LoPAQ) was used to assess the PA level.
Results: Light physical activity (LPA) was associated with higher HGS and shorter 5-STS time, but there was no significant relationship with SMI. The results showed that when 10 minutes of LPA was used to substitute for daytime inactivity, the SMI level of patients increased significantly (β=0.007, 95%CI: 0.001~0.013, P<0.05), the HGS increased significantly (β=0.118, 95%CI: 0.031~0.149, P<0.001), and the 5-STS time was shortened (β=-0.045, 95%CI: -0.078~-0.012, P<0.01). Also, when 10 minutes of walking was used to substitute for daytime inactivity, the 5-STS time of patients was also shortened (β=-0.077, 95%CI:-0.135~-0.019, P<0.05). Logistic regression showed that there was no significant statistical relationship between LPA, moderate-to-vigorous physical activity (MVPA), and the occurrence of sarcopenia. Ten minutes of LPA or MVPA or walking was substituted for daytime inactivity had no significant statistical effect on the occurrence of sarcopenia.
Conclusion: Clinician should encourage patients to replace sedentary or prolonged lying during the daytime with LPA or walking in an isochronous manner, which can improve skeletal muscle mass and physical performance function in PD patients. The Walking and LPA may have positive implications for the prevention and adjuvant treatment of PD-related sarcopenia.

P577

RETROSPECTIVE COMPARATIVE STUDY OF THE INTRAOPERATIVE FRACTURE GAP COMPRESSION IN THE TREATMENT OF INTERTROCHANTERIC FRACTURE USING PROXIMAL FEMORAL NAIL ANTIROTATION

H. M. Cho[1], W. C. Chung[2], E. H. Choi[2]

[1]Department of Orthopedic Surgery, Gwangju Veterans Hospital, Gwangju, South Korea, [2]Department of Orthopedic Surgery, St Garollo Hospital, Suncheon, South Korea

Objective: Intertrochanteric fractures can be treated using proximal femoral nail antirotation (PFNA). This study examined the clinical and radiological results of the intraoperative fracture compression.

Materials and Methods: Ninety-four patients underwent intraoperative compression (Group I), and 88 patients underwent natural sliding only (Group II). The patients were followed-up for more than two years. All patients met the following seven conditions: (1) AO/OTA 31-A1, A2 type intertrochanter fracture, (2) availability of compression of more than one cortical bone in the anterior or medial region of the fracture site under the preoperative imaging test, (3) Singh index grade ≥3, (4) blade position: center-center, center-inferior, (5) tip-apex distance <25 mm, (6) reduction status of good or very good, and (7) positive or neutral medial cortical support position with slightly valgus reduction.

Results: A slight tendency toward significant differences in acute phase pain between the two groups was observed at six weeks postoperatively (p=0.073). Twenty-four months after surgery, lateral extension of the PFNA helical blade between the two groups showed significant differences (p=0.017). Fracture gaps measured immediately after surgery showed significant differences (p=0.001), and a clear tendency for a significant difference in the average fracture union time was found (p=0.065).

Conclusion: Intraoperative fracture compression, intraoperative fracture compression appears beneficial to achieve a successful union of trochanteric fractures provided that all conditions are met to apply the method safely.

P578

DISCONTINUATION AND NON-PUBLICATION OF CLINICAL STUDIES ON OSTEOARTHRITIS (EXCLUDING KNEE JOINT) IN 8,931,447 PATIENTS

M. A. Abdelsalam[1], B. E. Badwy[2], O. El-Sedafy[2], M. T. Lasheen[2], O. S. El-Sayed[3], A. M. Hafez[4], M. A. Ali[2], M. R. Awad[1], H. M. Hafez[5]

[1]Rheumatology and Rehabilitation Dept., Faculty of Medicine, Misr Univ. for Science and Technology, Giza, Egypt, [2]Faculty of medicine, Misr university for science and technology, Giza, Egypt, [3]Faculty of Medicine, Zagazig University, Zagazig, Egypt, [4]Faculty of medecine, Damietta university, Damietta, Egypt, [5]Faculty of medicine, October 6th University, Giza, Egypt

Objectives: While knee osteoarthritis (KOA) has been extensively studied and remains a primary focus of osteoarthritis (OA) research, OA of other joints (hip, hand, ankle, and shoulder) receive comparatively less attention. Many clinical studies are discontinued or remain unpublished, which limits the availability of evidence to guide clinical practice. The lack of dissemination restricts the evidence base and may expose patients to medical interventions without proven benefits. This study aims to assess the prevalence, characteristics, and publication history of non-KOA clinical studies and investigate reasons for their non-publication or discontinuation.

Methods: We conducted a comprehensive search of ClinicalTrials.gov for non-KOA studies up to January 12, 2025. We excluded studies completed within the last 24 months to allow for ongoing peer review. Published trials were determined through their NCT identifiers. We collected and analyzed data on gender, age, study type, funding source, intervention type, enrollment size, and location were extracted. Multiple logistic regression analyzed characteristics linked to unpublished or discontinued trials.

Results: A total of 1,456 registered osteoarthritis studies were reviewed, divided into 832 (57.14%) completed, 298 (20.47%) discontinued, and 326 (22.39%) remained with unknown status. Completed and discontinued studies were analyzed, including 862 interventional studies (76.9%) and 259 observational studies (23.1%). Among these, 298 were discontinued, with 9.7% of them being published despite being discontinued, and 35.9% of unknown studies were also found published. As for publication, Industry-funded studies were significantly more likely to be published than non-industry-funded studies (OR = 0.326, 95% CI: [0.213–0.497], p < .001), Studies with more than 100 participants were significantly more likely to be published than those with fewer than 100 participants (OR = 0.459, 95% CI: 0.3268 to 0.646, p <.001), and Studies using behavioral interventions were significantly more likely to be published than those using device interventions (OR = 2.950, 95% CI: 1.525 to 5.706, p < .001).

Conclusion: Non-KOA osteoarthritis studies are often discontinued or left unpublished, limiting the evidence base needed to guide clinical practice and improve patient outcomes. Factors such as funding source, enrollment size, and intervention type play a significant role in the likelihood of study completion and publication. Addressing these gaps through stricter regulatory policies, transparent reporting practices, and enhanced funding strategies is crucial to reducing research waste and advancing osteoarthritis management.

P579

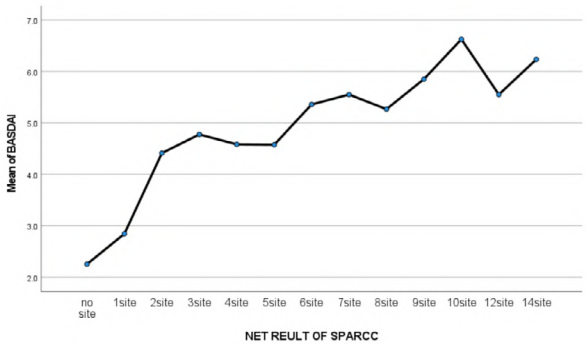
THE RELATIONSHIP BETWEEN ENTHESITIS INDICES AND DISEASE ACTIVITY PARAMETERS IN IRAQI PATIENTS WITH ANKYLOSING SPONDYLITIS

H. M. Omer[1]

[1]Anwar sheikha Medical city, Sulaimania , Iraq

Chapter Three : Results

Figure 5 : Relation between BASDAI and SPARCC.



p-value :<0.001

Figure 6: Relation between BASFI and SPARCC

Background: Ankylosing spondylitis (AS) is a chronic, progressive inflammatory rheumatic disease involving primarily the sacroiliac joints and the axial skeleton. It is characterized by back pain and progressive stiffness of the spine. Oligoarthritis of the hips and shoulders, enthesopathy, and anterior uveitis are common, patients with AS can experience significant long-term functional impairment and disability, with reduced quality of life and an increased risk of comorbid conditions.

Aim: The aim of this study was to investigate the relationship between both enthesitis indices Maastricht ankylosing spondylitis enthesitis score (MASES) and Spondyloarthritis Research Consortium of Canada (SPARCC) with disease activity in form of clinical and laboratory parameters in Iraqi patients with ankylosing spondylitis (AS).

Methods: A total of 101 patients aged between 18_60 years old with AS were enrolled in the study, disease activity was assessed by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional capacity by Bath Ankylosing Spondylitis Functional Index (BASFI), and enthesitis severity by Maastricht ankylosing spondylitis enthesitis score) MASES (index and Spondyloarthritis Research Consortium of Canada)SPARCC(index. The erythrocyte sedimentation rate (ESR) and serum C-reactive protein (CRP) levels of the patients were measured in the laboratory assessments.

Results: In this cross-sectional study, we included 101 ankylosing spondylitis patients with enthesitis. The mean age of patients was 37.2±8.3 years, (83.2%) were men and (16.8%) were women. The most frequent regions of enthesitis was L5 spinous process, according to MASES and VAchilles tendons, according to SPARCC and the less frequent were LT 7th costocondral joint and RT iliac crest according to MASES and LT lateral condyle according to SPARCC. There is an important, strong positive correlation between (MASES and SPARCC) and (General assessment by patient GAP and general assessment by Doctor GAD) .There was weak positive correlation between (SPARCC and MASES) and morning stiffness.

There was no correlation found between them (SPARCC and MASES) with laboratory parameters CRP, ESR and disease duration.

Conclusion: Iraqi AS patients had relatively severe enthesitis associated with the disease activity and severe functional impairment. The evaluation of enthesitis therefore remains a reliable tool in the assessment and outcome of AS.

P580

PREVALENCE OF OSTEOPENIA AND OSTEOPOROSIS IN FEMALES OF SULAYMANIAH CITY, KURDISTAN REGION OF IRAQ

H. Hassan[1], H. M. Omer[1]

[1]Anwar sheikha Medical city, Sulaimania , Iraq

Hawar Sardar Hassan /Afr.J.Bio.Sc. 6(13)(2024).1816-1825

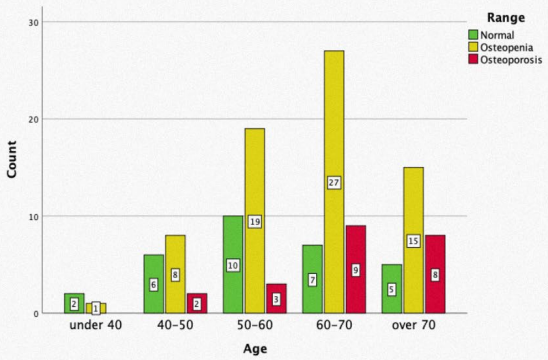


Figure No.02 Bone mineral density and T scores of patients with osteoporosis and osteopenia

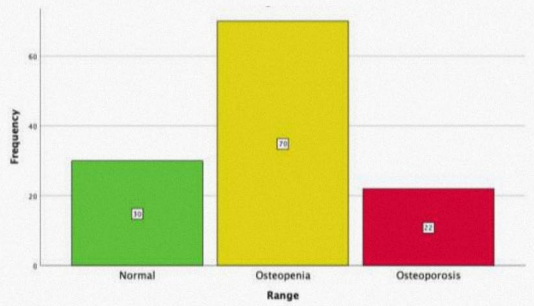


In the present study, 122 females are included, out of which 57.4% are found to have osteopenia and 18% are found to have osteoporosis. From this observational study, it is found that as the age progresses the risk for osteopenia and osteoporosis increases. In women going through menopause, the prevalence of osteopenia and osteoporosis has considerably increased.

Osteopenia is a clinical term referring to the condition of decreased bone mineral density which reflects the underlying damage occurring in the microarchitecture of the bone. A specific pattern of bone mineralization is seen with respect to person's age and gender right from birth to adulthood. A few researchers proved that after the age of 30, there will be a steady and natural

loss of bone mass as the age progresses. However, the bone mineralization maintenance is determined by hereditary factors, nutritional status, body mass and hormonal environment. The present study includes the measurement of bone density of female individuals by DEXA scan. The sample size includes 122 females from Sulaymaniyah of Kurdistan region, Iraq. The bone density is determined and compared with the T-score to check the prevalence of osteoporosis and osteopenia. Thus, obtained results are statistically analyzed by using SPSS software and age-wise distribution and trend of osteopenia and osteoporosis is obtained. The present investigation showed that as age progresses the risk for osteopenia and osteoporosis increases. The incidence of osteopenia and osteoporosis has risen significantly in the females with menopause. It is evidenced from the results that the women with the age below 40 are presented with osteopenia and the women above the age of 40 with osteoporosis. The maximum number of women presented with both osteoporosis and osteopenia is seen in age group ranging from 60-70 years of age. This investigation helps the medical team to focus on therapeutic management and lifestyle changes to be followed to lessen the chances of loss of bone mass. The recommendations include correction of calcium and vitamin D deficiency, cessation of smoking and alcohol consumption, consumption of balanced diet that include dairy products and exposure to sunlight.

P581

VERTEBRAL FRACTURES IDENTIFIED BY LATERAL SPINE DXA SCANS AND MORTALITY RISK IN ADULTS

H. Orces[1]

[1]Laredo Medical Center, Laredo, United States

Background

Vertebral fractures identified by radiographic morphometry are associated with increased mortality risk. However, there is scarce data regarding the association between vertebral fractures identified by lateral spine DXA scans and the mortality risk.

Methods

The present study was based on data from participants aged ≥ 40 years in the National Health and Nutrition Examination Survey (NHANES) cycle 2013-2014. Vertebral fracture assessment (VFA) was obtained during lateral spine DXA scans to provide fracture information for vertebrae T4-L4. Vertebral fracture severity was categorized according to Genant's semiquantitative technique and the NHANES 2019 public-use linked mortality files were used to determine mortality status.

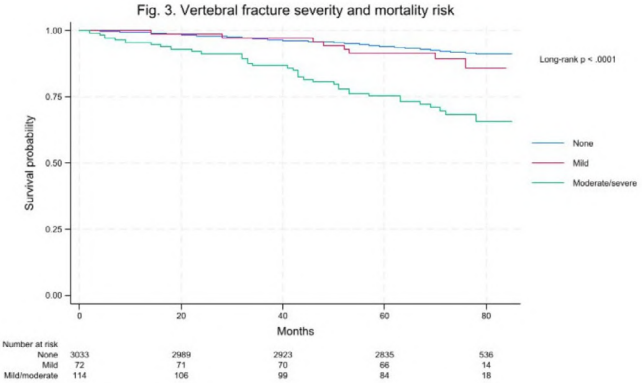
Results

Of 3,219 participants, the crude prevalence of vertebral fractures identified by VFA was 5.5% (95% CI, 4.7-6.5). During a median follow-up of 71.0 months, 277 participants died, 18.2% (95% CI, 12.2-26.3) with vertebral fractures and 6.3% (95% CI, 5.0-8.0) without fractures (p < .0001). Cox regression analysis demonstrated that participants with moderate to severe vertebral fractures (> 25% height loss) were 1.9 times more likely to die compared with their counterparts without fractures (HR, 1.95; 95% CI, 1.14-3.32). Notably, among participants with a T-score of ≤ -1, those with moderate to severe vertebral fractures had a 2-fold higher mortality risk than those who did not (HR, 2.44; 95% CI, 1.31-4.54).

Conclusions

The severity of vertebral fractures identified by VFA was associated with greater all-cause mortality risk. This association was particularly accentuated in older adults and those with low bone mass.

Fig. 3. Vertebral fracture severity and mortality risk



P582

COMPARISON OF LUMBOPELVIC ROTATION MOTION ASYMMETRY BETWEEN INDIVIDUALS WITH AND WITHOUT CROSS-LEGGED SITTING POSTURE

H. S. Y. Han[1], K. O. Y. Kwon[1], A. I. K. Ahn[1]

[1]Yonsei university, Wonju, South Korea

Objective: This study compared the asymmetry of lumbopelvic rotation motion between individuals with and without habitual cross-legged sitting posture (CLSP), focusing on the transverse plane pelvic rotation angle (TrPRA) in the supine position, during the active straight leg raise (ASLR), and the range of motion (ROM) of active lumbopelvic rotation (ALPR).

Material and Methods: This cross-sectional study recruited 30 healthy participants, divided into a CLSP group (n = 15) and a control group (n = 15). The CLSP group consisted of individuals who sat in a knee-on-knee CLSP. A Smart KEMA motion sensor was used to measure the TrPRA in the supine position and during the ASLR. Additionally, the ROM of ALPR was measured in the side-lying position using equipment developed in the author's laboratory. Independent t-tests were used to examine group differences in the TrPRA in the supine position, the asymmetry index (AI) of the TrPRA during the ASLR, and the ROM of ALPR.

Results: In the CLSP group, the TrPRA was 1.50° ± 0.96° in the supine position, while the AI of the TrPRA during the ASLR and the ALPR ROM was 18.72% ± 12.66% and 13.21% ± 6.64%, respectively. The control group showed a TrPRA of 1.26° ± 0.94° in the supine position, an AI of 17.88% ± 14.16% for the TrPRA during the ASLR, and 7.06% ± 4.9% for the ALPR ROM. No significant differences were found in the TrPRA in the supine position or the AI of the TrPRA during the ASLR between groups (p > 0.05); however, the AI of the ALPR ROM differed significantly (p < 0.05).

Conclusion: This study found that individuals with habitual CLSP

exhibited greater lumbopelvic rotation asymmetry during active movements. Notably, a new side-lying measurement method minimized compensatory actions during ASLR, effectively revealing CLSP-related asymmetry. These findings suggest that habitual CLSP may contribute to musculoskeletal imbalances, highlighting the need for greater awareness among clinicians and individuals.

P583

IS THERE AN ASSOCIATION BETWEEN SARCOPENIA AND THE SEVERITY OF KNEE OSTEOARTHRITIS

S. Mhamdi[1], K. Zouaoui[1], R. Ben Othmane[2], S. Rahmouni[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department-La Rabta Hospital, Tunis, Tunisia, [2]National Institute of Nutrition, Tunis, Tunisia

Objective:
To determine whether there is an association between the impact of knee osteoarthritis (OA) and sarcopenia.
Material and Methods:
Female patients with knee OA meeting the ACR criteria were enrolled. Demographic, clinical, and paraclinical data were collected. Knee osteoarthritis severity was assessed using the Kellgren and Lawrence (KL) grading system, ranging from grade 0 (no OA) to grade 4 (severe OA).
The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) was used to evaluate the impact of knee OA. It is a self-reported instrument with 24 questions, each scored from 0 to 4. Three domains are assessed: pain, stiffness and physical function. The total score ranges from 0 (normal knee) to 96 points (severe disability in daily life).
To assess sarcopenia, muscle mass was quantified using the appendicular skeletal muscle mass index (ASMI), determined via Bioelectrical Impedance Analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). The ASMI was calculated by dividing the appendicular muscle mass by the square of height. Muscle strength was evaluated through a handgrip test using a dynamometer. A patient was considered sarcopenic when the ASMI was ≤ 5.5 kg/m² and grip strength was <16 kg.
Results:
A total of 31 female patients were included, with a mean age of 61±8 years [48-74]. The majority of patients (48.4%) were in stage II of the KL grading. The mean WOMAC score was 39 ±16 [11-67]. For the WOMAC, the mean pain, stiffness, physical function scores were 9±3[4-16], 2±1[0-6] and 27±12[6-48] respectively. The total WOMAC score was 39±16[11-67].
The mean handgrip strength was 11±4 kg [6 -23]. The mean ASMI was 8±1 kg/m² [5-9] measured by BIA and 7±1 kg/m² [4-9]by DEXA. Sarcopenia was detected in 9.7% (n=3) of participants.
No significant association was found between sarcopenia and the WOMAC score (p=0.4).
Conclusion:
This study found no significant association between sarcopenia and the severity or functional impact of knee osteoarthritis.

P584

EXPLORING THE ASSOCIATION BETWEEN OBESITY AND SARCOPENIA IN WOMEN WITH KNEE OSTEOARTHRITIS

K. Zouaoui[1], S. Mhamdi[1], R. Ben Othmane[2], S. Rahmouni[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department-La Rabta Hospital, Tunis, Tunisia, [2]National Institute of Nutrition, Tunis, Tunisia

Objective:
The aim of this study was to investigate whether there is an association between obesity and sarcopenia in women with knee osteoarthritis (OA).
Material and Methods:
We included female patients with knee osteoarthritis (OA) who met the ACR criteria.
Demographic, clinical, and paraclinical data were collected.
The severity of knee OA was assessed using the Kellgren and Lawrence (KL) grading system, which ranges from grade 0 (no OA) to grade 4 (severe OA). This classification evaluates joint space narrowing, osteophytes, sclerosis, and bone deformities.
Sarcopenia was identified by evaluating muscle mass and strength. Muscle mass was measured using the appendicular skeletal muscle mass index (ASMI) through Bioelectrical Impedance Analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). Muscle strength was assessed using a handgrip test with a dynamometer. The ASMI was calculated by dividing appendicular muscle mass by the square of height. Sarcopenia was diagnosed when the ASMI was ≤ 5.5 kg/m² and grip strength was <16 kg. Obesity was defined as a body mass index (BMI) ≥ 30 kg/m².
Results:
Thirty-one female patients were enrolled. The mean age was 61±8 years [48-74]. Diabetes was present in 19.4% (n=6) of participants, while 25.8% (n=8) had dyslipidemia. Eighty-point six percent had regular physical activity.
Knee OA was bilateral in 80.6% (n=25). Concerning the KL grading, the majority were classified as grade II (48.4%) or grade III (38.7%) according to the Kellgren-Lawrence (KL) grading system. The mean weight of the participants was 79.3±14 kg [42-105] with an average height of 156.4±7 cm [140-168]. The mean BMI was 32.4±5 Kg/m² [19-43] and obesity was observed in 64.5% (n=20) of patients.
Sarcopenia was observed in 9.7% (n=3). The average handgrip strength was 11±4 kg [6 -23]. The mean appendicular skeletal muscle index (ASMI) was 8±1 kg/m² [5-9] measured by BIA and 7±1 kg/m² [4-9]by DEXA.
Obesity was statistically associated with sarcopenia (p=0.014)
Conclusion:
This study showed a significant association between obesity and sarcopenia in women with knee osteoarthritis, highlighting the importance of addressing both conditions in patient management.

P585

IMPACT OF SELENIUM INTAKE ON SARCOPENIA IN FEMALE PATIENTS WITH RHEUMATOID OSTEOARTHRITIS

S. Mhamdi[1], K. Zouaoui[1], R. Ben Othmane[2], S. Rahmouni[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department-La Rabta Hospital, Tunis, Tunisia, [2]National Institute of Nutrition, Tunis, Tunisia

Objective:
The aim of this study was to investigate whether the selenium intake is associated with sarcopenia in female patients with rheumatoid osteoarthritis (RA).
Material and Methods:
We included female patients with RA meeting the ACR criteria. Demographic, clinical and paraclinical data were collected.
A nutritional survey was conducted to estimate daily selenium intake in 40 participants, with a sufficient intake level defined as ≥ 70 µg.
Muscle mass was assessed by evaluating the appendicular skeletal mass using both Bioelectrical Impedance Analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). Afterward, the appendicular skeletal muscle mass index (ASMI) was calculated by dividing appendicular muscle mass by the square of height. Muscle strength was evaluated through a handgrip test using a dynamometer.
Sarcopenia was confirmed when the ASMI was the ASMI was ≤ 5.5 kg/m² and handgrip strength was <16 kg.
Results:
Fifty-two female participants were included, with an average age of 58±8 years [40-76]. RA was
immunopositive in 92% (n=48) and erosive in 90% (n=47) of patients.
The participants had a mean disease duration of 9 ± 6 years [1-30]. Active RA with a DAS28-CRP > 3.2 was present in 90% (n=47) of patients. All of the patients had received at least one conventional treatment, and 40% (n=21) were treated with biologic therapy.
The average selenium intake in our population was 127± 54 µg [28-228] and it was insufficient in 15.4% (n=8) of patients.
The mean appendicular skeletal muscle index (ASMI) was 7.4 ± 1.5 kg/m² [5-11] by BIA and 6.5 ± 1 [4-9] kg/m² by DEXA. The mean handgrip test was 9.3 ± 5.6 kg [2-26]. Twenty percent (n=10) of participants had sarcopenia.
No significant correlation was found between daily selenium intake and sarcopenia (p = 0.182).
Conclusion:
This study found no significant association between selenium intake and sarcopenia in women with rheumatoid osteoarthritis.

P586

SHOULD THE PRESENCE OF OSTEOPOROSIS WITH KNEE OSTEOARTHRITIS INCITE THE SEARCH OF SARCOPENIA?

K. Zouaoui[1], S. Mhamdi[1], R. Ben Othmane[2], S. Rahmouni[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department-La Rabta Hospital, Tunis, Tunisia, [2]National Institute of Nutrition, Tunis, Tunisia

Objective:
To explore a potential association between osteoporosis and sarcopenia in woman with knee osteoarthritis (OA).
Material and Methods:
Female patients with knee OA who met the ACR criteria were enrolled in this study. We collected Demographic, clinical, and paraclinical data.
Knee osteoarthritis severity was classified using the Kellgren and Lawrence (KL) scale, ranging from grade 0 (no OA) to grade 4 (severe OA), based on joint space narrowing, osteophytes, and bone changes.
Bone densitometry was conducted to diagnose osteoporosis, defined as a T-score of ≤ -2.5 standard deviations at the lumbar spine and/or femoral neck.
To detect sarcopenia, muscle strength was assessed by a handgrip test using a dynamometer. Muscle mass was evaluated through the appendicular skeletal muscle index (ASMI), calculated by dividing appendicular muscle mass by the square of height. Appendicular muscle mass was measured using both bioelectrical impedance (BIA) and dual-energy X-ray absorptiometry (DEXA). Sarcopenia was confirmed if the ASMI was ≤ 5.5 kg/m² and the grip strength was < 16 kg.
Results:
Our study was conducted on 31 female participants with an average age of 61±8 years [48-74]. Nighteen percent (n=6) had a sedentary lifestyle.
Most participants were classified as grade II (48.4%) or grade III (38.7%) based on the KL grading scale.
Osteoporosis was present in 29% (n=9) of the participants while sarcopenia was detected in 10% (n=3).
The mean handgrip strength was 11±4 kg, [6 -23]. The average ASMI was 8±1 kg/m² [5-9] when measured by BIA, and 7±1 kg/m² [4-9] when assessed by DEXA.
There was no significant correlation between osteoporosis and sarcopenia in this population (p=0.144).
Conclusion:
According to our study, there is no link between osteoporosis and sarcopenia in patients with knee osteoarthritis.

P587

SEXUAL DYSFUNCTION IN RHEUMATOLOGY: A SURVEY OF TUNISIAN PHYSICIANS' KNOWLEDGE AND PRACTICES

E. Rabhi[1], S. Rahmouni[1], K. Zouaoui[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rabta hospital, rheumatology department, Tunis , Tunisia

Introduction :
Sexual dysfunction is a significant but often overlooked issue in the management of patients with rheumatological conditions. Despite its potential impact on quality of life, sexual health remains inadequately addressed in many clinical settings.
Objective :
This study aimed to assess the awareness and management of sexual dysfunctions among Tunisian rheumatologists and family physicians.
Methods :
A cross-sectional study was conducted among Tunisian healthcare professionals, including rheumatologists and family physicians with rheumatology training. Data were collected through a Google Forms questionnaire addressing knowledge, attitudes, and practices related to sexual dysfunction in rheumatological patients.
Results :
The study included 37 participants, comprising 29 rheumatologists and 8 family physicians. The mean age of participants was 29 [25 42] years. The mean years of practice was 4.14 [1 10] years. Among the participants, 26 were residents, 2 were specialist physicians, and 8 were hospital-university professionals.
Regarding formal training in sexual dysfunction, 29 participants (78%) reported that they had never received specific training on this topic during their medical education, while 8 (22%) had received some form of training. When asked about the adequacy of current medical education on sexual dysfunction in rheumatology, 32 participants (86%) felt that it was insufficient, while 5 (14%) believed it was adequate. Additionally, 36 participants (97%) acknowledged they lacked detailed knowledge about the effects of rheumatological treatments on sexual health, with only 1 participant (3%) feeling sufficiently informed.
In practice, the majority of participants (24, or 65%) stated they only address sexual health if the patient raises the issue first. A small number of participants (3, or 8%) regularly discuss sexual health with their patients, while 2 (5%) reported they never bring up the subject. The conditions most commonly associated with inquiries about sexual health included low back pain or sciatica (24 responses), hip pathology (16 responses), spondyloarthritis (20 responses), and rheumatoid arthritis (10 responses). Regarding when sexual health is addressed, 9 participants (24%) raised it during the initial consultation, 5 (14%) during follow-up visits, and 27 (73%) only if the patient mentions it.
Time constraints were identified as the primary barrier to discussing sexual health, with 30 participants (81%) citing this as a major challenge. Other barriers included personal discomfort (12 participants, or 32%), a lack of information about treatment options for sexual dysfunction (25 participants, or 68%), and patient reluctance or discomfort (21 participants, or 57%). When patients did raise sexual health concerns, 21 participants (57%) indicated they would explore the topic further, while 20 (54%) would refer the patient to a specialist. Regarding treatment adjustments based on sexual health concerns, 12 participants (32%) said they always adjust treatment, 19 (51%) do so occasionally, and 6 (16%) never modify treatment based on sexual health issues.
When sexual dysfunction was related to a rheumatological condition or treatment, 19 participants (51%) always referred the patient to a specialist, such as an andrologist, gynecologist, or sexologist. 16 participants (43%) referred depending on the severity of the dysfunction, while 2 (5%) never recommended specialist consultations. Regarding proactive discussions on sexual health, 20 participants (54%) agreed that it is essential to address the topic with rheumatology patients, while 17 (46%) felt it should depend on the individual patient's context.
Finally, when asked if the management of sexual dysfunction in rheumatological care should be improved, 35 participants (95%) agreed that there is significant room for improvement, while 2 participants (5%) felt that other issues should take priority over sexual health.
Conclusions :
This study highlights significant gaps in addressing sexual dysfunction among Tunisian physicians. Challenges include a lack of training, limited knowledge of treatment side effects, and barriers such as time constraints and patient discomfort. Improving education and resources, as well as adopting a more proactive approach, is crucial for better managing sexual health in rheumatology care.

P588

EXPERIENCE IN MANAGING TUBERCULOSIS IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

S. Rahmouni[1], E. Rabhi[1], K. Zouaoui[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], S. Mhamdi[1], H. Sahli[1]

[1]Rabta hospital, rheumatology department, Tunis , Tunisia

Background :
Patients with chronic inflammatory rheumatic diseases (CIRD) are at increased risk of tuberculosis , particularly when receiving immunosuppressive treatments[1]. Screening for latent TB and proper management are critical to prevent the development of active TB in this vulnerable population.
Objectives :
This study aimed to describe the clinical and therapeutic management of TB in CIRD patients.
Methods :
This was a retrospective, descriptive study conducted in a rheumatology department, including patients hospitalized between 2018 and 2024. The study focused on individuals with chronic inflammatory rheumatic diseases (CIRD), such as rheumatoid arthritis and spondyloarthritis, who had a history of tuberculosis (TB), latent TB diagnosed during pre-therapeutic screening, or ac-

tive TB during the course of CIRD treatment.

Results :

A total of 33 patients were enrolled in the study, 15 women and 20 men, with a mean age of 55.29 ± 12.9 years and a sex ratio of 0.75. Among these, 22 were diagnosed with rheumatoidarthritis (RA), and 13 had spondyloarthritis (SpA).

Regarding tuberculosis (TB) status, 15 patients had a history of TB before the diagnosis of CIRD. Specifically, 13 patients had previously experienced pulmonary TB, and two patients had ganglionic TB. Additionally, latent TB was identified in 12 patients during pre-therapeutic screening before the initiation of treatment for their chronic inflammatory rheumatic diseases (CIRD).

Eight patients (x: RA, x= SpA) had developed active TB after the diagnosis of CIRD (pulmonary TB : 4 patients, digestive TB : 2, lymphatic TB=1, multifocal TB : 1). They were all receiving disease-modifying antirheumatic drugs (DMARDs) at the time of TB diagnosis. Among them, one patient was on nonsteroidal anti-inflammatory drugs (NSAIDs), two were treated with methotrexate (MTX), and five were on biologic DMARDs (bDMARDs)(adalimumab :n=1, Certolizumab : n=1, Etanercept : n=1, Infliximab : n=2). The average duration between the initiation of methotrexate and the onset of active TB was x and it was 24.59 months [1-60] for bDMARDs. None of the patients with a history of correctly treated TB experienced reactivation of TB while receiving either cDMARDs or bDMARDs. Furthermore, patients who developed active TB under bDMARDs, did not report any history of contact with active TB, and the infectious screening conducted during the pre-therapy assessment was negative.

Patients with latent TB were all administered chemoprophylaxis, and none of these patients developed active TB during the follow-up period.

Conclusion :

This descriptive study highlights the importance of TB screening and prophylaxis in patients with CIRD, particularly those receiving immunosuppressive therapies. The findings suggest that while patients with a history of treated TB did not experience reactivation under cDMARDs or bDMARDs, careful management of latent TB with chemoprophylaxis can prevent the development of active TB. Further studies are needed to explore the long-term outcomes and best practices for TB management in CIRD patients, particularly those initiating biologic therapies.

NON-PHARMACOLOGICAL APPROACHES TO MANAGING KNEE OSTEOARTHRITIS IN PRIMARY CARE

E. Rabhi[1], S. Rahmouni[1], K. Zouaoui[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rabta hospital, rheumatology department, Tunis , Tunisia

Introduction: Knee osteoarthritis (gonarthrosis) is a prevalent reason for consultation in primary care settings(1). Its management requires a holistic approach, combining both pharmacological and non-pharmacological strategies. This study aimed to assess the practices of primary care physicians in the non-pharmacological management of gonarthrosis.

Patients and Methods: A self-administered survey consisting of 20 questions, developed via Google Forms, was conducted among primary care physicians in Tunisia.

Results: Our study included 70 physicians (51 women and 19 men) with a mean age of 41.42 years (± 11.45) and an average of 5.63 years (± 6) of clinical practice. Regarding the non-pharmacological management of gonarthrosis, 68.6% of physicians routinely recommend lifestyle modifications, including weight loss (recommended by 70% of respondents) and physical exercise (recommended by 65%). Additionally, 20% recommended avoiding sports, and 15% suggested avoiding stairs.

Concerning assistive devices, 48.6% of physicians rarely recommended them, 30% suggested them frequently, 14.3% provided them on patient request, 1.4% prescribed them systematically, and 5.7% did not recommend them. Among those who prescribed assistive devices, the most commonly recommended were canes (40%) and unloading orthoses (35%). Soft knee braces were prescribed by 20%, orthopedic insoles by 15%, and special soft shoes with insoles by 10%. For physical therapy, 48.6% of physicians recommended it frequently, 34.3% rarely, 11.4% routinely, and 5.7% only at the patient's request.

The most commonly prescribed rehabilitation exercises included muscle strengthening and stretching (50%), aerobic exercises (30%), and joint mobilization (20%). Aquatic therapy was recommended by 10% of physicians.

With regard to sick leave, 32% of physicians prescribed it routinely during flare-ups, 14% offered it at the patient's request, 18% rarely prescribed it, and 6% never prescribed it. In terms of acupuncture, 41% of physicians had never prescribed it, 19% prescribed it rarely, 6% prescribed it often, and 1% prescribed it routinely. In 14% of cases, acupuncture was suggested by the patient.

Lastly, for spa therapy, 40% of physicians prescribed them rarely, 17% only at the patient's request, 11% frequently, and 1% routinely.

Conclusion: In this study, primary care physicians in Tunisia primarily favored lifestyle modifications and rehabilitation for the non-pharmacological management of gonarthrosis. Assistive devices and specific interventions were used less frequently. These findings highlight opportunities to improve and diversify

non-pharmacological treatment strategies for this condition in primary care settings.

EXPERIENCE OF PRIMAY CARE PHYSICIANS IN THE DIAGNOSIS OF KNEE OSTEOARTHRITIS : METHODS AND CURRENT PRACTICES

S. Rahmouni[1], E. Rabhi[1], K. Zouaoui[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rabta hospital, rheumatology department, Tunis , Tunisia

Background: Knee osteoarthritis (gonarthrosis) represents a significant public health challenge. Primary care physicians are often involved in the management of patients with this condition, making it crucial for them to stay updated on diagnostic strategies to ensure optimal care [1].

Objectives: The aim of our study was to evaluate the level of knowledge among primary care physicians regarding the diagnostic approach to gonarthrosis.

Methods: A 19-question survey, self-administered online via Google Forms, was conducted among primary care physicians in Tunisia.

Results: Seventy physicians participated in the study, with a male-to-female ratio of 0.3. Of the participants, 81.2% were public health physicians, 15.9% were in private practice, and 2.4% were medical residents. The average age was 41.42 ± 11.45 years, with an average of 5.63 ± 6 years in practice (range: 0–35).

Among the participants, 23.5% had completed an internship in a rheumatology department, and 58.6% had attended a seminar or training on gonarthrosis.

Most participants (81.4%) considered the diagnosis of gonarthrosis to be clinico-radiological, 12.9% considered it clinical, and 7.1% considered it radiological.

In the case of non-traumatic knee pain, 30% of physicians routinely ordered radiographs, 11.4% did so for the first episode, 51.4% when the pain was unusual, and 7.1% rarely. Of those who requested radiographs, 34.8% prescribed an X-ray of the affected knee, while 65.2% ordered X-rays of both knees. In terms of radiographic views, 92.9% requested anteroposterior and lateral views, 17.1% requested a 30° femoropatellar view, and 11.4% ordered a Schuss view. In the case of normal radiographs, 34.3% of physicians requested an MRI, 25.7% sought a specialist's opinion, 14.3% ordered an ultrasound, 14.3% recommended a follow-up X-ray, and 11.4% requested a CT scan.

Regarding laboratory tests, 15.7% of physicians ordered them routinely, 47.1% frequently, 35.7% rarely, and one physician only when requested by the patient. These tests typically included an inflammatory panel (95.7%), uric acid levels (53.6%), calcium-phosphate levels (44.9%), and other tests (7.2%). In cases of knee swelling, 57.1% of physicians performed joint aspiration, 47.1% ordered an ultrasound, and 47.1% prescribed laboratory tests. Additionally, 20% referred patients to an orthopedic specialist, 25.7% to a rheumatologist, and 1.4% chose other referral options. Regarding joint aspirations, 10% of physicians performed them when necessary, while 90% did not. Among those who did not perform joint aspirations, 32.3% had not been trained in the procedure, 13.8% were uncomfortable doing so, and 32.3% believed it should be performed by a specialist. As for risk factors for gonarthrosis, 41.4% of participants systematically screened for them.

Conclusion:

Our study highlights several areas for improvement in current practices. The results suggest that many aspects of care could be enhanced, underscoring the need for better training and increased collaboration with rheumatologists to improve the management of this condition.

THERAPEUTIC MANAGEMENT OF OSTEOPOROSIS: KNOWLEDGE AND PRACTICES AMONG PRIMARY CARE PHYSICIANS IN TUNISIA"

S. Rahmouni[1], E. Rabhi[1], K. Zouaoui[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rabta hospital, rheumatology department, Tunis , Tunisia

Introduction although it is a public health problem, osteoporosis remains largely underdiagnosed and inadequately managed, particularly in developing countries. In Tunisia, primary care physicians play a crucial role in managing this condition.

Objective This study aims to assess the practices of primary care physicians in Tunisia regarding the management of osteoporosis.

Methods A 20-item questionnaire was distributed to primary care physicians via Google Forms.

Results A total of 59 physicians participated in the survey, consisting of eight residents, 31 general practitioners, and 17 family doctors. The sex ratio was 0.43. The mean age of participants was 39.2 ± 7.4 years. The mean number of years in practice was 13.1 ± 7.2 years.

Regarding treatment prescription, 38 (64.4%) physicians stated that they typically consult a rheumatologist before prescribing osteoporosis treatments. Seven physicians (11.9%) prescribed treatments frequently, while four did so systematically. When prescribing bisphosphonates, 13 (22%) physicians took patient preferences regarding the administration route into account, while 34 (57.6%) based their decision on the severity of Bone Mineral Density (BMD).

In cases of fracture recurrence during treatment, 36 physicians

sought specialist consultation. Other actions included investigating poor adherence (8, 13.6 %), reevaluating BMD (6, 10.2 %), or considering a treatment change (3, 5.1 %). Regarding their knowledge about the adverse effects, the most cited ones were: digestive disorders (24, 40.7%), aseptic femoral head osteonecrosis (22, 37.3 %), and renal insufficiency (14, 23.7%).
Additionally, 32 physicians (54.2%) routinely requested a medical workup before initiating treatment, and 45 (76.3%) physicians recommended lifestyle modifications, including physical activity, as part of osteoporosis management.
Conclusion: While many adhere to national and international guidelines, there are gaps in areas such as treatment adherence, management of side effects, and the pre- treatment workups.

ASSOCIATED FACTORS WITH FIBROMYALGIA IN PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: A RETROSPECTIVE STUDY

S. Boussaid[1], E. Rabhi[1], O. Ben Abdallah[1], S. Rahmouni[1], K. Zouaoui[1], M. Abbes[1], R. Dhahri[2], S. Rekik[1], H. Sahli[1]

[1]Rabta hospital, rheumatology department, Tunis , Tunisia, [2]Department of Rheumatology, Military Hospital, Tunis, Tunisia

Introduction Fibromyalgia is a common comorbidity in patients with rheumatoid arthritis (RA) and significantly impacts their quality of life, exacerbating pain, fatigue, and disability. This is especially challenging in patients with difficult-to-treat (D2D) RA, as defined by the European Alliance of Associations for Rheumatology (EULAR), where the coexistence of fibromyalgia complicates disease management and therapeutic outcomes.
Objective The goal of this study was to assess the prevalence of fibromyalgia in patients with difficult-to-treat RA and identify factors associated with its occurrence.
Methods This was a retrospective study conducted within a rheumatology department, including patients diagnosed with RA who met the criteria for D2D disease according to EULAR guidelines 2020. Data were collected from medical records, focusing on patient demographics, disease duration, immunological profiles, and the presence of clinical features such as deforming RA and joint complications. The diagnosis of fibromyalgia was recorded, and potential associations with various clinical and immunological factors were explored.
Results A total of 284 patients were included in the study, consisting of 237 women (83.5%) and 47 men (16.5%), with a mean age of 60.21 ± 11.22 years and a mean disease duration of 10.65 ± 7.44 years. Regarding immunological profiles, 84.2% of patients were positive for rheumatoid factor (RF), and 67.6% tested positive for anti-CCP antibodies. At the time of diagnosis, 40.5% of the patients exhibited deforming RA. In terms of joint complications, 26 patients had unilateral coxitis, 3 had bilateral coxitis, and 29 patients presented with atlanto-axial luxation. Erosions were observed in 258 patients (90.8%). Fibromyalgia was diagnosed in 28 patients (9.9%).
In terms of immunological factors, fibromyalgia was significantly associated with the presence of rheumatoid factor (p = 0.01), while no significant relationship was found with anti-CCP antibodies. A significant association between fibromyalgia and the absence of coxitis (p = 0.04) and the absence of joint deformities at the time of diagnosis (p = 0.05). No significant association was found between fibromyalgia and the presence of atlanto-axial luxation (p = 0.4).
Conclusion Fibromyalgia is a prevalent comorbidity in patients with difficult-to-treat RA. The absence of coxitis and joint deformities at diagnosis were identified as protective factors, while the presence of rheumatoid factor was found to be a significant risk factor for the development of fibromyalgia. These results highlight the importance of considering fibromyalgia in the management of difficult-to-treat RA.

Objective: Osteogenesis imperfecta (OI) is an uncommon genetic condition affecting connective tissue, with 90% of cases resulting from dominant mutations in the COL1A1 and COL1A2 genes. The objective of this study is to evaluate the link between genotype and phenotype in a cohort of IO patients from Turkey.
Method: A total of 125 clinicaly diagnosed OI patients included in this study. Diagnosis of Osteogenesis Imperfecta based on clinical presentation by experienced endocrinologists, assessed for standing height, craniofacial, cardiac anomalies, scleral coloration, dermatological issues, and joint hyperlaxity.
Patients underwent clinical evaluation by multidisciplinary teams and were classified by three experienced doctors using the Van Dijk and Sillence criteria, specifically regarding the through clinical presentation and severity grading scale, based on clinical, radiological, and hereditary findings. The study encompasses only people with a clearly defined clinical diagnosis of Osteogenesis Imperfecta types I–IV; patients without extraskeletal involvement or with potential alternative diagnoses were excluded. All genetic analyses were conducted at the Medical Genetics units of the hospitals.
Results: The study population included 125 OI patients. There were 74 female and 51 male patients. Mean age was 33±11.3 years. Median age of first and last fracture were 4 (0-62) and 20 (6-69). Mean fracture number was 8.2±7.8. Disease severity was classified as 43 cases of type I (34.4%), 25 cases of type III (20%), and 57 cases of type IV (45.6%). As expected, our results showed blue sclera was most common in type I group but there is no significant difference between groups (p= 0.125).
Conclusion: OI types I–IV the mutation rate discovered by Sanger sequencing of collagen I was 75.2%, depending on inclusion criteria used. Genotype–phenotype analysis confirmed previous studies on severity of disease vs chain affected and mutation type.

Table 1: Clinical Characteristics of Our Patients Subdivided by OI Types

	Type I (n=43)	Type III (n=25)	Type IV (n=57)
Gender F/M	26/17	12	33/24
Familial/Sporadic Cases	17/17	6	30/22
Dentinogenesis Imperfecta n (%)	10 (24.4%)	12 (50%)	12 (25.9%)
Cardiac Defects n (%)	1 (2.5%)	2 (9.1%)	0 (0%)
Blue/Gray Sclera n (%)	34 (80.9%)	17 (70.8%)	37 (64.9%)
Wormian Bones n (%)	0 (0%)	1 (4%)	4 (7%)
Triangular Face n (%)	2 (4.7%)	3 (12%)	4 (7%)
Frontal Bossing n (%)	0 (0%)	1 (4%)	4 (7%)
Mutations n (%)			
COL1A1	33 (76.7%)	11 (44%)	35 (61%)
COL1A2	7 (16.3%)	6 (24%)	6 (10.5%)
SERPINF1	0 (0%)	0 (0%)	1 (1.8%)
P3H1	0 (0%)	1 (4%)	3 (5.3%)
FKBP10	2 (4.7%)	3 (12%)	4 (7%)
SP7	0 (0%)	1 (4%)	0 (0%)
BMP1	0 (0%)	0 (0%)	1 (1.8%)
WNT1	1 (2.3%)	0 (0%)	0 (0%)
PLOD2	3 (7%)	1 (4%)	0 (0%)
Negative for any mutation	2 (4.7%)	3 (12%)	7 (12.3%)

Objective: Paget's disease of bone (PDB) is a metabolic bone disorder that has been infrequently documented in Eastern countries. Genetic mutations in the Sequestrom1 (SQSTM1) gene have been shown to be linked to the etiology of the disease. Over 20 mutations in the SQSTM1 gene have been documented as influential in Paget's disease. The most often documented mutation occurs at position 392, resulting in the substitution of the amino acid proline with leucine. This study aims to analyze the mutation areas in a cohort of PDB patients from Türkiye, focusing on the SQSTM1 gene.
Methods: An invitation was sent to tertiary endocrinology clinics to participate in a survey regarding the demographic, clinical, radiological, and laboratory parameters associated with PDB, as well as to collect peripheral blood samples for genetic analysis. Genomic DNA was isolated from peripheral blood using the Zymo kit. Pathogenic mutations in the SOSTM1 gene were examined using the HGMD program, revealing mutations in exons 7 and 8; thus, primers were developed for these specific areas. Amplicons were examined using Next Generation Sequencing.
Results :The study included 103 patients with PDB and 50 healthy controls from 14 endocrinology centers located in 8 western cities of Turkey. This cohort of PDB (Female/Male: 53/51) had a mean age of 66.9 ± 10.5 years at diagnosis, with an illness duration of 9.5 ± 5.9 years. At diagnosis, 47.5% of the patients had symptoms. The primary clinical symptoms were bone pain and headache. Polyostotic illness was identified in 67.9% (n=70) of the patients. Bones that were frequently affected were the pelvis (43.6%) (n=45), skull (30%) (n=31), spine (29.5%) (n=30%), and femur (14.1%) (n=15).
No mutations were identified in exon 7. A heterozygous mutation was identified in 11 patients (5 females and 6 males) out of the 103 participants in the research for exon 8 (ACMG/P). A same mutation was detected in 10 individuals (P392L heterozygotes), whereas a distinct mutation was identified in one individual (M4404V heterozygotes). Among the 44 controls in the study, 43 exhibited wild type (WT) characteristics, whereas one presented a benign heterozygous polymorphism (S328S).
Conclusion: 10% of the PDB cohort from Türkiye exhibits Sequestrom1 mutations. comprehensive genetic and epigenetic investigations are essential to clarify the etiology of Paget's disease.

P595

THE ROLE OF VITAMIN D LEVELS IN OCCUPATIONAL HEALTH: A RETROSPECTIVE STUDY OF MEDICAL CENTER EMPLOYEES

Y. L. Teng[1], S. Y. Lin[1], H. T. Lee[1]

[1]Taichung Veterans General Hospital, Taichung , Taiwan

Objective: This study aimed to investigate changes in serum vitamin D levels between two measurements among employees of a medical center in central Taiwan and to analyze their associations with age, gender, job position, and body mass index (BMI).
Methods: A retrospective analysis was conducted on 392 employees, categorized into four groups: supervisors and physicians (n=96), nurses (n=154), administrative and medical technicians (n=97), and labor workers (n=45). Changes in vitamin D levels between two time points were analyzed, and baseline data (age, gender, BMI) were recorded. Generalized estimating equations (GEE) were used to assess the associations between vitamin D levels and related factors.
Results: The mean vitamin D levels at the first and second measurements were 22.2 ± 9.7 ng/mL and 25.4 ± 10.7 ng/mL, respectively, showing a statistically significant increase ($p<0.001$). Adjusted employees aged >50, sex, job categories, two vitamin D levels and interval measurement time, overweight or obesity had significantly lower increases in vitamin D levels compared to those with normal BMI ($p=0.002$, $p=0.042$), and overweight was a risk factor for vitamin D levels <30 ng/mL or vitamin D levels <20 ng/mL (OR=2.32, $p = 0.004$; OR = 1.92, $p = 0.004$), respectively.
Conclusion: This study demonstrated an overall increase in vitamin D levels among medical center employees, with age >50 years and normal BMI being significant factors in maintaining sufficient vitamin D levels. Future interventions should focus on overweight and obese individuals to improve their vitamin D status.
Keywords: Vitamin D、Occupational Health、Body Mass Index (BMI)

P596

CHARACTERISTICS AND RISK FACTORS OF VITAMIN D DEFICIENCY AMONG HOSPITAL EMPLOYEES IN DIFFERENT OCCUPATION CATEGORIES

Y. L. Teng[1], H. T. Lee[1]

[1]Taichung Veterans General Hospital, TAICHUNG, Taiwan

Objective
To investigate the prevalence and characteristics of vitamin D deficiency among hospital employees across different occupation categories and analyze the associations of demographic factors, health indicators, and seasonal variations with vitamin D status.
Methods
This retrospective study included 1,161 hospital employees who underwent their first blood tests between 2017 and 2024. Participants were divided into four occupational groups: department heads and physicians (n=314), nursing staff (n=460), administrative and medical technicians (n=282), and technical workers (n=105). Data on demographic characteristics (gender, age, BMI), health indicators (waist circumference, blood pressure, blood lipids, blood glucose), and the season of blood sampling (spring, summer, autumn, winter) were collected. Univariate and multivariate logistic regression models were applied to identify factors associated with vitamin D deficiency.
Results
The prevalence of vitamin D deficiency was 43.6%, with 37.3% of employees categorized as insufficient and only 19.1% as sufficient. Among occupational groups, technical workers had the highest deficiency rate (60.9%), while department heads and physicians had the lowest (32.4%). Female employees and younger staff (<30 years) were identified as high-risk groups (p<0.001). Higher BMI and abnormal triglycerides were significantly associated with increased risk of vitamin D deficiency (p<0.05). Seasonal analysis showed the highest deficiency rates in spring and the lowest in autumn (p=0.015). Multivariate logistic regression indicated that age ≥50 years (OR=0.50, p<0.001) and male gender (OR=0.58, p<0.001) were protective factors, while spring (OR=2.07, p=0.015) and elevated triglycerides (OR=1.003, p=0.028) were risk factors.
Conclusion
Vitamin D deficiency is highly prevalent among hospital employees, particularly in technical workers, younger staff, and females. Higher BMI, elevated triglycerides, and the spring season were identified as significant risk factors. Targeted interventions, such as vitamin D supplementation and increased outdoor activities, are recommended to improve vitamin D status and overall health, especially for high-risk groups.
Keywords
Vitamin D deficiency, hospital employees, BMI

COMPARISON OF THE PELVIC ROTATION ANGLE DURING HIP LATERAL ROTATION IN THE STANDING AND PRONE POSITIONS IN PARTICIPANTS WITH AND WITHOUT TENSOR FASCIA LATAE SHORTNESS

H. Y. Baek[1], O. Y. Kwon[1], I. K. Ahn[1]

[1]Department of Physical Therapy, The Graduate School, Yonsei University, Wonju, South Korea

Objective: This study aimed to compare the pelvic rotation angle (PRA) during a hip lateral rotation (HLR) test in the standing position (HLRS) and the HLR in the prone position (HLRP) between individuals with and without tensor fascia latae (TFL) shortness.
Material and Methods: Thirty participants with (n = 15) and without (n = 15) TFL shortness were recruited. The PRA was measured during active HLRS and HLRP using a Polhemus Liberty electromagnetic motion tracking system. Two-way mixed analysis of variance (ANOVA) was used to identify significant differences in the PRA between groups and within positions.
Results: A significant interaction effect was identified between groups and positions on the PRA ($p < 0.05$). Individuals with TFL shortness had a significantly greater PRA during HLRS than those in the control group. The PRA during HLRS was significantly greater than that during HLRP in individuals with TFL shortness. However, no statistically significant differences in PRA were found in the prone position between groups with and without TFL shortness ($p > 0.013$). When HLRP and HLRS were performed, the PRA in the horizontal plane occurred at 1.65 ± 0.98° and 7.68 ± 4.69°, respectively, in the TFL shortness group, and at 1.27 ± 1.07° and 2.37 ± 1.96°, respectively, in the control group.
Conclusion: These results suggest that assessments should be conducted in the standing and TFL shortness may lead to increased PRA during HLRS, which can be clinically useful for confirming PRA.

P598

EVALUATION OF THE CLINICAL EFFECTIVENESS OF SPA TREATMENT OF PATIENTS WITH DEFORMING OSTEOARTHROSIS, GONARTHROSIS OF DIFFERENT DURATION

I. A. Grishechkina[1], M. Y. Yakovlev[1], M. V. Nikitin[1], I. V. Semenova[1], V. N. Trukhina[1], L. A. Marchenkova[1], V. I. Berov[1], S. A. Kim[1], M. Y. Tekeeva[1], E. A. Koscheeva[1], T. A. Knyazeva[1]

[1]National Medical Research Center for Balneology and Rehabilitation, Moscow, Russia

Aim - To evaluate the clinical effectiveness of health resort treatment (HRT) in patients with deforming osteoarthritis, gonarthrosis (DOA) of different duration (7, 14, 18 and 21 days).
Material and methods: an open prospective randomized clinical study of 43 patients with DOA was carried out in “Gorny Vozdukh”

(Zheleznovodsk) and "Rossiya" (Yessentuki) sanatoria. Patients were divided into 4 comparable groups depending on the period of treatment (7, 14, 18, 21 days).
The assessment was made on the first and last day of HRT and included: clinical examination, testing ("Up and Go" test, the VAS questionnaire, the WOMAC scale, the Quality of Life Test questionnaire, the Hospital Anxiety and Depression Scale (HADS)).
The treatment included recommendations regarding diet and physical activity, symptomatic drug therapy, exercise therapy, a course of dosed walking along the Terrainkur routes (30-40 minutes), peloid therapy, magnetic therapy for the knee joints ("Polyus 2", Russia), laser therapy for the knee joints ("Rikta 04/4", Russia) in the amount of 6, 12, 16 and 18 procedures, respectively.
Results: In all groups of patients, regardless of the period of HRT, there was a decrease in the number of pain complaints, a decrease in the intensity of pain syndrome according to the VAS scale and an improvement in the results of the "Up and go" test. In patients with the period of HRT of 7 days the level of depression and anxiety according to the results of the HADS test decreased statistically significantly following the treatment, and the quality of life improved. In patients with the period of HRT of 14 days there was only statistically significant decrease in the level of depression. In patients with 18 and 21 days of HRT after treatment, there was an improvement in functioning on the WOMAC scale, a decrease in anxiety, depression.
Statistically significant differences were obtained between treatment periods of 7 and 18, 7 and 21 days according to the "Up and go" test, the WOMAC scale, the reduction of anxiety and depression levels and the patient's quality of life.
Conclusion: The highest clinical effectiveness of HRT is registered in patients with deforming osteoarthritis with a period of stay of 18 and 21 days.

P599

IMBALANCE OF LIPOPOLYSACCHARIDE-BINDING SYSTEMS AS A POTENTIAL LINK IN THE PATHOGENESIS OF RHEUMATOID ARTHRITIS

V. A. Beloglazov[1], I. A. Yatskov[1], A. A. Gorlov[1], K. V. Bubley[1], M. G. Nikolashin[1], S. Kulanthaivel[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: To analyze the role of lipopolysaccharide-binding systems (LBP and BPI) in the development and maintenance of inflammation in rheumatoid arthritis (RA) and to evaluate the impact of their imbalance as a potential pathogenetic factor.
Methods: Literature review conducted using keywords "rheumatoid arthritis and lipopolysaccharide", "rheumatoid arthritis and lipopolysaccharide-binding protein", "rheumatoid arthritis and BPI" in scientific databases (e-Library, PubMed). Studies highlighting the involvement of LBP and BPI in inflammation regulation and their interplay with lipoproteins (HDL and LDL) were included.
Results: Elevated levels of circulating lipopolysaccharides (LPS) are frequently detected in RA patients. LPS interacts with a range of receptors and carrier molecules, prominently including lipopolysaccharide-binding protein (LBP) and bactericidal/permeability-increasing protein (BPI), which together form the lipopolysaccharide-binding systems. LBP primarily facilitates the transfer of LPS to CD14 and TLR4 receptors, initiating pro-inflammatory signaling pathways. In contrast, BPI exhibits strong anti-inflammatory properties by neutralizing LPS and inhibiting its interaction with cellular receptors. An imbalance between LBP and BPI levels in RA patients can shift the immune response towards persistent inflammation. Studies indicate that elevated LBP levels correlate with increased disease activity markers, such as C-reactive protein (CRP) and interleukin-6 (IL-6), while decreased BPI activity may fail to adequately counteract LPS-induced inflammation. Furthermore, dyslipidemia, a common comorbidity in RA, exacerbates the inflammatory potential of LPS. In RA patients, the altered balance between low-density lipoproteins (LDL) and HDL may contribute to a pro-inflammatory milieu, intensifying joint damage and systemic inflammation.
Conclusion: The combination of an imbalance in lipopolysaccharide-binding systems and dyslipidemia is a significant aggravating factor in RA pathogenesis. Further research into the mechanisms of LBP and BPI activity and their therapeutic modulation is a promising direction for improving RA treatment outcomes.

P600

LIPOPOLYSACCHARIDE PATHOPHYSIOLOGY IN RHEUMATOID ARTHRITIS

V. A. Beloglazov[1], I. A. Yatskov[1], A. A. Gorlov[1], K. V. Bubley[1], M. G. Nikolashin[1], S. A. Khamidova[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Rheumatoid arthritis (RA) is by far the most prevalent autoimmune arthritis worldwide. It features progressive joint deformity, decreased quality of life and shortened lifespan. A complex array of different pathways is implicated in the onset and development of RA. Environmental triggers play especially important role in the RA pathogenesis. Lipopolysacharides (LPS) are considered to be the main environmental "culprit" of autoimmunity phenomena seen in the setting of RA. Since that it is of value to dive deeper into understanding of LPS signalling pathway and how exactly it contributes to the progression of the disease and what available treatment strategies are at our disposal to date.
Methods: According to the scope of the current article a literature narrative review has been performed. Authors have critically approached 31 literary sources.
Results: It has been shown that LPS can exert its influence via multiple ways all leading to the same much expected outcome – an increase in proinflammatory state. It includes B- and T-cell activation, synovial inflammation and subsequent gradual joint destruction, increased citrullination of both bacterial and host proteins, steering up IgM and IgG antibodies production, activation of the complement cascade. Vascular Endothelial Growth Factor (VEGF) effects and reactive oxygen species (ROS) signalling both play a

part in spiraling detrimental inflammatory changes as well. An intricate balance system helps to mitigate the intensity of LPS signalling. Its components include LPS binding protein, bactericidal/permeability-increasing protein. Certain environmental changes (smoking, "leaky gut" syndrome, nonsteroidal anti-inflammatory drugs) can cause the alterations in this self-regulating balance.
Conclusion: To date there is no formally guideline-directed treatment adressing LPS signalling specifically. Being a prolific antigen, LPS requires a deeper attention from the practical standpoint. Largely, preventive treatment strategies remain overlooked. Our position is that non-arthritis RA drugs should be implemented in the composite antirheumatic treatment.

P601

THE PATHOLOGIC «LUNG-JOINT AXIS» AS A POTENTIAL CAUSE OF OSTEONECROSIS

V. A. Beloglazov[1], I. A. Yatskov[1], A. A. Gorlov[1], K. V. Bubley[1], M. G. Nikolashin[1], S. Kulanthaivel[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: The study aims to explore the mechanisms by which viral infections, particularly SARS-CoV-2, and lipopolysaccharide (LPS) contribute to the pathological "lung-joint axis" leading to osteonecrosis.
Methods: Analysis of the interactions between SARS-CoV-2, LPS, and bone tissue based on a literature review. Examination of pathophysiological changes triggered by LPS and viral infections in endothelial cells, alveolocytes, and osteocytes. Focus on the role of hypercoagulability and systemic inflammation in bone ischemia.
Results: SARS-CoV-2 directly damages alveolocytes and endothelial cells through ACE2 receptor binding and TMPRSS2-mediated mechanisms, causing increased vascular permeability and hypercoagulability. This damage reduces ACE2 activity, disrupting blood flow regulation and leading to endothelial apoptosis, as shown in autopsy studies. Simultaneously, lipopolysaccharide (LPS), a key component of gram-negative bacterial membranes, activates TLR4 receptors, stimulating pro-inflammatory cytokines such as IL-1β, IL-6, and TNF-α via the NF-κB pathway. LPS also impairs bone metabolism by increasing osteoclast activity, inhibiting osteoblast function, and inducing bone resorption. Viral infections, including SARS-CoV-2, disrupt the lung microbiome, creating dysbiosis that raises systemic LPS levels. This results in exacerbated systemic inflammation, further weakening the alveolar epithelial barrier and facilitating endotoxin translocation into the bloodstream. The combination of viral damage, hypercoagulation, and systemic endotoxemia promotes ischemic damage to bone tissue, increasing the risk of osteonecrosis. Evidence particularly highlights the role of these processes in femoral head ischemia in severe SARS-CoV-2 cases.
Conclusion: Viral infections, particularly SARS-CoV-2, and LPS significantly contribute to the pathological lung-joint axis, exacerbating systemic inflammation and hypercoagulability. This creates a favorable environment for bone ischemia and osteonecrosis. Understanding these mechanisms is critical for developing preventive and therapeutic strategies for osteonecrosis in patients with viral infections and endotoxemia.

P602

ESTIMATION OF MAIN RISK FACTORS FOR THE DEVELOPMENT OF OSTEOPOROSIS IN RHEUMATOID ARTHRITIS

V. A. Beloglazov[1], I. A. Yatskov[1], M. G. Nikolashin[1], S. Kulanthaivel[2], S. A. Khamidova[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India, [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Rheumatoid arthritis (RA) as one of the most common rheumatic diseases leads to the development of secondary osteoporosis (OP), the complications of which often determine unfavorable outcomes in RA. In the pathogenesis of secondary OP, along with traditional risk factors (tRF), specific risk factors (sRF) play an important role, as well as the adverse effect of antirheumatic therapy on bone metabolism. In this regard, the assessment of the contribution of the entire spectrum of these risk factors to the development of OP in RA is of great scientific and practical importance.
Methods: The study included 124 patients diagnosed with RA (ACR/EULAR criteria, 2010). Patients were divided into 2 groups depending on the presence or absence of signs of systemic AP based on the results of clinical and instrumental examination: respectively: AP+/AP- groups. All patients underwent an analysis of clinical features of RA, as well as tFR and sFR of AP. The results were subjected to statistical analysis using the methods of variation statistics, paired correlation. The reliability of differences between the frequency of detection of RP in the observed groups was assessed using the Fisher criterion.
Results: Among 124 patients with RA included in the study, there were 96 female (77.42%) and 28 male patients. (22.58%) aged 25 to 79 years, the average age was 59.19±1.32 years, the duration of RA according to the anamnesis ranged from 3 to 28 years, the average duration of the disease was 11.41±4.09 years. In the group of RA patients we observed, the majority were over 50 years old (81.45% of the total number of patients). The clinical form of RA was characterized by polyarthritis with predominant damage to the joints of the upper extremities, with typical deformation of the hands, the presence of symptoms of morning stiffness, and symmetry of the lesion. RA activity, determined by the DAS-28 index, corresponded to a low degree (DAS-28 ≤3.2) in 19.35%, moderate (3.2> DAS-28 ≤5.1) - in 53.23% and high (DAS-28>5.1) - in 27.42% of patients. Seropositive RA was diagnosed in 65.32% of patients, 21.78% of patients had negative rheumatoid factor (RF), 12.90% were not tested for RF. Anti-cyclic citrullinated peptide (ACP) antibodies were tested in 80.64% of patients, 68% of those examined were seropositive for this marker. According to the results of standard radiography of joints and spine, ultrasound densitometry and X-ray osteodensitometry, systemic OP was diagnosed in 76 (61.28%) patients, 7 (9.21%) of whom had osteopo-

rotic fractures. Of the traditional RFs in people with RA, the most common were female gender, age > 50 years, BMI < 20 kg/m2. Of the specific RFs, the most significant were: RA duration > 5 years, activity of stage 2-3, high titer of RF and ACPA, radiographic stage > 2, long-term use of glucocorticoids. A comparative analysis of the frequency of registration of the specified tRF and sRF using the χ^2 criterion showed that it was significantly higher in the OP+ subgroup.

Conclusion: Systemic OP was diagnosed in 61.28% of RA patients. The association of OP with traditional RFs was confirmed: female gender, age over 50 years, and low body mass index. Of the disease-associated RFs, the most important were high and moderate disease activity, RA duration of more than 5 years, the presence of immunological markers in high titer, and the experience of glucocorticoid therapy. The analysis substantiates the range of preventive measures in individuals with secondary OP.

P603

EXTRACELLULAR TRAPS FORMATION BY NEUTROPHILS IN PATIENTS WITH RHEUMATOID ARTHRITIS

V. A. Beloglazov[1], I. A. Yatskov[1], A. A. Gorlov[1], K. V. Bubley[1], R. H. Useinova[1], M. G. Nikolashin[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: Currently, the improvement of rheumatoid arthritis (RA) diagnostics is aimed at finding and validating new biomarkers, which is especially important in light of the trend towards personalized therapy of rheumatic diseases. In this study, the intensity of spontaneous and induced formation of extracellular traps by peripheral blood neutrophils in patients with RA was studied.

Methods: The study included 25 patients with a verified diagnosis of RA in accordance with the ACR/EULAR 2010 criteria and 30 healthy people. Neutrophils were isolated by one-stage centrifugation in a double Ficoll-amidotrizoate density gradient with the density of the upper and lower gradients of 1080 kg/m^3 and 1090 kg/m^3, respectively. The qualitative composition of the neutrophil fraction was assessed using microscopy of standard smears, the degree of neutrophil activation was assessed using a standard nitroblue tetrazolium test. Stimulation of the formation of neutrophil extracellular traps (NETs) was performed by incubation with phorbol-12-myristate-13-acetate. The intensity of NETs formation was recorded by fluorescence microscopy with SYBR green.

Results: At the time of inclusion in the study, the RA activity according to DAS28 was no more than 2.6 points. The average age was 51.4 ± 4.5 years, the average duration of the disease was 2.3 ± 0.8 years. Antibodies to cyclic citrullinated peptide were detected in 15 patients with RA (60%). The purity of the neutrophil fraction in RA was 93.3%, the proportion of viable cells exceeded 95%. Spontaneous NET formation was observed in the RA group and in healthy individuals. In RA patients, the incidence of spontaneous and induced NET formation was significantly higher compared to healthy individuals. The incidence of spontaneous and induced neutrophil trap formation in RA patients with high levels of anticitrulline antibodies tended to increase compared to samples from other patients.

Conclusion: Increased spontaneous and induced NET formation in RA patients allows the use of neutrophil extracellular traps as potential biomarkers of RA.

P604

EFFECT OF ENDOMETRIOSIS ON AUTOANTIBODY PROFILE IN POSTMENOPAUSAL WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. V. Aleksandrova[1], I. A. Zborovskaya[1], A. V. Aleksandrov[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Volgograd State Medical University, Volgograd, Russia

An increased risk of comorbid autoimmune diseases in endometriosis, such as systemic lupus erythematosus (SLE), has been determined in women of reproductive age and hardly considered after menopause.

Purpose of the study:

Study of autoantibody profile features in patients with SLE depending on the presence of endometriosis.

Materials and Methods.

Fifty-three postmenopausal patients with SLE (17 of them with endometriosis) were included in the study. The diagnosis of endometriosis was established on the basis of physical examination of the patients by a gynecologist and was confirmed by instrumental methodsLaboratory examination included a panel of autoantibodies established as part of the diagnostic criteria for SLE: determination of antinuclear antibodies (ANA) by indirect immunofluorescence antibody test on HEp-2 cell substrate (diagnostic titer ≥ 1: 80), antibodies to double-stranded DNA (anti-DNA), Smith antigen (anti-Sm), cardiolipin (aCL-IgG and aCL-IgM), β2-glycoprotein-I (anti-GP-I) using appropriate enzyme immunoassay kits.

Results and Discussion.

A higher proportion of patients with positive ANA titers (≥ 1:80) was found in the group of SLE patients with endometriosis ($p = 0.034$). Levels of anti-DNA and anti-Sm were more often higher in SLE patients with endometriosis, but the differences did not reach statistical significance ($p = 0.069$ and $p = 0.08$, respectively). Similarly, no intergroup differences were observed for antibodies to cardiolipin of different classes and anti-GP-I ($p > 0.05$).

Determination of ANA by indirect immunofluorescence antibody test on HEp-2 cells also allowed characterizing the types of nucleus staining: homogeneous (45.3%) and granular (41.5%) types of nuclei luminescence were determined most frequently. Antibody titers of 1:320 or higher were detected in a significant percentage of ANA-positive patients in the group of SLE patients with endometriosis. Presumably, higher titers of SLE-specific autoantibodies may be associated with the risk of more severe stages of endometriosis.

Conclusions.

ANA are frequent serologic manifestations in patients with SLE and occur in endometriosis. The marked ANA positivity in patients

with SLE in the presence of endometriosis reflects the similarity of the underlying humoral immune dysfunction in these diseases.

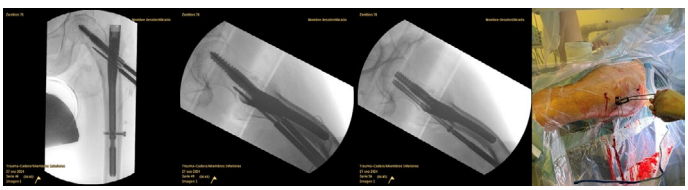
P605

A TECHNICAL NOTE ON THE MODIFICATION OF INTRAMEDULLARY NAILING TECHNIQUE FOR BASICERVICAL HIP FRACTURES USING A CANNULATED SCREW TO PREVENT ROTATION

I. Aguado-Maestro[1], A. E. Sanz-Peñas[1], V. Álvarez-García[1], S. Valle-López[1], I. García-Cepeda[1], I. De Blas-Sanz[2], A. Espinel-Riol[1], E. Paredes-Herrero[1]

[1]Hospital Universitario del Río Hortega, Valladolid, Spain, [2]Complejo Asistencial de Palencia, Palencia, Spain

Background: Basicervical fractures of the hip present a unique challenge due to their transitional location between the femoral neck and intertrochanteric region, often leading to a higher rate of fixation failure. Current treatment commonly involves the use of intramedullary nails. However, rotational instability remains a significant issue. We present a technical modification designed to address this limitation by incorporating an additional cannulated screw to enhance rotational stability.
Methods: We utilized the ZNN Bactiguard nail (Zimmer) in combination with a 7.3 mm diameter cannulated screw. After positioning the intramedullary nail and its proximal screw, a Kirschner wire was inserted through the proximal screw of the nail. Using a parallel wire guide, a second Kirschner wire was introduced parallel to the proximal screw. The 7.3 mm cannulated screw was then inserted over this wire to act as an additional rotational stabilizer.
Results: We have employed this surgical technique in numerous patients, successfully avoiding cut-out (Aguado-Maestro I, Escudero-Marcos R, Nistal-Rodríguez J, et al. *Hip fractures with rotational instability: concept and surgical technique.*Surgery Curr Res. 2013). The novelty of this technique lies in the use of the parallel wire guide, which facilitates the precise placement of the cannulated screw and enhances the overall rotational stability of the construct.
Conclusion: The addition of a 7.3 mm cannulated screw, using a parallel wire guide, provides a simple yet effective solution to the problem of rotational instability in basicervical hip fractures treated with intramedullary nailing. This technique offers potential for improved outcomes and may reduce the incidence of fixation failure.



P606

LONG-TERM ASSESSMENT OF OSTEOARTHRITIS AND ANKLE INSTABILITY IN PATIENTS TREATED WITH CASTAING TECHNIQUE: A RETROSPECTIVE ANALYSIS

C. Valverde-Gestoso[1], R. Llombart-Blanco[1], L. Olías-Ortiz[1], M. Cabrera-López[1], I. Aguado-Maestro[2], J. Palencia-Ercilla[2], M. Alfonso-Olmos-García[1]

[1]Clínica Universidad de Navarra, Pamplona, Spain, [2]Hospital Universitario Río Hortega, Valladolid, Spain

Objective: The aim of this study is to evaluate the clinical and radiological outcomes of patients treated for chronic ankle instability using the non-anatomic Castaing plasty technique.
Material and Methods: This study included patients who had undergone the Castaing procedure and consented to participate. Clinical evaluation was based on the Visual Analog Scale (VAS) for pain and the Cumberland Ankle Instability Tool (CAIT). Physical examination assessed joint stability and range of motion, while weight-bearing radiographs were used to classify osteoarthritis using the Van Dijk system. Statistical analysis was conducted using SPSS 20.0, with significant p-values set at <0.05.
Results: 20 patients were included, with a follow-up ranging from 3 to 32 years. Of these, 90% reported a pain score of 0 on the VAS. The median stability score on the CAIT was 83.5%, with 80% of patients scoring above 70%. Two patients experienced discomfort at the fibula or base of the 5th metatarsal, but all patients demonstrated stable ankles, with 100% showing no anterior drawer or varus instability. However, 64.7% of patients exhibited reduced mobility compared to the contralateral side, and one patient had weakened eversion. Radiological findings showed that 30% (6 patients) experienced a one-grade progression in osteoarthritis, with three progressing from mild to moderate and one from moderate to severe. The median age of these patients was 54 years, with a median follow-up of 16 years. Statistically significant differences were noted in osteoarthritis progression (p=0.014), although this did not correlate with clinical outcomes, as all patients with osteoarthritis changes reported a VAS pain score of 0 and a median CAIT score of 88.5%.
Conclusions: Patients treated with the Castaing technique for ankle instability demonstrate satisfactory long-term stability, with excellent pain relief on the VAS. Radiological progression of osteoarthritis was observed in 30% of patients, though this did not result in clinically significant symptoms. The procedure offers reliable long-term outcomes with minimal complications.

P607

MANAGEMENT OF PERIPROSTHETIC HUMERAL FRACTURES IN THE ELDERLY

I. Aguado-Maestro[1], A. E. Sanz-Peñas[1], I. García-Cepeda[1], I. De Blas-Sanz[2], S. Valle-López[1], P. Almena-Rodríguez[1], C. Pareja-Frade[3], J. Palencia-Ercilla[1]

[1]Hospital Universitario del Río Hortega, Valladolid, Spain, [2]Complejo Asistencial de Palencia, Palencia, Spain, [3]Hospital de Cruces, Baracaldo, Spain

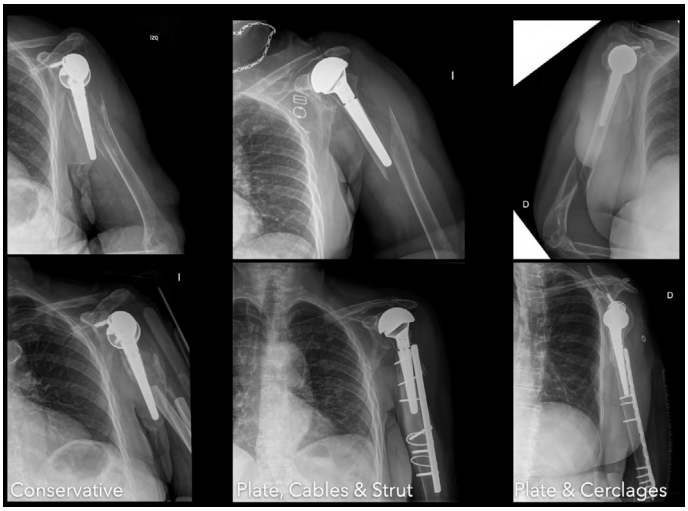
Introduction Periprosthetic humeral fractures in elderly patients present significant challenges due to poor bone quality and co-morbidities. This case series reports the management of such fractures, focusing on three different treatment approaches and their outcomes.

Methods We present a series of cases involving elderly patients with periprosthetic humeral fractures, managed using the following approaches:

- Conservative Management: Selected for frail patients with high anesthetic risk. Despite its necessity in this group, fracture non-union was observed, and no consolidation was achieved.
- Open Reduction and Internal Fixation (ORIF) with Plate, Cerclage, and Cortical Strut Allografts: Applied to fractures at the tip of the prosthesis, combining plate fixation, cerclage wiring, and cortical strut allografts to enhance stability.
- ORIF with Posterolateral Humeral Plate and Cerclage: Used for fractures distal to the prosthesis, with posterolateral plating and cerclage providing robust fixation.

Results Conservative treatment failed to achieve fracture consolidation, leading to poor functional outcomes. Both surgical methods demonstrated successful bone healing and better functional recovery. Cortical strut allografts provided essential support in fractures at the prosthesis tip, while posterolateral plating for distal fractures ensured stable fixation. The most commonly observed complication was transient radial nerve palsy, which resolved spontaneously in all cases.

Conclusion Surgical management, either with cortical struts or posterolateral plating, achieved favorable outcomes in elderly patients with periprosthetic humeral fractures, in contrast to the poor results of conservative treatment, which failed to promote fracture healing. Transient radial nerve palsy was the most frequent complication but resolved in all cases. Surgical intervention should be prioritized when patient conditions allow.



P608

POSTERIOR QUADRATUS LUMBORUM BLOCK AS A TREATMENT FOR CHRONIC HIP PAIN IN OSTEOARTHRITIS PATIENTS

I. Aguado-Maestro[1], M. T. Fernández-Martín[1], P. Almena-Rodríguez[1], J. A. Aguirre[2], A. E. Sanz-Peñas[1], C. Valverde-Gestoso[1], I. García-Cepeda[1], E. Paredes-Herrero[1]

[1]Hospital Universitario del Río Hortega, Valladolid, Spain, [2]Stadtspital Zürich Europaallee, Zurich, Switzerland

Background: Hip osteoarthritis is a prevalent condition that significantly affects morbidity and quality of life. Effective management of chronic hip pain necessitates a multimodal approach to enhance joint function and overall well-being. This study aimed to evaluate whether the posterior quadratus lumborum block (PQLB) could reduce pain and improve quality of life in patients suffering from chronic hip pain.

Methods: Following Ethics Committee approval (No. PI 21-PI104 on June 26, 2021) and registration (ClinicalTrials registration number: NCT04438265), we conducted a prospective cohort study. A total of 200 patients with chronic hip pain unresponsive to previous treatments were enrolled, divided into two groups of 100 each. The intervention group received the PQLB as an analgesic technique, while the control group did not. The PQLB was performed under ultrasound guidance with the patient in the lateral decubitus position. After identifying the quadratus lumborum muscle, 15 ml of levobupivacaine 0.25% with 8 mg of dexamethasone was injected into the fascial space. Patients were discharged 30 minutes post-block. Pain levels were measured using the Numeric Pain Rating Scale (NRS), and quality of life was assessed using the Western Ontario and McMaster Universities Osteoarthritis Index Questionnaire (WOMAC) at 3 weeks and 3 months post-intervention.

Results: Demographic data showed no significant differences between the groups. Pain and quality of life scores improved significantly at the third visit for the PQLB group (NRS mean values from 7.28 to 4.79; WOMAC mean values from 54.31 to 35; p=0.001). In contrast, the control group maintained their baseline scores (NRS

7.69/8.07 and WOMAC 61.10/61.3). Notably, 40 patients in the PQLB group exhibited improvements in NRS and WOMAC scores exceeding 50% by the third month, with ten patients reporting sustained improvement over one year post-block. Patients with avascular necrosis experienced less improvement overall. Only two adverse events were recorded.

Conclusions:

Our findings suggest that the posterior quadratus lumborum block could be a minimally invasive option for managing chronic hip pain, leading to significant reductions in pain and enhancements in quality of life.

P609

ARE THERE NEGATIVE PREDICTIVE FACTORS FOR THE OUTCOMES OF LUMBAR FACET INJECTIONS?

C. Valverde-Gestoso[1], R. Llombart-Blanco[1], I. Martínez-Burgos[1], N. Mateo-Guarch[1], J. Palencia-Ercilla[2], I. Aguado-Maestro[2], M. Alfonso-Olmos-García[1]

[1]Clínica Universidad de Navarra, Pamplona, Spain, [2]Hospital Universitario Río Hortega, Valladolid, Spain

Objective: To identify predictive factors for negative outcomes following lumbar facet joint injections.

Materials and Methods: All patients who presented with low back pain over a two-month period completed various questionnaires: the Numerical Rating Scale (NRS) for pain, Oswestry Disability Index (ODI), SF-12 Health Survey, Pain Catastrophizing Scale, Fear-Avoidance Beliefs Questionnaire (FABQ), and Neck Disability Index (NDI). Additional data collected included body mass index (BMI), physical activity levels, employment status, and recommended treatments. A descriptive analysis was conducted on the data from patients who underwent lumbar facet joint injections.

Results: A total of 160 patients attended the consultation and completed all the questionnaires, with a mean age of 54.7 years (range 18-89), 60.6% being women, and a BMI of 18.2 or higher (24.4% had a BMI of 21.3). Of these, 51.3% engaged in sports activities, and 62.5% were employed. The scores recorded were: NRS for the spine 7 [5-8], NRS for the leg 5 [0-7], and Oswestry 22 [13.3-36].

Out of the 160 patients, 36 were recommended for lumbar facet injections, 26 underwent the procedure, and 21 reported outcomes. Of these, 17 showed a positive response (improvement within the first two hours), while 4 reported no improvement, indicating a negative outcome. Patients with negative outcomes had a mean age of 63.3 years and a BMI over 20.3 (46.2% had a BMI between 26.7 and 33.1). Additionally, 53.8% of these patients did not engage in sports, and 50% were employed.

Patients with negative outcomes had higher scores on the NRS for leg pain, Oswestry Disability Index, SF-12 Physical Component Summary, and FABQ. Their scores on the Pain Catastrophizing Scale were similar to those with positive outcomes.

Conclusions: Patients recommended for lumbar facet injections tend to be older, have a higher BMI, lead a more sedentary lifestyle, and have lower employment rates. Those with negative outcomes following the injection appeared to have greater daily limitations due to low back pain and engaged more in avoidance behaviors due to fear of pain onset.

P610

PREDICTORS OF RECOVERY AND MORTALITY IN MEN FOLLOWING FRAGILITY HIP FRACTURES: A SINGLE-CENTER OBSERVATIONAL STUDY

I. Almeida[1], M. Rocha Sebastião[2], B. Fernandes Esteves[3], M. Correia Natal[3], M. Diz Lopes[3], C. Marques Gomes[3], C. Vaz[3], L. Costa[3], G. Terroso[3]

[1]ULS Viseu Dão-Lafões/Rheumatology Unit, Viseu, Portugal, [2]Hospital do Divino Espírito Santo de Ponta Delgada EPER/Rheumatology Department, Ponta Delgada, Portugal, [3]ULS São João/Rheumatology Department, Porto, Portugal

Objective: To investigate the impact of sociodemographic and clinical characteristics on recovery and mortality outcomes in men following fragility hip fractures (FHF).

Methods: Retrospective single-center study including men aged 50 years or older, referred to a Fracture Liaison Service during their hospitalization in the orthopedics department due to FHF, between October 2022 and October 2024, registered in Reuma.pt. Sociodemographic, clinical and outcome data were collected. Recovery was defined as a return to the level of dependency prior to the event according to the Elderly Mobility Scale. Univariate analyses and binary logistic regression were performed to evaluate predictors of recovery and mortality at 12 months after the FHF, adjusting for age. A p-value ≤ 0.05 was considered statistically significant.

Results: A total of 82 patients were included, with a mean age of 78.04±10.69 years. Of these, 39 patients fully recovered and 21 patients died within 12 months after the FHF. Patients who recovered were younger (p=0.023), had shorter hospital stays (p=0.016), were more likely to engage in regular physical exercise (p=0.007) and adhere to a rehabilitation program (p=0.018), and were less likely to have cardiovascular diseases (p=0.018) and dementia (p=0.029). Cardiovascular diseases (p=0.001), polypharmacy (p=0.014), the use of fall-risk-increasing drugs (p=0.021) and non-adherence to a rehabilitation program (p=0.001) were associated with mortality.

Binary logistic regression analyses identified regular physical exercise as an independent predictor of recovery: patients who engaged in regular physical exercise had a 5.34-fold higher likelihood of recovery (OR=5.34; 95%CI: 1.28–22.19; p=0.021). Longer hospital stays were significantly associated with reduced odds of recovery, with each additional day of hospitalization decreasing the odds by 8% (OR=0.92; 95%CI: 0.87–0.98; p=0.012). Adherence to a rehabilitation program after discharge was associated with an 82% lower risk of mortality (OR=0.18; 95%CI: 0.04–0.87; p=0.033).

Conclusions: Regular physical exercise and hospitalization length were independent predictors of recovery, whereas adherence to a rehabilitation program after discharge independently predicted reduced mortality 12 months after the FHF.

P611

FEATURES OF THE ORGANIC AND FUNCTIONAL PATHOLOGY OF THE THYROID GLAND IN PATIENTS WITH PRIMARY OSTEOARTHRITIS

I. Bashkova[1], I. Madyanov[2]

[1]Chuvash State University named after I.N. Ulyanov; Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), Cheboksary, Russia, [2]Chuvash State University named after I.N. Ulyanov; Institute for the Improvement of Doctors, Cheboksary, Russia

Objective. The aim of the study was to assess the frequency and nature of organic and functional thyroid pathology in patients with primary osteoarthritis (OA), as well as to identify the features of the course of the joint process depending on the state of thyroid status.

Methods. 295 people were examined, 90 of them were patients with a clinically manifest form of primary OA (the main group) and 205 practically healthy residents of Chuvashia (the control group). All patients with OA underwent comprehensive clinical, laboratory and X-ray examination of the joints. The thyroid echostructure and volume were evaluated in patients with OA and in the control group, and the blood levels of thyroid-stimulating hormone (TSH), free fractions of thyroxine (T4) and triiodothyronine (T3) were determined by enzyme immunoassay. The Statistica 10.0 program was used for statistical processing of the obtained data. The threshold level of statistical significance was p=0.05.

Results. The frequency of organic thyropathies in the two compared groups was approximately at the same level. At the same time, it turned out that among the organic thyroid lesions in patients with OA, nodular euthyroid goiter prevails (20.0±4.2%), the prevalence of which is 2.5 times (px2=0.003) higher than the population level (8.1±2.2%). In the control group, organic thyroid diseases were represented by diffuse euthyroid goiter by more than 70%.In patients with OA, increased risk factors for the development of nodular euthyroid goiter were identified: female, age over 50 years, damage to the distal interphalangeal joints of the hands with the formation of Heberden nodules, the presence of pronounced radiological changes in the joints.

The results of the study indicated a more unfavorable course of OA in individuals with organic thyroid pathology. They showed higher values of joint indices, had more intense joint pain during exercise, assessed on a visual analog scale (p=0.007), significantly higher was the total value of the algofunctional index of severity of Leken's gonarthrosis (p=0.043) and a significant deterioration in quality of life (p=0.006) in comparison with patients with OA without organic thyroid pathology. Patients with OA with organic thyroid lesions were significantly more likely (p<0.031) to have X-ray stages III and IV of gonarthrosis (according to Kellgren and Lawrence).

When comparing the concentration of thyroid hormones in the blood of patients with OA (without structural changes in the thyroid gland) and those in the control group, statistically significant decreases in the average levels of T3 (1.9±0.1 versus 2.7±0.2 nmol/l, p=0.007) and TSH (0.9±0.1 versus 1.6±0.3 mIU/l, p=0.023). A thorough analysis of the hormonal spectrum in patients with OA allowed us to conclude that the so-called "euthyroid pathology syndrome" (SEP) is highly prevalent among this category of patients. This condition was diagnosed in 42.9% of patients with OA without thyroid pathology. SEP was represented mainly by two variants: a "low" level of T3 (37.5%) and "anomalies" (decrease in level) TSH (58.3%). The development of "low" T3 syndrome was more often observed in OA patients with more pronounced pain syndrome and manifestations of reactive synovitis.

Against the background of symptomatic therapy aimed at reducing the severity of pain and reactive synovitis, the thyroid status in patients with OA with organic thyroid pathology did not undergo significant dynamics, whereas in patients with functional abnormalities in the thyroid axis it underwent positive changes, which were expressed in an increase in initially low levels of T3 and TSH.

Conclusion. Thus, patients with primary OA were more likely than the general population to have both organic (predominantly nodular euthyroid goiter) and functional (SEP variants with "low" T3 levels and "TSH abnormalities") thyroid pathology. Patients with organic thyroid pathology had more pronounced clinical and radiological manifestations of joint syndrome. In patients with SEP, additional therapeutic measures aimed at correcting thyroid status abnormalities were not required. Therapy aimed at reducing the severity of pain syndrome and relieving reactive synovitis provided positive changes in thyroid status, which were expressed in an increase in initially low T3 and TSH.

P612

STATE OF BONE MINERAL DENSITY IN PATIENTS WITH JOINT AND SPINE LESIONS DUE TO OCHRONOSIS

I. Bashkova[1], N. Bezludnaya[2]

[1]Chuvash State University named after I.N. Ulyanov; Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), Cheboksary, Russia, [2]Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), Cheboksary, Russia, Cheboksary, Russia

Introduction. Ochronosis is a rare metabolic disease resulting from a gene mutation that leads to the accumulation of homogentisic acid in the body, which under the influence of tyrosinase is converted into alkapton, which is partially excreted by the kidneys and deposited in cartilage and connective tissue to a greater extent. In the late stage of the disease, the latter inevitably leads to marked degenerative arthropathy and vertebral lesions. There is progressive calcification of intervertebral discs with fusion of neighbouring vertebral bodies, formation of spondylophytes and calcification of intervertebral ligaments. It has been shown that ochronosis has a higher rate of bone resorption, which in turn can lead to rapid loss of bone mass and the development of osteoporosis.

The aim of the study was to evaluate the state of cartilage tissue and bone mineral density (BMD) of the central skeleton in patients with late-stage ochronosis.

Methods. The study included 6 patients (2 of them men) aged

53-64 years (median (Me) age - 60 years) with a verified diagnosis of ochronosis with joint and spine lesions. All patients were assessed for axial skeletal BMD using a Lunar X-ray osteodensitometer.

Results. All patients clearly showed the stage of appearance of all the main signs of the disease: from early childhood - alkaptonuria, at the age of 34 [30; 50] years (hereinafter Me and interquartile range - Me [Q1; Q3]) - pigmentation of the auricles and sclera, ochronotic spondylo- and arthropathy - at 38.5 [22; 50] and 42 [30; 52] years respectively. However, the diagnosis of 'ochronosis' was established on average 23 years after the clinical manifestation of the disease, all these years the patients were observed with the diagnoses of 'ankylosing spondylitis'/'spondylopathy' and 'osteoarthritis'. The qualitative test for alkaptonuria was positive in all patients.

Periodic pain and stiffness in the lumbar spine with subsequent involvement of the thoracic spine, mechanical back pain, calcification of intervertebral discs, calcification of the anterior longitudinal and lateral ligaments of the spine, and fusion of vertebral bodies were observed on radiographs. The latter two features resembled the changes in the spine occurring in the late stage of ankylosing spondylitis.

Persistent reactive synovitis of the knee joint was found in 3 cases. The lesions of the hip and knee joints were more often asymmetrical. Aseptic necrosis of the femoral head developed in 3 cases (women). Due to the development of secondary gonarthrosis and coxarthrosis, 5 patients underwent consecutive endoprosthesis of large joints of the lower limbs: 3 joints (3 patients) and 2 joints (2 patients) with restoration of the limb axis and joint function. 1 patient is scheduled to undergo knee arthroplasty in 2025. It is noteworthy that the development of osteoarthritis was rapidly progressive - implantation of the first endoprosthesis was performed within 4 to 7 years from the moment of clinical manifestation of arthropathy. Intraoperatively, black pigment deposits were detected in the subchondral bone; articular cartilage was thinning, and in some places it was absent. Cement fixation of the respective endoprosthesis components was performed in all cases.

Dual-energy X-ray absorptiometry of the central skeletal regions revealed a significant decrease in BMD in the proximal femur (T-criterion averaged -2.5 [-2.5; -1.5] SD) with no changes in BMD in the lumbar spine (T-criterion -0.7 [-1.1; 0.6] SD). The results of osteodensitometry in 3 patients were consistent with osteoporosis and in 3 cases with osteopenia. A 53-year-old man had a history of a low-energy femoral fracture sustained a year earlier. A 59-year-old woman had pathological fractures of distal forearm bones on both sides. All patients were recommended bisphosphonate therapy, two of them - for prophylactic purposes. One year later, a slight increase in BMD was observed in the lumbar vertebrae (by 3.4% on average) and the proximal femur (by 2.3% on average).

Conclusions. In patients with ochronosis, rapid development of secondary osteoarthritis of weight-bearing joints was observed, which led to implantation of the first endoprosthesis within 4 to 7 years from the moment of clinical manifestation of arthropathy. A total of 5 patients have now undergone 13 total major joint endoprosthetics. Our results show increased bone resorption, with a marked discrepancy between the BMD values of the proximal femur (consistent with osteoporosis or osteopenia) and lumbar vertebrae (leading to falsely elevated results, probably due to extensive calcification of the intervertebral discs and degenerative spinal lesions). One-third of cases had a history of previous low-energy bone fractures. In patients with ochronosis, periodic assessment of proximal femoral BMD should be performed from a young age to plan prophylactic anti-osteoporotic therapy.

P613

CHONDROCALCINOSIS IN PATIENTS WITH HEREDITARY HEMOCHROMATOSIS

I. Bikanova[1], A. Mihailova[2], A. Tarasova[3], I. Tolmane[4]

[1]Rīga Stradiņš University, Riga, Latvia, [2]Rīga Stradiņš University, ORTO Clinic, Riga, Latvia, [3]ORTO Clinic, Riga, Latvia, [4]Latvian Centre of Infectious Diseases, Riga East University Hospital, Riga, Latvia

Objectives Hereditary hemochromatosis (HH) is a common autosomal recessive disorder, particularly prevalent in Caucasian populations. It is characterized by iron overload affecting various organs. Chondrocalcinosis (CC) is a frequent feature of HH-associated arthropathy. This study aimed to investigate the radiological features of CC, including crowned dens syndrome (CDS), in patients with HH.

Materials and Methods This retrospective study analysed data collected between January 1, 2008, and December 31, 2023, from Riga East Clinical University Hospital and the outpatient clinic ORTO.

Results The study included 69 patients with HH, with a mean age of 49.1 ± 14.4 years; 55.1% of the cohort were female. The mean ferritin level and transferrin saturation coefficient (TSAT) at diagnosis were 810.3 ± 844.0 ng/mL and 67.0% ± 22.5%, respectively. Conventional knee X-rays were performed in 22 (31.9%) patients, revealing CC in 4 (18.2%) patients aged 63-76 years. Additionally, 3 out of 4 patients were female. No statistically significant differences were found in ferritin levels or TSAT between patients with and without CC. Interestingly, a higher proportion of patients with CC reported fatigue compared to those without CC, but the association between symptoms (joint pain and fatigue) and CC findings was not statistically significant. In addition, 26 patients (37.7%) underwent CT head scans for various clinical indications. Among them, 3 patients (11.5%), aged 65-73 years, exhibited typical radiographic findings of periodontal calcification, known as crowned dens syndrome. For two patients these changes were seen 5 years before and for one patient – 3 years after the HH diagnosis. Ferritin levels and TSAT did not differ significantly between patients with and without CDS findings on head CT scans.

Conclusions Arthropathy is a common feature of HH and may present as the initial manifestation of the disease. This condition can be severe and disabling, yet its pathogenesis remains poorly understood. The clinical implications and long-term consequences of HH-associated arthropathy are not fully comprehended. Future studies should prioritize exploring the pathogenesis and

progression of HH arthropathy to identify potential therapeutic targets.

P614

FREQUENCY OF TIBIA FRACTURES IN PERSONS OVER 40 YEARS OF AGE IN THE REPUBLIC OF CRIMEA

V. Kaliberdenko[1], L. Ametova[1], I. Bykovskiy[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: to study the incidence of tibia fractures in individuals over 40 years of age in the Republic of Crimea. Materials and methods: medical records of trauma centers and trauma departments with a stable population, where primary morbidity was recorded, were analyzed. Only fractures resulting from low-level trauma were assessed. A specially developed questionnaire with verification of patients in alphabetical order was filled out. The incidence of fractures was calculated by 5-year strata and per 100,000 person-years of observation. Results: the population over 40 years of age was 68,133 for women and 43,470 for men. In women, the incidence of tibia fractures ranged from 110.1/100 thousand person-years at the age of over 70 years to 207.8/100 thousand person-years in the age group 50-54 years, averaging 146.0/100 thousand person-years of observation. In men, the highest incidence was found at the age of 45-49 years 145.1/100 thousand person-years and in the age group over 70 years - 141.5/100 thousand person-years. The lowest rates were in the age groups 60-64 years 101.7/100 thousand and 65-69 years – 103.0/100 thousand. The average rate of tibia fractures in men was 126.5/100 thousand person-years of observation and was lower than in women. Conclusions: in women, the frequency of tibia fractures was higher than in men and there are differences in fracture rates by age groups depending on gender.

P615

LOW-ENERGY FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE OBSERVATIONAL STUDY

L. Ametova[1], I. Bykovskiy[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective. To determine the frequency and risk factors of low-energy fractures in patients with RA that occurred during long-term prospective observation. Material and methods. The study included 103 women with RA (ACR/EULAR2010). The average follow-up period was 8.45±1.34 years, the average age was 63.5±8.13 years, the average duration of RA was 22.8±9.50. All patients underwent a clinical examination with anamnestic data assessment, radiography of the thoracic and lumbar spine, dual-energy X-ray absorptiometry of the lumbar spine and femoral neck. Vertebral fracture was determined by a semi-quantitative method when detecting deformity of grade I and higher. Radiographs of the hands and feet of 85 patients were assessed using the Sharp van der Heijde method at baseline and over time. Results. During the observation period, the number of patients with fractures increased from 36 (35%) to 60 (58%), 43 (42%) patients had one or more low-energy fractures during the observation period, including 19 (44%) patients with a history of low-energy fracture and 24 (56%) patients with their first fracture. Two or more fractures during the observation period were experienced by 9 (9%) patients. A total of 55 fractures occurred during the observation period, of which 27 (49%) were vertebral and 28 (51%) were peripheral. We divided the patients into two groups: Group I - 43 patients "with fractures", Group II - 60 patients "without fractures" that occurred during the observation period. 43 (100%) patients in Group I and 53 (90%) patients in Group II were in menopause (p=0.032). The mean age, disease duration, RA activity (DAS28), and HAQ did not differ significantly. At baseline, there were more patients in Group I receiving GC (p=0.002), including those taking GC for a long time (more than 3 months) (p=0.011). The baseline erosion score (p=0.053), joint space narrowing score (p=0.044), and total Sharp van der Heijde score (0.031) were significantly higher in Group I. Long-term GC use (p=0.011), menopause (p=0.032), and erosion score (p=0.053) were defined as a set of factors associated with low-energy fractures. The sensitivity/specificity of the model is 83%/55%, respectively. Conclusion. During the observation period, the number of patients with fractures increased by 23%. In women with long-standing RA, 42% developed a fragility fracture during an eight-year follow-up period. Risk factors for fractures included long-term GC therapy, high Sharp van der Heijde erosion score, and menopause.

P616

ASPECTS OF DISABILITY FORMATION IN PATIENTS WITH DYSFUNCTIONS OF THE PELVIC ORGANS CAUSED BY SPINAL CANAL STENOSIS, INJURIES OF THE THORACIC AND LUMBOSACRAL SPINE

I. Chapko[1], J. Ovsjanik[1], A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objective. To analyze the factors causing disability in patients with dysfunction of the pelvic organs caused by spinal canal stenosis, injuries of the thoracic and lumbosacral spine.

Material and methods. The study included 73 patients with dysfunction of the pelvic organs due to spinal stenosis and spinal cord injury of the thoracic and lumbosacral spine.

During the study, an assessment was made of the rehabilitation potential and prognosis, categories of impairments, and limitations of life activity in interaction with environmental factors, which made it possible to identify the main criteria for the risk of disability and its severity.

Results. The risk of disability in patients with dysfunction of the pelvic organs is determined by the influence of several factors related both directly to the clinical manifestations of the disease and its consequences, and to the clinical and labor prognosis.

Conclusion. The result of the study was a diagnostic algorithm for determining the presence and severity of dysfunction of the pelvic organs in patients with spinal stenosis, injuries of the thoracic and lumbosacral spine for use in the practice of medical and social examination.

P617

FOOT DEFORMITIES IN ELDERLY : WHAT ARE THE PREDICTORS OF FALLS?

D. Ben Nessib[1], I. Cherif[1], M. Gdaiem[1], L. Kharrat[1], F. Majdoub[1], H. Ferjani[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Med Kassab Institute of orthopedics, Mannouba, Tunisia

Background: Falls are common among older adults, both in community settings and care homes. Several risk factors have been suggested, including foot abnormalities.
Objective: To assess the impact of foot deformities on fall risk among elderly
Methods: A cross-sectional comparative study was conducted. Patients older than 60 years, able to walk independently, and without cognitive impairment were included. Participants' foot and ankle characteristics were assessed across four specific domains: foot deformities and skin lesions, range of motion (ROM), foot sensation, and foot pain. The evaluation of foot deformities included the presence and severity of hallux valgus (measured using the Manchester scale) and other toe deformities. Foot pain and its impact on functionality were assessed using the Manchester Foot Pain and Disability Index (MFPDI). Participants were categorized into two groups: 'fallers' and 'non-fallers,' based on their fall history over the past 12 months. Both univariate and multivariate analyses were performed, with a significance level set at $p < 0.05$ for all tests.
Results: Ninety-six participants were included in the study (mean age = 67.20 ± 5.54 years; sex ratio = 0.15). Among them, 42 participants (43.8%) reported at least one fall in the past year. Fallers demonstrated a significantly higher prevalence of foot deformities (53.9% vs. 46.1%, p<0.0001), including more severe hallux valgus (56.3% vs. 43.8%, p=0.026), increased plantar fat pad atrophy (67.3% vs. 32.7%, p<0.0001), and a greater incidence of intertrigo (86.7% vs. 13.3%, p<0.0001). Additionally, fallers exhibited significantly reduced tactile sensitivity (60.9% vs. 39.1%, p=0.05), reported more severe foot pain (MFPDI = 9.71 ± 4.198 vs. 5.72 ± 2.811, p=0.001), had a higher prevalence of pes planus (54% vs. 46%, p=0.035), and showed significantly decreased ankle dorsiflexion (68.8% vs. 31.3%, p=0.027). However, no significant differences were observed between the groups regarding the range of motion of the first metatarsophalangeal joint or the number of corns and calluses present.
The multivariate analysis identified foot deformities as the most significant predictor of fall risk (OR = 34.449), with plantar fat pad atrophy (OR = 10.390) and foot pain, as measured by the MFPDI score (OR = 1.688), also being significant contributors.
Conclusion: Foot deformities, especially plantar fat pad atrophy, significantly contributed to fall risk in elderly individuals. Assessing and addressing these conditions in this population is crucial to prevent falls and related injuries.

P618

THE ROLE OF FOOTWEAR IN FALL RISK AMONG OLDER ADULTS

D. Ben Nessib[1], I. Cherif[1], M. Gdaiem[1], L. Kharrat[1], F. Majdoub[1], H. Ferjani[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Med Kassab Institute of orthopedics, Mannouba, Tunisia

Background: Falls are the primary source of injuries for individuals over 65 years (1). While many factors contribute to falls, footwear abnormalities are among the modifiable ones.
Objective: To assess the impact of footwear on fall risk among the elderly.
Methods: A cross-sectional comparative study was conducted, including patients aged 60 years or older who were able to walk independently and had no cognitive impairment. Various types of footwear, including athletic shoes, loafers, sandals, high heels, and slippers, were assessed. Key evaluation criteria included heel type, presence of a platform, upper material composition, and areas of wear. Participants were divided into two groups: 'fallers' and 'non-fallers', based on their fall history in the past 12 months. Both univariate and multivariate analyses were performed, with a significance level set at $p < 0.05$ for all tests.
Results: Ninety-six participants were included in the study (mean age = 67.2 ± 5.54 years; male-to-female ratio = 0.15). Forty-two participants (43.8%) reported at least one fall in the past year. Slippers were the most commonly worn footwear (78.6% of fallers and 63% of non-fallers), followed by sandals (14.3% of fallers and 29.6% of non-fallers) and athletic shoes (6% of fallers and 5.5% of non-fallers). Block heels were the most frequent heel type (64.3% of fallers and 53.7% of non-fallers), followed by wedge heels (35.7% of fallers and 35.2% of non-fallers). Platform shoes were worn by 52.3% of fallers and 37% of non-fallers. Stiffness of the upper material was observed in 81% of fallers and 63% of non-fallers. No significant differences were found between the two groups regarding shoe model, heel type, platform presence, or upper material stiffness. However, increased wear on the shoe soles was significantly more common among fallers (76.2% vs. 42.6%, p=0.001). Multivariate analysis indicated that sole wear was an independent predictor of fall risk (OR = 23.113, p=0.001).
Conclusion: Footwear characteristics, particularly wear on the soles, were associated with an increased risk of falls among the elderly. Regular monitoring of footwear condition may provide an opportunity for early intervention.

REMS TECHNOLOGY FOR THE PREVENTION AND REDUCTION OF FRAGILITY FRACTURES IN FRAGILE PATIENTS AND PREGNANT WOMEN

I. Covelli*[1], C. Greggi*[2], G. Mazzaglia*5,[3], B. Moretti*[1], L. Murena*[4], A. Notarnicola*[1], E. Piccirilli*[2], C. Ratti*[4], G. Solarino*[1], U. Tarantino*[2], S. M. Tecce*[2], M. L. Brandi[5]

[1]Clinica Ortopedica Universitaria, Azienda Consorziale Policlinico di Bari, Bari, Italy, [2]Policlinico Tor Vergata, Rome, Italy, [3]Dipartimento Di Medicina E Chirurgia, Università degli Studi di Milano Bicocca, Milan, Italy, [4]Azienda Sanitaria Universitaria Giuliano Isontina (ASU GI), Trieste, Italy, [5]Osservatorio Fratture da Fragilità Italia (OFF Italia), Florence, Italy

*** Equal contribution listed in alphabetical order**

Objective(s): The "SVOLTA" project (Development of a Service for the Prevention and Reduction of Fragility Fractures) aims to evaluate and monitor the reduction of bone mineral density (BMD) and fracture risk in young and elderly individuals, bedridden patients, immobilized individuals, and pregnant or breastfeeding women. The study addresses an unmet clinical need by providing systematic evaluation for patient's categories currently not assessable with existing diagnostic technologies. The aim is to boost participation in prevention programs, improve osteoporosis diagnosis, and ultimately reduce fragility fractures (FF), while ensuring continuous care, even for pregnant and breastfeeding women.

Material and Methods: 50 individuals aged 50-75 with primary fragility fractures and 50 women in their third trimester of pregnancy will be enrolled. Each patient' bone health will be assessed by DXA (at femur and spine) or REMS (through a simple and quick ultrasound scan at the same bone sites, or only the proximal femur for pregnant women, without exposing the patient to ionizing radiation) and will be monitored over time. Any bone density variations together with the quality of the bone microarchitecture and the 5-yrs imminent fracture risk will be monitored by REMS. Any occurrence of fractures or re-fractures during the follow-up will also be tracked.

Results: The expected outcomes of this study include optimizing the patient's continuity of care through the implementation of guidelines, preventing and reducing fragility fractures, and lowering costs for the National Health Service. Furthermore, the findings from this project will enable risk stratification for primary and secondary fracture in fragile patients, as well as the development of a risk chart to define treatment protocol for osteoporosis/fragility fractures and for pregnant and breastfeeding women.

Conclusion(s): The implementation of this model will address unmet clinical needs by accurately evaluating and monitoring potential reductions in BMD and the risk of FF in individuals who have not been assessable by X-ray techniques, promoting early diagnosis and facilitating the continuity of care also during pregnancy.

P620

BONE DENSITY, STRUCTURE AND STRENGTH, AND THEIR DETERMINANTS IN ATHLETE CHILDREN AND YOUTH

I. Dr. Kalabiska[1], A. Dr. Zsakai[2], R. Prof. Dr. Malina M[3], T. Prof. Dr. Szabo[4]

[1]Research Center for Sport Physiology, Hungarian University of Sports Science, Budapest, Hungary, [2]Department of Biological Anthropology, Eotvos Lorand University, Budapest, Hungary, [3]Department of Kinesiology and Health Education, University of Texas at Austin, Austin, Texas, United States, [4]Hungarian Handball Federation Sport Sciences and Diagnostic Research Centre, Budapest, Hungary

Objectives. The influence of sport activity on bone development is known from the former sport anthropological studies, however the need of using athlete references in bone development estimation of athlete children and youth has just emerging in DEXA analysis practice. The main aim of the study was to construct bone mineral density (BMD) and bone mineral content (BMC), also BMD excluding the head (TBLH) references of athletes for the widely used DEXA scanner.

Methods. Subjects were 1385 athletes, 1019 males and 366 females, 11-20 years of age, who volunteered to participate in this cross-sectional study. The athletes represented several Hungarian sport academies – primarily basketball, football and handball, with smaller numbers for ice hockey and several individual sports: pentathlon, rhythmic gymnastics, swimming, athletics, fencing, kayak, canoe, rowing, wrestling, karate and weight-lifting. Age- and sex- specific means and standard deviations, and selected percentiles (10^{th}, 25^{th}, 50^{th}, 75^{th}, 90^{th}) were calculated for BMD, BMC and TBLH BMD using the LMS chart maker pro version 2.3.

Results. The athletes were grouped into single year chronological age groups with the whole year as the midpoint (11 years = 10.50 to 11.49, etc.). The total BMD of male athletes is considerably higher than the age-specific references for males ($p<0.001$ in each age-group). The median BMD curve exceeds the 90^{th} percentiles of the references. The corresponding trend for total BMD among female athletes also indicates higher BMD ($p<0.001$ in every age-group with the exception 20 years, $p=0.02$). The 25^{th} percentile for female athletes is higher than the 90^{th} percentile of the reference. The percentiles for BMC among male athletes are also consistently higher than the references ($p<0.001$ in every age-group). The median percentile of the athletes approximates the 90^{th} percentile of the references across the age range except at 12 years when the 25^{th} percentile of the athletes approximates the 90^{th} percentile of reference. The corresponding trends in the BMC of female athletes generally parallel the reference percentiles from 14 years on, and are significantly higher than the references ($p<0.001$ in every age-group, with the exception of 13 years, $p= 0.04$). Percentiles of BMD excluding the head (TBLH BMD in male athletes also differ from the references. The percentiles are higher than the references beginning at 11 years ($p<0.001$ in every age-group), and the 25^{th} percentiles of the athletes approximate the 90^{th} percentiles of the reference. The trend in TBLH BMD

percentiles of female athletes is similar to that noted in males ($p<0.001$ in every age-group with the exception of age-group 13, $p=0.04$).
Conclusion. Compared to reference values for the general population, BMD and BMC of the youth athletes were better developed. Comparison of DEXA observations of athletes with reference values for the general population must be done with care avoid potential misinterpretations.

P621

ALTERATION OF MINERALIZATION PROCESS AND ROLE OF ENDOCANNABINOID SYSTEM IN AN IN VITRO MODEL OF MANDIBULAR FIBROUS BONE DYSPLASIA

I. Falsetti[1], G. Palmini[2], S. Donati[1], C. Aurilia[1], G. Galli[1], R. Zonefrati[1], L. Margheriti[3], T. Iantomasi[1], A. Moro[3], M. L. Brandi[2]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy, [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O. Onlus), Florence, Italy, [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy

Introduction: Fibrous bone dysplasia (FBD) is a rare skeletal disease, which is caused by a mutation in *GNAS* gene. The mutation in osteoprogenitor cells impairs their differentiation into mature osteoblasts and osteocytes. It has been observed that the Endocannabinoid System (ES) has also implicated in bone remodeling process. The aim of this work is to study the altered mineralization process and to assess how the ES may be involved in this alteration.
Materials and Methods: A primary cell line, marked as FD-1, was established and characterized by cellular and molecular biology analysis. An osteogenic differentiation assay was established for up to 28 days in FD-1 and in adipose tissue mesenchymal stem cell line, marked as PA24, to assess the expression and modulation of bone mineralization markers and ES genes. The analyses were carried out using Taqman technology.
Results: FD-1 was characterized as a mesenchymal stem line for the presence of mesenchymal stem cells markers (i.e. CD44 and CD105) and for the expression of *ADAMTS2,* identified as a marker gene of FBD. Following osteogenic differentiation, the expression of the main osteogenic differentiation genes (i.e. *OCN, OPG, RUNX2, RANKL, ALPL, DKK1*) was assessed in both lines studied. Significant differences were found in the expression levels of these genes and their modulation, indicating an altered mineralization process in FD-1. Differences were observed in the expression levels and modulation of the main ES receptors, *CB1* and *CB2*. Evaluation of alkaline phosphatase enzyme activity and hydroxyapatite deposition production levels in both differentiated FD-1 and PA24 is ongoing.
Conclusions and future prospects: The study carried out on FD-1 has allowed to highlight the alterations in the mineralization process, but also to observe, for the first time, the involvement of ES in this altered osteogenic process. Studies are underway to determine the expression levels of the other components of ES and to evaluate the effects of *in vitro* treatment with phytocannabinoids to identify new therapeutic targets and assess the possible therapeutic role of cannabinoids in this rare bone disease.
Acknowledgments: Supported by Fondazione Ente Cassa di Risparmio di Firenze and by F.I.R.M.O. Onlus.

P622

INVOLVEMENT OF ENDOCANNABINOID SYSTEM IN HUMAN SKELETAL MUSCLE MYOGENESIS

I. Falsetti[1], G. Palmini[2], C. Aurilia[1], S. Donati[1], G. Galli[1], R. Zonefrati[1], L. Margheriti[3], T. Iantomasi[1], A. Moro[3], M. L. Brandi[2]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy, [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O. Onlus), Florence, Italy, [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy

Introduction: In the last years several studies have demonstrated that the Endocannabinoid System (ES) plays an important role in numerous physiological and pathophysiological processes. Muscle regeneration is a finely regulated process involving satellite cells (SCs) and the activation of Myogenic Regulatory Factors (MRFs). The aim of the present work is to evaluate the presence and role of ES in an *in vitro* model of human skeletal muscle satellite cells and to investigate their possible involvement in myogenesis.
Materials and Methods: Two primary satellite cell lines, marked SC-1 and SC-2, were established from two human muscle biopsies. Both lines were characterized by cellular and molecular biology analysis. Subsequently, a myogenic differentiation assay was established for up to 9 days and the expression of MRFs (i.e. *Myf-5, MyoD-1, MRF-4* and *Myogenin*) and ES components was assessed at different time points (0, 3, 6 and 9 days). The expression levels of these genes were assessed using TaqMan technology.
Results: After characterization of the two SCs cell lines, an increase in the expression levels of MRFs and myogenic differentiation marker genes (*Desmin* and *Myosin Heavy Chain*) was observed following myogenic differentiation. The results obtained showed that the ES receptor genes (i.e., *CB1, CB2, TRPV1*) as well as those of the enzymes involved in the synthesis and degradation of endocannabinoids (i.e., *NAPE, FAAH, DAGLα*) are not only present in SCs, but also that their levels were positively modulated during the myogenic differentiation process in both cell lines studied, demonstrating how the ES is activated during this process. Studies on the effects of endocannabinoids on myogenic differentiation are ongoing.
Conclusions and future perspectives: Two cell lines of SCs from muscle tissue biopsies were established and characterized. This study demonstrated not only the presence of ES but also their positive modulation during myogenic differentiation. Thus, understanding the role of ES in skeletal muscle physiology is important for the possible future development of new therapeutic approach-

es in treatment of muscle diseases as well as therapies based on non-psychotropic phytocannabinoids contained in *Cannabis Sativa*.

P623

METABOLIC DETERMINANTS OF BONE HEALTH IN SPONDYLOARTHRITIS

R. Dhahri[1], I. Fenniche[1], L. Ben Ammar[1], H. Ben Ayed[1], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia

Objective: The aim of our study was to evaluate the relationship between adiposity indices and bone mineral density in patients with spondyloarthritis.

Material and methods: This was a cross-sectional study conducted over 2-month period (November-December 2024) involving patients followed for spondyloarthritis, according to the 2009 ASAS criteria. Socio-demographic and clinical data were collected. Adiposity indices were assessed using body mass index (BMI), waist-to-hip ratio, body fat mass pourcentage, visceral adiposity index (VAI), and hepatic steatosis index (HSI). The body fat mass percentage was calculated using the Deurenberg formula: (1.20 × BMI) + (0.23 × Age) − (10.8 × Sex) − 5.4 (1 for males and 0 for females). The VAI was calculated using the appropriate formula for each gender, incorporating waist circumference, BMI, and lipid profile parameters. The HSI was calculated using the formula: 8 × (ALT/AST) + BMI + 2 (if diabetic) + 2 (if female). Bone mineral density (BMD) was measured using dual-energy X-ray absorptiometry (DEXA) at the lumbar and femoral sites. Data analysis was performed using SPSS software. Results were considered statistically significant if the p-value was less than 0.05.

Results: A total of 54 patients were included. The sex ratio (M/F) was 6.71 (47 men and 7 women). The mean age was 41.07 years (range: 23–67 years). The mean age at disease onset was 35.01 years (range: 18–67 years). The mean disease duration was 6.26 years. The disease phenotypes were as follows: axial spondyloarthritis (n=28), axial and peripheral spondyloarthritis (n=20), arthritis associated with inflammatory bowel disease (n=5), and psoriatic arthritis (n=1). The mean weight was 75.94 kg ± 13.27 (range: 47–103 kg), and the mean BMI was 25.43 kg/m² ± 4.38 (range: 17.24–34.54 kg/m²). Three patients (5.56%) were underweight, 22 patients (40.74%) had normal weight, 22 patients (40.74%) were overweight, and 7 patients (12.96%) were obese. The mean waist-to-hip ratio was 0.918 ± 0.070 (range: 0.76–1.05). The mean body fat mass percentage was 25.17% ± 8.21 (range: 12.84–45.58%). The mean VAI was 1.59 ± 0.94 (range: 0.44–4.36). The mean HSI was 32.77 ± 5.35 (range: 22.11–46.42). The mean BMD at the lumbar spine and femoral sites was 1.12 g/cm² ± 0.216 (range: 0.724–1.862 g/cm²) and 0.956 g/cm² ± 0.155 (range: 0.641–1.446 g/cm²), respectively. The mean T-score at the lumbar spine was -0.933 SD ± 1.12 (range: -4.30 to 5.20 SD), while the mean T-score at the femoral site was -0.886 SD ± 0.98 (range: -3.50 to 3.70 SD). A total of 21 patients had normal bone mineral density. Low BMD was observed in 21 patients, with osteopenia in 16 patients and osteoporosis in 5 patients. In contrast, 2 patients presented with high bone density. Bone mineral density at the femoral site was positively correlated with weight (r = 0.569; p<0.001), waist circumference (r = 0.392; p = 0.006), HSI (r = 0.467; p = 0.001), and VAI (r = 0.390; p = 0.012). Bone mineral density at the lumbar spine was positively correlated with weight (r = 0.464; p = 0.001), waist circumference (r = 0.347; p = 0.015), and HIS (r = 0.446; p = 0.001). In multivariate linear regression analysis, waist circumference was significantly associated with bone mineral density at the lumbar spine (β = -0.673; p = 0.042).

Conclusion : Approximately 39% of our patients demonstrated reduced bone mineral density. A positive correlation was observed between various adiposity indices and bone mass, suggesting a potential link between these parameters. These findings highlight the importance of assessing metabolic and body composition factors in managing patients at risk of osteoporosis. Further studies are needed to confirm these associations.

P624

IS VITAMIN D DEFICIENCY LINKED TO INCREASED INFLAMMATORY ACTIVITY IN SPONDYLOARTHRITIS?

R. Dhahri[1], I. Fenniche[1], L. Ben Ammar[1], H. Ben Ayed[1], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia

Objective The aim of our study was to assess the 25-hydroxy vitamin D levels in patients with spondyloarthritis and investigate the association between vitamin D levels and disease activity.

Material and methods This was a cross-sectional study including patients diagnosed with spondyloarthritis (SpA) according to the 2009 ASAS criteria. The study was conducted over a 6-month period (July to December 2024).

Sociodemographic, clinical, and biological data were collected. Disease activity was assessed using ASDAS-CRP, ASDAS-ESR, and BASDAI.

The Systemic Inflammation Index (SII) was calculated based on the complete blood count using the following formula: SII = (Platelet count × Neutrophil count) / Lymphocyte count. 25-hydroxy vitamin D levels were measured using the chemiluminescence technique with the DXI Beckman Coulter system. Levels were classified as low when < 30 ng/mL: insufficiency (vitamin D levels between 10–30 ng/mL) and deficiency (vitamin D levels < 10 ng/mL).

Results A total of 62 patients were included. The mean age was 39.95 years (range: 23–68 years). The mean age at disease onset was 34.86 years (range: 18–67 years). The mean

disease duration was 5.26 ± 5.87 years. The SpA phenotypes were distributed as follows: axial SpA (n=34), axial and peripheral SpA (n=21), arthritis associated with inflammatory bowel disease (n=4), and psoriatic arthritis (n=3). The mean C-reactive protein (CRP) level was 8.50 ± 17.20 mg/L (range: 0–91 mg/L), and the mean erythrocyte sedimentation rate (ESR) was 25.05 ± 24.42 mm/h (range: 5–105 mm/h). The mean systemic inflammatory index (SII) was 644.972 ± 531.659 × 10^3 /µL (range: 109.666–2539.466 × 10^3/µL). Disease activity scores were as follows: ASDAS-CRP 1.93 ± 1.22 (range: 0–5.70), ASDAS-ESR 2.29 ± 1.12 (range: 0.70–6.20), and BASDAI 2.12 ± 1.71 (range: 0–8.10). The mean 25-hydroxyvitamin D level was 22.75 ± 7.62 µg/L (range: 6–50 µg/L). A normal vitamin D level was observed in 6 patients (9.7%). In contrast, 56 patients (90.3%) had low levels: vitamin D insufficiency in 55 patients and vitamin D deficiency in 1 patient. There was a significant negative correlation between vitamin D levels and CRP (p=0.012, r=-0.330) and between vitamin D levels and ASDAS-ESR (p=0.024, r=-0.307). Patients with low vitamin D levels were associated with higher disease activity: ASDAS-CRP (1.97 ± 1.28 vs 1.55 ± 0.43, p=0.033) and ASDAS-ESR (2.36 ± 1.15 vs 1.64 ± 0.19, p=0.039). Multivariate analysis showed a negative correlation between vitamin D levels and ASDAS-ESR (β=-0.744, p=0.042).

Conclusion Low vitamin D levels are significantly associated with higher disease activity in patients with spondyloarthritis. Supplementing vitamin D insufficiency may help control inflammation and improve disease management in this population.

P625

ATTITUDES AND PRACTICES OF RHEUMATOLOGISTS IN MANAGING AVASCULAR NECROSIS OF THE FEMORAL HEAD

R. Dhahri[1], I. Fenniche[1], H. Ben Ayed[1], L. Ben Ammar[1], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia

Objective The aim of this study was to evaluate the attitudes and experiences of rheumatologists in the management of avascular necrosis of the femoral head (ANFH).
Material and Methods A cross-sectional descriptive study was conducted among rheumatologists from December 2024 to January 2025 using a self-administered online questionnaire. The questionnaire was designed and distributed via Google Forms.
Results Fifty-one rheumatologists (42 women, 9 men) participated in the questionnaire. The mean age was 40 years (range 26–70). The average duration of practice was 14.4 years (range 1–39). Among the respondents, 13.7% were trainees and 86.3% were senior practitioners. Overall, 84.3% worked in hospitals and 15.7% in private practice.
ANFH was perceived as rare by 70.6%, very rare by 15.7%, and frequent by 13.7%. The main presenting complaint was hip pain (72.5%), followed by limping or functional impairment (19.6%), and referral from another practitioner (3.9%). At first consultation, Arlet and Ficat stage 2 (56.9%) was most common, followed by stage 3 (23.5%), stage 1 (13.7%), and stage 4 (5.9%).
In patients with painful hip and normal radiographs, 72.5% ordered pelvic MRI, while 15.7% ordered pelvic MRI only under specific circumstances. For unilateral ANFH at Stage ≥ 2, 51% systematically requested MRI to guide management, 70.6% to detect contralateral involvement, 17.6% to confirm the stage, and 5.9% considered radiographs sufficient. Additional joint involvement was systematically investigated by 60.8% of respondents, typically via standard radiographs (57.8%) or bone scintigraphy (46.7%). Etiological factors were investigated by 98% of participants. Regarding leg-length discrepancy, 49% did not assess it routinely, 31.4% checked it systematically, 29.4% corrected it with heel lifts after hip replacement, and 13.7% performed systematic evaluation post–hip replacement to prevent contralateral collapse. Hyperbaric oxygen therapy was not used by 82.4% of respondents, however, 15.7% employed it in the early stages with favorable outcomes. As for bisphosphonates, 78.4% reported having no experience, 17.6% considered them experimental, and 5.9% observed mixed results. Core decompression was not performed by 35.3%, indicated as first-line therapy in early stages by 29.4%, and combined with bone grafting by another 29.4%. Treatment decisions were primarily guided by radiographic stage (96%), patient age (82%), and the hip's algofunctional index (74%). Furthermore, 54.9% of rheumatologists considered early-stage medical therapy to be successful, while 45.1% regarded it as disappointing. Additionally, 78.4% estimated that ANFH is a complex pathology with management protocols that are not yet clearly standardized.
Conclusion The majority of rheumatologists in our study recognized the complexity of ANFH and underscored the need for standardized management protocols. Establishing unified guidelines could enhance patient outcomes and improve clinical practices.

P626

ETHICAL DILEMMAS IN RHEUMATOLOGY: A CLINICAL APPROACH

R. Dhahri[1], I. Fenniche[1], H. Ben Ayed[1], L. Ben Ammar[1], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia

Objective The aim of this study was to assess the frequency and nature of ethical dilemmas faced in rheumatology practice, as well as the approaches favored by physicians to address them.
Material and methods A cross-sectional descriptive study was conducted among rheumatologists from December 2024 to January 2025 via a self-administered online questionnaire. The questionnaire was designed using Google Forms. Ten real-life ethical scenarios were developed to explore practitioners' perspectives.
Results Thirty rheumatologists participated in the survey. The mean age was 28.66 years (range 25–43). There were 28 women and 2 men. Most participants (80%) were residents, 13.3% hospital-university, and 6.7% hospital-sanitary.

In the scenario of an elderly illiterate patient with chronic inflammatory rheumatism, 13.3% delegated medical decisions to the partner, 30% to children, and 63.3% demanded the patient's consent before sharing any information. Among patients in a terminal phase, 50% believed that directly revealing the diagnosis to family members violated medical confidentiality, while 33.3% believed that simply confirming the fatal outcome was also a breach of confidentiality. When a relative requested a medical report, 40% felt that providing it without telling the patient broke confidentiality, and 33.3% considered that allowing chart review or giving oral explanations posed the same issue. In cases where pre-anti-TNF testing revealed a positive HBsAg, 86.7% informed the patient about the need to screen the partner, 10% contacted the wife directly or let the patient tell her, and 6.7% requested tests without patient consent. For a suspected multiple myeloma in an asymptomatic patient, 56.7% disclosed the possible diagnosis and explained the need for a bone marrow biopsy, while 50% preferred to wait for biopsy results. In a young patient with severe sciatica and a history of dependence, 43.3% prescribed low-dose opioids under surveillance, 80% referred the patient to a pain-management center, and 3.3% either prescribed strong opioids or refused analgesics. Faced with a patient with advanced lung cancer bone metastases refusing palliative care, 86.7% insisted he remains in the hospital despite his refusal, whereas 7% allowed discharge against medical advice or informed his family. In a 28-year-old woman with idiopathic osteoporosis worried about bisphosphonate teratogenicity, 56.7% suggested egg preservation or deferring treatment until after pregnancy, 46.7% respected her refusal and offered alternatives, 23.3% underscored fracture risks, and 13.3% recommended closer follow-up. For announcing chronic inflammatory rheumatism to a patient who wanted her partner present, 80% suggested a private discussion first, 16.7% refused any additional presence, and one physician immediately agreed to include him. Finally, when a patient with rheumatoid arthritis wished to discontinue specialized care, 86.7% explained the risks, 26.7% respected her decision, and 2 rheumatologists opposed it. **Conclusion** This survey highlights the complexity of ethical dilemmas in rheumatology, emphasizing the delicate balance between patient autonomy, confidentiality, and shared decision-making. Clear guidelines and targeted ethics training are needed.

P627

IMPACT OF MODERATE PHYSICAL ACTIVITY ON BONE HEALTH IN SPONDYLOARTHRITIS: A CROSS-SECTIONAL STUDY

R. Dhahri[1], I. Fenniche[1], L. Ben Ammar[1], H. Ben Ayed[1], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia

Objective The aim of this study was to evaluate the association between physical activity levels and bone mineral density in patients diagnosed with spondyloarthritis. **Material and Methods** This was a cross-sectional study involving patients followed for spondyloarthritis (SpA), according to the 2009 ASAS criteria. The study was conducted over a 6-month period (July to December 2024). Socio-demographic and clinical data were collected. Physical activity was assessed using the IPAQ questionnaire. The data collected included the number of days per week and the minutes per day of vigorous, moderate, and walking activities. The results in metabolic equivalent tasks (MET), expressed in minutes per week (min/week), were calculated, and activity levels were categorized as inactive, moderately active, or very active. Bone mineral density (BMD) was measured using dual-energy X-ray absorptiometry (DEXA) at the lumbar and femoral sites. Data analysis was performed using SPSS software. Results were considered statistically significant if the p-value was less than 0.05. **Results** A total of 48 patients were included in the study. The male-to-female ratio was 3.8 (38 men and 10 women). The mean age was 40.65 years (range: 23 - 67 years). The mean age at disease onset was 35.17 years (range:18 - 67 years). The average disease duration was 5.71 years. The phenotypes of SpA were categorized as follows: axial SpA (n=25), axial and peripheral SpA (n=15), rheumatism associated with inflammatory bowel disease (n=5), psoriatic arthritis (n=2), and SAPHO syndrome (n=1). The mean MET/min/week for intense, moderate, and light activities were 959.27 ± 2 546.64 (range: 0–13 440), 1 112.08 ± 1 938.15 (range: 0–10 080), and 1 002.92 ± 1 725.26 (range: 0–10 080), respectively. The total MET/min/week was 2 735.75 ± 3 440.59 (range: 120–15 066). Based on activity levels, 11 patients were classified as inactive, 23 patients as having moderate activity, and 14 patients as very active. The mean lumbar spine T-score was -0.94 ± 1.55 standard deviations (SD) (range: -4.30 - 4.70 SD). The mean femoral T-score was -0.814 ± 1.22 SD (range: -2.90 - 3.70 SD). The average lumbar spine BMD was 1.117 g/cm² ± 0.185 (range: 0.724 - 1.806 g/cm²). The femoral BMD was 0.959 g/cm² ± 0.145 (range: 0.710 - 1.446 g/cm²). Twenty patients had normal BMD. Twenty-seven patients showed reduced BMD, including 17 cases of osteopenia and 10 cases of osteoporosis. Only one patient presented with increased bone mineral density. The T-scores at the vertebral and femoral sites were higher in active patients compared to inactive patients, but the differences were not statistically significant (-0.897 ± 1.169 SD vs -1.618 ± 1.703 SD, p=0.116; and -0.745 ± 1.255 SD vs -1.136 ± 1.128 SD, p=0.362, respectively). A significant positive correlation was observed between the lumbar spine T-score and MET for moderate activities (r=0.352, p=0.014), as well as between the femoral T-score and MET for moderate activities (r=0.311, p=0.033). Additionally, a significant positive correlation was identified between lumbar spine bone mass and MET for moderate activities (r=0.394, p=0.007) and with total MET (r=0.326, p=0.029). **Conslusion** This study demonstrated a significant positive association between moderate physical activity and bone mineral density in patients with spondyloarthritis. These findings indicate that maintaining even moderate levels of physical activity may en-

hance bone health in this population.

P628

INFLUENCE OF MEDITERRANEAN DIET ADHERENCE ON SYSTEMIC INFLAMMATION AND DISEASE ACTIVITY IN SPONDYLOARTHRITIS

R. Dhahri[1], I. Fenniche[1], L. Ben Ammar[1], H. Ben Ayed[1], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia

Objective To evaluate the relationship between adherence to the Mediterranean diet, systemic inflammation, and disease activity in patients with spondyloarthritis (SpA). **Material and Methods** This was a cross-sectional study involving patients diagnosed with SpA according to the 2009 ASAS criteria. The study was conducted over a three-month period (November 2024 to January 2025). Socio-demographic, clinical, and biological data were collected. Dietary habits were assessed using the Chrono Med-Diet Score (CMDS), which evaluates 11 food categories: fruits, vegetables, legumes, refined products, whole cereals, fish, meats and meat products, milk and dairy, olive oil, butter, margarine and lard, and alcohol consumption. Additionally, it includes two categories: timing of refined product intake and physical activity. The final CMDS score ranges from −13 to 25, with higher scores reflecting greater adherence to the Mediterranean diet. Disease activity was assessed using ASDAS-CRP, ASDAS-ESR, and BASDAI. The Systemic Inflammation Index (SII) was calculated using the following formula: SII = (Platelet count × Neutrophil count) / Lymphocyte count. Data analysis was performed using SPSS software. A p-value of less than 0.05 was considered statistically significant. **Results** Forty-three patients were included in the study. The male-to-female ratio was 5.14, with 36 men and 7 women. The mean age was 40.33 years (range: 23-65 years). The mean age at disease onset was 34.38 years (range: 18-62 years). The average disease duration was 6.19 years. The mean CRP level was 6.16 ± 10.95 mg/L (range: 0-45 mg/L). The mean ESR was 25.04 ± 23.36 mm/h (range: 5-91 mm/h). The mean SII was 558.810 ± 416.387 × 10^3/µL (range: 109.666 - 2109.937 × 10^3/µL). The mean scores for ASDAS-CRP, ASDAS-ESR, and BASDAI were 1.86 ± 1.20 (range: 0-5.70), 2.18 ± 1.14 (range: 0.70-6.20), and 2.09 ± 1.85 (range: 0-8.10), respectively. The mean CMDS score was 9.58 ± 4.64 (range: 2-20). A significant negative correlation was observed between fruit consumption and ASDAS-ESR (r = -0.342, p = 0.044), as well as between vegetable consumption and ESR (r = -0.363, p = 0.032). Additionally, a significant negative correlation was found between fish consumption and SII (r = -0.385, p = 0.020). A significant positive correlation was identified between the consumption of refined products and ASDAS-CRP, ASDAS-ESR, and CRP levels (r = 0.415, p = 0.012) (r = 0.400, p = 0.021) and (r = 0.464, p = 0.007). **Conclusion** Adherence to the Mediterranean diet, particularly the consumption of fruits, vegetables, and fish, was associated with lower inflammation and disease activity in SpA patients in our study. These findings emphasize the potential benefits of dietary adjustments in the management of SpA.

P629

THE IMPACT OF THE MEDITERRANEAN DIET ON BONE MINERAL DENSITY IN SPONDYLOARTHRITIS

R. Dhahri[1], I. Fenniche[1], L. Ben Ammar[1], H. Ben Ayed[1], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia

Objective To assess the relationship between adherence to the Mediterranean diet, as measured by the Chrono Med-Diet Score (CMDS), and bone mineral density in patients with spondyloarthritis. **Material and Methods** This was a cross-sectional study involving patients followed for spondyloarthritis (SpA), according to the 2009 ASAS criteria. The study was conducted over a 3-month period (Novembre 2024 to January 2025). Socio-demographic and clinical data were collected. Dietary habits were assessed using the Chrono Med-Diet Score (CMDS), which evaluates 11 food categories: fruits, vegetables, legumes, refined products, whole cereals, fish, meats and meat products, milk and dairy, olive oil, butter, margarine and lard, and alcohol consumption. Additionally, it includes two categories: timing of refined product intake and physical activity. The final CMDS score ranges from −13 to 25, with higher scores reflecting greater adherence to the Mediterranean diet. Bone mineral density (BMD) was measured using dual-energy X-ray absorptiometry (DEXA) at the lumbar and femoral sites. Data analysis was performed using SPSS software. Results were considered statistically significant if the p-value was less than 0.05. **Results** Forty patients were included in the study. The male-to-female ratio was 5.66 (34 men and 6 women). The mean age was 40.60 years (range: 23–65 years). The mean age at disease onset was 34.25 years (range: 18–62 years). The average disease duration was 6.60 years. The SpA phenotypes were distributed as follows: axial SpA (n=20), axial and peripheral SpA (n=13), arthritis associated with inflammatory bowel disease (n=4), psoriatic arthritis (n=2), and SAPHO syndrome (n=1). The mean lumbar spine T-score was −0.957 ± 1.635 SD, and the mean femoral T-score was −0.840 ± 1.308 SD. Bone mineral density was 1.120 ± 0.193 g/cm² at the lumbar spine and 0.964 ± 0.156 g/cm² at the femur. Sixteen patients had normal BMD, while 23 patients presented reduced BMD (osteopenia in 14 patients and osteoporosis in 9 patients). One patient had increased BMD. The mean final CMDS score was 9.65 ± 4.7 (range: 2–20). Patients with normal BMD had a higher mean CMDS score compared to those with reduced BMD, with no statistically significant difference (11 ± 4.65 vs 8.41 ± 4.63, p=0.092). A statistically significant higher olive oil consumption was observed in patients with normal BMD compared to those

with reduced BMD (1.71 ± 0.469 vs 1.10 ± 1.165, p=0.043). A significant positive correlation was observed between the final CMDS score and femoral T-score (r=0.389, p=0.014) as well as femoral bone mass (r=0.449, p=0.005). Additionally, a significant positive correlation was found between the timing of refined product intake—specifically consumption earlier in the day—and the femoral T-score (r=0.493, p=0.004) and femoral BMD (r=0.501, p=0.004). However, a significant negative correlation was identified between fish consumption and vertebral T-score (r=-0.501, p=0.003) as well as vertebral BMD (r=-0.473, p=0.005). **Conclusion** Good adherence to the Mediterranean diet was associated with normal bone mineral density in our study, particularly the use of olive oil and the early consumption of refined products during the day.

P630

LOW SERUM CREATININE IN RHEUMATOID ARTHRITIS: ASSOCIATED FACTORS

I. Fenniche[1], M. Somaï[1], F. Daoud[1], I. Arbaoui[1], B. Ben Dhaou[1], S. Kochbati[1], F. Boussema[1], I. Rachdi[1], Z. Aydi[1]

[1]Internal Medicine Department, Habib Thameur Hospital, Tunis ElManar University, Tunis, Tunisia

Objectives The aim of this study was to evaluate serum creatinine levels in patients with rheumatoid arthritis (RA) and determine the factors associated with a decline in these levels.
Material and methods This was a retrospective study including 95 patients diagnosed with RA based on the ACR-EULAR 2010 criteria, followed in an internal medicine department from January 2015 to December 2023. Serum creatinine levels were extracted from medical records. Epidemiological, biological, radiological characteristics, and treatments received were collected. Low serum creatinine levels were defined as <60 µmol/L in men and <45 µmol/L in women. Patients with chronic kidney disease were excluded.
Results Ninety-five patients were included, with a mean age of 61.74 ± 14.70 years. The mean age at disease onset was 48.53 ± 15.68 years. The mean disease duration was 12.64 ± 9.69 years. The sex-ratio (F/M) was 4.59. The mean serum creatinine level was 62.27 ± 16.63 µmol/L (range: 25–111 µmol/L). The mean CRP level was 26.38 ± 30.97 mg/L. The mean DAS28-CRP score was 4.09 ± 1.16. The mean glomerular filtration rate was 91.78 ± 19.71 mL/min/1.73 m² (range: 45.49–142.44 mL/min/1.73 m²). Serum creatinine levels were positively correlated with age (p=0.032; r=0.229) and age at disease onset (p=0.005; r=0.320) and negatively correlated with CRP levels (p=0.046; r=-0.214), DAS28-CRP scores (p=0.009; r=-0.359), and corticosteroid dosage (p=0.040; r=-0.223). Thirteen patients (16.68%) had low serum creatinine levels. Low serum creatinine was significantly associated with age at disease onset and DAS28-CRP scores (p=0.020 and p=0.019, respectively). All these patients were on biologic therapy.
Conclusion In our study, 16.68% of RA patients presented with abnormally low serum creatinine levels. This decline was associated with age at disease onset, inflammation, and disease activity. These findings suggest that low serum creatinine may serve as an additional marker for monitoring disease progression and guiding therapeutic decisions in RA patients.

P631

EROSIVE RHEUMATOID ARTHRITIS: A STUDY OF ASSOCIATED FACTORS

I. Fenniche[1], M. Somaï[1], F. Daoud[1], I. Arbaoui[1], B. Ben Dhaou[1], S. Kochbati[1], F. Boussema[1], I. Rachdi[1], Z. Aydi[1]

[1]Internal Medicine Department, Habib Thameur Hospital, Tunis ElManar University, Tunis, Tunisia

Objective The aim of this study was to investigate the specific characteristics of erosive rheumatoid arthritis (RA).
Material and methods This was a retrospective study involving 70 patients diagnosed with RA according to the ACR-EULAR 2010 criteria. Sociodemographic characteristics, as well as clinical, biological, and radiographic parameters, were collected. The patients were divided into two groups: G0 (non-erosive RA) and G1 (erosive RA).
Results Seventy patients were included in the study. The sex ratio (F/M) was 7.75. The mean age was 61.10 ± 14.74 years. The mean age at disease onset was 47.52 ± 16.12 years. The mean disease duration was 13.54 ± 9.95 years. Fifty-four patients (77.14%) had erosive RA. No significant differences were found between the two groups regarding sex (p=0.878), age (p=0.079), and age at disease onset (p=0.635). Disease duration was significantly longer in the erosive group (15.54 ± 9.88 years vs 7.13 ± 7.28 years; p=0.001). Erosive disease was significantly associated with rheumatoid factor (RF) positivity, with a higher prevalence in the G1 group compared to the G0 group (91.11% vs 69.23%; p=0.044). No significant differences were observed regarding seropositivity for anti-citrullinated protein antibodies (ACPA) (p=0.344), extra-articular manifestations (p=0.453), or associated autoimmune diseases (p=0.273). The CRP levels were significantly higher in the G1 group compared to the G0 group (32.43 ± 36.11 mg/L vs 9.11 ± 8.52 mg/L; p<0.001). Therapeutically, no significant differences were found in the use of conventional synthetic DMARDs (CsDMARDs) or corticosteroids. However, the duration of corticosteroid treatment was significantly longer in the G1 group compared to the G0 group (10.41 ± 8.28 years vs 4.82 ± 3.97 years; p=0.047). Biologic therapies were also more frequently prescribed in the G1 group than in the G0 group (31.48% vs 6.25%; p=0.043).
Conclusion Erosive rheumatoid arthritis was associated with longer disease duration, higher RF positivity, and significantly elevated CRP levels compared to the non-erosive form in our study. Patients with erosive RA required longer corticosteroid treatment durations and benefited more frequently from biologic therapies. These findings highlight the importance of distinguishing between erosive and non-erosive forms of RA to personalize therapeutic approaches.

P632

FAT MASS INDEX AS A PREDICTOR OF METABOLIC AND INFLAMMATORY STATUS: A CROSS-SECTIONAL STUDY IN HEALTHY ADULTS

I. Fomcenko[1], I. Bikulciene[1], D. Karciauskaite[1], J. Urboniene[2], M. Tamulaitiene[3], V. Sapoka[1]

[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [2]Center of Infectious Diseases, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania, [3]National Osteoporosis Center, Vilnius, Lithuania

Objective: The study aimed to investigate the relationship of fat mass index (FMI) and metabolic and inflammatory markers.
Material and Methods: Study included 169 healthy individuals (60 men and 109 women aged 20-49 years). Body composition including fat mass was measured by dual-energy X-ray absorptiometry (iDXA, GE Lunar), FMI was calculated (FMkg/height^2). Participants were divided into 3 groups based on FMI: low fat (female FMI<5 kg/m², male FMI<3 kg/m²), normal fat (female FMI5-9kg/m²,male FMI3-6kg/m²), and high fat (female FMI>9 kg/m², male FMI>6 kg/m²). Lipid profile, glucose, insulin, and C-reactive protein (CRP) were measured. One-way ANOVA test was used to compare groups, multivariable linear regression analysis - to evaluate the association. The study was approved by the Ethics Committee, all participants provided informed consent.
Results: A total of 99 (58.6%) of participants had high fat, and 11 (6.5%) had low fat. Individuals with high fat had significantly higher fat in each body region compared to those with normal fat (respectively: total fat 40.34%vs.27.9%, trunk fat 43.4%vs.26.4%, android fat 50.7%vs.31.6%, gynoid fat 47.2%vs.37.3%, appendicular fat 38.9%vs.29.9%). High fat individuals had significantly higher LDL-cholesterol (3.31±0.86 vs. 2.85± 0.65 mmol/L), triglycerides (1.29±0.77vs.0.92±0.54mmol/L), glucose (5.55±0.43 vs. 5.11±0.48 mmol/L), insulin (13.28±7.61vs.6.79±2.91mU/L), and CRP (2.71±3.16vs0.69±0.61 mg/L), and lower HDL-cholesterol (1.39±0.32vs1.81±0.44 mmol/L) levels compared to those with normal fat. Regression analysis revealed positive association of FMI with LDL-cholesterol (β=0.55, 95% CI 0.02–1.07, p=0.043), glucose (β=1.34,95% CI 0.33–2.35, p=0.01), insulin (β=0.18, 95% CI 0.10–0.26, p<0.001) and CRP (β=0.45, 95% CI 0.27–0.63, p<0.001) and inverse association with HDL-cholesterol (β= -1.85, 95% CI -3.18 – -0.52, p=0.007)
Conclusions: Healthy adults with high fat exhibit a less favourable metabolic profile. FMI is associated with cholesterol, glucose, insulin and CRP levels, making it a valuable predictor of metabolic and inflammatory status.

P633

BODY COMPOSITION AND ADIPOSITY INDEXES IN WOMEN WITH ANOREXIA NERVOSA

I. Fomcenko[1], B. Baks[1], J. Urboniene[2], M. Tamulaitiene[3], V. Sapoka[1]

[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [2]Center of Infectious Diseases, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania, [3]National Osteoporosis Center, Vilnius, Lithuania

Objective: The study aimed to investigate the body composition of women diagnosed with anorexia nervosa (AN) and to assess the discriminating abilities of adiposity indexes for predicting AN.
Material and Methods: The study included 24 women with AN and 45 healthy women with a body mass index (BMI) < 30 kg/m². Body composition was measured by dual-energy X-ray absorptiometry (iDXA, GE Lunar). Fat mass index (FMI) and lean mass index (LMI) were calculated. Low fat was defined as FMI <5kg/m². Underweight was defined as BMI <18.5kg/m². Statistical analysis included descriptive statistics, Student's t-test, ROC analysis, and the Youden index. The study was approved by the Ethics Committee, and all participants provided informed consent.
Results: Women with AN had lower total bone mass (2.11±0.35 vs. 2.45±0.27 kg), fat mass (8.96±4.05 vs. 18.65±5.25 kg), lean mass (35.57±3.53 vs. 40.72±4.66 kg), FMI (3.19±1.47 vs.6.42±1.66 kg/m²), and LMI (12.61±0.93 vs. 14.05±1.07 kg/m²) compared to healthy women (p<0.001). They also had lower fat in each body region: trunk (15.03% vs. 27.01%), android (15.94% vs. 31.83%), gynoid (27.65% vs. 43.42%), and appendicular (23.27% vs. 35.30%). A fat deficit was observed in 91.7% of women with AN compared to 17.8% of healthy women. 87.5% of women with AN and 13.3% of healthy women were underweight. ROC analysis revealed that FMI and BMI had comparable discriminating abilities for AN: FMI AUC 0.93 (95% CI 0.86 – 0.99, p < 0.001) and BMI AUC 0.95 (95% CI 0.90 – 1.00, p < 0.001). A BMI of 17.61 kg/m² discriminates healthy women with 97.8% sensitivity and 87.5% specificity, while an FMI of 4.89 kg/m² discriminates healthy women with 84.4% sensitivity and 91.67% specificity.
Conclusions: Women with anorexia nervosa exhibited significantly lower bone, fat, and lean mass, with a marked fat deficit compared to healthy women. Both FMI and BMI demonstrated strong discriminatory abilities for predicting AN, with high sensitivity and specificity.

P634

PREDICTORS OF 5-YEAR SURVIVAL IN PATIENTS WITH HIP FRACTURE: FINDINGS FROM A PROSPECTIVE REAL-WORLD STUDY

I. G. Macchione[1], M. Baroni[1], M. Pizzonia[2], A. Giusti[3], G. Rinonapoli[4], V. Bini[1], E. Martini[5], C. Becker[6], O. Sahota[7], A. Johansen[8], C. Ruggiero[1]

[1]Orthogeriatric and Geriatric Units, Gerontology and Geriatrics Section, Department of Medicine and Surgery, University of Perugia, S. Maria Misericordia Hospital, Perugia, Italy, Perugia, Italy, [2]Geriatrics Clinic, Department of Internal Medicine and Medical Specialties (DIMI), University of Genoa, Genoa, Italy - IRCCS Policlinico San Martino Hospital, Genoa, Italy, Genoa, Italy, [3]Department of Mechanical Engineering, Imperial College London, London SW7 2AZ, U.K., London, United Kingdom, [4]Orthopaedics and Traumatology Department, University of Perugia, Perugia, Italy, Perugia, Italy, [5]Orthogeriatric Unit, Baggiovara Hospital, Modena, Italy, Modena, Italy, [6]Department of Clinical Gerontology and Geriatric Rehabilitation, Robert Bosch Hospital, Stuttgart, Germany, Stuttgart, Germany, [7]Nottingham University Hospital, Nottingham, UK, Nottingham, United Kingdom, [8]Trauma and Orthopaedics, University Hospital of Wales, Cardiff, UK, Cardiff, United Kingdom

Objective: older patients with hip fractures (HF) are complex to manage, impacting both health and economic systems. Identifying those with longer survival may help to better allocate resources and develop more appropriate treatments. However, no real-world study has focused on such an approach. Main objective of this study is to identify predictors of 5-year survival since hospital admission and within 30-day post-surgery.
Material and methods: prospective observational study conducted on older patients affected by HF, who underwent a comprehensive geriatric assessment (CGA) at baseline and 30 days after discharge. CGA includes measures of comorbidity, polypharmacy, and pre- and post-fracture functional status according to Basic Activities of Daily Living (BADL).
Results: among 231 HF patients recruited, the 5-year survival rate was 38.3% for men and 61.9% for women. At hospital admission, pre-fracture BADL level was a protective factor (HR 0.742; 95% CI 0.668-0.825), while age (HR 1.070; 95% CI 1.037-1.105) and multimorbidity (HR 1.096; 95% CI 1.007-1.193) were independent mortality risk factors. At the 30-day post-discharge follow-up visit, the BADL recovery gap (HR 1.439; 95% CI 1.158-1.789) and pre-fracture BADL (HR 0.621; 95% CI 0.528-0.730), were independent predictors of 5-year survival, independent of comorbidity (HR 1.083; 95% CI 0.994-1.179).
Conclusion: more than half of patients with a HF survives for more than 5 years after surgery. The main factors affecting survival are pre-fracture functional status and functional recovery in the first 30 days after surgery. Although more evidence is needed, our findings might help to better tailor interventions for secondary prevention of fragility fractures and improving quality of life.

P635

MANAGEMENT OSTEOPOROTIC VERTEBRAL FRACTURES: CONSERVATIVE VERSUS SURGICAL?

I. Genrinho[1], A. Beco[2], B. D. Carneiro[3], A. Barcelos[4]

[1]Rheumatology Department, Unidade Local de Saúde Viseu Dão Lafões, Viseu, Portugal, [2]Orthopaedic Department, Unidade Local de Saúde da Região de Aveiro, Aveiro, Portugal, [3]Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal, [4]Rheumatology Department, Unidade Local de Saúde da Região de Aveiro, Aveiro, Portugal

Introduction: Osteoporotic vertebral fractures (OVF) are among the most debilitating complications of osteoporosis, significantly impacting patient morbimortality and quality of life.[1] Most patients with OVF achieve pain relief within 3–6 weeks with conservative treatment, however, the risk of secondary fractures increases more than fourfold.[2-4]
Aim: To evaluate and compare patients with OVF treated conservatively and surgically, and to identify factors influencing the likelihood of surgical intervention.
Methods: We retrospectively identified patients ≥ 50 years old with OVF admitted in our FLS between 2023 and 2024. The patients were categorized into two groups based on whether they received conservative (group 1) or surgical treatment (group 2). Demographic data, comorbidities, fracture location, type, and severity were collected. Data analysis was performed using SPSS version 25.
Results: A total of 119 patients were included, the majority were women (86.6%). The mean age was 84.4±8.6 in group 1 and 73.9±7.8 years old in group 2 ($p<0.001$). The body mass index was 25.8±4.6 in group 1 and 27.1±4.6 Kg/m^2 in group 2 ($p<0.001$). The lumbar spine was the most affected site, followed by the thoracic in both groups. Wedge-type fractures were the most frequent in both groups (71.6% in group 1 and 46.7% in group 2) ($p = 0.001$). The majority of OVF were classified as severe (61.4% and 66.7%), followed by moderate (26.1% and 23.3%) and mild fractures (12.5% and 10.0%) in groups 1 and 2, respectively. In group 2, 74.2% of patients underwent surgical treatment due to persistent intractable back pain. Older age was associated with less surgical intervention [OR de 0.86 (IC 95%: 0.81–0.92, $p < 0.001$)].
Conclusion: Surgical intervention in OVF was primarily driven by severe pain, and occurred in younger patients. These results emphasize the importance of individualized management strategies for OVF to optimize outcomes and address the specific needs of different patient subgroups.

SYSTEMIC SCLEROSIS WITH AND WITHOUT LUNG INVOLVEMENT: COMPARATIVE CHARACTERISTICS OF THE CLINICAL PICTURE OF THE DISEASE

I. H. Gasanova[1], Z. H. Gasanli[2], N. G. Nikolashina[1], S. A. Khamidova[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]"Crimean Smile" Clinic, Simferopol, Russia, [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: The aim of the study was to comparatively evaluate the clinical picture of Systemic sclerosis (SSc), occurring with and without lung involvement.
Methods: 87 patients with a reliable diagnosis of SSc were examined. Average age is 52.7±13.2 years. Average duration of the disease is 12.0±10.8 years. The ratio of clinical forms is diffuse: limited: crossed: juvenile as 18:52:15:2. The initial stage of SSc was diagnosed in 3.4%, the stage of advanced clinical manifestations – in 66.7%, late – in 29.9% of patients. High degree of SSc activity was noted in 11.5%, moderate – in 72.4%, low - in 16.1% of cases. All patients underwent computed tomography (CT) of the chest organs.
Results: Radiological signs of lung damage according to CT data were detected in 66 patients with SSc (75.9%), of which only in every 3rd case (25 patients) were linear and reticular changes detected, while in 41 patients, areas of local increase (ground glass opacity, consolidation areas) or decrease (honeycomb lung symptom, bronchiectasis, bullae) of lung tissue density were detected. Almost all patients had dyspnea of varying severity (in 45.4% of cases – with little physical exertion) and unproductive cough. The comparison group consisted of 21 patients without CT signs of lung damage. Patients with CT signs of lung damage did not differ statistically significantly in the age of SSc onset (42.2±15.4 years versus 36.3±14.4 years, p=0.078) and disease duration (12.5±11.4 years versus 10.4±9.1 years, p=0.884). Respiratory tract damage was noted on average 3.2±2.2 years after SSc onset. Lung damage was detected in different clinical forms of SSc: in 16 (89%) of 18 patients with the diffuse form, in 38 (73%) of 52 with the limited form, and in 10 (67%) of 15 with the overlap form. In patients without lung damage, the limited form prevailed. In 2 patients with SSc onset in adolescence, lung damage was not noted. The overall SSc activity index was higher in patients with lung lesions (3.4±1.8 vs. 2.7±1.3, p=0.045). Digital ischemia (ulcers, scars) was detected in 13 patients with lung lesions, and only in 1 case in the comparison group (pχ2=0.094). No reliable differences (pχ2=0.856) were obtained in the frequency of arthritis in patients of both groups. Pulmonary arterial hypertension (PAH) was detected in almost every 3rd patient with lung lesions (30.3%), while in the absence of pneumopathy only in 1 patient (4.8%, pχ2=0.037). Other visceropathies were significantly more often detected in patients with radiographic lung damage: kidney damage (pχ2=0.043), heart (pχ2=0.042) and gastrointestinal tract damage (pχ2=0.028). The frequency of detection of antibodies to Scl-70 was 2 times higher in patients with lung damage (18.2% versus 9.5%, pχ2=0.347), while anticentromere antibodies were more often detected in patients without lung damage (33.3% versus 19.7%, pχ2=0.196). Over the 8-year observation period, 2 patients (men) with diffuse SSc (with a disease duration of up to 1 year) died in the group of patients with lung damage; the cause of death in both cases was rapidly progressing renal failure.
Conclusion: CT signs of lung damage were detected in 76% of SSc patients. Such patients had a later onset of the disease, a high SSc activity index, a higher frequency of visceropathies and PAH.

P637

A STRUCTURE OF COMORBID PATHOLOGY AND ITS RELATIONSHIP WITH CLINICAL AND ULTRASONIC FEATURES OF PSORIATIC ARTHRITIS

Z. H. Gasanli[1], I. H. Gasanova[2], S. Kulanthaivel[3], N. G. Nikolashina[2]

[1]"Crimean Smile" Clinic, Simferopol, Russia, [2]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Psoriatic arthritis (PsA) is characterized by heterogeneity of clinical manifestations and is associated with the development of comorbid pathology (CP). CP in PsA, compared to other chronic inflammatory arthritis, is poorly studied, as well as its effect on the activity of the underlying disease. Purpose of this study was to study the structure of CP and its relationship with clinical, ultrasound and laboratory activity of PsA.
Methods: The study included 63 patients from 18 to 60 years old, with an established diagnosis of PsA, among whom there were 33 (52.4%) female and 30 (47.6%) male patients. The average age was 42.9±10.3 years, PsA duration was 7 (3; 10) years, psoriasis duration was 10 (8; 22) years; DAPSA 16.5 (11.6; 25), PASI 6.1 (1.5; 14.4), NAPSI 42 (12; 73), hs-CRP 8.7 (2.7; 20.8) g/l, ESR 20 (11; 30) mm/h, BMI 27±4.7 kg/m2; cutaneous psoriasis in 62 (98.4%), psoriatic onychodystrophy in 54 (85.7%) patients. All patients underwent clinical examination (number of swollen joints, number of painful joints, number of painful entheses), CP analysis (structure, number of comorbid diseases), ultrasound (US) examination of large joints and entheses of the upper and lower extremities (882 joints, 3402 entheses).
Results: Among the immune-mediated diseases (12.8%) there were inflammatory bowel diseases (Crohn's disease) (1.6%), autoimmune thyroiditis (4.8%), uveitis (3.2%), diabetes mellitus (DM) type 1 (3.2%). Anemia (chronic inflammation and iron deficiency) in 20.6%, osteoporosis – 9.5%, osteopenia – in 1.6% of patients. The presence of more than 1 CP was noted in 56.3% of patients. Cardiovascular diseases were observed in 34.9% of patients: arterial hypertension 34.9%, ischemic heart disease 4.8%, atherosclerosis in 22.2% of patients, acute cerebrovascular

accident in 1.6% of patients. Among endocrine diseases, type 2 diabetes mellitus (9.5%) and hypothyroidism of various etiologies (6.3%) were identified. Gastrointestinal diseases were present in 37.5% of patients, among which cholelithiasis (4.8%), gastric ulcer and duodenal ulcer (12.7%) prevailed. Other diseases of the musculoskeletal system included gout (3.2%) and osteoarthritis (17.5%). ENT diseases were observed in 9.5% of patients. Diseases of the urinary system were present in 11.2% of patients. Obesity (BMI> 30 kg/m2) – in 27% of patients. The number of CP correlated with age (r=0.454, p<0.01), with the number of synovitis (r=0.308, p<0.05). The relationship between the number of CP and anthropometric and clinical data was not revealed (p>0.05). A higher number of CP was significantly more common among women (p<0.05).

Conclusion: The presence of more than 1 CP was noted in 56.3% of patients. Most patients have CP, primarily CVD, gastrointestinal and musculoskeletal diseases, as well as immune-mediated conditions (12.8%). The number of CP increased with age and was more common among women (p<0.05). The number of CP was not associated with clinical data, including PsA and psoriasis activity, laboratory markers of inflammation. Among the ultrasound data, a relationship was found between the number of CP and the number of ultrasound synovitis.

P638

EFFECTS OF CERVICAL DECOMPRESSION AT THE C2-C4 SEGMENTS ON SCAPULAR UPWARD ROTATOR STRENGTH IN SUBJECTS WITH SCAPULAR DOWNWARD ROTATION SYNDROME

I. K. Ahn[1], O. Y. Kwon[1], H. Y. Baek[1]

[1]Department of Physical Therapy, The Graduate School, Yonsei University, Wonju, South Korea

Objective

To investigate the effect of cervical decompression (CD) in C2-C4 segments on scapular upward rotator strength (SURS) in individuals with scapular downward rotation syndrome (SDRS).

Material and Methods

Thirty-one SDRS participants (male: 12 and female: 19) were recruited. All participants performed the SURS pre- and post-CD. The CD is performed on the participants in supine position, with 10 seconds of decompression followed by 5 seconds of rest, for a total duration of 10 minutes. Following this, strength is measured again in the post-CD. The examiner fixed the spinous process at the C4 level with the index finger of one hand while applying superior-direction traction to the C2 level spinous process using the index finger of the other hand. The force grade is based on the Maitland concept, using Grade 4, with careful monitoring to ensure the procedure is pain-free throughout. SURS was measured in the sitting position using a SMART KMEA strength sensor. The scapula was then fixed to the floor using an orthopedic belt. At this time, the angle between the fixed part of the ground and the fixed part of the shoulder was set to 45 degrees so that the resistance acts in the SUR direction, not the scapular elevation direction. The measurement was performed in the scapular upward rotation direction through isometric contraction. If SDR were present on both sides, the more severe side was selected. The significance of the difference between the two conditions was assessed using a paired t-test, with the level of statistical significance set at 0.05

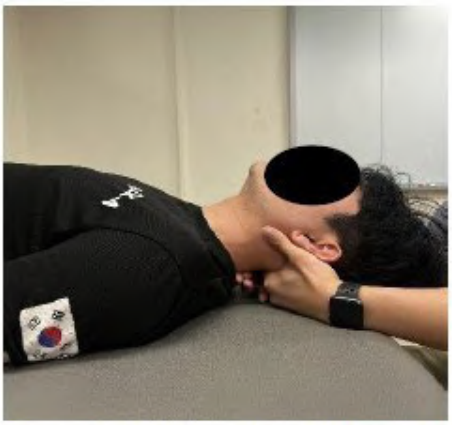

Figure 1. Cervical decompression at the C2-C4 segments

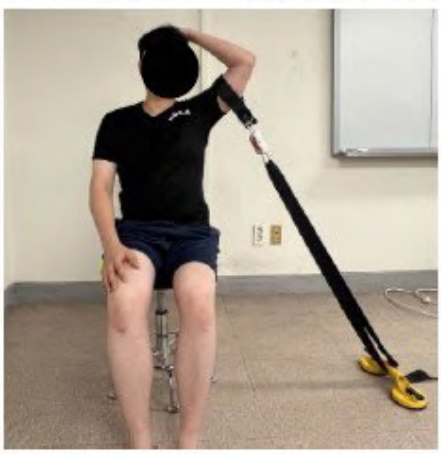

Figure 2. scapular upward rotator strength measurement

Results

The data collected for all variables were normally distributed. The results of the paired *t*-test revealed significant differences between pre- and post-CD measures, indicating that the CD increased the scapular upward rotator strength (from 0.113±0.032 to 0.141±0.047) (p<0.05).

Conclusion

CD at C2-C4 segments is effective on SURS in individuals with SDRS.

P639

FEATURES OF 1,25(OH)2D3 METABOLISM DURING PREGNANCY

I. Katsobashvili[1], E. Pigarova[1], L. Dzeranova[1], S. Vorotnikova[1], E. Bibik[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective. Study of the features of 1,25(OH)2D3 metabolism in pregnant women with gestational diabetes mellitus (GDM) in comparison with a control group of healthy pregnant women.

Material and Methods:
Two groups of patients participated in the study. Group 1 - pregnant patients with GDM (n=34) aged 18 to 45 years at a gestational age of 24-28 weeks (second trimester) and 30-38 weeks (third trimester), group 2 - healthy pregnant women (n=24) aged 18 to 45 years at a gestational age of 24-28 weeks and 30-38 weeks, who had their blood sampled for total calcium, albumin, parathyroid hormone (PTH) by immunochemiluminescent analysis and for total 25(OH)D and 1,25(OH)2D3 by high-performance liquid chromatography with mass spectrometric detection (HPLC-MS/MS).
Results:
The following results were obtained in group 1 in the in the second trimester: albumin-adjusted calcium - 2.25 mmol/l [2.21; 2.74], PTH– 29.74 pg/ml [22.29; 38.19], total 25(OH)D – 30.25 ng/ml [15.0; 43.5], 1,25(OH)2D3 – 32.87 pg/ml [21.70; 57.00]; in the third trimester: albumin-adjusted calcium – 2.27 mmol/l [2.23; 2.30], PTH- 27.79 pg/ml [22.62; 39.80], total 25(OH)D – 32.95 ng/ml [25.1; 40.4], 1,25(OH)2D3 – 42.95 pg/ml [34.46; 65.00]. In group 2: in the second trimester: albumin-adjusted calcium - 2.24 mmol/l [2.21; 2.33], PTH- 22.75 pg/ml [17.735; 31.90], total 25(OH)D - 46.95 ng/ml [35.2; 50.8], 1,25(OH)2D3 - 52.10 pg/ml [40.34; 68.66]; in the third trimester: albumin-adjusted calcium - 2.25 mmol/l [2.22; 2.32], PTH- 25.20 pg/ml [20.30; 32.41], total 25(OH)D - 42.65 ng/ml [33.75; 51.65], 1,25(OH)2D3 – 70.44 pg/ml [47.70; 87.35]. According to the specified parameters, statistically significantly higher levels were obtained in the healthy group for total 25(OH)D both in the second trimester (p= 0.001) and in the third trimester (p=0.018). The ratio of metabolites 1,25(OH)D3/25(OH)D3, reflecting the activity of 1-alpha-hydroxylase, in the second trimester was 1.59 [1.00; 2.36] vs. 1.39 [1.05; 1.62] (p = 0.463); in the third trimester – 1.39 [1.02; 1.94] vs. 1.86 [1.35; 2.07] (p = 0.252) for groups 1 and 2, respectively. When comparing and dynamically monitoring the total 25(OH)D and the ratio of metabolites 1,25(OH)D3/25(OH)D in the second trimester vs in the third trimester, it was found that in group 1 (GDM), respectively p = 0.059 and p = 0.607; in group 2 p= 0.838 and p= 0.025.
Conclusions:
The data obtained indicate that in the third trimester of pregnancy in healthy patients, the activity of 1α-hydroxylase increases, which increases the level of 1,25(OH)2D3 in the blood, which may be associated with initially higher values of total 25(OH)D compared to pregnant women with GDM. The results of the study indirectly confirm the contribution of vitamin D to the development of GDM.

P640

METABOLISM OF VITAMIN D DURING PREGNANCY

I. Katsobashvili[1], E. Pigarova[1], L. Dzeranova[1], S. Vorotnikova[1], E. Bibik[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective.
Study of the features of vitamin D metabolism and their relationship with the main complications of pregnancy and the features of calcium-phosphorus metabolism.
Materials and Methods:
Vitamin D metabolism was assessed in a 24-year-old patient with gestational diabetes mellitus (GDM) at 24 weeks of gestation, in the absence of cholecalciferol supplementation. The vitamin D metabolites were obtained via HPLC-MS/MS (DEQAS sertified).
Results:
The following results were obtained: pronounced deficiency of total 25(OH)D — 3.0 ng/ml (reference range: 20.0–60.0), 3-epi-25(0H)D3 — 0.8 ng/ml (1.0–10.0), 24,25(OH)2D3 – 0.1 ng/ml (0.5–5.6), 25(OH)D3/24,25(OH)2D3–25.0 (7.0–25.0), 1,25(OH)2D3 – 15.0 pg/ml (18.00–78.00). Despite these findings, the patient demonstrated normal levels of parathyroid hormone (PTH) – 33.06 pg/ml (15–65), phosphorus –1.02 mmol/l (0.74–1.52), normocalcemia (total calcium–2.34 mmol/l (2.15–2.55), albumin–38.3 g/l (35–50), albumin-corrected calcium — 2.37 mmol/l. The patient also had a normal body mass index (BMI = 24 kg/m2) before pregnancy.
Conclusions:
This clinical case highlights a potential relationship between GDM and the development of vitamin D deficiency, which may lead to impaired calcitriol (1,25(OH)2D3) activation despite normal PTH levels. The findings suggest that PTH-related peptide may play a significant role in vitamin D regulation during pregnancy. Further investigation into the relationship between 1,25(OH)2D3 and 25(OH)D levels during pregnancy is essential for advancing our understanding of vitamin D metabolism and its impact on optimizing maternal and fetal health outcomes.

P641

SUCCESSFUL CONSERVATIVE MANAGEMENT OF PRIMARY HYPERPARATHYROIDISM

I. Kostoglou-Athanassiou[1], L. Athanassiou[2], X. Poimenidi[1], A. Pastroudis[3], P. Athanassiou[4]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece, [2]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece, [3]6th Department of Orthopedics, Asclepeion Hospital, Voula, Athens, Greece, [4]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Background: Primary hyperparathyroidism is a multi-faceted disease with multiple causes. It may be due to a solitary adenoma of the parathyroid glands or multiple adenomas or to hyperplasia of the parathyroids. The disease may be therapeutically managed via multiple ways. It may be managed surgically by surgical excision of the parathyroid adenoma or the multiple adenomas. It may also be managed conservatively as surgical management may not be indicated in the case of parathyroid hyperplasia or in cases in which surgery is not feasible. The disease causes osteoporosis. Osteoporosis is one of the main clinical manifestations of primary hyperparathyroidism. Osteoporosis may be managed by the administration of bisphosphonates, in particular alendronate.
Objectives: The aim of the study was to describe the successful management of osteoporosis in the context of primary hyperpara-

thyroidism with alendronate in the effervescent form.
Methods: In a group of 15 patients, 12 female and 3 male, with primary hyperparathyroidism, aged 51-75 years osteoporosis was managed by the administration of alendronate in the effervescent form. Patients had primary hyperparathyroidism due to a solitary adenoma in 12 cases, to primary hyperplasia in 2 cases and relapsed primary hyperparathyroidism after surgical excision of an adenoma in 1 case. Patients presented with osteoporosis, T score ranging from -2.5 to -3.6. Alendronate 70 mg/wk in the effervescent form was administered for a period ranging from 6 months to 4 years. In all patients blood Ca, P and PTH were followed up. Bone mineral density was measured yearly.
Results: In all patients with primary hyperparathyroidism a significant improvement in bone mineral density was noted ($p<0.001$). In 12 of the patients T score improved and was in the range of osteopenia. No significant adverse events were noted.
Conclusion: It appears that primary hyperparathyroidism may be managed conservatively by the administration of bisphosphonates, in particular alendronate in the effervescent form, if surgery is not indicated or is not feasible. In these cases alendronate may improve osteoporosis, a main clinical manifestation of primary hyperparathyroidism, which, if left untreated may lead to fractures and disability.

P642

THE RELATIONSHIP BETWEEN PAIN, MUSCLE STRENGTH AND FUNCTIONAL PERFORMANCE IN PATIENTS WITH KNEE OSTEOARTHRITIS

I. M. Borda[1], R. A. Ungur[1]

[1]University of Medicine and Pharmacy Iuliu Hatieganu / Rehabilitation Dept. / Rehabilitation Hospital, Cluj-Napoca, Romania

Objective: To assess pain, muscle strength and functional performance in knee osteoarthritis patients and to verify the correlation between these parameters.
Methods: 55 patients (61.4±3.2 years, 28 men and 27 women) diagnosed with knee steoarthritis based on the ACR criteria were included in this cross-sectional study. Pain was quantified on the visual analogue scale (SAV). Knee extensor strength was evaluated by the isokinetic method at the angular velocity of 120°/s, using a Gymnex Iso 2 Dynamometer. Timed up-and-go (TUG) test, chair rising test (CRT) and 6-minute walk (6MW) test were used to assess functional performance. Analyses of the relationship between pain, muscle strength and functional performance parameters was based on Pearson's correlation coefficients, with significance set at $p<0.05$.
Results: Pain score on SAV negatively correlated with CRT ($r=-0.211$, $p<0.05$) and 6MW test ($r=-0.225$, $p<0.05$), and positively with TUG score ($r=0.397$, $p<0.05$). Knee extensor strength positively correlated with CRT ($r=0.477$, $p<0.05$) and 6MW test ($r=0.482$, $p<0.05$), and negatively with TUG score ($r=-0.324$, $p<0.05$). Knee extensor strength negatively correlated with pain score on SAV ($r=-0.273$, $p<0.05$).
Conclusion: Muscle strength not only correlated with functional performance, but also significantly influenced pain in patients with knee osteoarthritis. Therefore, muscle training should be emphasized in the rehabilitation programs, in order to improve functionality and to alleviate pain.

P643

EFFECT OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ON HIP JOINT DAMAGE IN AXIAL SPONDYLOARTHRITIS

R. Mnevets[1], I. Ostrovska[2], S. Kulanthaivel[3]

[1]ESC Institute of Biology and Medicine of Taras Shevchenko National University of Kyiv, Kyiv, Ukraine, [2]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine, [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Coxitis is one of the most common causes of early disability in patients with axial spondylitis (axSpA). Currently, coxitis is detected in a significant number of patients with ankylosing spondylitis (AS). Mild axSpA is almost never seen in cases of hip joint (HJ) damage. Thus, the aim of this study was to evaluate the effectiveness of non-steroidal anti-inflammatory drug (NSAID) therapy in patients with axSpA and coxitis.
Methods: 25 patients (19 men and 6 women) with axSpA who had been observed for at least 2 years and had been taking NSAIDs on a regular basis were selected. All patients, regardless of complaints, underwent X-ray examination, ultrasound and magnetic resonance imaging (MRI) of the hip joints (HJ). Coxitis on HJ ultrasound was defined as an increase in the neck-capsular distance (NCD) of more than 7 mm and the presence of asymmetry between the joints of more than 1.5 mm. Coxitis on MRI was defined as the presence of synovitis and/or osteitis. The BASRI hip index was assessed for each HJ, and its increase to stage 2 and higher was considered X-ray coxitis. The average age was 31.1±7.0 years with an average disease duration of 74.52±100.1 months. HLA-B27 was positive in 23 (92%) patients.
Results: A comparative analysis of clinical, laboratory and instrumental parameters of the disease was conducted during a 2-year follow-up. At inclusion in the study, MRI signs of coxitis were detected in 25 (100%), after two years only 15 (60%) ($p<0.05$). Against the background of constant intake of NSAIDs, the number of MRI detected synovitis decreased from 25 (100%) to 13 (52%) ($p<0.05$). However, a reliable increase in radiographic coxitis was also obtained, at inclusion BASRI hip ≥2 was detected in 1 (4%), and after two years in 9 (36%) patients ($p<0.05$). The median SCR at the time of inclusion was 6.8 mm, and after two years it decreased to 6.2 mm ($p>0.05$). Other clinical activity indicators such as BASDAI, BASFI, ASDAS CRP, ESR and CRP also decreased, but no reliable difference was obtained between them ($p>0.05$).
Conclusion: Regular use of NSAIDs in most cases allows to reduce the amount of effusion in the hip joint according to MRI data, however, therapy does not affect the radiographic progression of coxitis.

ANALYSIS OF PREVALENCE, GENDER AND AGE DIFFERENCES IN OSTEOPOROTIC BONE FRACTURES

R. Mnevets[1], K. Ostrovskyy[2], S. Kulanthaivel[3], I. Ostrovska[4]

[1]ESC Institute of Biology and Medicine of Taras Shevchenko National University of Kyiv, Kyiv, Ukraine, [2]Pharmaceutical Product Development, Warsaw, Poland, [3]Naarayani Multispeciality Hospital, Erode, India, [4]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine

Objective: Systemic osteoporosis (OP) plays a leading role in the occurrence of bone fractures due to falls from one's own height. Among all injuries in osteoporosis, fractures of the proximal femur and humerus, compression fractures of the vertebral bodies, and distal radius are the most common. All of them lead to a significant decrease in the quality of life of patients, their disability, and death. An important area of research is the study of the prevalence, gender, and age differences in bone fractures in the population in order to develop an early prevention system and identify high-risk groups for osteoporotic fractures. Therefore, the aim of the study was to analyze the prevalence, gender, and age differences in patients with osteoporotic bone fractures.
Methods: 597 patients with osteoporotic bone fractures were examined: anamnesis of life was collected, comprehensive clinical, laboratory and instrumental examination was performed. Statistical analysis was performed using the Statistics 12.0 software package.
Results: The 597 patients had the following distribution by fracture localization: in 1st place, 424 (71%) patients were hospitalized with femoral neck fractures; in 2nd place, 142 (23.8%) patients were hospitalized with vertebral compression fractures; in 3rd place, 31 (5.2%) patients were hospitalized with radius fractures. During the gender analysis, we found that out of the total number of 597 patients examined, 329 (55.1%) were women and 268 (44.9%) were men. A more detailed analysis by nosology revealed that among patients with femoral neck fractures, there were 157 men (37.1%) and 267 women (62.9%). Among patients with vertebral compression fractures, there were 95 men (66.9%) and 47 women (33.1%). Among patients with distal radius metaphysis fractures, there were 13 men (41.9%) and 18 women (58.1%). The average age of men with femoral neck fractures was 64.9 years, while that of women was 78.1 years. The average age of women with vertebral compression fractures was 49.3 years, while the average age of men was 42.6 years. The average age of men with distal radius metaphysis fractures was 52.8 years, while that of women was 53.2 years. Among all 597 patients included in the study, 44 (7.4%) patients had a history of fractures of the bones of the extremities and spine. Moreover, the time after the previous fractures ranged from 3 years, 3 months and to 4 years.
Conclusion: In the structure of osteoporotic fractures, femoral neck fracture was significantly more common ($p<0.005$) than compression fractures of the vertebrae and fractures of the distal metaepiphysis of the radius. Osteoporotic fractures in total, as well as fractures of the femoral neck and fractures of the distal metaepiphysis of the radius, were significantly more common ($p<0.005$) in women than in men. Compression fractures of the vertebrae were significantly more common ($p<0.005$) in men than in women. Episodes of repeated fractures of the bones of the extremities and spine (3-4 years before the current fracture) were established only in 7.4% of patients. Among male patients, osteoporotic fractures occurred at a younger age than in female patients, which requires a detailed study and analysis of other risk factors for osteoporosis and chronic diseases.

P645

MEDICAL REHABILITATION OF A POSTMENOPAUSAL WOMAN AFTER RECONSTRUCTIVE SURGERY FOR FEMORAL NECK FRACTURE USING VIRTUAL REALITY TECHNOLOGIES AND ROBOTIC MECHANOTHERAPY: THE CLINICAL CASE

I. Otvetchikova[1], A. Marchenkova[1]

[1]Federal State Budgetary Institution "National Medical Research Center for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russia

Background. Rehabilitation after reconstructive surgeries for lower limb injuries combined with osteoporosis is important, as trauma ranks fifth among medical and social problems that harm health and lead to the death of the working population.
Objective: to describe our experience of rehabilitation a woman with postmenopausal osteoporosis after total hip arthroplasty due to a femoral neck fracture using virtual reality, robotic mechanotherapy with biological feedback (BFB) and physiotherapy.
Description of the clinical case. In 04/24 a woman S. with postmenopausal osteoporosis, 54 y.o., have been rehabilitated after left hip arthroplasty on 14/02/24. She complained of limited movement in the operated joint (flexion 110°), impaired weight-bearing ability of the left lower limb, need for support while walking, and limitations in self-care. According to X-ray, the position of the prosthesis was satisfactory. Results by the Harris scale – 46 pt, performed the "Get Up and Go" test in 16 s. According to biomechanical assessment of the joint using isokinetic dynamometry on a robotic complex with BFB, Max extension strength was 45.3 N, and Max flexion strength was 45.1 N. Walking speed measured on a sensory treadmill-ergometer was 21 steps per min, with a step length of 0.8 m. DXA showed a T-score in the L1-L4 at -2.8, in the right femoral neck -3.1 and in the total hip -2.8.
The rehabilitation program consisted of sessions in a virtual reality system with projections on the floor (25 min, №12), robotic mechanotherapy on an interactive sensory treadmill-ergometer C-Mill (25 min, №15), therapeutic exercises in the gym (30 min, №15), laser therapy on the operated area in pulse mode (power 20 W, infrared range 80 Hz, №15), magnetic field exposure on lower limb muscles (35 mT, №15), and therapeutic baths (10-15 min, 36-37°C, 30-35 g/L, №9).
Results after completing rehabilitation over 18 days: There was an increase in the volume of active pain-free movements in the

joint - flexion to 90º, transition to using a cane while walking, improvement in weight-bearing ability of the left leg, and significant improvement in self-care skills. The "Get Up and Go" test result was 13 s. Max extension strength was 57.0 N, and Max flexion strength was 47.6 N. Walking speed increased to 50 steps per min, with a step length of 1.04 m.
Conclusion. This case demonstrates the possibilities of a comprehensive rehabilitation program using virtual reality technologies and robotic mechanotherapy with BFB for a woman with postmenopausal osteoporosis after reconstructive surgery for a femoral neck fracture.

P646

CORRELATION OF CLINICAL FEATURES OF SYSTEMIC LUPUS ERYTHEMATOSUS AND OSTEOPOROSIS

I. Ovcina[1], S. Popovic Pejicic[2], S. Saric[1], J. Mrdja[1], L. J. Bozic Majstorovic[1]

[1]University Clinical Centre of the Republic of Srpska, Banjaluka, Bosnia & Herzegovina, [2]Faculty of Medicine, University of Banjaluka, Banjaluka, Bosnia & Herzegovina

Objective: The main goal was to detect correlation between clinical features and occurrence of osteoporosis (OSP) in sytemis lupus erythematosus (SLE).
Material and methods: The 50 SEL patients were included in the study. The demographics, antibodies and laboratory parameters were collected. All collected variables were compared with the presence of OSP.
Results: The mean age was 47.48±12.93, disease duration 10.46±7.72 years and there was 48 (96%) female patients. In this group, there were 3 (6%) smokers, 2 (4%) diabetics and 4 (8%) patients had lupus nephritis. On corticosteroids treatment were 38 (76%) and on hydroxychloroquine 40 (80%). Eighteen (36%) patients had positive anti-Ro antibodies and 26 (52%) anti-dsDNA. Total cholesterol were 6.0±0.95 and LDL 3.92±1.12. OSP had 10 (20%) patients. There were statisticaly significant correlation between osteoporosis and: age ($p<0.01$), disease duration ($p<0.01$), total cholesterol ($p=0.04$) and LDL ($p=0.05$). The correlation between osteoporosis with the presence of anti-Ro antibodies was statistically significant ($p=0.02$), but with anti-dsDNA not ($p=0.29$). Correlations with other variables were not statistically significant.
Conclusion: The correlation between the occurrence of OSP and age, as well as the duration of the disease, is well known. The relationship of hypercholesterolemia and OSP indicates metabolic activity that includes bone tissue itself. Statistically significant correlation with anti-Ro antibodies specify the importance of the antibody profile in bone metabolism in SLE. We need larger studies to definitively prove this relationship.

P647

POLYPHARMACY AND VITAMIN D LEVELS IN HIP FRACTURED ELDERLY PATIENTS WITH AND WITHOUT DIABETES MELLITUS TYPE 2

I. P. Papaioannou[1], G. P. Pantazidou[2], Z. K. Kokkalis[3], N. G. Georgopoulos[4], E. J. Gelastopulu[5], T. R. Repantis[1], A. B. Baikousis[1]

[1]Orthopaedic Department, General Hospital of Patras, Patras, Greece, [2]Public Health MSc Program, University of Patras, Patras, Greece, [3]Orthopaedic Department, University Hospital of Patras, Patras, Greece, [4]Endocrinology Department, University Hospital of Patras, Patras, Greece, [5]Public Health, University of Patras, Patras, Greece

Objectives: This study aims to evaluate the impact of polypharmacy on vitamin D (VD) levels in hip-fractured elderly patients with and without diabetes mellitus type 2 (T2DM).
Material and Methods: We retrospectively studied 114 elderly patients (> 65 years old) with osteoporotic hip fractures, treated between January 2021 and January 2022. The non-diabetic group consisted of 49 patients, while the diabetes group included 65 subjects. 11 patients were newly diagnosed with impaired hemoglobin A1C (HbA1C) and switched to the diabetic group. 4 out of 11 patients were diagnosed with T2DM, and 7/11 had prediabetes. We recorded the number of medications, and polypharmacy was defined as four or more drugs. The 25-hydroxy vitamin D (25OH Vit D) was measured using an automated enzymatic immunoassay.
Results: The mean value of medications in the non-diabetic group (Group A) was 4,39 ± 2,71 standard deviation, while in the diabetic group (Group B), it was 6,31 ± 2,70. As it was expected, the diabetic group consumed more drugs, and the difference was statistically significant as the p-value was < 0,001. Polypharmacy was recorded in 59,2% of Group A patients, while only 13,8% of Group B patients received up to three medications. This difference was also statistically significant with p-value < 0,001. Inductive analysis was performed to evaluate the impact of polypharmacy on VD levels. In Group A, the difference of VD values (10,58 ± 5,61 ng/ml with polypharmacy vs 9,23 ± 5,19 ng/ml without polypharmacy) wasn't statistically significant (p-value 0,399). In contrast, in Group B patients, VD values differ statistically significantly. Patients with polypharmacy had a mean value of VD 10,56 ± 5,16 ng/ml, while those without polypharmacy had 6,56 ± 2,99 ng/ml. This difference is statistically significant as the p-value was to be 0,028. Regression analysis revealed that patients with polypharmacy are expected to have 2,603 higher levels of VD (95% CI: 0.357 – 4.849).
Conclusions: Our study revealed a paradox of increased VD levels among hip fractured diabetic patients with polypharmacy. Diabetic patients with more medications probably have better glycemic control and, consequently, higher VD levels. Our study has the limitation of not recording the type of medication, and more studies are necessary to evaluate the abovementioned conclusions. Clinicians should be aware that polypharmacy and psychotropic drug intake are associated with more unstable hip fractures, se-

vere VD deficiency, and increased levels of PTH. Steroids (such as prednisone), cholesterol-lowering drugs (such as cholestyramine and colestipol), seizure-preventing drugs (such as phenobarbital and phenytoin), and rifampin are directly correlated with lower VD levels.

P648

HIP FRACTURE SEVERITY IN ELDERLY PATIENTS WITH AND WITHOUT DIABETES MELLITUS TYPE 2

I. P. Papaioannou[1], G. P. Pantazidou[2], Z. K. Kokkalis[3], N. G. Georgopoulos[4], E. J. Gelastopulu[5], T. R. Repantis[1], A. B. Baikousis[1]

[1]Orthopaedic Department, General Hospital of Patras, Patras, Greece, [2]Public Health MSc Program, University of Patras, Patras, Greece, [3]Orthopaedic Department, University Hospital of Patras, Patras, Greece, [4]Endocrinology Department, University Hospital of Patras, Patras, Greece, [5]Public Health, University of Patras, Patras, Greece

Objectives: This study aims to record the severity of hip fractures in elderly patients with and without diabetes mellitus type 2 (T2DM).
Material and Methods: We retrospectively studied 114 elderly patients (> 65 years old) with osteoporotic hip fractures, treated between January 2021 and January 2022. The non-diabetic group consisted of 49 patients, while the diabetes group included 65. 11 patients were newly diagnosed with impaired hemoglobin A1C (HbA1C) and switched to the diabetic group. 4 out of 11 patients were diagnosed with T2DM, and 7/11 had prediabetes. The hip fractures were categorized as extracapsular (intertrochanteric) or intracapsular (sub-capital). Severe sub-capital fractures were defined as grades 3 or 4 according to the Garden classification. In contrast, severe intertrochanteric fractures were defined as grades A2.2, A2.3, and all A3 fractures according to the AO/OTA classification.
Results: Group A had 30 (61,2%) extra-capsular fractures and 19 (38,8%) intracapsular fractures, while their counterparts had 44 (67,7%) extra-capsular and 21 (32,3%) intracapsular fractures without any statistical significance (p= 0,474, χ^2 test). The difference in hip fracture severity between the two groups wasn't significant (p=0,344), although people with diabetes suffered more frequently from unstable fractures (75,4% versus 67,3%). More comminuted fractures were noted in patients on oral antidiabetic medications alongside insulin and with less than five years of antidiabetic therapy.
Conclusions: Unstable and severe comminuted hip fractures are linked to higher mortality rates and poorer functional status. Notably, the functional status before the injury is the only independent predictor of long-term functional outcomes and mortality. Our study corroborated that diabetic patients are more prone to experience displaced hip fractures. Interestingly, while diabetic patients generally correlate with higher bone mineral density (BMD), this observation presents a paradox that clinicians should be aware of BMD alone is not a reliable measure of bone quality in diabetic patients, necessitating additional diagnostic tools.

P649

VD LEVELS IN ELDERLY PATIENTS WITH AND WITHOUT DIABETES MELLITUS TYPE 2

I. P. Papaioannou[1], G. P. Pantazidou[2], Z. K. Kokkalis[3], N. G. Georgopoulos[4], E. J. Gelastopulu[5], T. R. Repantis[1], A. B. Baikousis[1]

[1]Orthopaedic Department, General Hospital of Patras, Patras, Greece, [2]Public Health MSc Program, University of Patras, Patras, Greece, [3]Orthopaedic Department, University Hospital of Patras, Patras, Greece, [4]Endocrinology Department, University Hospital of Patras, Patras, Greece, [5]Public Health, University of Patras, Patras, Greece

Objectives: This study aims to record vitamin D (VD) levels in elderly patients with and without diabetes mellitus type 2 (T2DM).
Material and Methods: We retrospectively studied 114 elderly patients (> 65 years old) with osteoporotic hip fractures, treated between January 2021 and January 2022. The non-diabetic group (group A) comprised 49 patients, while the diabetes group (group B) included 65 patients. 11 patients were newly diagnosed with impaired hemoglobin A1C (HbA1C) and switched to the diabetic group. 4 out of 11 patients were diagnosed with T2DM, and 7/11 had prediabetes. An automated enzymatic immunoassay measured 25-hydroxy vitamin D (25OH Vit D).
Results: VD values were similar in both groups (10,03 ± 5,43 ng/mL in group A versus 10,01 ± 5,09 ng/mL in group B), without any statistical significance (p=0,986, Pearson equation). Severe vitamin D deficiency was more prevalent in Group A, affecting 29 patients (59.2%), compared to Group B, which affected 37 patients (56.9%). Notably, none of the patients in either group had normal vitamin D levels.
Conclusions: Despite differences in glycemic status, the participants shared several characteristics that contributed to these results regarding vitamin D levels. All patients were elderly with minimal sun exposure and age-related skin changes. Additionally, liver and kidney function, which are often impaired in elderly patients, negatively impact the synthesis of vitamin D. Poor nutrition, characterized by low serum albumin levels and the fact that food and milk in Greece are not adequately fortified with vitamin D, further exacerbates vitamin D deficiency.

P650

PARATHORMONE LEVELS IN DIABETIC AND NON-DIABETIC ELDERLY PATIENTS WITH LOW ENERGY HIP FRACTURE

I. P. Papaioannou[1], G. P. Pantazidou[2], Z. K. Kokkalis[3], N. G. Georgopoulos[4], E. J. Gelastopulu[5], T. R. Repantis[1], A. B. Baikousis[1]

[1]Orthopaedic Department, General Hospital of Patras, Patras, Greece, [2]Public Health MSc Program, University of Patras, Patras, Greece, [3]Orthopaedic Department, University Hospital of Patras, Patras, Greece, [4]Endocrinology Department, University Hospital of Patras, Patras, Greece, [5]Public Health, University of Patras, Patras, Greece

Objectives: This study aims to identify if there is any difference in parathormone levels between diabetic and non-diabetic elderly patients with hip fractures.
Material and Methods: We retrospectively studied 114 elderly patients (>65 years old) with low-energy hip fractures, with and without a history of diabetes mellitus type 2, which were treated in our department during the last two years between January 2021 and January 2023. We measured the values of 25 OH vitamin D (VD), parathormone (PTH), and glomerular filtration rate (eGFR). Secondary hyperparathyroidism (SHPT) was defined if PTH levels exceeded 65 pg/ml. The diabetic group consisted of 65 patients, and their counterparts were 49. Patients with chronic kidney disease (CKD) grades 4 and 5 were excluded from the study because severe renal failure results in reduced synthesis of calcitriol and secondary hyperparathyroidism.
Results: VD levels were similar in both groups (10,03 ± 5,43 g/dL non-diabetic vs 10,01 ± 5,09 g/dL diabetic) without any statistically significant difference (p=0,986). PTH levels differ significantly between the two groups (p= 0,018). PTH levels in non-diabetic patients were 79,71 ± 57,6 pg/mL, while in diabetic patients, the values were 56,42 ± 45,57 pg/mL. The e GFR values were 72,14 ± 24,81 and 66,55 ± 21,43 for non-diabetic and diabetic patients, respectively. SHPT was more prevalent in non-diabetic patients (Group A) with 42,9% (21 patients) in comparison with diabetic subjects (Group B) with 24,6% (16 patients). This difference was statistically significant, as the p-value was 0,039. We performed further statistical analysis, and based on the Pearson equation, we found statistical significance when we correlated PTH and VD levels among participants of group A. The p-value was 0,014. Based on regression analysis, VD is expected to decrease by 0.029 for every unit increase in PTH concerning all the participants (95% CI: 0.011-0.048) and not only Group A patients.
Conclusions: Current studies show a direct suppressive effect of high glucose concentrations on PTH secretion, while higher PTH levels within the normal range may enhance beta-cell function. Human beta cells have been shown to express parathyroid hormone-1 receptors, supporting the correlation between PTH levels and beta-cell function. Recent experimental studies demonstrate regeneration following partial pancreatectomy, and administration of PTH-related peptides reinforces this relationship. A more straightforward explanation for the lower PTH levels in patients with T2DM could be that inflammation induced by hyperglycemia hinders PTH production. Additionally, diabetes-related microangiopathy might contribute to parathyroid gland dysfunction. The dysregulation of PTH due to hyperglycemia could play a role in this finding and warrants further investigation.

P652

THE LARGEST STUDY ON PRIMARY HYPERPARATHYROIDISM (LATVPHPT) AT RIGA EAST UNIVERSITY HOSPITAL, LATVIA: FOCUS ON OSTEOPOROSIS, OSTEOPENIA, AND BONE FRACTURES

D. Sturite[1], I. Rasa[2]

[1]Rīga Stradiņš University, Latvian Osteoporosis and Bone Metabolic Diseases Association, Riga, Latvia, [2]Riga East University Hospital, Rīga Stradiņš University, Latvian Osteoporosis and Bone Metabolic Diseases Association, Riga, Latvia

Background. Primary hyperparathyroidism (PHPT) can manifest with a variety of clinical symptoms, ranging from asymptomatic cases to those with significant involvement of multiple organs, including osteoporosis and osteopenia. The literature shows variability in the prevalence of organ involvement and related conditions.
Methods. This LATVPHPT study included 177 PHPT patients diagnosed between January 1, 2021, and January 1, 2024. Using IBM SPSS 29.0 software, we conducted a detailed retrospective analysis of medical records, laboratory data, radiologic findings, surgical outcomes, and histopathology reports.
Results. 177 patients (mean age 63.8±11.9 years), 89% were females. 65% (n=115) of patients underwent parathyroidectomy, 14.7% (n=26) had surgery postponed due to unknown adenoma location, 1.1% (n=2) declined, 19.2% (n=34) – awaiting surgery, 3 – needed reoperation due to negative histopathology. Hungry bone syndrome occurred in 3 patients. 2 patients had MEN1 syndrome. Histopathological analysis and imaging in patients who underwent surgery identified a single adenoma in 94.0% (n=106), double adenomas – 1.7% (n=2), hyperplasia – 2.6% (n=3), carcinoma – 1.7% (n=2). Among imaging modalities, contrast-enhanced ultrasonography (CEUS) showed superior performance for identifying typically localized adenomas compared to ultrasonography (b = −1.68, p = 0.020), scintigraphy (b = −1.70, p = 0.026), and 3D-CT (b = −1.66, p = 0.046). While SPECT/CT demonstrated a similar trend, the results did not reach statistical significance (b = −1.2, p = 0.099). The mean preoperative calcium was 2.9±0.3mmol/L, intact parathyroid hormone (iPTH) – 251.2±242.1pg/mL, phosphorus – 0.8±0.2mmol/L, 25-OH vitamin D – 27.6±13.3ng/mL. The mean postoperative calcium was 2.4±0.1mmol/L, iPTH – 59.9±36.5pg/mL, phosphorus – 1.1±0.2mmol/L, 25-OH vitamin D – 43.4±16.1ng/mL. Comorbid conditions were in 35% (n=62) had with osteoporosis, 54% (n=95) – osteopenia, 15% (n=26) – osteoporotic fractures. In 17.5% (n=31) of patients, PHPT was suspected and later confirmed only due to a prior diagnosis of osteoporosis or osteopenia based on DXA or QCT. 17.5% (n=31) of patients received oral bisphosphonates, 4.0% (n=7) – intrave-

nous bisphosphonates, 8.5% (n=15) – denosumab, 1.1% (n=2) – medication holidays. 25% (n=44) had kidney stones, 23% (n=41) – gallstones. 31.1% (n=55) of patients were asymptomatic PHPT based on retrospectively reviewed previous medical records. Thyroid conditions included thyroid nodules in 81% (n=143), nontoxic goitre in 53% (n=93), and autoimmune thyroiditis in 29% (n=51). Other associated conditions included hypertension 43% (n=76), type 2 diabetes 14% (n=24), and malignancies 20% (n=36), most commonly breast and thyroid cancers.
Conclusions. High rates of skeletal complications and malignancies in PHPT emphasize its clinical impact. Precise imaging, timely diagnosis, and appropriate treatment are essential for managing its complex manifestations. It is important to exclude the possibility of/rule out PHPT in patients with osteopenia and osteoporosis.

P653

THE EFFECTS OF TIBIA FRACTURE AND INTRAVENOUS STEM MESENCHYMAL CELLS AT DIFFERENT TIMES AFTER SURGERY ON MAXILLARY ALVEOLAR BONE LOSS

I. Soloviova[1], V. Luzin[1], V. Ryabkov[1], S. Kovalenko[1], N. Muzychuk[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia, Lugansk, Russia

Objective: Aim of the study is to test maxillary alveolar bone loss after tibia fracture modeling and intravenous injection of mesenchymal stem cells (MSC) at different times after surgery.
Material and Methods: 162 male rats with the body weight of 190-225 g were distributed into 7 groups: group 1 - controls, group 2 - animals with tibia fracture, and groups 3-7 for the animals with the same tibia fracture that received intravenous injections of 5 million MSC per injection at 3rd, 10th, 15th, 24th and 45th days after surgery. Bone marrow cells were obtained from the tibia and phenotyped according to standard methods. Upon expiration of observation terms (7, 15, 30, 60 and 90 days) the animals were withdrawn from the experiment. Measurements of linear distance (mm) between the cement-enamel junction (CEJ) and the alveolar bone crest (ABC) of the mesial root of the first molar were performed on the buccal and the palatal surfaces.
Results: In group 2 the buccal CEJ-ABC exceeded than that of the group 1 by 6.23%, 9.59%, 10.54%, and 5.16% in the period from the 15th to the 90th day and the palatal CEJ-ABC – by 5.80%, 6.21%, 12.17%, 9.72%, and 6.60% in the period from the 7th to the 90th day. In group 3 palatal CEJ-ABC was lowered than that of the group 2 by 6.42%, 5.69% and 5.16% in the period from the 30th to the 90th day, and on the buccal side by 30th and 60th day - by 5.11% and 6.21%. In group 4 the palatal CEJ-ABC was lowered than that of the group 2 by 6.07%, 8.85%, 7.07% and 7.08% in the period from the 15th to the 90th day, and on the buccal side by 4.63%, 6.71% and 8.64% in the period from the 15th to the 60th day. In the groups 5-7 the restoration maxillary alveolar bone were expressed to a significantly lesser extent.
Conclusion(s): Administration MSC into the defect of the tibia at different times after surgery was accompanied by a faster recovery of the maxillary alveolar bone. The most effective was administration of MSC on the 10th day after surgery.

P654

CONSEQUENCES OF FALLS IN ELDERLY

I. Tamulaityte-Morozoviene[1], J. Dadoniene[1], R. Stukas[1], M. Tamulaitiene[2], V. Alekna[1]

[1]Faculty of Medicine of Vilnius University, Vilnius, Lithuania, [2]National Osteoporosis Center, Vilnius, Lithuania

Objective This study aimed to evaluate physical and psychological consequences among older adults living in the community.
Material and Methods People, aged 60 years and above, who attended the National Osteoporosis Center for diagnostic or treatment purposes, participated in interviews. According to these interviews, the outcomes and healthcare measures related to falls experienced in the previous 12 months were documented. There was used a specially prepared questionnaire for demographic and falls data, fear of falling questionnaire „Falls Efficacy Scale International"(FES-I) and physical activity questionnaire „Physical Activity Scale for the Elderly"(PASE).
Results The study population consisted of 972 community-dwelling elderly people (mean age 73.7±5.9 years). Falls were reported by 361 (37.14%) of respondents. One in three of the interviewed people had fallen two or more times in the period of one year. Most of all fallen elderlies reported various injuries and 79 (23.3%) of them experienced bone fractures. Fear of falling was reported by 272 (74.1%) respondents. Almost half (42.7%) of fallers restricted their everyday activities. The primary self-reported cause of restriction of everyday activities was identified as pain.
Conclusions Fear of falling was reported by 75.4% of respondents who experienced a fall in the past 12 months. Furthermore, all older adults who sustained hip or vertebral fractures subsequently restricted their daily activities.

REFERENCE INTERVALS FOR SERUM CONCENTRATIONS OF OSTEOCALCIN FOR GREEK ADULT MEN AND WOMEN

I. Tryfonidi[1], P. Lukas[2], S. Tournis[3], C. Croupis[4], E. Vasiliadis[5], E. Cavalier[2], E. Chronopoulos[3], K. Makris[6]

[1]KAT GENERAL HOSPITAL, ATHENS, Greece, [2]Department of Clinical Chemistry, University of Liege, CHU de Liege, Liege, Belgium, [3]Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece, [4]Department of Clinical Biochemistry, Attikon University General Hospital, Medical School, University of Athens, Athens, Greece, [5]Third Department of Orthopaedic Surgery, KAT General Hospital, Medical School, University of Athens, Athens, Greece, [6]Clinical biochemistry Department, KAT General Hospital, Kifissia, Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece

Background-Objective: Bone turnover markers (BTMs) reflect the metabolic activity of bone tissue and can be used to monitor osteoporosis therapy. To adequately interpret BTMs, method-specific and population specific reference intervals are needed. We aimed to determine reference intervals (RI) for serum concentrations of Osteocalcin (OC) for the Greek adult population.
Methods: We collected samples from 431 apparently healthy Greeks (142 men, 150 pre- and 139 postmenopausal women), who volunteered to participate in our study. Data on socio-demographic characteristics, medical histories and medications were collected and subjects with clinical conditions or receiving medications affecting bone metabolism were excluded. Dual-energy X-ray absorptiometry (DXA) was used to measure bone mineral density (BMD) in all participants. All blood collections were performed in the morning after overnight fast. Serum OC concentrations were measured by an automated immunoassay on the IDS-iSYS analyzer (Immunodiagnostic Systems, Boldon, UK). The RI was defined as the central 95% range and determined according to CLSI guideline C28-A3 and using the MedCalc Software.
Results: The mean ages of men, pre- and post-menopausal women were 50.7, 40.7 and 58.4 years respectively. DXA results revealed that 348 participants had normal BMD, 73 were osteopenic, while 10 who had osteoporosis were excluded from analysis. Since our data were not normally distributed (Shapiro-Wilk test) in any group and we used the non-parametric method suggested by the CLSI guide in order to determine the RI. Subjects with osteopenia, regardless of sex, exhibited significantly higher values for OC compared to those with normal BMD [median (25.75 percentiles)] 16.78ng/mL (13.51-20.72) vs 20.06ng/mL (15.08-27.13). Post-menopausal women exhibited significantly higher values 18.42ng/mL(14.84-26.65) compared to pre-menopausal women 16.31ng/mL(12.47-20.42) and men 17.17ng/mL(13.59-21.11). Separate RI were calculated and suggested for subjects with normal BMD (8.67-39.2ng/mL), with osteopenia (8.37-48.01ng/mL) as well as for men (9.77-39.81ng/mL), pre-menopausal (7.62-35.12ng/mL) and postmenopausal women(10.52-50.24).
Conclusion: We provide RI for OC concentrations in serum for the Greek adult population using an automated immunoassay. Our data may aid to interpret bone turnover in the Greek adult population

P656

REFERENCE INTERVALS FOR SERUM CONCENTRATIONS OF TARTARATE RESISTANT ACID PHOSPHATASE 5B FOR GREEK ADULT MEN AND WOMEN

I. Tryfonidi[1], P. Lukas[2], S. Tournis[3], C. Croupis[4], E. Vasiliadis[5], E. Cavalier[2], E. Chronopoulos[3], K. Makris[6]

[1]KAT GENERAL HOSPITAL, ATHENS, Greece, [2]Department of Clinical Chemistry, University of Liege, CHU de Liege, Liege, Belgium, [3]Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece

Background-Objective: Bone turnover markers (BTMs) reflect the metabolic activity of bone tissue and can be used to monitor osteoporosis therapy. Tartrate-resistant acid phosphatase, isoform 5b (TRACP5b) is a bone resorption marker not influenced by renal function or food intake and can be measured in serum by immunoassays. We aimed to determine reference intervals (RI) for serum concentrations of TRACP5b for the Greek adult population.
Methods: We collected samples from 431 apparently healthy Greeks (142 men, 150 pre- and 139 post-menopausal women), who volunteered to participate in our study. Data on socio-demographic characteristics, medical histories and medications were collected and subjects with clinical conditions or receiving medications affecting bone metabolism were excluded. Dual-energy X-ray absorptiometry (DXA) was used to measure bone mineral density (BMD) in all participants. All blood collections were performed in the morning after overnight fast. Serum TRACP5b concentrations were measured by an automated immunoassay on the IDS-iSYS analyzer (Immunodiagnostic Systems,Boldon,UK). The RI was defined as the central 95% range and determined according to CLSI guideline C28-A3 and using the MedCalc Software.
Results: The mean ages of men, pre- and post-menopausal women were 50.7, 40.7 and 58.4 years respectively. DXA results revealed that 348 participants had normal BMD, 73 were osteopenic, while 10 who had osteoporosis were excluded from analysis. Since our data were not normally distributed (Shapiro-Wilk test) in any group, we used the non-parametric method suggested by the CLSI guideline in order to determine the RI. Subjects with osteopenia, regardless of sex, exhibited significantly higher values for TRACP5b compared to those with normal BMD [median (25.75 percentiles)] 3.22U/L (2.71-3.83) vs 2.41U/L (1.96-3.13). Post-menopausal women exhibited significantly higher values 3.19U/L(2.63-3.83) compared to pre-menopausal 2.19U/L(1.75-2.70) and men 2.48U/L(2.07-3.13). Separate RI are calculated and suggested for subjects with normal BMD (1.11-4.78U/L), with osteopenia (1.24-5.47U/L) as well as for men (1.38-4.61U/L), pre-menopausal (1.08-4.54U/L) and postmenopausal women(1.57-6.44U/L).
Conclusion: We provide RI for TRACP5b concentrations in serum for the Greek adult population using an automated immunoassay. Our data may aid to interpret bone turnover in the Greek adult population.

P657

IMPROVED COMPARABILITY OF B-ISOMERIZED C-TERMINAL TELOPEPTIDE OF TYPE I COLLAGEN (B-CTX-I) IMMUNOASSAYS

I. Tryfonidi[1], P. Lukas[2], S. Tournis[3], E. Cavalier[2], E. Chronopoulos[3], K. Makris[4]

[1]KAT GENERAL HOSPITAL, ATHENS, Greece, [2]Department of Clinical Chemistry, University of Liege, CHU de Liege, Liege, Belgium, [3]Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece, [4]Clinical biochemistry Department, KAT General Hospital, Kifissia, Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece

Background-Objective: β-CTX-I has been recommended as a reference marker for bone resorption in research studies. Studies have showed significant disagreement in patient results from existing commercial assays. Recently one IVD manufacturer (IDS) developed an new version of its assay claiming improved performance . We aim to evaluate the current status of harmonization of three commercial assays measuring β-CTX-I.

Methods: Serum samples from 431 subjects (348 healthy, 73 osteopenic and 10 osteoporotic patients) were collected in Athens, Greece and were tested in Athens and Liege, Belgium with three automated commercial assays (new- and old-IDS on ISYS, Roche on Cobas e-411 and SNIBE on Maglumi). All measurements were performed according to manufacturers instructions. Passing-Bablok regression was used to determine the agreement between results in methods comparison.

Results: The paired comparisons (figure) performed between the old-IDSvsRoche and vsSNIBE revealed significant differences as the regression equation 95%CI of intercept and slope do not include 0 [-109.31(-127.32,-91.99), -88.29(-110.03,-69.29)] and 1 [1,37(1.32,1.43), 1.28(1.22,1.36)] respectively. The comparison between the SNIBE and Roche show good agreement of these methods, since the 95%CI of the intercept included 1 [-18.50(-36.97,2.24)] and the slope 0 [1.04(0.98,1.09)]. The new-IDS assay showed significantly improved comparability with both Roche and SNIBE assays. The 95%CI of slope includes 1 in both compariosns [1.03(0.99,1.07) and 1.00(0.95,1.03)] and the intercept corresponds to limit of quantitation of the new-IDS assay [25.25(12.09,37.49) and 33.52(18.61,46.11)].

Objective:Todescribetheclinicalandtreatmentcharacteristicsofosteoporoticpatientsover80yearsinareal-worldscenarioinColombia. Material and Methods: This observational, retrospective study analyzed medical records of over 80-year-old with osteoporosis, treated by endocrinologists from 2022 to 2024. clinical, densitometric, and treatment data were collected using REDCap and analyzed using descriptive statistics (Excel & SPSS-27) Results: Among 211 patients, 92.4% were women ($\bar{x}$ 85.4, 80-103 years) vs men ($\bar{x}$ 84.9, 80-98) undergoing BMD evaluation. Women's BMI (24.8±4.1kg/m², range 16.65-40.79) was similar but more varied than men's BMI (23.3±3.7kg/m², range 17.97-31.23). 25.1% of participants had >4cm height loss and 11.8% smoked. Over half had fragility fractures (57%, N=120), with vertebral fractures being most common (35.5%, N=75), and 50% of these had two vertebral fractures. The mean T-score for the lumbar spine was -2.50±0.94; femoral neck -2.35 ±1.10; and total hip, -2.14±1.08. The distal radius had the lowest T-scores, even in repeated measurements (-3.51±1.73 in the second and -4.14±1.20 in the third). Most prescribed treatments were zoledronic acid (23.2%), denosumab (22.3%), alendronate (21.3%), and teriparatide (20.4%). Notably, 75.8% adhered to initial treatment. 85.3% received calcium and/or vitamin D. Therapeutic failure was 19.4% after initial treatment and 10.9% after the second. Second-line treatments included denosumab (26.1%) and teriparatide (10.0%). Reportedadverseeffectswereminimal,gastrointestinalintolerance (4.7%),flu-likesyndrome(2.4%)andmusculoskeletalpain(1.4%).No cases of atypical fractures, osteonecrosis, or uveitis were reported. 57.2% of patients had at least one frailty criterion, yet

over half were totally independent in daily activities, with only 5% showing moderate or severe dependence. 64% walked without support, but 25% had a fall in the past year. Conclusion: This real-world study of patients over 80 on osteoporosis treatment shows high adherence rates and minimal adverse effects. Addressing treatment failures and improving access to first-line anabolic therapies is critical for optimizing outcomes in this vulnerable population.

P659

IMPROVING BONE HEALTH IN A TERTIARY FRAGILITY FRACTURE CENTRE WITHOUT A DEDICATED FRACTURE LIAISON SERVICE

Z. Milner[1], J. Agwada-Akeru[1]

[1]Whipps Cross Hospital, London, United Kingdom

Objective In 2019, Whipps Cross Hospital became the dedicated Fragility Fracture Centre for Barts Health Trust. Despite the lack of a specialist Fracture Liaison Service (FLS) recommended by national guidelines, the hospital's Older People's Services (OPS) has improved bone health practices through evaluation and implementation audit cycles.

Aim

- Assess 100% of OPS patients for fragility fracture risk.
- Offer secondary prevention to all identified at-risk patients.

Methods

A 2020 audit revealed high in-patient femoral fracture rates and insufficient risk assessments (21%). In 2021, the National Audit for Inpatient Falls (NAIF) highlighted the need for a Multifactorial Risk Assessment (MFRA). Initial data showed only 2% of at-risk patients received MFRAs, 4% bone health reviews, and 8% bone health treatments. A survey identified a lack of confidence among healthcare professionals in bone health management.

A multi-faceted plan was developed, including:

1. Comprehensive Geriatric Assessments incorporating MFRAs.
2. A bone health flowchart and discharge summary template.
3. A nurse-led bone health clinic.
4. Electronic referral forms.

Training programs targeted knowledge gaps among Emergency Department practitioners, OPS clinicians, and trainees in Geriatric Services and General Practice.

Results Re-audits demonstrated:

- Increased bone health assessments to 99.3%.
- A rise in prescribing anti-resorptive medications, from 11 in 2019 to 864 in 2023, with improved drug selection (e.g., romosozumab).
- Enhanced patient engagement: 94% received counseling, and 84% reported confidence in understanding osteoporosis.

Conclusion

Through iterative audits and education, Whipps Cross achieved near-complete bone health assessments and significantly improved prescribing practices without a dedicated FLS. Patient outcomes, staff knowledge, and satisfaction have improved, reducing fragility fractures. Future goals include sustaining progress and addressing identified gaps.

POSTMENOPAUSAL WOMEN WITH LOW-TRAUMA FRACTURES HAVE A HIGHER NUMBER OF CLINICAL RISK FACTORS

J. Aleksic[1], J. Zvekic Svorcan[2]

[1]Railway Healthcare Institute, Belgrade, Serbia, Belgrade, Serbia, [2]University of Novi Sad, Medical Faculty of Novi sad, Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, Novi Sad, Serbia

OBJECTIVES: FRAX is the recommended method for risk assessment in almost all world guidelines. It has its advantages and disadvantages. In the absence of precise strategies, individuals are identified with an individual approach strategy based on the previous existence of a low trauma fracture or the existence of significant risk factors[1].
AIM: To investigate the difference between subgroups of subjects with and without fractures in relation to the number of clinical risk factors (RFs) mentioned in the FRAX.
METHODS: In this cross-sectional study, data were collected related to fractures and RFs. The research included 515 female respondents aged 45-70 years. In data analysis χ^2 test is used.
RESULTS: Subjects with a previous fracture due to minor trauma had at least one RF present (100%) and more than half had ³3 RFs, while 10% without fracture had ³3 RFs. The highest percentage of respondents with fractures (52.6%) had ³3 RFs, while the highest percentage of women without fractures had 1 FR (47.4%) (χ^2=190,07,df=3, p=0,000). Women with a spinal fracture had: ³3 RFs - 58.0%, 2 RFs - 36%, while subjects without fractures had 1 RF - 37%(χ^2=90,70, df=3, p=0,000). Women with non-vertebral fractures had ³3 RFs- 52.9%, while the highest percentage without fractures had 1 RF -39.4% (χ^2=103,45, df=3, p=0,000). Women with hip fractures had ³3 RFs -61.3%, while without fractures have 1 (31.6%) or 2 RFs (31.0%)(χ^2=21,06, df=3, p=0,000). Women with forearm fracture had: ³3 RFs- 51.2%, 2 RFs (41.5%), while without fractures had 1 RF (34.4%) (χ^2=46,02, df=3, p=0,000). Women with upper arm fractures had ³3 RFs - 56%, while without fractures had 1 (31.2%) or 2 RFs(30.8%) (χ^2=13,53, df=3, p=0,004). Women with other fractures (52.7%) had ³3 RFs, while without fractures had 1 (32.8%) or 2 RFs (30%) (χ^2=29,99, df=3, p=0,000).
CONCLUSION: More than half of the respondents with a fracture due to minor trauma had 3 or more RFs. In daily work, it is important to actively search for individuals with RFs for the best possible selection for treatment and prevention of the first and subsequent fractures.

TELEHEALTH-DELIVERED CIRCUIT TRAINING: A NON-INFERIOR APPROACH TO REDUCING INTERMUSCULAR FAT IN KNEE OSTEOARTHRITIS PATIENTS

J. B. Aily[1], M. Noronha[2], R. J. Ferrari[1], N. Casonato[1], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil, [2]La Trobe University, Bendigo, Australia

Objective
To investigate whether a periodized circuit training program delivered via telehealth is as effective as the same protocol delivered face-to-face in reducing thigh intermuscular adipose tissue (IMAT) in adults with knee osteoarthritis (OA).
Material and Methods
This randomized controlled trial included 100 adults aged 40 years or older with radiographic evidence of knee OA (grades II or III, Kellgren and Lawrence scale). Participants were assigned to one of two groups: (1) Face-to-Face (FtF), which involved presential, supervised periodized circuit training; or (2) Telehealth, where the same protocol was delivered asynchronously via online videos, DVDs, or YouTube, combined with periodic phone calls from a physical therapist. IMAT was quantified using computed tomography scans (Multislice Brilliance CT 16-slice, Philips) at baseline and after 14 weeks. Tissue composition analysis was conducted using ITK-SNAP software, with attenuation rates indicating fat presence. An intention-to-treat (ITT) and a per-protocol (PP) analysis were conducted using mixed-effects models to compare group (FtF vs. Telehealth) and time (baseline vs. 14 weeks) effects on IMAT.
Results
A total of 100 participants (mean age 54 ± 8 years, 60% female, BMI 27 ± 2.5 kg/m²) completed the trial, with similar baseline characteristics between the FtF (n=50) and Telehealth (n=50) groups. Baseline IMAT values were comparable (FtF = 13.7 cm², Telehealth = 13.3 cm²). Both groups showed significant reductions in IMAT after 14 weeks: FtF group mean decreases of 1.6 cm² (PP) and 1.5 cm² (ITT), and Telehealth group mean decreases of 1.5 cm² (PP) and 1.1 cm² (ITT). Mixed-effects models confirmed that the telehealth approach was not inferior to face-to-face training.
Conclusion
Periodized circuit training delivered via telehealth is as effective as face-to-face delivery in reducing IMAT depots in adults with knee OA. This finding supports the adoption of telehealth as a viable, cost-effective approach to reduce IMAT and improve outcomes for patients with knee OA, while addressing barriers such as physical distance and healthcare costs.

P662

IMPACT OF OBESITY ON PAIN AND FUNCTION IN KNEE OSTEOARTHRITIS: A CROSS-SECTIONAL STUDY

J. B. Aily[1], N. Casonato[1], F. E. Sette[1], P. J. F. Venturini[1], M. G. Silva[1], D. K. White[2], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil, [2]University of Delaware, Newark, United States

Objective

To investigate the relationships between body composition, physical activity, knee pain, and functional status in patients with knee osteoarthritis (KOA), with a particular focus on differences between obese and non-obese individuals. Additionally, the study aimed to explore these associations in obese KOA patients to identify potential targets for intervention.

Material and Methods

This cross-sectional study was conducted in São Carlos, São Paulo, Brazil, between January 2023 and October 2024, including 86 participants aged 40 years or older with symptomatic KOA. Participants were categorized into two groups—obese and non-obese—based on body mass index (BMI), with obesity defined as BMI ≥ 30 kg/m². Primary outcomes included knee pain assessed using the Western Ontario and McMaster Universities Osteoarthritis Index-pain (WOMAC-P) scale. Secondary outcomes included functional status measured via the WOMAC-function (WOMAC-F) scale and the 40m Fast Paced Walk Test (40m FPWT). Statistical analyses included t-tests and multiple linear regression models to evaluate the relationships among body composition, physical activity, and knee pain/function across obesity statuses. Body composition parameters such as fat mass index (FMI) and fat percentage were included in the models to explore their associations with outcomes.

Results

Of the 86 participants (median age: 58 years, range: 40–87; 64% female), obese individuals (n=44) reported significantly greater knee pain compared to non-obese participants ($p<0.05$). Additionally, obese participants exhibited significantly lower walking speed than their non-obese counterparts ($p<0.05$). Among obese participants, higher body fat percentage was positively associated with worse functional status, as measured by WOMAC-F scores (β=0.32; 95% CI: 0.01–0.36), though it showed no association with WOMAC-P scores or 40m FPWT velocity. Similarly, FMI was positively associated with WOMAC-F scores (β=0.29; 95% CI: 0.00–0.17) but was not linked to WOMAC-P or 40m FPWT outcomes in obese participants.

Conclusion

Obese individuals with knee osteoarthritis experience greater knee pain and slower walking speeds compared to non-obese individuals. In obese participants, higher body fat percentage and fat mass index are associated with worse functional outcomes, as reflected in higher WOMAC-F scores. These findings emphasize the importance of targeted interventions focusing on body composition and physical activity for obese patients with KOA.

P663

NF-KB SIGNALING PATHWAY-BASED RESEARCH OF ANTAGONISM BETWEEN VASPIN AND LEPTIN IN OSTEOARTHRITIS

J. Bao[1]

[1]The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China

Abstract :

Leptin and visceral adipose tissue-derived serine protease inhibitor(Vaspin) both belonged to the adipokines family. They were closely related to the pathophysiology of osteoarthritis (OA). Our studies showed that leptin plays a catabolic role on articular cartilage. Recently, we demonstrated that the vaspin levels were markedly decreased in patients with OA, and vaspin prevented the inflammation and degradation of chondrocytes, which closely related to the NF-κB signaling pathway. Besides, our pre-experiment studies demonstrated vaspin suppress leptin-induced degradation on chondrocytes, while the current mechanism was still absent. We speculate that the antagonism and imbalance between vaspin and leptin may play an important role during the pathophysiology of OA. In the present study, we will inspect the metabolism induced by vaspin and leptin in chondrocytes and also inflammatory and angiogenesis in synovial tissues, and find out the antagonism role between vaspin and leptin. We will assess the effects of vaspin and leptin on the NF-κB signaling pathway changes and find out related mechanisms. Through the animal model with intra-articular injection, we will find out the precise antagonism role between these two adipokines. This project will explore the role of antagonism between adipokines during the pathophysiology of OA.

P664

COMPARISON OF EARLY CURATIVE EFFECTS OF LATERAL UNICOMPARTMENTAL KNEE ARTHROPLASTY WITH TOTAL KNEE ARTHROPLASTY AND THE LEGACY CONSTRAINED CONDYLAR KNEE ARTHROPLASTY IN THE TREATMENT OF ISOLATED LATERAL OSTEOARTHRITIS: A SINGLE-CENTER RETROSPECTIVE STUDY

J. Bao[1]

[1]The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China

Background: Aims of this study were to compare the functional and radiographic results, perioperative complication after lateral unicompartmental knee arthroplasty (LUKA) with total knee arthroplasty (TKA) and the legacy constrained condylar knee (LCCK) arthroplasty for the treatment of lateral compartmental knee osteoarthritis (LCKOA), and to provide a basis for the treatment of LCKOA.

Methods: From January 2021 to January 2024, analyzed retrospectively clinical data of 74 patients with LCKOA treated with

LUKA, TKA and LCCK arthroplasty. According to the operation plan, the patients were divided into three groups: LUKA group (23 cases), TKA group (23 cases) and LCCK group (28 cases). The changes of hip-knee-ankle (HKA) angle of the affected knee before and after operation were measured. All patients were assessed using the operation time, blood loss during operation, incision length, visual analogue scale (VAS) score before operation and after operation, Hospital for Special Surgery score (HSS), Oxford Knee Score (OKS), range of motion (ROM).
Results: All 74 patients were followed up for (2.38±0.33) years. The operation time, blood loss during operation, incision length and VAS score after operation in the LUKA group were significantly less than those in the TKA group and LCCK group (P<0.05); HKA valgus angle, ROM, HSS score and OKS score of the three groups after operation were significantly better than those before operation (P<0.05); There was no significant difference among the three groups in HSS score and OKS score (P>0.05).
Conclusion: To sum up, LUKA, TKA and LCCK prosthesis for the treatment of LCKOA have good clinical effects; Compared with TKA and LCCK prosthesis, LUKA has the advantages of less trauma, less bleeding, less pain and quick recovery, but the indications and contraindications of surgery should be strictly evaluated, and the short-term effect is satisfactory, while the long-term effect remains to be observed.

P665

SYNERGIZING ADAPTIVE IMMUNITY AND REGENERATIVE SIGNALS TO ENHANCE OSTEOCHONDRAL DEFECTS REPAIR

J. Bao[1]

[1]The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China

Abstract :
In clinical practice, repairing osteochondral defects (OCDs) is challenging because of the complex cartilage/subchondral bone structure and intricate immunological microenvironment. Here, we identify the crucial role of adaptive immunity dysfunction by revealing that an increase of T helper 17 (Th17) cells exacerbated osteochondral tissue degradation via its pro-inflammatory cytokine interleukin-17 (IL-17) in the early-stage OCDs. Next, we leveraged this adaptive immunity mechanism and combined it with regenerative signals to develop a multifunctional hydrogel system capable of simultaneously tackling immune dysfunction and regenerative deficiency. Rapid IL-4 release from the methacrylated hyaluronic acid (HAMA) hydrogel exerts a potent immunomodulatory effect by inhibiting the differentiation and function of Th17 cells. Moreover, transforming growth factor-beta1 anchored on methacrylated hyaluronic acid and heparin (HAMA@HepMA) microparticles provides sustained regenerative signals, which synergistically transform the pro-inflammatory microenvironment into a pro-regenerative niche for enhanced OCDs healing. Our study suggests that targeting specific immune pathways can significantly enhance the efficacy of regenerative strategies, paving the way for innovative treatments in orthopedic medicine.

THE EFFECTS OF SHORT-TERM DIETARY ENERGY RESTRICTION WITH OR WITHOUT EXERCISE ON INFLAMMATION AND JOINT PAIN IN PATIENTS WITH KNEE OSTEOARTHRITIS

J. Bilzon[1], R. Deere[1], M. Farrow[2], B. Spellanzon[1], E. Chowdhury[3], D. Thompson[1]

[1]University of Bath, Bath, United Kingdom, [2]The Ohio State University, Columbus, United States, [3]Versus Arthritis, London, United Kingdom

Objectives: There is limited research on the effects of short-term caloric restriction and exercise on systemic inflammation and clinical outcomes in knee osteoarthritis. The objective of this study is to determine the effects of 4-weeks dietary energy restriction alone (D only) or combined with aerobic exercise (D+E) on systemic inflammation and index knee pain in overweight and obese individuals with knee osteoarthritis.
Material and Methods: Twenty-three individuals with knee osteoarthritis completed this trial. Participants randomised to the D group (n= 9, BMI = 30.0±2.4 kg.m^2, Age = 56±5 years) were asked to reduce their habitual energy intake by 5,000kcal per week for 4 weeks, and those randomised to the D+E group (n= 14, BMI = 32.3±4.8 kg.m^2, Age = 57±5 years) were asked to follow the same dietary energy restriction and perform five, 30-minute bouts of moderate intensity cycle ergometer exercise per week. Blood samples and Visual Analogue Scale pain ratings were collected at baseline, after a 4-week control period and following the 4-week intervention period. Data are presented as mean ± SD.
Results: C-Reactive Protein (CRP) remained relatively high but was unchanged in both groups post-intervention (D, 3.07±3.91 mg/L; D+E, 2.28±2.03 mg/L). An interaction effect was present for IL-6, which decreased (p<0.01) and was lower post-intervention in the D+E group (1.47±0.70 mg/L) compared to D (2.71±1.31 mg/L). VAS index knee pain was reduced in both groups (p<0.01), but to a greater extent in the D+E group.
Conclusions: Four weeks of dietary energy restriction reduces index knee pain in obese individuals with knee osteoarthritis. When combined with regular bouts of moderate intensity aerobic exercise, dietary energy restriction leads to greater reductions in knee pain and some biomarkers of systemic inflammation.
Disclosures: This research was sponsored Versus Arthritis as part of the National Centre for Sport Exercise and Osteoarthritis Research.

OPPORTUNISTIC IDENTIFICATION OF VERTEBRAL FRACTURES ON CT BY ARTIFICIAL INTELLIGENCE; DOES IT SAVE EXPERT PHYSICIAN TIME?

J. Boylan[1], J. Turton[1], J. Threlkeld[2], D. Chappell[3], J. Connor[2], M. Vindlacheruvu[4], E. Curtis[5], M. Stone[1], K. Javaid[6]

[1]Bone Research Unit, University Hospital Llandough, Cardiff and Vale University Health Board, Penarth, United Kingdom, [2]Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom, [3]Department of Medicine, NIHR Cambridge Biomedical Research Centre, Cambridge, United Kingdom, [4]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [5]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [6]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Objective

To determine the accuracy of Nanox-AI HealthVCF in identifying Vertebral Fractures (VF) and whether physician time is saved. The ADOPT study is evaluating the patient and economic outcomes of VF detection on CT scans using artificial intelligence (AI) enabled Fracture Liaison Service identification (FLS).

Material and Methods

In a single hospital centre, CT scans of adults aged 50 and over were analysed by Nanox-AI HealthVCF and then re-read by expert physicians with experience in identifying VF using the grade 2/3 semi-quantitative Genant score. Three re-reading of CT scans were conducted, dated October 2017, October 2023 and October 2024.

Results

In 2017, a total of 484 scans were analysed by the AI with 143(29.5%) flagged to contain VF and of these, 45(31.4%) confirmed by the expert. 983 scans in 2023 had 392(39.8%) AI VF flagged and of these, 68(17.3%) confirmed by experts. In 2024, a total of 1201 scans were analysed with 497(41.4%) AI VF flagged, 86(17.3%) confirmed by the experts.

Conclusion

Between 17.3% – 31.4%% of scans flagged by the AI were confirmed to have a VF. This equates to 1730 - 3140 VF per 10,000 CT scans. The variability between 2017 and 2023/24 indicates the value of post market surveillance and clinical confirmation.

Experts agreed with similar proportions of AI flagged scans between 2023 and 2024. Due to limitations with commencing the AI, not all scans from October 2017 were analysed, which may account for the larger proportion of positive scans. Nevertheless, due to the AI experts had to review significantly less CT than the total number of raw scans, saving time in identifying VF. AI enabled FLS could provide a time effective way to identify potential treatment appropriate patients.

THE OSTEOPOROSIS TREATMENT GAP IN IRELAND: REALITY OR ECOLOGIC FALLACY?

L. Yang[1], B. Whelan[1], B. Attracta[1], D. Gonzalez Garza[1], E. Erjiang E[2], T. Wang[3], R. Egan[4], K. Gorham[4], F. Heaney[4], C. Armstrong[4], G. Morote Ibarrola[4], A. Gsel[4], M. Yu[5], M. Dempsey[1], J. Carey[1]

[1]University of Galway, Galway, Ireland, [2]Guangxi Minzu University, Nanning, China, [3]University of Oxford, Oxford, United Kingdom, [4]University Hospital Galway, Galway, Ireland, [5]Tsinghua University, Beijing, China

Objective: The treatment gap for osteoporosis represents the disparity between individuals who require treatment and those who receive it. A European report indicates this gap is 32% in Ireland; however, our findings suggest a different outcome. We conducted an investigation into the treatment gap among Irish men and women.

Materials and Methods: We analyzed treatment rates among patients from a previously characterized cohort in the West of Ireland, known as The DXA HIP Project, following appropriate ethical approval. The development, validation, and clinical characteristics of this cohort have been published. We compared the use of calcium and vitamin D, as well as osteoporosis medications (including bisphosphonates, denosumab, estrogen, raloxifene, and teriparatide), between two groups: those referred for a DXA scan and those who completed a DXA scan. Participants were categorized into three risk groups based on treatment criteria: low risk (none), moderate risk (at least one), and high risk (two or more).

Results: Data were available for analysis from 978 patients (28%) in the referral group and 2,090 in the post-scan group. Within the referral group, 271 individuals had a previous fracture, while 707 did not. Calcium and vitamin D were prescribed to 48% of those with a prior fracture compared to 45% of those without, while osteoporosis medications were prescribed to 30% of the former and 35% of the latter. The majority of individuals in the post-DXA group were prescribed calcium and vitamin D, regardless of their risk status, as detailed in the table below. Conversely, a significant majority of at-risk men and women did not receive osteoporosis medications. Notably, fewer than one in three men and one in two women categorized as high risk were provided with appropriate therapy.

Conclusions: The actual treatment gap for osteoporosis in Ireland remains unacceptably wide. The prevalence of unnecessary treatments among those at low risk has contributed to a misleading perception that the issue is minimal (ecologic fallacy). Further efforts are essential to comprehend and enhance the factors con-

tributing to ineffective prescribing practices.

Variable		Low Risk	Intermediate Risk	High Risk
Calcium and Vitamin D	Men	60%	48%	58%
	Women	53%	48%	70%
Osteoporosis Medication	Men	21%	21%	31%
	Women	16%	28%	46%
Both	Men	17%	16%	22%
	Women	14%	23%	37%

P669

A COMPARISON OF OSTEOPOROSIS INTERVENTION THRESHOLDS: A DATA-DRIVEN ANALYSIS

L. Yang[1], B. Attracta[1], B. Whelan[1], D. Gonzalez Garza[1], E. Erjiang E[2], T. Wang[3], R. Egan[4], K. Gorham[4], F. Heaney[4], C. Armstrong[4], G. Morote Ibarrola[4], A. Gsel[4], M. Yu[5], M. Dempsey[1], J. Carey[1]

[1]University of Galway, Galway, Ireland, [2]Guangxi Minzu University, Nanning, China, [3]University of Oxford, Oxford, United Kingdom, [4]University Hospital Galway, Galway, Ireland, [5]Tsinghua University, Beijing, China

Background: Clinical guidelines indicate that osteoporosis medication should be considered for individuals diagnosed with osteoporosis, those who have experienced a major osteoporotic fracture, patients on chronic glucocorticoid therapy, and individuals at high risk of fractures. However, many eligible patients remain untreated, making it essential to identify the most appropriate intervention criteria for osteoporosis treatment in order to optimize patient care and address the treatment gap.
Purpose: This study aims to compare the agreement between different intervention thresholds for osteoporosis treatment.
Methods: A validated subset of The DXA-HIP cohort, previously published, was utilized to evaluate five intervention thresholds: 1) Major Osteoporotic Fracture (MOF); 2) central DXA T-score ≤ -2.5; 3) chronic glucocorticoid therapy; 4) Irish FRAX® with BMD showing MOF ≥ 20% or Hip fracture (HF) ≥ 3%; and 5) Irish FRAX® without BMD indicating MOF ≥ 20% or HF ≥ 3%. The agreement among these thresholds was analyzed using Cohen's kappa coefficient, alongside a Venn diagram to illustrate the overlap between thresholds.
Results: A total of 1,254 adults aged 40–90 years participated: 290 men and 964 women, with a mean age of 69 years and a mean lowest T-score of -1.4. The FRAX® scores with BMD indicated a MOF risk of 13% and an HF risk of 4%.
Out of the participants, 220 (18%) did not meet any treatment criteria, while 1,025 (82%) met one or more criteria, and 9 (<1%) met all criteria. Significant variability was noted in the proportion of individuals considered eligible for treatment across different criteria: 48% based on prior MOF, 13% on T-score ≤ -2.5, 20% on glucocorticoid therapy, 46% for FRAX® with BMD, and 66% for FRAX® without BMD.
The Venn diagram presented below highlights considerable variability and overlap among different thresholds, with notable discrepancies particularly concerning patients on glucocorticoid therapy.
Agreement levels ranged from very poor (kappa: -0.15) to moderate (kappa: 0.48).
Conclusions: There is significant heterogeneity and inconsistency among various intervention thresholds for osteoporosis treatment, which may contribute to the observed differences in treatment rates. This finding emphasizes the need for the standardization of intervention thresholds to effectively address the osteoporosis treatment gap.

MUSCLE ULTRASOUND AND PHYSICAL ASSESSMENT AS PART OF A COMPREHENSIVE FRAILTY EVALUATION IN HEMATO-ONCOLOGY PATIENTS: PILOT STUDY

R. S. Salinas Gonzalez[1], J. D. Rivadeneira Cando[1], I. Figueroa Vega[1], M. Rodas Pradillos[1], D. Borda Lorente[1], M. Q. Queralt Salas[2]

[1]Physical Medicine and Rehabilitation Department. Hospital Clínic de Barcelona., Barcelona, Spain, [2]Hematopoietic Transplantation Unit, Hematology Department, Institute of Cancer and Blood Diseases (ICAMS), Hospital Clínic de Barcelona, Barcelona, Spain

Frailty status significantly increases morbidity and mortality in allogeneic hematopoietic cell transplantation (allo-HCT). However, the role of physical function and muscle ultrasound evaluation remains unclear **Objective:** Evaluation of physical, muscle ultrasound, and functional parameters in the assessment of frailty in allo-HCT candidates
Material and Methods: A single-center, consecutive sampling study was conducted on allo-transplant candidates evaluated in the Rehabilitation Department. Frailty was evaluated using the HCT Frailty Scale. The physical assessment included morpho-functional parameters such as bioelectrical impedance, muscle ultrasound, one-minute sit to stand test (1-MSTST), grip strength

(GS), and validated questionnaires (DASI and IPAQ).
Results: 16 patients were included, with 56.3% females and 43.8% males. The mean age was 57.75yo (SD=14.15), with a BMI of 26.51kg/m² (SD=4.47), 28.21% body fat (SD=7.50), and 67.41% lean mass (SD=7.74). 50% were classified as fit and 50% as pre-frail. The average grip strength was 28.50kg (SD=9.91), and the 1-MSTST had a mean of 23 repetitions (SD=11.81). The mean DASI score was 40.95 (SD=14.73), and estimated weekly METs from the IPAQ were 3563.5 (SD=2400.51). No significant differences were found between frailty groups (p>0.05).
Significant correlations were observed between 1-MSTST performance and %lean mass (r=0.592, p=0.026), DASI scores (r=0.666, p=0.025), and weekly METs (r=0.784, p=0.003). Additionally, femoral rectus circumference significantly correlated with handgrip strength (r=0.612, p=0.012). No significant correlations were found with the TUG test.
Conclusion: In patients eligible for alloHCT, indicators such as lean mass percentage, 1-MSTS, grip strength, DASI, and IPAQ are valuable tools for assessing functional capacity. Additionally, ultrasound parameters, such as the circumference of the rectus femoris, show potential in the comprehensive approach. However, the small sample size and the lack of post-transplant follow-up limit the interpretation of this findings.

ASSOCIATION BETWEEN 11-YEAR CHANGE OF TOTAL HIP BONE MINERAL DENSITY AND SARCOPENIA IN 500 POSTMENOPAUSAL WOMEN

A. Bellanger[1], J. De Filette[2], F. K. Youssa Nzintcheu[3], D. Sanchez-Rodriguez[4], A. Mugisha[4], F. Baleanu[2], L. Iconaru[2], A.-S. Hambye[5], F. Benoit[4], M. Surquin[4], P. Bergmann[5], J.-J. Body[2]

[1]Laboratoire de Recherche Translationnelle, CHU Brugmann, Université Libre de Bruxelles, 1020, Belgium, [2]Endocrinology, CHU Brugmann, Université Libre de Bruxelles, 1020, Belgium, [3]Faculty of Medicine, Université Libre de Bruxelles, 1070, Belgium, [4]Internal Medicine, CHU Brugmann, Université Libre de Bruxelles, 1020, Belgium, [5]Nuclear Medicine, CHU Brugmann, Université Libre de Bruxelles, 1020, Belgium

Background: Sarcopenia and osteoporosis are common conditions in aging populations, yet their interplay remains poorly understood. Sarcopenia, characterized by reduced muscle mass and strength, may contribute to bone loss and fracture risk through impaired mechanical loading and shared risk factors. We investigated the association between sarcopenia components and total hip bone mineral density (THBMD) changes in postmenopausal women in the FRISBEE cohort.
Methods: Five hundred elderly postmenopausal women, median age 77.4 (IQR 74.7-81.8) years, were followed during a median duration of 11 years for the occurrence of incident fractures. All subjects underwent evaluation of THBMD and appendicular lean mass index (ALMi) with DXA as well as handgrip strength and gait speed testing. Associations between these sarcopenia components and THBMD changes compared to baseline were examined using linear and logistic regression models, adjusted for clinical risk factors for fracture (CRFs).
Results: Higher handgrip strength, gait speed, and ALMi, as well as a dedicated treatment for osteoporosis (≥1 year in the preceding 10 years) and menopausal hormone therapy were significantly associated with lesser THBMD loss, while a sedentary lifestyle and a history of central fracture were linked to greater loss. Multivariate analysis identified low handgrip strength (<16 kg) as the only independent predictor of THBMD loss (adjusted OR=2.27; p<0.01), even after adjusting for confounders. Although ALMi and gait speed were significant variables in univariate analysis, they lost predictive value after adjustment.
Conclusions: We identified a significant association between sarcopenia components, particularly handgrip strength, and changes in THBMD after an 11-year period in a large cohort of elderly postmenopausal women. These findings suggest that a low handgrip strength should alert clinicians on possible BMD loss in the previous years, with a subsequent increased fracture risk.
Keywords: Fracture prediction; Bone loss; Sarcopenia; Osteosarcopenia; Grip strength.

FRACTURE PATIENTS WHO ARE INFORMAL CAREGIVERS EXPERIENCE CHALLENGES IN MANAGING THEIR BONE HEALTH

J. E. M. Sale[1], L. Frankel[1], V. Elliot-Gibson[1], J. I. Cameron[2], M. C. Ashe[3], E. Bogoch[1], L. Funnell[4], L. Meadows[5]

[1]Unity Health Toronto, Toronto, Canada, [2]University of Toronto, Toronto, Canada, [3]University of British Columbia, Vancouver, Canada, [4]Patient Partner, Surrey, Canada, [5]University of Calgary, Calgary, Canada

Objective: Our objective was to examine the experience of bone health management in fragility fracture patients who were also serving as informal caregivers at the time of fracture.
Material and Methods: A phenomenological study was conducted. Eligible patients were English-speaking males and females, 45+ years old with a fragility fracture who 1) presented as outpatients to the fracture clinic at an urban hospital or as inpatients to a rehabilitation hospital in Toronto, Canada, and 2) reported that they were informally caring (not paid) for at least one family member, friend or person in the community on a regular basis at the time of their fracture. Patients were interviewed (60-90 minutes) within six months of the fracture in their homes or by telephone, and one year later (30-60 minutes) by telephone. Analysis was guided by Giorgi's procedures.
Results: We interviewed 25 patients (22 females, 3 males) aged 50-83 years old. This sample size met sample size requirements for phenomenological studies*. Participants reported that caregiving was prioritized over fracture recovery and managing bone health. Participants described the fracture as adding to the burden of being a caregiver both emotionally and physically. After the

fracture, participants reported that their caregiving responsibilities were temporarily put on hold, reduced or modified, depending on the severity of the fracture and the needs of the care recipient. They often had to make alternative arrangements for care recipients during the time they were admitted to hospital or recovering at home. The fracture was a reminder of participant's own fragility and the importance of staying well so they could maintain the health of their care recipient.

Conclusions: Our results suggest that fracture patients who are caregivers experience challenges in continuing the caregiving role as well as looking after their own health. It is important that patients have access to supports that will relieve their caregiver burden so that they can focus on fracture recovery and bone health.

PROVISION OF MEDICATION PRESCRIPTION IN A FRACTURE LIAISON SERVICE DID NOT DIMINISH DURING COVID

J. E. M. Sale[1], A. Yang[1], A. Ali[1], D. Theriault[2], L. Meadows[3], R. Jain[2], J. Weldon[2], E. Bogoch[1]

[1]Unity Health Toronto, Toronto, Canada, [2]Osteoporosis Canada, Toronto, Canada, [3]University of Calgary, Calgary, Canada

Objective: Our objective was to examine the impact of COVID on medication prescription in Ontario's Fracture Screening and Prevention Program (FSPP), after adjusting for fracture risk status and equity-related variables.

Material and Methods: We conducted a logistic regression analysis in a province-wide Fracture Liaison Service (the FSPP) with medication prescription as the outcome. Medication prescription was defined as a prescription for pharmacotherapy by either a bone health specialist or primary care provider. Covariates in the model included COVID time periods (T1 - April 2019 to March 2020: "pre-COVID" (n=2796); T2 - April 2020 to March 2021: "during COVID" (n=1575); T3 - April 2021 to March 2022: "COVID recovery" (n=2208)), fracture risk status (high risk versus not high risk) and equity-related variables (sex, age, marital status, living arrangement, education status, geographic location, and presence of comorbidities). Goodness of fit was assessed with the area under the receiver operating characteristic curve (AUC) and the Hosmer and Lemeshow test.

Results: Fracture risk status was the primary driver of treatment prescription with high risk patients eight times more likely to receive a medication prescription compared to patients who were not high risk for future fracture, after adjusting for all covariates (Odds Ratio = 8.01 [95% CI 7.09, 9.05]). COVID time period was not statistically significant. Of the equity-related variables, female patients, those who were married or in a common-law relationship, lived alone, or resided in urban areas were more likely to be prescribed medication. The model had adequate prediction power and fit the data well (AUC: 0.77; Hosmer and Lemeshow test P-value: 0.23).

Conclusions: We did not observe a significant association between COVID time periods and medication prescription after adjusting for all potential confounders. Fracture risk status, sex, marital status, living arrangement, and geographic location were significantly associated with medication prescription.

SETTING FLS TARGETS FOR PHARMACOTHERAPY IN FRAGILITY FRACTURES OF THE HIP, SHOULDER AND WRIST

J. E. M. Sale[1], V. Elliot-Gibson[1], K. Dang[1], S. Ward[1], E. Bogoch[1]

[1]Unity Health Toronto, Toronto, Canada

Objective: Our objective was to develop Fracture Liaison Service (FLS) targets for pharmacotherapy in patients with a fragility fracture of the hip, shoulder, and wrist.

Material and Methods: From January 2011 to September 2021, 3846 fracture patients were identified by an FLS in a Level 1 Trauma Centre in Toronto, Canada. Of these, 1425 patients 50+ years old presented with a fragility fracture of the hip, shoulder or wrist (659 hip; 273 shoulder; 493 wrist), were not on pharmacotherapy for bone health, and had a femoral neck T-score available if not automatically considered high risk for future fracture. According to the prevailing 2010 Canadian clinical practice guidelines* (and consistent with the updated 2023 guidelines), all patients with a hip fracture (n=659), 130 patients with a shoulder fracture, and 156 patients with a wrist fracture were indicated for pharmacotherapy. Data on contraindications to pharmacotherapy (gastrointestinal, renal impairment, liver failure, allergy or intolerance to bisphosphonates) were collected as well as other reasons to consider not prescribing medication to this population (age>90 years; end of life; end-stage cancer; mental health or social circumstances; severe dementia; death).

Results: Of patients indicated for pharmacotherapy, 84.4% of hip, 90.8% of shoulder, and 95.5% of wrist fracture patients should have been prescribed medication as they did not have any contraindications to pharmacotherapy. Other reasons for not prescribing medication were found in hip fracture patients only and reduced the pharmacotherapy target for hip fractures to 68.8%.

Conclusions: Based on contraindications alone, treatment targets for hip, shoulder and wrist fracture patients indicated for pharmacotherapy ranged from 84.4% to 95.5%. Additional reasons for not prescribing pharmacotherapy reduced the target to 68.8% for hip fracture patients, indicating the medical complexity of this population.

THE COMPLIANCE CHALLENGE: MIND THE GAP WITH IV BISPHOSPHONATES

J. Elilnesan[1], F. Rayan, H. Shukla

[1]Kettering General hospital, University Hospitals of Northamptonshire, Kettering, United Kingdom

Objective
To assess compliance with oral bisphosphonates in patients admitted with fragility fractures of the femur at Kettering General Hospital.
Neck of femur (NOF) fractures are associated with significant morbidity and mortality in older adults. Bisphosphonates are critical for reducing future fracture risk. This study evaluates compliance with oral bisphosphonates 120 days post-fracture, as per National Hip Fracture Database (NHFD) KPI-7. Johansen et al (2023) recommended intravenous zoledronic acid (IV Zol) as the first-line treatment for fragility hip fractures due to its cost-effectiveness and ability to reduce re-fracture risk within six months, aligning with National Osteoporosis Guideline Group (NOGG) guidelines.
Method
A retrospective review included patients aged 60 and over admitted with NOF fractures (July–September 2024). Data from NHFD and PAS was collected, excluding deceased and end-of-life patients. Key data points included initiation of bisphosphonates during admission, reasons for non-initiation, and the type prescribed (oral vs. IV). Follow-up interviews assessed compliance and satisfaction for patients on oral bisphosphonates.
Results
Of 97 eligible patients, 49 were started on bisphosphonates during admission: 20 on oral bisphosphonates and 29 on IV bisphosphonate. Five were already on treatment (3 on alendronic acid). Reasons for non-initiation included referral to the Osteoporosis Clinic (26), renal impairment at baseline (9), renal impairment as inpatient (2), poor dentition (2), and poor prognosis (1).
At 120 days, 14 of 19 respondents (71%) on oral bisphosphonates reported compliance, but 11 (58%) experienced issues with treatment.
Conclusions
This study reveals suboptimal compliance with oral bisphosphonates and supports IV bisphosphonate as a superior first-line therapy for fragility fractures, consistent with the Five Nations Consensus. This study has signified the importance of patient education in raising awareness of bone health.

P676

PLATELET-RICH PLASMA INJECTIONS FOR LUMBAR DEGENERATIVE MONODISCOPATHY: A PILOT STUDY

J. F. Kaux[1], C. Demoulin[1], M. A. Ferrara[2], R. Fontaine[2], S. Grosdent[1], S. Bethlen[2], M. Tomasella[1], M. Vanderthommen[1], P. Gillet[1]

[1]University of Liège, Liège, Belgium, [2]University Hospital of Liège, Liège, Belgium

Objective:
This longitudinal pilot study aimed to evaluate the feasibility, safety, and potential benefits of platelet-rich plasma (PRP) injections into lumbar intervertebral discs in patients with chronic low back pain and degenerative monodiscopathy, assessing potential efficacy on disability.
Material and Methods:
Six participants with chronic low back pain and lumbar degenerative intervertebral disc disease underwent a single PRP injection into the affected lumbar intervertebral disc. Follow-up assessments were conducted over 1 year. Outcomes included the Roland Morris Disability Questionnaire (RMDQ) for disability, numeric rating scale (NRS) for pain, Tampa Scale for Kinesiophobia (TSK), and lumbar flexion range of motion. Magnetic resonance imaging (MRI) was used to evaluate disc structural changes.
Results:
No adverse events were reported. At 1 year, 50% of participants showed significant improvements in disability scores (RMDQ), while the remaining 50% experienced no change. Pain (NRS) and kinesiophobia (TSK) scores showed no consistent pattern of improvement across the cohort. MRI analysis revealed no significant changes in intervertebral disc morphology.
Conclusion:
PRP injections may offer potential benefits for selected patients with degenerative lumbar intervertebral discopathy and low back pain, particularly in reducing disability. However, the findings are limited by the small sample size and absence of a control group. Further research with larger, randomized controlled trials is needed to establish efficacy and optimize PRP therapy protocols for this population.

UNCONTROLLED ASTHMA: ASSOCIATIONS WITH ALTERED BODY COMPOSITION, REDUCED EXERCISE CAPACITY, AND MENTAL HEALTH IMPLICATIONS

F. Schleich[1], S. Ziant[2], S. Louis[2], C. Moermans[2], R. Deroisy[2], R. Louis[1], J. F. Kaux[1], T. Bury[1]

[1]University of Liège, Liège, Belgium, [2]University Hospital of Liège, Liège, Belgium

Objective:
This study aimed to evaluate the relationship between body composition, inflammatory phenotypes, and exercise capacity in patients with uncontrolled asthma, focusing on the impact of fat and lean mass on lung function and patient-reported outcomes.
Material and Methods:
Fifty-six patients with moderate-to-severe uncontrolled asthma and 14 healthy controls were recruited. Dual-energy X-ray absorptiometry (DXA) was used to assess body composition, including fat mass, lean mass, and bone mineral content. Inflammatory phenotypes were determined using induced sputum and fractional exhaled nitric oxide (FeNO). Exercise capacity was measured via VO_2 max, and spirometry evaluated lung function. Patient-reported outcomes included asthma control (ACT), quality of life (AQLQ), and mental health (HAD).
Results:
Asthmatics exhibited higher body mass index (BMI), fat mass index (FMI), and visceral adipose tissue (VAT) compared to controls ($p<0.0001$). Lean mass was lower in asthmatics ($p=0.0012$) and correlated with better asthma control, reduced depression scores, and improved lung function. Eosinophilic asthma was associated with lower fat mass and superior exercise tolerance compared to non-eosinophilic asthma (VO_2 max: 20.7 vs 17.3 mL/min/kg, $p=0.04$). Increased fat mass correlated with restrictive lung patterns and higher systemic inflammatory biomarkers (CRP and fibrinogen).
Conclusion:
Uncontrolled asthma is associated with significant alterations in body composition, including increased fat mass and reduced lean mass, which impact lung function, exercise tolerance, and mental health. Eosinophilic asthma demonstrates a favorable phenotype with lower fat mass and improved exercise capacity. Interventions focusing on nutritional support and physical rehabilitation may enhance disease management and patient outcomes.

CLINICAL ASSESSMENT OF PURESSENTIEL® MUSCLES AND JOINTS GEL AROMATHERAPY IN THE MANAGEMENT OF OSTEOARTHRITIS-RELATED KNEE PAIN

N. Barizien[1], P. Capron[2], T. Mamou[3], F. Louni[4], R. Krzentowski[5], P. Fogel[6], J. F. Kaux[7]

[1]1 Service de Réadaptation Fonctionnelle, Hôpital Foch, Suresnes, France, [2]Clinique du Sport, Paris, France, [3]Institut Médico-Sportif Préfontaine, Paris, France, [4]Service des Maladies Infectieuses, Hôpital Bichat, Paris, France, [5]Comité Départemental Olympique de Paris, Paris, France, [6]ForvisMazars, Courbevoie, France, [7]University of Liège, Liège, Belgium

Introduction : Knee osteoarthritis (OA) is a degenerative joint disease that affects millions globally, causing chronic pain and limited mobility. Pharmacological treatments for OA-related knee pain come with risks, making alternative or complementary therapies attractive. This post-market trial evaluates the efficacy of Puressentiel® Muscles and Joints gel, an aromatherapy gel with 14 essential oils, in managing OA-related knee pain.
Method : In this 12-week open-label trial (NCT04736563), participants aged 45–90 with OA-related knee pain applied Puressentiel® Muscles and Joints gel twice daily for 4 weeks, following a 4-week run-in period without treatment. Pain, joint stiffness, and function were assessed using the Western Ontario McMaster Universities Arthritis Index (WOMAC) and Visual Analog Scale (VAS) at baseline, 4 weeks, 8 weeks, and 12 weeks, and oral analgesic intake was recorded daily.
Results : Significant improvements in WOMAC and VAS scores were observed during treatment ($p = 0.0262$; $p < 0.0001$, respectively) and sustained 4 weeks post-treatment ($p = 0.0190$; $p < 0.0001$, respectively). Paracetamol intake significantly decreased from baseline to the end of treatment ($p = 0.0230$), though anti-inflammatory intake did not change significantly. No adverse events were reported.
Conclusion : Puressentiel® Muscles and Joints gel was well-tolerated, improved WOMAC and VAS scores, and reduced paracetamol use, presenting a viable natural option for pain management in knee OA.
Conflicts of Interest: P.C., T.M., and F.L. received funding from Puressentiel® to perform the trial. The funders had no role in the design of the trial, in the collection, analysis, or interpretation of the data; in the writing of the manuscript; nor in the decision to publish the results.

CURRENT PRACTICES AND CHALLENGES IN PERIPROSTHETIC BMD ASSESSMENT: TOWARDS STANDARDIZATION

J. F. Torres-Naranjo[1], R. E. Lopez-Cervantes[2], A. C. Guzman-Rico[1], D. E. Garin-Zertuche[3], L. G. Padilla-Rojas[4], J. M. Gomez-Acevedo[3], C. A. Alvarez-Rengiffo[4]

[1]Centro de Investigación Ósea y de la Composición Corporal, CIO, Guadalajara, Mexico, [2]Clinica de Fracturas por Osteoporosis, CFO, Hospital de Especialidades San Francisco de Asis de Guadalajara, Guadalajara , Mexico, [3]Mexican Society of Orthopedics and Trauma Research, SMIOT, Zapopan, Mexico, [4]Mexican Federation of Orthopedics and Trauma Colleges, FEMECOT, Guadalajara, Mexico

Periprosthetic bone mineral density (pBMD) assessment is essential in optimizing outcomes for arthroplasty patients. However, inconsistencies in dual-energy X-ray absorptiometry (DXA) protocols, region of interest (ROI) placement, and analysis techniques limit precision, reproducibility, and the development of standardized, evidence-based guidelines.

Objectives: To evaluate the variability in DXA protocols for pBMD assessment as reported in the literature and clinical practice and to estimate the impact of this variability on pBMD measurements.

Material and Methods: An extensive review of the published literature was conducted, focusing on:

1. Variability in pBMD acquisition and analysis protocols reported in the literature, including ROI placement, DXA machine settings, and post-processing software.
2. The variability in pBMD evolution in clinical trials, when protocol details were available.
3. Estimating the impact of protocol differences on pBMD measurements by analyzing a patient dataset and simulating changes in pBMD measurement based on the factors identified in the reviewed studies.

Results: There was substantial variability in pBMD measurement, with differences of up to 24% between pBMD protocols. The most significant contributors to variability were related to:

- Inconsistent ROI placement, especially at the bone-prosthesis interface.
- Differences in software algorithms, particularly edge detection and ROI definition.
- Patient positioning (e.g., rotation and flexion) during DXA scans.

Many studies did not fully report the protocols used for pBMD assessment, further complicating reproducibility and cross-study comparisons. Protocol inconsistencies between studies were frequent when reported, particularly in ROI definitions.

Conclusions: The study highlights a pressing need for standardized DXA protocols in periprosthetic BMD assessment to reduce variability and improve reliability. Key recommendations include:

- Establishing consensus guidelines for ROI placement and patient positioning.
- Ensuring transparency and uniformity in reporting DXA protocols in clinical trials and studies.
- Encouraging manufacturers to harmonize software algorithms for pBMD analysis.

Addressing these challenges will enhance the clinical utility of pBMD measurements and facilitate the development of evidence-based strategies for managing bone health in arthroplasty patients.

NANO-COMPOSITION OF CISSUS QUADRANGULARIS: ENHANCED EFFICACY AND PROMISING PHARMACOKINETIC PROFILE IN THE MANAGEMENT OF OSTEOPOROSIS

J. Garg[1], S. K. Bhadada[2], O. Katare[3], S. Kaur[2]

[1]E-YUVA centre, Panjab University chandigarh, Chandigarh, India, [2]Department of Endocrinology, PGIMER Chandigarh, Chandigarh, India, [3]UIPS, Panjab University Chandigarh, Chandigarh, India

Osteoporosis is a chronic condition characterised by decreased bone mass density and weakening bones, making them fragile and more prone to fractures. Fractures can lead to reduced quality of life, disability and increased mortality. Risk factors for osteoporosis include ageing, hormonal changes, unhealthy eating habits and lifestyle, certain medication's side effects etc. Post-menopausal women are at high risk of Osteoporosis. As per the World Health Organization worldwide, osteoporosis affects approximately 2/3rd of postmenopausal women. By 2050, the worldwide incidence of hip fracture will be increased by 240% in women and 310% in men, compared to rates in 1990.

Due to the chronic nature of the disease, high cost & severe side effects associated with conventional treatment, there is a need for effective herbal formulation.

However, the main obstacle to treating chronic diseases with herbal preparations is their poor bioavailability, palatability and hence poor efficacy.

In this contrast, the osteoprotective herb; *Cissus quadrangularis* was properly characterised, screened, standardised and prepared its bioactive form. While blending with natural and biodegradable excipients and processing with improved methodology, nano-formula for oral delivery was developed. The bioavailability and efficacy of the developed nano-formula were enhanced significantly as proved by pre-clinical osteoporotic rat model studies.

P681

ASSOCIATION BETWEEN VITAMIN D DEFICIENCY AND OSTEOPOROSIS IN SYSTEMIC SCLEROSIS: A META-ANALYSIS

E. S. Kang[1], S. H. Baik[2], J. H. Jung[1]

[1]Division of Rheumatology, Department of Internal Medicine, Korea University Ansan Hospital, Ansan, Korea, Seoul, South Korea, [2]Department of Orthopedic Surgery, Yonsei University Wonju College of Medicine, Wonju, Korea, Seoul, South Korea

Introduction Systemic sclerosis (SSc) is a chronic autoimmune disease associated with high morbidity and mortality. Its pathogenesis remains poorly understood, but vitamin D deficiency has been implicated as a contributing factor. Given the established link between vitamin D deficiency and osteoporosis, SSc patients may also be at increased risk of compromised bone health. This meta-analysis aimed to quantify serum vitamin D levels in SSc patients compared to healthy controls, evaluate differences between diffuse and limited SSc subtypes, and explore associations with clinical phenotypes, including those with potential implications for osteoporosis, such as gastrointestinal (GI) and lung involvement, digital ulcers, and anti-Scl-70 antibody positivity.

Methods This meta-analysis evaluated serum vitamin D levels in 12 studies comprising 836 SSc patients and 537 healthy controls. Subgroup analyses examined differences by SSc subtype and clinical phenotypes. Serum 25(OH)D levels were used as the marker for vitamin D status. Heterogeneity was assessed using the I^2 statistic, and publication bias was evaluated with funnel plots.

Results SSc patients exhibited significantly lower vitamin D levels than healthy controls (mean difference [MD]: -9.44, 95% confidence interval [CI]: -12.07 to -6.80, P < 0.00001). Subgroup analyses revealed no significant differences in vitamin D levels between diffuse and limited SSc subtypes or among patients with complications such as gastrointestinal (GI) involvement, lung involvement, digital ulcers, or anti-Scl-70 antibody positivity. The high prevalence of vitamin D deficiency in SSc patients suggests a potential exacerbation of osteoporosis risk, particularly given the systemic nature of the disease and its impact on bone metabolism.

Conclusion Vitamin D deficiency is frequently observed in SSc patients and may not only play a role in disease pathogenesis but also contribute to secondary complications, such as osteoporosis. These findings underscore the importance of addressing vitamin D deficiency in clinical practice, particularly to mitigate the potential burden of osteoporosis, and highlight the need for further research to clarify its therapeutic potential.

META-ANALYSIS: COMPARISON OF ANKLE ARTHROPLASTY AND ARTHRODESIS IN RHEUMATOID ARTHRITIS PATIENTS

E. S. Kang[1], S. H. Baik[2], J. H. Jung[1]

[1]Division of Rheumatology, Department of Internal Medicine, Korea University Ansan Hospital, Ansan, Korea, Seoul, South Korea, [2]Department of Orthopedic Surgery, Yonsei University Wonju College of Medicine, Wonju, Korea, Seoul, South Korea

Objectives

The objective of this meta-analysis is to compare the clinical outcomes of ankle arthroplasty and arthrodesis in rheumatoid arthritis patients, focusing on pain relief, functional improvement, complication rates, and reoperation rates.

Methods

A systematic review was conducted based on PRISMA guidelines, including six studies with a total of 216 patients (112 treated with arthroplasty and 104 with arthrodesis). Relevant studies were identified through a comprehensive search of PubMed, Embase, and Cochrane Library databases. Data on pain scores, functional outcomes, complication rates, and reoperation rates were extracted and analyzed using a random-effects model. Heterogeneity among studies was evaluated using the I^2 statistic, and statistical significance was set at $p < 0.05$.

Results

Both ankle arthroplasty and arthrodesis significantly reduced postoperative pain in rheumatoid arthritis patients. Ankle arthroplasty demonstrated greater pain relief, with a mean improvement

of 1.5 points on the visual analog scale (VAS) compared to arthrodesis. Functional improvement, as measured by standardized scoring systems such as AOFAS scores, was also higher in the arthroplasty group, with an average improvement of 10 points. However, arthroplasty was associated with higher complication rates, including implant loosening and infection, compared to arthrodesis. Reoperation rates were also higher in the arthroplasty group (25%) compared to the arthrodesis group (12%).

Conclusions

In rheumatoid arthritis patients, ankle arthroplasty provides superior pain relief and functional improvement compared to arthrodesis. However, it carries a higher risk of complications and reoperations. These findings highlight the importance of individualized treatment planning and shared decision-making when selecting surgical interventions for ankle involvement in rheumatoid arthritis. Further randomized controlled trials are needed to confirm these findings.

PERSISTENT FLU-LIKE SYMPTOMS IN A PATIENT WITH OSTEOPOROSIS ON ALENDRONIC ACID THERAPY

J. Hankollari[1], V. Duraj[2]

[1]Vora Health Center, Rheumatology, Vore, Albania, [2]University Hospital Center ´´Mother Teresa``, Tirane, Albania

Introduction: According to the recommendation of the International Foundation of Osteoporosis, bisfosfonates are the first line treatment for osteoporosis in postmenopausal women. Vertebral fractures, hip fractures, and other non-vertebral fractures can be prevented by taking alendronate.

Case report: After undergoing bone densitometry, a 52-year-old postmenopausal woman was found to have lumbar and hip osteoporosis. She received treatment only for arterial hypertension throughout her life, and all basic control laboratory tests were within the norm, as well as calcium, ALP, TSH, and PTH levels. The level of vitamin D3 was insufficient. The use of alendronic acid was started once a week.The patient experienced flu-like symptoms like a temperature reaching 37.5 degrees Celsius, myalgia, arthralgia, and chills that lasted for 24 hours after the first dose. It was thought to wait since the literature reports cases of flu-like symptoms in patients receiving alendronate therapy, but these symptoms are transient and can be minimized by taking other doses until they disappear. The patient stated that she had been experiencing flu-like symptoms for two months, 24 hours after taking the medication, and they were getting worse and not improving. It was decided to change the therapy to risedronate and the patient no longer experienced any side effects.

Conclusions: Flu-like symptoms are reported in patients receiving alendronate therapy, but they are temporary and can be minimized by taking other doses until they disappear. If flu-like symptoms become more severe, it is recommended to alter the treatment so the patient no longer experiences any negative side effects.

Keywords: flu-like symptoms, postmenopause osteoporosis, alendronate

THE PREVALENCE OF OSTEOPOROSIS AMONG PATIENTS WITH FIBROMYALGIA

V. Duraj[1], J. Hankollari[2]

[1]University Hospital Center ´´Mother Teresa``, Tirane, Albania, [2]Vora Health Center, Rheumatology, Vore, Albania

Introduction and Objective(s): Fibromyalgia is associated with the risk of osteoporosis. The reason may be linked to the lack of adequate physical activity due to chronic pain and low levels of vitamin D3 due to less sunlight exposure. The purpose of this study is to assess whether osteoporosis is common among patients with fibromyalgia.

Material and methods: This study included 47 patients (45 F: 2 M) in the age range of 40-55 years, who were diagnosed with fibromyalgia. The patients didn't take glucocorticoids, had no history of thyroid diseases, had no history of other rheumatological diseases, or any chronic diseases, and neither smoked nor consumed alcohol. The female patients were not experiencing postmenopause. All the patients had normal body mass index (BMI). Bone densitometry was recommended for each patient.

Results: 29.78% of the patients had osteoporosis, but not severe osteoporosis. All of the patients were female. No male patients were diagnosed with osteoporosis. 14,89 % had lumbar osteoporosis, 8,51% had only hip osteoporosis and 6,38% had lumbar and hip osteoporosis. Patients suffering from osteoporosis reported that they have a sedentary lifestyle and spend less time exposed to sunlight. Patients without osteoporosis reported that they walk for about an hour every day and take vitamin D3 supplements.

Conclusions: Fibromyalgia is considered a risk factor for osteoporosis only for patients who do not engage in physical activity and do not take vitamin D3 supplements.

Keywords: osteoporosis, fibromyalgia, vitamin D3, physical activity

P685

IMPORTANCE OF OSTEOPOROSIS CONTROL IN PATIENTS ATTENDING RESPIRATORY REHABILITATION CONSULTATION

M. R. Urbez Mir[1], D. Alexandres Ríos de Los Ríos[1], J. J. Estévez Espejo[1]

[1]Hospital Universitario La Paz, Madrid, Spain

Objective

In the respiratory rehabilitation practice it is common to see patients with chronic pulmonary diseases and patients requiring prehabilitation prior to surgery, who are at high risk of osteoporosis due to factors such as immobility, sarcopenia, prolonged immunosuppressive treatment and systemic inflammatory status. In this context, management of osteoporosis in patients attending a respiratory rehabilitation clinic may lead to improved physical function, especially by reducing the risk of fragility fractures. To this end, we analyse our clinical experience in the manage-

ment of osteoporosis in the respiratory rehabilitation clinic of our hospital.

2. Material and Methods

Observational, descriptive and retrospective study, based on the review of clinical records of patients seen in the respiratory rehabilitation clinic. The study population consisted of patients seen in the respiratory rehabilitation clinic during the last year, who completed at least six months of follow-up in the service, and in whom bone metabolism studies were carried out, a total of 43 patients. The mean age was 67 years. Through clinical, analytical and densitometric parameters, the prevalence of normal bone metabolism (8), osteopenia (13), osteoporosis (17) and severe osteoporosis (4) was established, as well as the risk of fracture as low (20), moderate (1), high (15) or very high (6). The incidence of new fragility fractures (6) was also analysed. Functional tests and quality questionnaires were also carried out to establish the physical functionality of the patients.

3. Results

In the patients studied in whom osteoporosis control was established, an increase in bone mineral density, a low incidence of fractures, stabilisation of analytical parameters and improvement in physical function were observed.

4. Conclusions

The study of osteoporosis in the respiratory rehabilitation consultation is a crucial opportunity to promote improvements in the physical functionality of patients, reducing the risk of fractures, preventing sarcopenia and improving their quality of life.

P686

EFFECTIVENESS OF PRESCRIPTION GLUCOSAMINE SULFATE (PGS) IN A COHORT OF FILIPINO PATIENTS WITH MILD-MODERATE KNEE OSTEOARTHRITIS (OA)

J. J. Lichauco[1], C. Walker[2], R. Chiaese[3], H. Scott[4], S. Venugopal[5]

[1]Department of Rheumatology at St. Luke's Medical Center, Manila, Philippines, [2]Global Medical Affairs, Viatris, United Kingdom, [3]Global Medical Affairs, Viatris, Italy, [4]Global Clinical Development, Viatris, United Kingdom, [5]Global Clinical Development, Viatris, India

Objective

To evaluate the effectiveness of pGS in reducing the severity of pain in patients with mild to moderate knee OA pain.

Materials and Methods

A multicenter, low interventional parallel-group 8-week study in Manila, Philippines recruited participants aged 50-70 years with mild to moderate knee OA(diagnosed using American College of Rheumatology criteria). All patients had baseline Western Ontario and McMaster Universities Osteoarthritis Index(WOMAC) score≥40, a BMI<29.99 and received pGS for 4 weeks. Thereafter patients either remained on monotherapy for a further 4 weeks or had their pain relief supplemented with celecoxib 200 mg OD depending on patient preference and their response to treatment with pGS at 4 weeks. This abstract focuses on the pGS monotherapy arm only. The primary end point was reduction from baseline in knee pain severity at week 8 based on the WOMAC Pain and visual analogue scale(VAS)(0 to 100mm) scores.

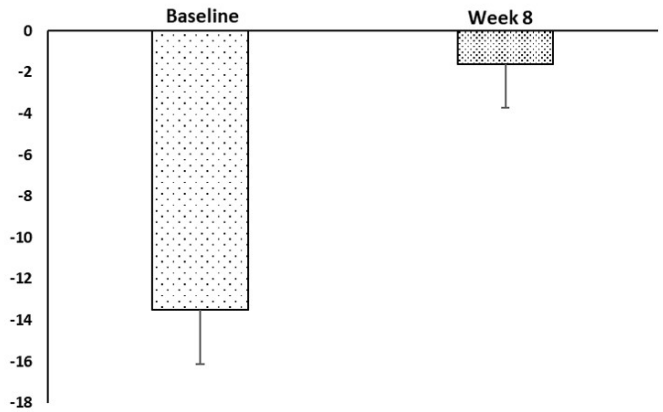
Results

Of 324 screened subjects, 281 treated; 244 completed 8 weeks of pGS treatment. At week 8, WOMAC pain scores showed a significant reduction (least square mean (LSM) change of -11.96,P< 0.0001)(Table 1)(Figure 1A). Similarly, VAS scores showed a significant reduction compared to baseline(LSM change of -56.36,P< 0.0001)(Table 1)(Figure 1B).

	Baseline	Week 8
	pGS(n=279)	pGS(n=244)
WOMAN pain score(SD)	13.5(2.63)	1.6(2.10)
WOMAN pain score LSM change		-11.96(95%CI;-12.26 to-11.67)
VAS score(SD)	68.4(10.89)	11.9(12.33)
VAS score LSM change		-56.36(95%CI; -58.05,-54.67)

Table.1: WOMAC pain outcomes mean value(SD) and VAS(SD) score in Full Analysis Set(FAS) population(n=279) with knee OA receiving pGS(1500 mg QD) for 8 weeks

A)



B)

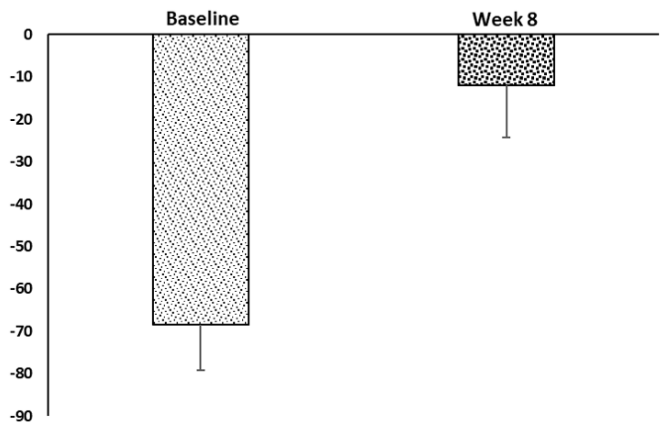


Fig.1: knee OA patients(FAS population,n=279) treated with pGS; A)WOMAC pain index at baseline and week 8(P<0.0001) in knee OA patients treated with pGS; B)VAS score at baseline and week 8(P<0.0001) .

Conclusion
Prescription Glucosamine Sulfate (pGS) demonstrated a significant reduction in knee OA pain in patients with mild to moderate osteoarthritis at the end of 8 weeks.

P687

A SINGLE INJECTION OF SAPHENOUS NERVE BLOCK IN OSTEOARTHRITIS PATIENTS AFFECTED THE REDUCTION OF POSTOPERATIVE BLEEDING

J. Kim[1], W. Jeong[1]

[1]Jeju National University School of medicine, Jeju, South Korea

Objectives
In elderly patients, the vital sign tends to fluctuate according to the volume status, which may cause sudden hypovolemic shock if postoperative bleeding continues. Elderly patients, especially those who undergo surgery for arthritis, need more attention because the bleeding may persist over the joints after surgery. The appropriate pain control is related to postoperative blood loss.
Recently, a continuous nerve block through the catheter has been widely used for analgesia and reducing the side effects of the drug. However, there is a disadvantage that it is difficult to manage the catheter. This study was conducted to assess postoperative pain control and reduction of blood loss with a single injection of saphenous nerve block in elderly osteoarthritis patients.
Material and Methods
We reviewed the electronic medical records of patients who had undergone uni-knee total arthroplasty with spinal anesthesia between January and May 2016. A total of 51 patients were enrolled in this study. All patients were treated with intravenous patient-controlled analgesia for postoperative pain control, and additional analgesic agents were administered at VAS above 6 scores. In 25 patients, the saphenous nerve block was performed using ultrasound with 0.75% ropivacaine 15ml before surgery.
Results
Patients administered additional analgesics during the maintenance period of intravenous patient-controlled analgesia were significantly lower in the nerve block group (p=0.007). In addition, the volume of blood loss from catheter drainage was significantly less at 2 and 3 days postoperatively (p=0.013, p=0.041, respectively) in the nerve block group.
Conclusion
In patients who underwent total arthroplasty with osteoarthritis, even if only a single injection of nerve block, is helpful for postoperative pain control and the reduction of bleeding.

P688

SURVEY OF KNOWLEDGE, ATTITUDES AND PRACTICES OF PRIMARY CARE PHYSICIANS ON EXERCISE PRESCRIPTION IN PATIENTS WITH OSTEOPOROSIS

J. L. A. Morales Torres[1], J. Romero Ibarra[2], H. Gutiérrez Hermosillo[3], J. Morales Vargas[4], C. L. Perez Sevilla[5], A. Hernandez Arellano[6], D. Pacheco Vargas[6], J. M. Valencia Correa[7]

[1]Morales Vargas Centro de Investigacion and Hospital Aranda de la Parra, León, GTO, Mexico, [2]Osteoporosis Clinic, Hospital Aranda de la Parra, Leon, Mexico, [3]3-Geriatrics, Hospital Aranda de la Parra, Leon, Mexico, [4]Morales Vargas Centro de Investigacion, Leon, Mexico, [5]Rheumatology, Hospital Aranda de la Parra, Leon, Mexico, [6]Hospital Aranda de la Parra, Leon, Mexico, [7]Internal Medicine, ISSSTE, Leon, Mexico

Physical activity has benefits on bone health and reduces the risk of falls(1). Osteoporosis guidelines include physical activity as relevant intervention. Are Primary Care Physicians (PCP) aware of the risks of physical inactivity? Are they knowledgeable and trained to prescribe exercise modalities in general or for specific conditions like osteoporosis?
Objective: To design and validate a questionnaire on knowledge, attitudes and practices on exercise prescription for PCP caring for patients at risk of osteoporosis.
Methods: An instrument was designed with 21 items (7 on knowledge, 11 on practice and 3 on attitude) and reviewed by a group of experts, on face validation and content and 4 of them proposed minor modifications for clarity. The target population is active PCP who agree to voluntarily participate in an anonymous survey. The final instrument, including 21 closed-ended questions, was applied face-to-face to 30 PCP (15 women and 15 men, with mean age of 30.5 years) by 2 trained observers, including information on demographics and years of practice. Cronbach's alpha test(2) was applied to the responses resulting in a reliability coefficient of 0.6830. The instrument was then applied to a larger group of PCP, both face to face and by E-Mail. Findings are reported with simple statistics.
Results: Final instrument was applied to 121 PCP (63.6% female) with a mean age of 42.7 years and time since graduation from School of Medicine of 17.5 years. Of these, 50 (41.3%) work in private practice and the rest in a public health institution. All agreed on participating, and 57% had an interview and the rest, online. There was high agreement among PCP in considering that exercise should be part of the routine management of osteoporosis, less solid confidence about its actual efficacy. Most prescribe combined forms of exercise but 65.2% are unsatisfied with their abilities in this field and all agree in the desire to know more about the prescription of exercise to patients at risk of osteoporosis.
Conclusions: This survey on prescription of exercise to people with osteoporosis shows reasonable reliability and reveals areas for potential improvement, where Clinicians see themselves with limited abilities.

SCREENING FOR ORAL HEALTH PROBLEMS IN PATIENTS WITH OSTEOPOROSIS: A PILOT STUDY WITH THE ORAL HEALTH ASSESSMENT TOOL (OHAT).

J. L. A. Morales Torres[1], J. Romero Ibarra[2], H. Gutiérrez Hermosillo[3], L. Guerrero Marquez[4], L. Anguiano Flores[4], J. Morales Vargas[5], A. Hernandez Arellano[6], D. Pacheco Vargas[6], N. Compean Villarreal[7]

[1]Morales Vargas Centro de Investigacion and Hospital Aranda de la Parra, León, GTO, Mexico, [2]Osteoporosis Clinic, Hospital Aranda de la Parra, Leon, Mexico, [3]Geriatrics, Hospital Aranda de la Parra and ENES Unidad Leon, UNAM, Leon, Mexico, [4]Dentistry, Hospital Aranda de la Parra, Leon, Mexico, [5]Morales Vargas Centro de Investigacion, Leon, Mexico, [6]Hospital Aranda de la Parra, Leon, Mexico, [7]Geriatrics, Hospital Aranda de la Parra, Leon, Mexico

Clinicians may have limited ability to identify oral health problems[1]. Drug-associated osteonecrosis of the jaw (DAONJ) is a rare complication in patients undergoing invasive dental procedures (IDPs) who receive anti-resorptive or anti-angiogenic drugs. Detection of problems that may require IDPs may aid in planning safer anti-resorptive therapy[2].
Objective: To determine the usefulness of OHAT in patients receiving treatment for osteoporosis, to identify oral problems that require referral for dental care.
Methods: Exploratory, observational study in the population of Dentistry, Rheumatology and Geriatrics of Hospital Aranda de la Parra, applying face to face in daily practice, a validated Spanish version of OHAT[3] as a table with space for answers. It was applied by 2 dentists in daily patients (≥ 50 years of age), evaluating whether the scale coincides with findings in dental evaluation. Then, it was applied by a rheumatologist and a geriatrician in patients with osteoporosis, with gloves, tongue depressor and source of light. Demographic information and Charlson Co-morbidity Index were included. For this study, candidates for dental referral are defined by one or more items rated 2 or an overall grade ≥4. We used simple descriptive statistics.
Results: 40 patients (mean age 68.3 ±8.8 years) seen by 2 dentists were included. Mean OHAT score was 7.5 (±3.8). All OHAT findings coincided with complete dental review. Besides 80 osteoporosis patients (mean age 75.1 ±8.8 years), had a mean OHAT score of 3.2 (±2.1). Charlston Co-morbidity Index was 4.28 (±1.65). Twelve of them (15%) had one or more items answered as 2 and 32 (40%) had an overall score of ≥4, defining them as candidates for dental evaluation. Most patients (58.7%) had not seen a dentist in 12 or more months. In both groups of patients, the highest ratings referred to tooth alterations (cavities, breakage, wear) and cleanliness (tartar and food debris).
Conclusions: OHAT is effective identifying common oral health problems and may aid to identify patients with osteoporosis requiring dental evaluation to plan potential IDPs before certain drugs, to limit the risk of DAONJ.

25OHD IN SUPPLEMENTED AND NOT SUPPLEMENTED WOMEN. RELATION WITH AGE, SEASONS, BMI AND WEIGHT

J. L. Mansur[1], M. J. Castro[2]

[1]Center of Endocrinology and Osteoporosis La Plata Argentina, La Plata, Argentina, [2]Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Departamento de Fisicomatemática., Buenos Aires, Argentina

Objective: relate 25OHD with age, seasons, BMI and weight.
M and M: Retrospective study of 1086 women from Argentina (2020-2024): 421 (SW) received 25OHD supplementation (≥3 months before measurement) and 665 (NSW) did not.
Variables measured: age, weight, height, 25OHD, season of the year, and osteoporosis treatment (OT yes=Ot, no=No.Ot).
Data are presented as mean ± SD. Spearman's cor. Coef., ANOVA with post hoc test, and Chi-square test were used, significance level 0.05.
Results:
SW: age: 63.4 ± 10.3 years; weight: 62.8 ± 12.3 kg; BMI: 25.3 ± 4.9; 25OHD: 42.6 ± 11.6 ng/mL; 35.2% received OT.
NSW: age: 53.1 ± 14.7 years; weight: 67.9 ± 15.8 kg; BMI: 26.5 ± 5.9; 25OHD: 21.8 ± 8.2 ng/mL; 4.5% received OT.
OT proportion differs (p<0.001) between SW and NSW groups.
-25OHD, supplementation and OT:
SW & Ot: 44,5 ± 12.2; SW & No.Ot: 41.6 ± 11.0;
NSW & Ot: 27,4 ± 9.3; NSW & No.Ot: 21.5 ± 8.1.
-Age (y) SW: < 50: 38.9 ± 8.5; 50-65: 42.6 ± 11.3; > 65: 43.3 ± 12.4;
NSW: < 50: 21.3 ± 8.4; 50-65: 22.4 ± 7.9; > 65: 21.4 ± 8.5
-BMI. SW: < 25: 43.5 ± 11.7; 25-30: 41.4 ± 11.7; > 30: 41.0 ± 10.6;
NSW: < 25: 22.8 ± 8.3; 25-30: 22.2 ± 8.2; > 30: 18.6 ± 7.5.
-Season
SW: Summer: 43.9 ± 13.1; Fall: 43.2 ± 13.0; Winter: 41.3 ± 10.8; Spring: 42.8 ± 10.1 (ns) NSW: Summer: 26.4 ± 9.0; Fall: 23.9 ± 8.3; Winter: 18.5 ± 6.4; Spring: 21.4 ± 8.0. Winter and spring differ from the rest, fall and summer don't differ from each other.
-Association of 25OHD
SW: Weight coef=-0.14 p=0.0043; BMI coef= -0.11 p=0.0268
NSW: Weight coef=-0.17 p<0.0001; BMI coef= -0.18 p<0.0001
The moving average grouped by three-year periods showed an increase in supplemented women over time.
Conclusions: 25OHD is lower in obesity and in winter and spring in NSW.

ABOUT A CASE: PARATHYROID ADENOMA AND PATHOLOGICAL HUMERAL FRACTURE IN A 54-YEAR-OLD MAN

M. A. Cerezuela Abarca[1], C. Celada Roldán[1], J. López Diez[2], M. C. Alcaraz Salvago[2], J. A. Lopez Diez[2], M. A. Saura Nuñez[3], E. Lopez Garcia[4], M. Martinez Ibañez[4], P. Jimenez Abarca[5]

[1]CS San Antón, Cartagena, Spain, [2]CS Cartagena Este, Cartagena, Spain, [3]CS Cartagena Casco, Cartagena, Spain, [4]CS Cartagena Oeste, Cartagena, Spain, [5]CS Los Boliches, Fuengirola, Spain

Objective

The objective of this paper is to present the case of a 54-year-old man who came to the Primary Care clinic with intense pain in the right arm, with functional impotence, and also reporting bone pain, generalized muscle weakness and lack of concentration, poor appetite and occasional nausea for weeks. There were no associated traumas that the patient remembers, but the functional impotence is believed to be related to a movement he made with his arm when getting up.

Material and Methods

We decided to order a humerus x-ray and requested a blood test, as well as a bone densitometry. The x-ray showed a fracture of the proximal humerus and the analysis showed severe hypercalcemia (greater than 14 mg/dl) with elevated parathyroid hormone, so we referred the patient to the emergency room, and the patient was admitted to hospital after administering treatment for the fracture and for the hypercalcemia with zoledronic acid, diuretics and intravenous fluid therapy.

Results

During hospital admission, it was concluded that the hypercalcemia and consequent osteoporosis that caused a pathological fracture were due to a carcinoma of the lower left parathyroid gland, and surgical treatment was indicated.

Conclusions

According to the Recommendations of the Spanish Society of Rheumatology for Osteoporosis, a fragility fracture in the proximal humerus (like our patient) in men over 50 years of age and with a T score <-1 is diagnostic of osteoporosis. In the case of our patient, bone densitometry indicated a T score of -3.5 in the hip and -3-6 in the spine, which are also diagnostic of osteoporosis.

The case of our patient exposes the association between hyperparathyroidism and osteoporosis: the onset was initiated by a pathological fracture. Excess parathyroid hormone alters the normal balance of calcium, leading to an increase in plasma calcium (hypercalcemia) and the symptoms of hypercalcemia, causing osteoporosis.

UPPER BACK PAIN REVEALING THORACIC SPONDYLODISCITIS: A CASE REPORT

J. López Díez[1], C. Celada Roldán[2], J. A. López Díez[1], M. A. Cerezuela Abarca[2]

[1]Cartagena Este Health Care Center, Cartagena, Spain, [2]San Antón Health Care Center, Cartagena, Spain

Objectives: Spondylodiscitis is an infection of the body and vertebral disc whose early detection and treatment can prevent future relevant pathologies, such as compressive myelopathy. It is important to perform a detailed physical examination and complementary tests that avoid a late diagnosis that increases the comorbidity of the condition. We present a case of 66-year-old male who presented with back pain and diagnosed to have spondylodiscitis.

Material and Methods: A 66-year-old male with no medical comorbidities, with 4 months history of upper back pain and intermittent fever of up to 39ºC coinciding with the same. Associated morning stiffness was present. He has received analgesic treatment without improvement. Dorso-lumbar X-ray: vertebral degenerative changes. Laboratory analysis revealed high acute inflammatory parameters and nuclear magnetic resonance of thoracic spine revealed signs of osteomyelitis in the disc-vertebral body complex D8-D9 with a large anterior paravertebral and epidural abscess causing severe dorsal stenosis with spinal cord compression and signs of compressive myelopathy. Blood cultures: Staphylococcus aureus positive.

Results: Based on collected results, we have concluded that diagnosis was infectious spondylodiscitis with left paravertebral abscess and antibiotic therapy was performed. The patient is currently without back pain or fever.

Conclusions: Early diagnosis of bacterial spondylodiscitis remains a challenge due to the nonspecific signs and symptoms reported by the patient and the wide variability of laboratory results and imaging. The basis for early diagnosis remains the clinical suspicion at the time of initial treatment.

EXERCISE-INDUCED RHABDOMYOLYSIS: A CASE REPORT

C. Celada Roldán[1], J. López Díez[2], J. A. López Díez[2], M. A. Cerezuela Abarca[1]

[1]San Antón Health Care Center, Cartagena, Spain, [2]Cartagena Este Health Care Center, Cartagena, Spain

Objectives: Rhabdomyolysis is a syndrome caused by disruption of skeleton muscle with the release of muscle tissue content into the circulation that can lead to the life-threatening systemic complications of acute kidney injury, compartment syndrome, and disseminated intravascular coagulopathy. Here we present a case of exercise-induced rhabdomyolysis caused by a lower extremity training.
Material and Methods: A 21-year-old man with a 2-day history of lower extremity pain and soreness and 1 day of gross hematuria. He reported that the pain began the second day after he went to the gym doing lower extremity exercise training. The day prior to his presentation, the patient developed gross hematuria, without back pain and fever. He reported no history of previous medical conditions or medications. Physical examination showed muscle tenderness but no edema. Urinalysis showed protein 2+ and urine occult blood +. Laboratory work-up demonstrated a creatinine kinase (CK) of 160,500 IU/L, alanine aminotransferase (ALT) of 320 IU/L, aspartate aminotransferase (AST) of 1419 IU/L. His blood urea nitrogen (BUN) and serum creatinine were 7.28 mmol/L and 95 µmol/L, respectively.
Results: Based on his markedly elevated CK, myalgia, and myoglobinuria, he was diagnosed with exercise-induced rhabdomyolysis. After treatment with vigorous hydration and sodium bicarbonate, his pain and laboratory tests improved.
Conclusion: Measures such as warming-up and periodic repetition of eccentric exercises, along with sufficient water intake, should be considered for people who exercise for the first time or those with poor body fitness to aim to prevent exertional rhabdomyolysis.

UNUSUAL INFLAMMATORY ARTHRITIS: A CASE REPORT

J. López Díez[1], C. Celada Roldán[2], M. A. Cerezuela Abarca[2], J. A. López Díez[1]

[1]Cartagena Este Health Care Center, Cartagena, Spain, [2]San Antón Health Care Center, Cartagena, Spain

Objectives: Adult Onset Still's disease (AOSD) is an inflammatory disorder characterized by quotidian (daily) fevers, arthritis, and an evanescent rash. It is a rare inflammatory disorder of unknown etiology. Due to lack of definitive diagnostic test, the diagnosis of AOSD can only be made after exclusion of other causes. We present a case of adult onset Still's disease.
Matherial and Methods: An 84-year-old woman with two weeks histoy of fever, polyarthritis with edema in both hands, sore throat and erythematous macular rash on the arms, neckline and back that did not improve despite conservative treatment. Exploration and complementary tests: Good general condition with good vital signs. Highlight the lung auscultation crackles in the right base, with rest unremarkable exploration. Hemogram with predominantly polymorphonuclear leukocytosis, elevated acute phase reactants, ferritin, and transaminases. Referred for hospital admission. Negative blood cultures, urine antigen detections, and autoimmunity. Chest, hands, wrists, lumbar spine, pelvis, and sacroiliac X- rays with marked signs of generalized degenerative osteoarthritis without lytic or blastic lesions. Chest CT showing bilateral pleural effusion and minimal pericardial effusion.
Results: When infectious and tumor processes were ruled out, treatment with high-dose steroids was started, associating weekly methotrexate. Clinical judgment: Adult Onset Still's disease. She is doing well and is completely symptom free.
Conclusions: Adult Still's disease is a systemic inflammatory pathology with a prevalence of 1/100,000 people, whose diagnosis and etiology remain unclear, and may be related to viral infections, a certain seasonality in the symptoms, as well as activity factors and prognosis, the concentration of interleukin 1 and the increase in serum ferritin. Since the delay in its diagnosis leads to a worsening in the prognosis of patients (40% will have a chronic course), it is essential a high clinical suspicion based on the Yamaguchi criteria (fever with evening peaks, rash, inflammatory arthralgia, intense sore throat, and leukocytosis with a predominance of polymorphonuclear cells and hyperferritinemia) for optimal and early treatment.

Madrid., Madrid, Spain, [8]Centro de Salud José Aguado I., León, Spain, [9]Hospital Universitario La Ribera, Alcira, Valencia, Spain

Introduction
Osteosarcopenia is a geriatric syndrome resulting from the combination of sarcopenia and low bone mineral density. It's a phenotype that is associated with a higher risk of falls, fractures,

dependence and health care costs than its separate components. The aim of this study was to assess the prevalence of sarcopenia in community-dwelling patients with osteoporosis (osteosarcopenia) in Spain and to determine associated risk factors.

Material and Method

Descriptive and analytical cross-sectional observational study done during the year 2023 in Primary Care Health Centres in Spain. Patients over 49 years of age with a diagnosis of OP (densitometry -2.5 SD) were included by simple probability analysis. Patients with other pathologies that alter bone mass were excluded, a sample of 490 patients was calculated and the presence of sarcopenia was assessed using the SARC-F questionnaire and lower leg circumference. To evaluate predictors, clinical and lifestyle variables were analysed using multiple regression analysis. Protocol and informed consent approved by the Ethics Committee (Ref.2526).

Results

A total of 1,123 patients were included with a mean age of 71.7 (±9.9) years, 91.5% female. The overall prevalence of osteosarcopenia in the sample was 42.7%. The most relevant associated risk factors were age (22.5%, 50-64 years, and 48.7%, ≥75 years; $p < 0.05$), female sex (46.4% vs. 32.0%, $p < 0.05$), diagnosis of cognitive deterioration (OR: 1.35-2.49, $p < 0.05$), poor nutritional status (OR: 1.99-3.17, $p < 0.01$), falls in the last year (OR: 2.23-4.25, $p < 0.05$), osteoporotic fractures (OR: 4.55-6.21, $p < 0.01$) and physical inactivity (OR: 5.67-8.35, $p < 0.001$).

Conclusions

The prevalence of osteosarcopenia is high, highlighting the importance of a comprehensive assessment of musculoskeletal health in patients with osteoporosis, and the need for interventions aimed at improving physical activity, nutritional status and fall prevention to reduce the prevalence of osteosarcopenia.

THE RELATIONSHIP BETWEEN BONE AND MUSCLE HEALTH IN A MONGOLIAN POPULATION: A FIRST LARGE-SCALE OBSERVATIONAL STUDY

J. M. Jaalkhorol[1], A. S. H. Avirmed[1], F. B. Fanny[2], D. A. Dashtseren[3], K. H. N. Khaidav[4], W. Wu Qi[5], D. G. Davaadorj[6], B. B. Baigabul[7], G. B. Ganjargal[8], O. B. Olivier Bruyere[2]

[1]Department of Health Research, Graduate School, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia, Ulaanbaatar, Mongolia, [2]Research Unit in Public Health, Epidemiology and Health Economics, University of Liege, Liege, Belgium, Liege, Belgium, [3]Department of Preventive Medicine, School of Public Health, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia, Ulaanbaatar, Mongolia, [4]Department of Health Social Work and Social Sciences, School of Public Health, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia, Ulaanbaatar, Mongolia, [5]Inner Mongolia Medical University, Hohhot, China, Hohhot, China, [6]Amgalan Maternity Hospital, Ulaanbaatar, Mongolia, Ulaanbaatar, Mongolia, [7]National Center for Communicable Diseases, Mongolia, Ulaanbaatar, Mongolia, [8]Department of Clinical pharmacy and Management, School of Pharmacy, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia, Ulaanbaatar, Mongolia

Objectives: To explore the correlation between muscle and bone health and to estimate the FRAX risk for major osteoporotic fractures and hip fractures in the Mongolian population, stratified by age and sex.

Methods: A cross-sectional study was conducted across various health units in Ulaanbaatar and regional Mongolia from May to August 2024. Participants (n=857) were assessed for handgrip strength, sarcopenia risk using the SARC-F test, and bone mineral density (t-score) via ultrasound. The FRAX model was used to calculate fracture risks.

Results: A total of 857 individuals (median age: 52 years, range: 44-66) were recruited, with 30.1% women. The median grip strength was 28 kg (range: 21-35). Most participants (69.5%) had a low risk of sarcopenia according to the SARC-F. The median T-score for bone mineral density (BMD) was -1.9. A very weak but significant correlation was found between FRAX MOF score and SARC-F ($p < 0.001$), FRAX hip score and SARC-F ($p = 0.004$), as well as between BMD T-score and handgrip strength ($p = 0.02$). Age- and sex-specific values for FRAX major osteoporotic and hip fracture risks were proposed. The risk of major osteoporotic and hip fractures increased with age in both sexes, with higher rates observed in women compared to men. Individuals with moderate to high sarcopenia risk (SARC-F ≥ 4) have significantly higher risks for major osteoporotic fractures and hip fractures, along with lower BMD T-scores, suggesting poorer bone health. In women, lower grip strength (<18 kg) is associated with higher risks of osteoporotic fractures, hip fractures, and lower bone mineral density. Men with lower grip strength (<28 kg) also face increased risk for hip fractures and lower BMD.

Conclusions: This study provides insights into the association between muscle and bone health in the Mongolian population. FRAX values for osteoporotic and hip fractures contribute to a better understanding of fracture risk across different age and sex categories

Keywords: muscle strength, sarcopenia, bone mineral density, FRAX, osteoporotic fractures, Mongolian population

P698

FOOTBALL AS A STRATEGY FOR IMPROVING BONE HEALTH IN WOMEN: A REVIEW AND META-ANALYSIS

J. M. Moran[1], J. M. Lavado-García[1], L. M. Puerto-Parejo[1], J. D. Pedrera-Zamorano[1], P. Rey-Sánchez[1], F. López-Espuela[1], O. Leal-Hernández[1], A. Sánchez-Fernández[1], R. Roncero-Martin[1]

[1]Nursing and Occupational Theray College, University of Extremadura., Cáceres, Spain

Objetive The research examined clinical trials using football as an intervention for female populations through both systematic

review processes and meta-analytic syntheses. The research investigated bone mineral density (BMD) and bone mineral content (BMC) parameters to measure quantitatively the effects of football training activities on bone health. This research combined multiple research studies to collect evidence about how football training can improve skeletal health through its osteogenic properties in female athletes.

Materials and Methods A random-effects meta-analysis was conducted based on clinical trials retrieved from comprehensive searches in the following databases: Medline (PubMed), Medline (OVID), Embase, Scopus, Web of Science, and Cochrane Library. Clinical Trialas that examined football as an intervention's effects on bone health among female subjects were included. Each study's bias risk received evaluation through assessment using the Cochrane Risk of Bias (ROB) tool.

Results A total of four studies met the inclusion criteria for this review. One of these studies included two follow-up time points, which were analyzed separately as independent data points, yielding a total of five datasets. The meta-analysis revealed that none of the analyzed parameters demonstrated statistically significant improvements in women who participated in football interventions. The meta-analysis results showed no significant changes to any analyzed parameters from football training for women participants.

Specifically, the analysis of total BMD resulted in a standardized mean difference (SMD) of 0.0105 with a 95% confidence interval (CI) ranging from -0.0062 to 0.0272 (p>0.05). Similarly, for lower limb BMD, the SMD was 0.0789 (95% CI: -0.0212 to 0.1790). The evaluation of BMC followed the same trend, with total BMC yielding an SMD of 0.4262 (95% CI: -0.4498 to 1.3022), and lower limb BMC showing an SMD of 0.7918 (95% CI: -0.2369 to 1.8205), neither of which reached statistical significance.

Conclusion This meta-analysis demonstrates that soccer interventions in women do not lead to achieve significant benefits for either bone mineral density or bone mineral content measurements. This conclusion requires cautious interpretation because the possibility of a Type II error remains a concern given the small sample sizes in reviewed studies and low number of qualified studies selected for analysis. Further research with larger, high-quality trials is warranted to conclusively determine the impact of football on bone health in female populations.

P699

CONSISTENT BONE DENSITY ACROSS GENOTYPES: A THREE-YEAR LONGITUDINAL STUDY OF THE GREB-1 RS5020877 POLYMORPHISM IN HEALTHY AND BREAST CANCER SURVIVING WOMEN USING PQCT AND HEEL ULTRASOUND

J. M. Moran[1], L. M. Puerto-Parejo[1], P. Rey-Sánchez[1], A. Sánchez-Fernández[1], J. M. Lavado-García[1], J. D. Pedrera-Zamorano[1], M. L. Canal-Macías[1], F. López-Espuela[1], O. Leal-Hernández[1]

[1]Nursing and Occupational Theray College, University of Extremadura., Cáceres, Spain

Objective: The GREB1 gene (Growth Regulation by Estrogen in Breast Cancer 1) has been frequently studied for its role in the progression of estrogen-stimulated tumors, such as breast cancer. However, its function outside of this oncological context remains poorly understood. Our aim was to determine whether the presence of the rs5020877 polymorphisms of the GREB1 gene associate with differences in volumetric BMD and quantitative heel ultrasound in breast cancer survivors and healthy controls and also to analyze the differences in the distribution of the studied genotype of the GREB1 gene in the study sample.

Materials and Methods: This study conducted a three-year longitudinal study on postmenopausal women, assessing bone mass at baseline, and then yearly up to three years. The cohort included breast cancer survivors and healthy controls. Techniques used included peripheral quantitative computed tomography (pQCT) with a Stratec XCT 2000 and quantitative heel ultrasound (QUS) via a GE Sahara sonometer. Additionally, SNP genotyping for GREB1 rs5020877 employing Taqman® probes to examine genetic influences on bone density was used.

Results: The analyzed sample comprised 344 controls and 104 breast cancer survivors. At baseline, the median age was 59 (IQR=7) and 62 (IQR 13.25) for controls and survivors, respectively (p=0.007). No significant differences were observed between the two groups regarding weight, BMI, and age at menarche. However, years since menopause differed significantly (9 years for controls and 11 years for survivors (p=0.003)). There were no significant differences in genotype frequencies between the groups (p=0.056), and notably, no GG genotype was found among the breast cancer survivors. Longitudinal comparisons of mean differences in bone density measures from baseline to the second year, from the second to the third year, and from baseline to the third year revealed no statistically significant variations between the groups or among rs5020877 genotypes (p>0.05 in all cases). These comparisons were adjusted for age and years since menopause, utilizing both pQCT and QUS.

Conclusions: In this study, no significant differences were observed in the distribution of the rs5020877 genotype of the GREB1 gene between healthy women and breast cancer survivors. Following a three-year follow-up, it appears that the rs5020877 genotype does not influence the progression of bone mass, as assessed by pQCT and QUS, in the studied postmenopausal women.

DRIVING KNEE OSTEOARTHRITIS STRUCTURAL PROGRESSOR PROGNOSIS INTO THE NEXT GENERATION: LEVERAGING MACHINE/DEEP LEARNING, MICRORNA AND MAGNETIC RESONANCE IMAGING

A. Jamshidi[1], O. Espin-Garcia[2], T. G. Wilson[3], I. Loveless[3], J.-P. Pellletier[1], S. A. Ali[4], J. Martel-Pelletier[1]

[1]Osteoarthritis Research Unit/University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada, [2]Department of Epidemiology and Biostatistics, University of Western Ontario; Dalla Lana School of Public Health and Department of Statistical Sciences, University of Toronto; Department of Biostatistics, Schroeder Arthritis Institute; Krembil Research In, Toronto, Canada, [3]Henry Ford Health + Michigan State University Health Sciences, Detroit , United States, [4]Henry Ford Health + Michigan State University Health Sciences; Center for Molecular Medicine and Genetics, Detroit , United States

Objective: Predicting knee osteoarthritis (OA) patients at risk of rapid structural progression remains challenging. Circulating micro-RNAs (miRNAs) showed promise as biomarkers for stratifying such patients. This study aimed to develop a miRNA-based prognosis model to identify knee OA structural progressors using machine/deep learning, with structural progressors defined via a methodology using MRI and X-ray data[1].

Methods: Baseline serum miRNAs from 152 Osteoarthritis Initiative (OAI) participants were isolated, sequenced, and used for model development. Dimensionality reduction was performed to identify the most informative miRNAs within the initial set of 456. Key miRNAs and OA determinants, including age, sex, BMI, and race (Caucasian and African American), were selected after a comprehensive exploration of 7 feature selection machine learning. The final model was developed after extensively exploring an array of machine/deep learning algorithms. The performance of the models was assessed using AUC, accuracy, sensibility, and specificity. Validation employed an independent cohort of 30 OAI baseline plasma samples.

Results: Feature clustering reduced the initial set to 107 miRNAs. Elastic Net was identified as the optimal feature selection model. The final prediction model utilized an Artificial Neural Network (ANN) comprised of age and four miRNAs, hsa-miR-556-3p, hsa-miR-3157-5p, hsa-miR-200a-5p, and hsa-miR-141-3p, and achieved an excellent performance (AUC, 0.94; accuracy, 0.84; sensitivity, 0.89; specificity, 0.75). The ANN model validation analysis confirmed the model's robustness (AUC, 0.81; accuracy, 0.83; sensitivity, 0.71; specificity, 0.94).

Conclusion: This study identifies, for the first time, a microRNA signature capable of predicting rapid structural progression in knee OA patients. The model demonstrated strong performance and was validated in an independent cohort, showcasing its potential for generalization. The translational potential of this prediction model is significant, as it will provide clinicians with a valuable tool for personalized and targeted treatment strategies as well as assist early identification of high-risk structural progressor patients for inclusion in trials.

PROFILE OF PATIENTS ON TREATMENT WITH ABALOPARATIDE IN CLINICAL PRACTICE: SHORT-TERM ADHERENCE AND SAFETY

J. Molina-Collada[1], S. Ojeda Bruno[2], A. Naranjo Hernandez[3], S. Perez Esteban[4], L. A. Hernández-Sánchez[5], O. Sánchez Gonzalez[6], V. Emperiale[4], P. Rodriguez Merlos[1], T. González Hernandez[1]

[1]Department of Rheumatology, Hospital General Universitario Gregorio Marañón. Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Madrid, Spain, [2]Department of Rheumatology, Hospital Universitario Doctor Negrin, Las Palmas de Gran Canaria, Spain, [3]Department of Rheumatology, Hospital Universitario Doctor Negrin, Las Palmas de Gran Canaria, Spain, Las Palmas de Gran Canaria, Spain, [4]Department of Rheumatology, Hospital Universitario del Sureste, Madrid, Spain, [5]Department of Geriatrics, Hospital Universitario Ramon y Cajal, Madrid, Spain, [6]Department of Rheumatology, Hospital Universitario Infanta Leonor, Madrid, Spain

Background Although clinical practice guidelines are available for initiating anti-osteoporotic treatment in patients at risk of fracture, their implementation in clinical practice is variable. On the other hand, adverse effects often appear in the first weeks of treatment, leading to its discontinuation. Abaloparatide (ABL) is a drug approved in May 2024 in our country for the treatment of postmenopausal osteoporosis (OP), so real-life experience is very limited yet.

Objectives To investigate the clinical profile of OP patients initiating ABL in real life, as well as to assess their adherence and safety in the short term.

Methods Observational, retrospective, multicenter study. Postmenopausal women with OP who initiated ABL between June and December 2024 were included. Demographic data, clinical risk factors for OP, previous anti-osteoporotic treatments, bone densitometry, laboratory data, reason for treatment with ABL, as well as side effects and adherence to treatment at 3 months, were collected. A simple descriptive analysis of the variables studied was performed.

Results A total of 69 women from 5 centers (4 rheumatology and one geriatrics department) were included in the analysis. The mean (SD) age was 73 (8.79) years. Twenty-nine (42%) patients had had previous fractures, and 62% of them had received treatment. The ABL was the first line of treatment in 68.1% of cases. The most frequent reason for initiating ABL was the presence of fractures in the previous year in 72.4% of patients, 68% in the lumbar spine, 64.7% of which were multiple, 13 in the hip, 2 in the pelvis and 4 in the shoulder. The second reason for prescribing ABL was very low bone mineral density (BMD (T ≤ -3.0)) in 71.6% of patients. A total of 43 patients completed the 3 months follow-up up to December 2024, of whom 6 (13.9%) presented adverse effects (myalgia), leading to ABL discontinuation in 5 patients (Table).

Conclusions Patients initiating ABL had a very high-risk OP due to recent fractures and/or very low BMD. ABL was the first anti-osteoporotic treatment in most patients. The safety profile was optimal and the persistence rate at 3 months was high.

FACTORS AFFECTING SERUM OSTEOCALCIN CONCENTRATION IN POLISH COHORT OF CHILDREN WITH OSTEOGENESIS IMPERFECTA – A SINGLE-CENTER OBSERVATIONAL RETROSPECTIVE STUDY

J. Nowicki[1], E. Jakubowska-Pietkiewicz[1]

[1]Department of Pediatrics, Neonatal Pathology and Metabolic Bone Diseases, Medical University of Lodz, Lodz, Poland

Osteogenesis imperfecta is a rare bone dysplasia occurring in 1/15,000–20,000 births, characterized by reduced bone mineral density, growth deficiency, and an increased risk of fractures throughout a patient's life. The clinical manifestation of OI usually includes additional features of connective tissue disorders.

The aim of this study was to analyze the factors that may influence serum osteocalcin levels in children with osteogenesis imperfecta treated with intravenous sodium pamidronate.

The study included 61 patients diagnosed with osteogenesis imperfecta type 1 or 3, aged 2 to 18, hospitalized for intravenous sodium pamidronate administration. A retrospective analysis of medical records was conducted, collecting information on age, sex, body weight, height, the number of long bone fractures throughout life, serum levels of osteocalcin, creatinine, alkaline phosphatase, 25(OH)D3, and DXA BMD z-scores for the L1-L4 spine segment.

The z-score for osteocalcin levels differed significantly depending on the type of osteogenesis imperfecta and was statistically correlated with fracture rate, serum alkaline phosphatase z-score, BMD z-score for L1-L4, and height and weight percentiles. In both univariate and multivariate linear regression models, the strongest predictor of osteocalcin z-score was the type of osteogenesis imperfecta, with BMD L1-L4 z-score also being significant factor.

The concentration of osteocalcin varies differs between types 1 and 3 of osteogenesis imperfecta. Type of OI has the strongest effect on OC concentrations of all the parameters studied.

P704

SELECTED ABNORMALITIES OF SOMATIC DEVELOPMENT IN POLISH CHILDREN WITH OSTEOGENESIS IMPERFECTA – A SINGLE-CENTRE RETROSPECTIVE COHORT STUDY

E. Jakubowska-Pietkiewicz[1], J. Nowicki[1], A. Maćkowska[1], A. Byrwa-Sztaba[1], E. Woźniak[1]

[1]Department of Pediatrics, Neonatal Pathology and Metabolic Bone Diseases, Medical University of Lodz, Lodz, Poland

Osteogenesis imperfecta (OI) causes a number of abnormalities in somatic development. The predominant symptoms are reduced bone mass and an increased risk of fractures as well as bone deformities and short stature. Due to the lack of causal treatment options, bisphosphonates are considered the gold standard of

therapy.
The aim of our study is to present selected anthropometric parameters (body weight, height, BMI) in children with type I and III of OI.
We performed a retrospective analysis of medical records of patients with osteogenesis imperfecta type I and III confirmed by genetic testing. The study group included individuals admitted to the Department in 2020. We analysed the anthropometric parameters of 108 children (receiving and not receiving bisphosphonates treatment).
In the group of children with OI type I admitted for follow-up (group 1), the median height percentile was 37, while in the group 2 it was 17. In the patients with OI type III (group 3), the median height percentile was 0.1. The median body mass percentile in group 1 was 21, in group 2 it was 5, whereas in group 3 - 0.1. The differences in anthropometric measurements of the patients with OI type I and OI type III were statistically significant ($p<0.001$).
Among the analysed patients, an abnormal BMI was found in 41.67% of whom 37.78% were underweight, 48.89% were overweight and 13.33% were obese.
Considering prevalence of the disease, it is not only low stature but also abnormal BMI, and especially excessive body weight, that play an important role in the somatic development disorder.

P705

EXPERT AND REHABILITATION ASSESSMENT OF ATAXIA IN PATIENTS WITH CEREBROVASCULAR ACCIDENTS

J. Ovsjanik[1], A. Filipovich[1], I. Chapko[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

A method for expert-rehabilitation assessment of the presence and severity of coordination disorders (ataxia) in patients with cerebrovascular accidents has been developed. A clinical and functional assessment of the health status of 72 patients with ataxic disorders caused by circulatory disorders in the vertebrobasilar basin (VBB) was conducted: 58 (80.6%) men and 14 (19.4%) women. By the duration of the disease, the examined individuals were distributed as follows: up to one year - 10 people. (13.9%); from 1 year to 3 years - 27 people. (37.5%); from 3 to 10 years - 23 people. (31.9%); more than 10 years - 12 people. (16.7%). Statodynamic disturbances in patients with cerebrovascular accidents were manifested in the form of ataxia of varying severity (72 patients; 100.0%): mild in 34 patients (47.2%), moderate in 29 patients (40.3%), and severe disturbances in 9 patients (12.5%).
The following groups of methods were used to assess coordination disorders and the resulting limitations of life activities: interviewing and analysis of subjective manifestations (complaints); analysis of anamnestic data presented in the medical documentation; examination and assessment of cranial nerves; examination and assessment of muscle tone; examination and assessment of postural stability; examination and assessment of simple sensorimotor reactions; examination and assessment of complex sensorimotor reactions using Schilder, Stuart-Holmes, and diadochokinesis tests; examination and assessment of static coordination of the upper and lower limbs; examination and assessment of dynamic coupled coordination of the trunk, upper and lower limbs; biomechanical assessment of gait function; examination and assessment of simple and complex types of sensitivity: pain and temperature, muscle-joint, vibration, two-dimensional-spatial, stereognosis; examination and assessment of brain structures using CT and MRI; assessment of the coordination sphere using computer stabilometry; hemodynamic study using ultrasound diagnostics of the brachiocephalic vessels; balance assessment under stress tests using the Berg Balance Scale; gait function assessment using the Dynamic Gait Index; assessment of daily living motor activity with risk of falls using the M. Tinnetti Falls Effectiveness Scale; assessment of functional independence (self-care ability) using the Functional Independence Measure (FIM); assessment of patient mobility (ability to move) using the Rivermead Mobility Index.

P706

DETERMINATION OF THE ABILITY TO CHANGE AND MAINTAIN BODY POSITION IN PATIENTS WITH POST-STROKE ATAXIA IN THE PRACTICE OF MEDICAL REHABILITATION

I. Chapko[1], A. Filipovich[1], J. Ovsjanik[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

A clinical and functional assessment of the health status of 72 patients with ataxia caused by vertebrobasilar circulation disorders was performed: 58 (80.6%) men and 14 (19.4%) women. According to the duration of the disease, the examined individuals were distributed as follows: up to one year – 10 people (13.9%); from 1 year to 3 years – 27 people (37.5%); from 3 to 10 years – 23 people (31.9%); more than 10 years – 12 people (16.7%). Statodynamic disorders in patients with CCI were manifested in the form of ataxia of varying severity (72 people; 100.0%): mild in 34 people (47.2%), severe in 29 people (38.5%), and severe in 36 people (38.5%). (40.3%) moderate and 9 patients (12.5%) had severe disorders.
Determination of the ability to change and maintain body position (using ICF) included assessment by categories: d410 (change of body posture), d415 (maintenance of body posture), d420 (body movement). Assessment of the ability to change body posture (d410) was carried out on the basis of the analysis of the ability to adopt and change body position with the implementation of body movement: turning on the side, rising from a lying position to a sitting position, rising from a sitting position to a standing position and back, rising from a chair to lie down in bed, squatting, rising from a squatting or kneeling position to a sitting and standing position, the ability to bend the body and move the center of gravity.
A rehabilitation assessment was performed on 29 patients with moderate ataxia. It was found that when assessing the ability to change body posture (d410), turning from back to stomach, taking positions (sitting, standing), rising from a squatting or kneel-

ing position to a sitting and standing position was performed by the patient with the help of additional efforts of the muscles of the lower limbs, trunk with additional support with the hands, at a slow pace and uncertainly, when taking a vertical posture, the joints were fixed in a combined active-passive manner. The ability to maintain stability when bending the body was moderately limited. When assessing the ability to maintain body position (d415), it was found that maintaining body position in a standing position is difficult for most patients and requires additional support, maintaining an elevated position of the upper body in a sitting position is carried out with the help of the trunk muscles and partial support with the hands. The ability to maintain body position in a squatting position is difficult: no more than 2 minutes and with support on the hands. Long-term holding of a standing position during everyday movements is accomplished with the help of a cane.

The assessment of body movement (d420) showed that in a sitting position, movement within surfaces of the same level (from a bed to a chair, without changing the body posture), between surfaces of different levels is carried out independently with a longer time expenditure, additional support is used with the use of hands, when repeating movements, the ability is preserved, but with a loss of pace.

The problems and limitations of the ability to change and maintain body position identified in patients were used to form a rehabilitation diagnosis and to set rehabilitation tasks for specialists of the multidisciplinary rehabilitation team.

P707

HISTOLOGICAL ANALYSIS OF BONE RESORPTION, COLLAGEN FIBERS AND TRAP OF EXPERIMENTAL PROTOCOL OF ACUTE AND CHRONIC STRESSORS IN SPONTANEOUSLY HYPERTENSIVE RATS IN LONG BONES

J. P. Mardegan Issa[1], M. Ribeiro Paulini[1], G. Crivelaro do Nascimento[1], D. Leonardo Pitol[1], A. P. Macedo[1], S. Feldman[2], V. Bonilha Valeri[1]

[1]University of São Paulo, Ribeirão Preto, Brazil, [2]University of Rosario, Rosario, Argentina

Arterial Hypertension (AH) is part of the group of cardiovascular diseases that represent the highest percentage of causes of mortality. Evidence suggests that psychosocial factors may play an important role in the development of high blood pressure. Exposure to chronic stress has been considered a risk factor for this chronic disease. *Objective*: Therefore, this study aims to investigate the effect of varied acute and chronic stress associated with hypertension on the skeletal system, through morphofunctional and metabolic assessments (Histology and Immunohistochemistry). *Material and Methods*: Male Hannover rats (n=40) and SHR rats (*Spontaneous Hypertensive Rats*) (n=40) were used, randomly divided into groups G1 (no stress/normal rat); G2 (no stress/SHR rat); G3 (control/acute stress/normal rat); G4 (acute stress/normal rat); G5 (control/acute stress/SHR rat); G6 (acute stress/SHR rat); G7 (control/chronic stress/normal rat); G8 (chronic stress/normal rat); G9 (control/chronic stress/SHR rat); and, G10 (chronic stress/SHR rat). The rats were euthanized on the 10th day after the start of the experiment, to obtain tibias for histological and immunohistochemical analyzes of bone resorption, collagen fibers and TRAP. *Results*: Regarding the histology of bone resorption, staining was performed with Masson's Trichrome and quantification using a light microscope coupled to a digital camera, Axioimager Z2 Zeiss and AxioVision 4.8 software (Carl Zeiss, Oberkochen, Germany). Kruskal-Wallis was used to compare controls for the same type of animal. No significant differences were found: Normal (p=0.077) and SHR (=0.123). The Wald Test was performed in a generalized linear model to compare groups G4 to G10, in which no significant differences were identified between the types of rats (p=0.203) and stress/handling (p=0.157) and no interaction Type of rat versus stress/ manipulation (p=0.420). A trend towards increased area was observed in the manipulated control groups, for both types of rats. Regarding collagen fibers, staining with Picro Sirus Red was used and images were captured using a light microscope coupled to a digital camera, Axioimager Z2 Zeiss and AxioVision 4.8 software (Carl Zeiss, Oberkochen, Germany). Kruskal-Wallis was used to compare control groups for the same type of animal. No significant differences were found: Proximal Picro - Normal (p=0.298) and SHR (=0.735); Proximal Picro - Normal (p=0.098) and SHR (=0.077). The variation of the control groups of SHR rats in the proximal regions: G2, G5 and G9. The highest average was found in group G9 (10-day manipulation for chronic stress - control). TRAP enzymatic activity was analyzed histochemical in bone focusing on the proximal regions (distal and proximal). The TRAP reaction was observed in the groups that suffered stress with the presence of a reddish-pink color. In other words, there was a reaction in the groups with the acute stress protocol (G4 and G6) and in the groups with the chronic stress protocol (G8 and G10). The Wald Test was performed in a generalized linear model to compare groups G4, G6, G8 and G10, in which no significant differences were identified between the types of rats (p=0.616) and stress/handling (p=0.501) and no interaction Type of rat versus stress/handling (p=0.923). The highest average % Area in the number of TRAP-positive osteoclasts per mm of bone surface was observed in the G6 group compared to the other groups. *Conclusion*: With the results, we conclude that the experimental protocol of chronic and acute stress is effective in associating bone resorption with emotional stress and arterial hypertension. Other analyzes should be considered to complement the effectiveness of the protocol and we can also suggest increasing the days of the experimental protocol. *Acknowledgments*: Acknowledgments to FAPESP (*Fundação de Amparo à Pesquisa do Estado de São Paulo*) for funding and research support related to the Regular Project (2023/06853-7), Doctorate (2021/08618-0) and Research Internship Abroad (2024/02633-5) processes.

IMMUNOHISTOCHEMICAL ANALYSIS OF VEGF, TRAP, SIALOPROTEIN AND OSTEOCALCIN IN THE EFFECTIVENESS OF THE EXPERIMENTAL PROTOCOL OF ACUTE AND CHRONIC STRESS ASSOCIATED WITH ARTERIAL HYPERTENSION ON THE MORPHOFUNCTIONAL CHARACTERISTICS OF LONG BONES

J. P. Mardegan Issa[1], M. Ribeiro Paulini[1], G. Crivelaro do Nascimento[1], D. Leonardo Pitol[1], A. P. Macedo[1], L. M. P. Dos Santos[1], E. Ervolino[2], R. Okamoto[2]

[1]University of São Paulo, Ribeirão Preto, Brazil, [2]Paulista State University, Araçatuba, Brazil

The prevalence of chronic disorders, high blood pressure and bone pathologies, as well as emotional disorders, such as stress, in the general population, requires studies on these topics, with the intention of better understanding the physiological and morphological aspects and biochemicals altered under these conditions. *Objective*: the main objective of the present study is to characterize the efficiency of the experimental protocol of varied acute and chronic stress associated with arterial hypertension on the skeletal system through a qualitative immunohistochemical analysis of the factors TRAP, VEGF, Sialoprotein and Osteocalcin. *Material and Methods*: All experimental protocols were carried out in accordance with the Local Ethics Committee for the Use of Animals of the University of São Paulo/Brazil, of the School of Dentistry of Ribeirão Preto, registered with number 0027/2021R2. Male Hannover rats (n=40) and SHR (spontaneous hypertensive rats) (n=40) were used. The animals were randomly divided into three large groups: control group without stress; group with acute stress; group with varied chronic stress. Each group was subdivided into normal rats and spontaneously hypertensive rats: G1 (no stress/normal rat); G2 (no stress/SHR rat); G3 (control/acute stress/normal rat); G4 (acute stress/normal rat); G5 (control/acute stress/SHR rat); G6 (acute stress/SHR rat); G7 (control/chronic stress/normal rat); G8 (chronic stress/normal rat); G9 (control/chronic stress/SHR rat); and, G10 (chronic stress/SHR rat). Regarding the acute stress protocol, the animals were subjected to a single episode of stress protocol (acute stress for 2 hours – physical restriction), followed by euthanasia. In the varied chronic stress protocol, the animals underwent 5 different types of stress for a period of 10 days, followed by euthanasia. Each day the animal went through a type of stress: day 1 and 6 were stress due to agitation; days 2 and 7 were stress due to forced swimming; days 3 and 8 were stress due to physical restriction; day 4 and 9 were cold stress; and day 5 and 10 were stress due to water deprivation. After euthanasia of the animals, the right tibia was collected and the samples were processed for qualitative analyzes of TRAP, VEGF, Sialoprotein and Osteocalcin. *Results*: in a qualitative immunoanalysis of histological images through captured images captured using a light microscope coupled to a digital camera, Axioimager Z2 Zeiss and AxioVision 4.8 software (Carl Zeiss, Oberkochen, Germany) it was observed that TRAP reactions (reaction enzymatic analysis of osteoclasts) occurred only in the groups that experienced acute and chronic stress (G4, G6, G8 and G10). The presence of the VEGF, Sialoprotein and Osteoclacin reaction was more intense in the groups that went through acute and chronic stress (G4, G6, G8 and G10), demonstrating that there was a bone remodeling process. Conclusion: with the results we conclude that the Experimental Protocol is efficient in demonstrating bone resorption among groups that have experienced acute and chronic stress. However, only with a qualitative analysis the relationship between stress and high blood pressure and bone resorption is limited, justifying other possible complementary analyses. *Acknowledgments*: Acknowledgments to FAPESP (*Fundação de Amparo à Pesquisa do Estado de São Paulo*) for funding and research support related to the Regular Project (2023/06853-7), Doctorate (2021/08618-0) and Research Internship Abroad (2024/02633-5) processes.

ANALYSIS OF CYTOKINE AND MMP GENE EXPRESSION IN BONE REMODELING ENHANCED BY MELATONIN AND RHBMP-2

J. P. Mardegan Issa[1], M. Ribeiro Paulini[1], L. Montarele Ferreira[1], D. Leonardo Pitol[1], G. Giannocco[2], R. Leone Buchaim[3], B. Fiorelini Pereira[2]

[1]University of São Paulo, Ribeirão Preto, Brazil, [2]Federal University of São Paulo, São Paulo, Brazil, [3]University of São Paulo, Bauru, Brazil, Bauru, Brazil

New therapies for treating significant bone defects are needed in medicine and destistry. Melatonin could play a key role in bone remodeling, while growth factors might boost the repair process. Objective: To assess the expression of cytokine genes (IL-1β, IL-6, IL-10, and TNF-α), osteoclastogenesis markers (RANK, RANKL, and OPG), and MMPs (MMP-1, MMP-2, MMP-8, and MMP-13) following treatment with melatonin combined with an osteogenic membrane and rhBMP-2 in bone injury recovery. Material and Methods: Sixty-four rats were allocated into 9 experimental groups based on the treatment applied to the bone lesion area, with melatonin concentrations of 1, 10, and 100 µmol/L. Gene expression was analyzed using real-time PCR, which involved measuring total RNA concentration and performing reverse transcription. To investigate the isolated and synergistic osteogenic potential of melatonin on the recovery of calvarial bone injury, the animals were distributed into 8 experimental groups, with 8 animals each. Melatonin (1, 10 and 100 µM), bone morpho- genetic protein (5 µg BMP-2) and osteogenic membrane in the form of a sponge or scaffold (Lumina-Coat Criteria®) were applied bilaterally to each animal, and the experimental groups were formed according to according to the treatment carried out in the region of the bone lesion, as shown in the table below.
Results: There were differences between groups when compared with clot or scaffold control, and improvement with a higher con-

centration of melatonin or rhBMP-2. The combination melatonin (1 µg) with 5 µg of rhBMP-2, using the guided bone regeneration technique, demonstrated some effects, albeit mild, on bone repair of critical bone defects. Conclusion: This indicates that the approach for administering these substances needs to be reassessed, with the goal of ensuring their direct application to the affected area. Therefore, future research must be carried out, seeking to produce materials with these ideal characteristics. *Acknowledgments*: Acknowledgments to FAPESP (*Fundação de Amparo à Pesquisa do Estado de São Paulo*) for funding and research support related to the Regular Project.

THE RELATIONSHIP BETWEEN BARIATRIC SURGERY AND RISK OF TOTAL HIP OR KNEE REPLACEMENT IN SEVERE OSTEOARTHRITIS IS OBESITY CLASS-SPECIFIC

J. Paccou[1], K. Fall[1], X. Lenne[1], D. Theis[1], F. Pattou[1], A. Bruandet[1]

[1]University of Lille, Lille, France

Background: In patients with osteoarthritis (OA), bariatric surgery is associated with diminished joint pain and improved functionality. The purpose of the study was to evaluate the relationship between the risk of total joint replacement (TJR) and the fact of having undergone bariatric surgery (yes/no) in people living with obesity (PwO).
Methods: This case-control study was conducted using data from the French National Hospitals Database to identify hospitalizations for TJR. The main exposure of interest was having undergone (or not) a bariatric surgery procedure between January 2017 and December 2021. After a 6-month run-in phase, data on hospitalizations for the first TJR (i.e., hip or knee) from July 2017 to December 2023 were classified by obesity class and surgical type.
Results: 160,773 patients who had undergone bariatric surgery (mean age 40.8 years, 79.5% female) and 160,773 matched controls were identified. The most frequent surgical technique was sleeve gastrectomy (72.2%), followed by gastric bypass (27.8%). Average follow-up was 4.7 years. An increase in the overall risk of TJR, with a hazard ratio (HR) of 1.09 (95% confidence interval (CI), 1.03–1.15), was observed. Depending on obesity class, patients with BMI < 40 kg/m² had a lower risk of TJR (HR=0.85, 95% CI, 0.78–0.93), whereas a higher risk was observed in patients with BMI ≥ 40 kg/m² (HR=1.25, 95% CI, 1.16–1.34).
Conclusions: In France, hospitalizations for TJR following bariatric surgery increased by 25% in patients with BMI ≥ 40 kg/m², whereas it decreased by 15% in patients with BMI < 40 kg/m².

COMPARATIVE EPIDEMIOLOGICAL STUDY OF HIP FRAGILITY FRACTURES BETWEEN TWO LEVEL 3 HOSPITALS

J. Palencia-Ercilla[1], I. Aguado-Maestro[1], C. Valverde[1], S. Valle-López[1], A. Espinel[1]

[1]HOSPITAL UNIVERSITARIO RIO HORTEGA, VALLADOLID, Spain

Introduction Current study aims to investigate the epidemiology of extracapsular hip fractures at the *Río Hortega Hospital* and the *University Clinical Hospital* de Valladolid (Spain)
Material and Methods A retrospective epidemiological study was carried out covering cases recorded between 2019 and 2021 in both hospitals. The parameters of age, sex, laterality and seasonality were analyzed in the sample of patients included in the study. Finally, a statistical analysis of the sample was performed with the SPSS program.
Results
- *Total Data:*
A total of 930 patients were included.
The cumulative incidence of 152 cases per 100,000 inhabitants.
The average age was 85.3 years
With a predominance of the female gender (73.2%) at the expense of the age group 70-79 and 80-89 years
Frequency in the left lower limb (51.4%), non-significant difference.
The seasonal distribution was similar throughout the year with a higher incidence in winter: spring (23.7%), summer (24.9%), autumn (24.7%) and winter (26.8%).
- *Río Hortega Hospital*
507 patients were operated on
Cumulative incidence of 194 cases per 100,000 inhabitants
Average age of 85.7 years
Predominance of the female gender (74%). The mean age of women was 86.6 years and that of men 82.9 years.
50% of the pertrochanteric hip fractures occurred in the left lower limb
Seasonal distribution: spring 26.8%, summer 22.3%, autumn 22.1%, winter 28.8%
- *University Clinical Hospital*
423 patients were operated on
Cumulative incidence of 121 cases per 100,000 inhabitants
Mean age of 84.9 years
Predominantly female (73%). The mean age of women was 85.8 years and that of men 83.9 years.
52.7% of the fractures occurred in the left lower limb
Seasonality: spring 19.9%, summer 28%, autumn 27.7%, winter 24.4%.
Conclusions
- There is a high prevalence of extracapsular hip fractures in elderly patients and mainly in women.
- There is a higher incidence in winter and there are no significant variations between laterality
- The Río Hortega Hospital has a higher number of extracapsular fractures than the Clinical Hospital

- The rest of the variables studied are comparable in both hospitals.
- These findings may be useful for establishing preventive measures and guiding future research.

P712

IMPORTANCE OF FLS UNIT FOR CLOSE UP FOLLOW-UP AND ADHERENCE TO OSTEOPOROSIS TREATMENT, A CASE REPORT

M. P. Contreras Lozano[1], J. Pereira Sobrado[1], M. Redondo Macías[1]

[1]Juan Ramon Jimenez Hospital, Huelva, Spain

Objectives: To highlight the importance of screening for secondary osteoporosis and fragility fractures and the need for FLS (Fracture Liaison Service) units for early diagnosis and treatment.
Material and Methods: Clinical case study of secondary osteoporosis in an FLS consultation. A 28-year-old male patient with no known drug allergies.
Personal background:

- *Cardiovascular Risk Factors: type I DM with microvascular complications: Diabetic retinopathy and Diabetic axonal polyneuropathy (DNP). Smoker.*
- *Osteochondral fracture of the patella in right knee, 2010.*
- *Righ*t hip acetabulum fracture in 2017 after fall from his own height.

The patient was referred from the Endocrinology service after a fragility fracture and the finding of osteoporosis in a densitometry (DXA) performed in July 2024. The patient developed DM in 2010, since then, he has had poor metabolic control despite being treated with different types of insulin. He started on cholecalciferol 25,000 IU monthly in 2021 as prescribed by his endocrinologist. Since his DM onset he has had two episodes of fragility fracture.
Results: During the first visit to FLS (October 2024), the tests carried out were evaluated: DXA with T-Score lumbar spine -3.5 and T-Score femoral neck -3.6. A bone metabolism blood test was requested with values of PTH 47.2 pg/mL, Ca 10 mg/dL, Vit D (25 OH) 28.4 ng/mL and FA 130 U/L. After the results obtained, it was proposed to start treatment with osteoanabolic therapy because of the very high risk of fracture: *Abaloparatida*, but the patient refused for economic reasons. On the second visit to FLS (December 2024) it was proposed to start with *Romozosumab* after ruling out cardiovascular risk factors, but the visa was denied. It should be noted that, in Spain, a visa is required to start this type of treatment. Finally, *Zoledronic Acid* has been proposed for initiation, but she is waiting for a dental surgery and has not yet started treatment.
Conclusions: The causes of secondary osteoporosis require special attention and should be assessed in FLS units that carry out a correct diagnosis and treatment in order to prevent fractures. We should highlight the difficulty in some cases to access optimal treatment.

OSTEOPOROSIS ASSESSMENT BY BONE DENSITY MEASUREMENT IN HOUNSFIELD UNITS IN LUMBAR AND FEMORAL NATIVE CT SCANS: A COMPARISON WITH QCT AND CTXA

J. R. Andresen[1], G. Schröder[2], T. Haider[1], H.-C. Schober[3], R. Andresen[4]

[1]Department of Trauma Surgery, University Clinic for Orthopaedics and Trauma Surgery, Medical University of Vienna, Vienna, Austria, [2]Department of Trauma, Hand and Reconstructive Surgery, University Medicine Rostock, Rostock, Germany, [3]OrthoCoast, Practice for Orthopedics and Osteology, Wolgast, Germany, [4]Institute of Diagnostic and Interventional Radiology / Neuroradiology, Westkuestenklinikum Heide, Academic Teaching Hospital of the Universities of Kiel, Lübeck, and Hamburg, Heide, Germany

Objective:
This study investigates the extent to which osteoporosis assessment is feasible through density measurement in Hounsfield Units (HU) and explores if HU values can be used to calculate quantitative BMD values.
Material and Methods:
A total of 240 patients, with an average age of 64.9 ± 13.1 years and a body mass index of 26.8 ± 6.8 kg/m², were examined for osteoporosis. For the spine, BMD in mg/cm³ was determined by QCT at L1, L2, and L3 vertebrae. Additionally, trabecular density in HU was measured in the same vertebrae, using a ellipsoid ROI positioned within the mid-vertebral spongy area in sagittal CT images. For the hip region, BMD in mg/cm² and DEXA-equivalent T-scores were quantitatively determined via CTXA. In the coronal CT image, trabecular density in HU was measured in the femoral head, neck, and subtrochanteric regions using circular ROIs.
Results:
For the spine, the median BMD was 73.2 (57.05–104.17) mg/cm³, and the median HU was 89.93 (67.90–126.95). With a correlation of 0.978 ($p < 0.001$), quantitative values in mg/cm³ can be calculated using the following formula: Xqct=0,83+0,81×HU (Fig. 1).

For the hip region, the median BMD was 0.684 (0.306–1.368) mg/cm², and the median HU was 125.68 (-11.93–308.67). With a correlation of R^2=0.8998 ($p < 0.001$), quantitative values in mg/cm² can be derived using the following formula: Xctxa=0,364+0,0027 ×HU (Fig. 2). The median T-score was -2.06 (-5.15–3.78), and with a correlation of R^2=0.9075 ($p < 0.001$), the values can be calculated by the formula: Xt=-4,8717+0,0234×HU (Fig. 3). Here, a T-score of -2.5 corresponds to an HU value of 101.35.

Conclusions:

Trabecular density measurements in HU can be converted into quantitative BMD values for the axial skeleton (mg/cm³) and the hip (mg/cm²), enabling a reliable estimation of osteoporosis. In our cohort, a trabecular density of less than 100 HU indicates the threshold for osteoporosis.

SERUM 25-HYDROXYVITAMIN D IN OSTEOPOROSIS WOMEN OF TAIWAN

J. S. Hwang[1], J. F. Chen[1]

[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Chang Gung Memorial Hospital, Chang Gung University, TAOYUAN, Taiwan

Objectives: The aim of this research study was to assess the vitamin D in postmenopausal osteoporosis women with and without vertebrae or hip fractures in Taiwan.

Background, study design and methods:Osteoporosis is a progressive systemic bone disease characterized by low bone mass and microarchitecture deterioration of bone tissue, leading to increased bone fragility and susceptibility to fracture. It is a major public health problem in many countries, as well as in Taiwan. Among the osteoporosis management factors, vitamin D plays an important role. Vitamin D is absorbed from food or synthesized in skin that is exposed to sunlight. The liver converts it to 25-hydroxyvitamin D [25(OH)D], which in turn is converted by the kidney to active form calcitriol 1,25(OH)2D. Vitamin D increases serum calcium by promoting intestinal calcium absorption and plays a role in bone formation and resorption. Synthesis of 1,25-dihydroxy vitamin D is stimulated by both PTH and hypophosphatemia. In addition, vitamin D deficiency is associated with muscle weakness and postural instability, leading to an increased risk of falls, which may lead to fractures.

This single center observational study analyzed the vitamin D level in Taiwanese postmenopausal osteoporotic patients with and without non- trauma fragility vertebral or hip fracture that received post-fracture medical care at osteoporosis clinic. A single, non-fasting blood sample to assess 25(OH)D and biochemical tests were performed in the study visit. Vitamin D inadequacy was defined as serum 25(OH)D level less than 30 ng/mL and deficiency as less than 10 ng/mL.

Results: A total of 72 patients were enrolled at Chang Gung Hospital, in Linko, Taiwan. Overall, the average age was 70.8 years. The mean years since menopause were 21.3 years. The mean serum 25(OH) D level was 26.6±8.2 ng/mL, and lower vitamin D level

25.7±7.8 ng/mL in 34 (47%) patients with hip and vertebral fractures, compared with 27.8±8.9 ng/mL in 38 (53%) patients without fractures, resulting in a prevalence of vitamin D inadequacy of 65% of patients.
Conclusions: International Osteoporosis Foundation recommends that a minimum level of 30 ng/mL 25(OH)D is necessary in older adults to reduce the risk of falls and fractures. The results of this study have shown high prevalence of vitamin D inadequacy was found among osteoporosis women with and without vertebrae or hip fractures in northern Taiwan. Recommendations and education for postmenopausal women with osteoporosis to receive adequate vitamin D supplementation should be reinforced.
Keywords: vitamin D, osteoporosis, fracture

PERIOPERATIVE HYPOVITAMINOSIS D AFFECT THE FUNCTIONAL OUTCOMES AFTER SURGERY IN FRAGILITY HIP FRACTURES

J. Saiyudthong[1], A. Unnanuntana[1], E. Vanitcharoenkul[1], P. Chotiyarnwong[1]

[1]Department of Orthopaedic Surgery, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Objectives: This study aimed to evaluate the association between serum 25-hydroxyvitamin D levels and functional outcomes, measured by the Barthel Index, at one year after fragility hip surgery. Secondary objectives included comparing quality of life, incidence of refractures, and mortality within one year between patients with lower versus higher vitamin D levels.
Materials and Methods: A retrospective analysis was conducted on patients aged ≥50 years who underwent hip surgery for fragility fractures at Siriraj Hospital (2017–2021) with recorded perioperative serum 25-hydroxyvitamin D levels. Patients with pathological or multiple fractures or prior hip surgery were excluded. Hypovitaminosis D was defined as serum 25-hydroxyvitamin D <20 ng/ml. Functional recovery was assessed using the validated Thai version of the Barthel Index, with scores ≥80 indicating good outcomes. Associations between hypovitaminosis D and functional outcomes were analyzed using univariate and multivariate models.
Results: Among 534 patients, 51.5% had hypovitaminosis D. These patients demonstrated significantly lower Barthel Index and EQ-VAS scores at one year post-surgery, indicating poorer functional outcomes and quality of life. However, no significant differences were observed in refracture rates or mortality within one year between groups.
Conclusions: Perioperative hypovitaminosis D is associated with poorer functional recovery and quality of life in fragility hip fracture patients. Screening and optimizing vitamin D levels in osteoporosis patients may improve postoperative outcomes.
Acknowledgements: The authors thank the medical and nursing staff at Siriraj Hospital and Ms. Wachirapan Narktang and Ms. Panisa Khaminta for their assistance with data collection and statistical analysis.
Disclosures: The authors declare no conflicts of interest and received no external funding for this study.

P717

HOW DO WE ADDRESS VITAMIN D DEFICIENCY AMONG PATIENTS HOSPITALIZED IN THE INTERNAL MEDICINE DEPARTMENT? A RETROSPECTIVE OBSERVATIONAL STUDY FROM SLOVAKIA

J. Smaha[1], M. Kužma[1], P. Jackuliak[1], J. Payer[1]

[1]5th Department of Internal Medicine, Faculty of Medicine Comenius University and University Hospital Bratislava, Bratislava, Slovakia

Objective: Current guidelines for vitamin D supplementation differ in defining deficiency thresholds and optimal dosing, thus creating confusion among physicians about the best approach.
Material and methods: In the monitored period from January 2018 to December 2023, health records of 18,076 hospitalized patients were assessed for serum 25(OH)D levels at the time of hospital admission and for vitamin D prescription among patients with deficiency upon hospital discharge. Analysis was made for the whole cohort, and comparisons were also made between the pre-COVID-19 years (2018-2019), the peak of the pandemic (2020-2021), and post-pandemic years (2022-2023). Vitamin D deficiency was defined as a serum 25(OH)D concentration < 20 ng/mL.
Results: The mean 25(OH)D concentration in hospitalized patients (n=6915) during the observed period was 18.05 ± 11.24 ng/mL. 5725 (83%) of patients were discharged, and 1163 (17%) died in the hospital. Of discharged patients, 3461 (60%) were vitamin D deficient. Of them, 1188 (34%) received supplementation with vitamin D at the time of discharge. The number of patients with identified vitamin D deficiency and prescribed supplementation did not reach 50% in any year of the monitored period. There was a significant difference between men and women regarding vitamin D prescription (29% vs 40%, p<0.001). 987 (83%) of patients received cholecalciferol and 209 (17%) alfacalcidol. In patients with cholecalciferol prescription, 798 (72%) received a daily and 279 (28%) weekly dosage schemes. The mean calculated daily dose of cholecalciferol in patients with a daily dosage scheme was 2563 ± 2023 IU compared to 1433 ± 606 IU in a weekly dosage scheme (p<0.001). At the beginning of the observation period (2018-2019), the mean prescribed daily dose of cholecalciferol was higher in men than in women (1671 ± 1463 IU and 1294 ± 918 IU, respectively, p=0.03). At the end of the observation period (2022-2023), women were prescribed higher doses than men (2550 ± 1571 IU and 2153 ± 1227 IU, respectively, p=0.01).
Conclusion: Vitamin D supplementation is highly heterogeneous. Physicians often don't reflect vitamin D status, and only one-third of patients with identified vitamin D deficiency are addressed upon hospital discharge.

P718

UNDIAGNOSED VERTEBRAL FRACTURES IN ROUTINE CT SCANS - HAVE WE LEARNED OUR LESSON?

H. P. Dimai[1], J. Igrec[2], J. Steiner[2], R. Riedl[3], M. Fuchsjaeger[2]

[1]Division of Endocrinology & Diabetology, Department of Internal Medicine, Medical University of Graz, Graz, Austria, [2]Divison of General Radiology, Department of Radiology, Medical University of Graz, Graz, Austria, [3]Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Graz, Austria

Objective

Vertebral fractures (vFXs) are the most common type of osteoporotic fracture. However, only one third of them occur acutely and therefore come to immediate clinical attention, while the majority remains clinically unrecognized and undiagnosed although present in different radiological modalities (1,2,3). In the early two-thousands, the International Osteoporosis Foundation (IOF) launched a global educational program, called "Vertebral Fracture Initiative", to improve awareness of healthcare professionals for vFXs . The aim of the present study was to evaluate if this global initiative has led to a sustainable improvement in the reporting and diagnosis of vFXs present in chest and abdominal/pelvic CT scans.

Material and Methods

The study included all CT scans of the chest or abdomen/pelvis that were performed between January 1st, 2023 to December 31st, 2023 in patients ≥ 50yrs (n = 8,500) at a large university hospital. A random sample of 1,500 CT scans from 1,380 patients was included in the analysis. Two board-certified radiologists independently reviewed each scan for vFXs, noting the number, location, and type of fracture. Severity of fracture was classified by visual semi-quantitative assessment according to the Genant classification (Grades 2 and 3). Inter-rater agreement was assessed using Kappa coefficient and AC1 statistic. Fracture documentation rates were calculated based on whether fractures were noted in the diagnostic summary of the report, or in the free-text narrative. Stratified analysis was performed by patient gender, fracture location, and the presence of multiple fractures.

Results

The prevalence of vertebral fractures was 11.5%. Inter-rater agreement was excellent, with a Kappa value of 0.94 (95% CI: 0.92–0.97) and an AC1 of 0.99 (95% CI: 0.98–0.99). However, in the original CT report, only 14.7% (95% CI: 9.8%–20.9%) of all fractures were mentioned in the diagnostic summary, and 35.3% (95% CI: 28.1%–43.0%) were mentioned in the free-text narrative only.

Conclusion

Despite excellent educational programs, reporting rates of vFXs in CT scans have not improved in the past decade. The findings of this study suggest an urgent need for improved reporting protocols to ensure vFXs are clearly communicated, thus improving clinical decision-making and patient outcomes.

ASSESSMENT OF SKELETAL HEALTH AFTER IDENTIFICATION OF VERTEBRAL COMPRESSION FRACTURES BY A NATURAL LANGUAGE PROCESSING ALGORITHM

Y. Zhang[1], D. Saha[1], J. T. L. Cheah[1], R. Tai[1], G. M. Joshi[1]

[1]UMass Chan Medical School, Worcester, United States

Objective: This retrospective study aimed to assess the rates of subsequent action following a vertebral compression fracture (VCFx) by identifying the completion of dual-energy x-ray absorptiometry (DXA) scans as a proxy to further assessment and management of osteoporosis.
Methods: Data were extracted from the reports of computed tomography (CT) scans from a single academic medical center between December 16, 2021, to January 2, 2022. Studies included those of the chest, abdomen, and pelvis in individuals aged 50 or over. A Natural Language Processing (NLP) algorithm (Aidoc, Tel Aviv, Israel) was then applied to the reports of the CT scans to code scans either positive or negative for VCFx. In positive cases, whether or not a DXA scan was performed within the prior 12 months or the subsequent 12 months was then identified as a proxy to determine if further assessment and management of skeletal fragility had been initiated.
Results: There were 7,050 individuals and 12,156 CT scans eligible for assessment. Of those, the NLP algorithm identified VCFx in 293 individuals. 3% (8/293) of individuals did have a DXA scan performed in the preceding 12 months of the index CT scan. Of the 285 individuals who did not have a preceding DXA scan, only 7% (19/285) were identified to have undergone a DXA scan in the subsequent 12 months.
Additionally, 7% (20/293) of patients with serial imaging available during the 12 months following the index CT scan, exhibited progression of disease, demonstrated by the occurrence of a new fracture or worsening of an existing fracture.
Conclusion: This study reveals a critical gap in osteoporosis assessment and management, with 93% of patients in this cohort with a VCFx missing evidence of follow-up assessment of bone health. These findings emphasize the need to integrate secondary prevention pathways after identification of a VCFx to reduce future fracture risk. NLP algorithms offer a promising tool to identify at-risk patients and therefore offer a unique opportunity to further close the osteoporosis treatment gap.

P720

DEVELOPMENT OF AN ELECTRONIC MEDICAL RECORD BASED DASHBOARD TO FACILITATE POST-FRACTURE CARE

Y. Chang[1], A. Money[1], J. T. L. Cheah[2]

[1]UMass Memorial Health, Worcester, United States, [2]UMass Chan Medical School, Worcester, United States

Objective: To develop a real time centralized dashboard utilizing multiple sources of data from the electronic medical record (EMR) in order to facilitate and identify appropriate individuals for post-fracture care programs.

Material and Methods: Within a single academic health system, candidate items were identified to be incorporated into the dashboard and abstracted from the Epic Caboodle (Epic Systems Corporation, Verona, WI) database. These included 1: demographic data such as race/ethnicity and primary insurance coverage, 2: ICD10 codes related to fracture, 3: details relating to inpatient admissions and outpatient visits with fracture as the primary diagnosis, 4: data regarding secondary work up of osteoporosis and 5: information on prescriptions for FDA-approved therapies for fracture risk reduction. Once these individual pieces of data were identified, a centralized dashboard was created in Tableau (Salesforce, Inc., San Francisco, CA) to present this data in an actionable format.

Results: A dashboard which can be updated on a daily basis was created in Tableau (Figure 1) to identify individuals who meet criteria to be included in post-fracture care programs. The dashboard is able to be configured at a health system level by variables such as date of admission for fracture, type of fracture as well as race/ethnicity and insurance status. At an individual patient level, the dashboard can identify who has been referred to and seen by Endocrinology or Rheumatology for assessment and management of osteoporosis, including if therapy for fracture risk reduction has been initiated. It is additionally able to track metrics such as 12-month readmission and mortality post-index fracture (Figure 2).

Conclusions: A post-fracture care dashboard utilizing data within the EMR has been created which is able to identify and follow individuals post-fracture to ensure that further assessment and medical management of osteoporosis occurs. Additional work is underway to utilize this dashboard with the aim to reduce the osteoporosis treatment gap.

Figure 1: example of individual level data within the post-fracture care dashboard

IMPORTANT PREDICTORS OF INCIDENT HIP FRACTURE VARY BY BODY MASS INDEX (BMI)

J. T. Schousboe[1], N. Binkley[2], W. D. Leslie[3]

[1]HealthPartners Institute Health Services Research, HealthPartners Inc, Bloomington, United States, [2]University of Wisconsin School of Medicine and Public Health, Madison, United States, [3]University of Manitoba Department of Internal Medicine, Winnipeg, Canada

Objective: Hip BMD measures are less precise at very high levels of BMI. Our aim was to determine if the relative importance of BMD and other variables for hip fracture prediction vary by BMI.

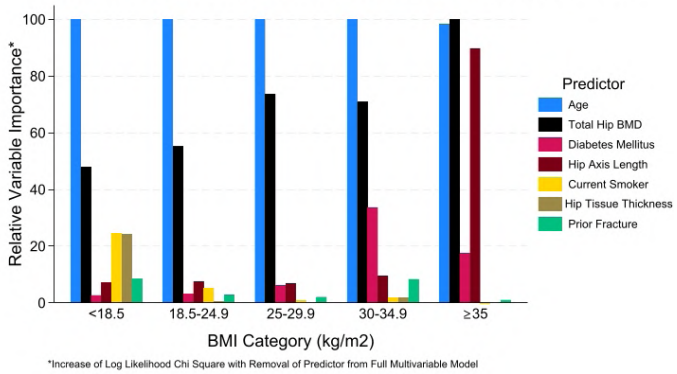
Material and Methods: 75,391 individuals (mean [SD] age 64.0 [10.8] years, 90.3% female) were followed for a mean (SD) 8.6 (5.3) years after baseline DXA for incident hip fracture ascertained through Manitoba linked health claims. Total hip BMD, hip axis length (HAL), and hip soft tissue thickness were ascertained on GE Lunar Prodigy (n=55790) or iDXA (n=19601) densitometers. Prior fracture, prior falls related hospitalizations, and diagnosis of diabetes mellitus were ascertained through linked health claims. Cox proportional hazards models were used to estimate the association of predictors with incident hip fracture stratified by BMI level (<18.5 kg/m^2, 18.5-24.9 kg/m^2, 25-29.9 kg/m^2, 30-34.9 kg/m^2, ≥35 kg/m^2). Relative variable importance for each predictor was separately estimated by the increase of model log-likelihood chi square value with removal of that predictor from the full multivariable model.

Results: Total hip BMD had a stronger association with incident hip fracture for those with BMI ≥ 35 kg/m^2 (HR 1.97 per SD decrease, 95% C.I. 1.49-2.59) than for those with BMI <18.5 kg/m^2 (HR 1.66 per SD decrease, 95% C.I. 1.29-2.13, BMD*BMI interaction p-value 0.033). Hip BMD was increasingly important as a predictor with increasing BMI (**Figure**). HAL was a particularly strong predictor of hip fracture if BMI ≥35 kg/m^2 (HR 2.27 per SD increase, 95% C.I. 1.66-3.11, HAL*BMI interaction p-value 0.031). Diabetes was more important as a predictor for those with BMI ≥ 30 kg/m^2, whereas smoking and hip soft tissue thickness were more important predictors if BMI <18.5 kg/m^2.

Conclusion: In those with high to very high BMI, hip BMD is as strong a predictor of hip fracture as for those with normal BMI, and HAL and diabetes are relatively more important hip fracture

predictors as well.

Figure: Relative Importance of Hip Fracture Predictors by BMI Level



*Increase of Log Likelihood Chi Square with Removal of Predictor from Full Multivariable Model

P722

ASSOCIATION OF NEIGHBORHOOD SOCIOECONOMIC DEPRIVATION INDEX WITH ABDOMINAL AORTIC CALCIFICATION: THE UK BIOBANK IMAGING STUDY

J. T. Schousboe[1], M. Sim[2], R. Woodman[3], G. Gebre[4], A. Saleem[4], S. Z. Gilani[4], J. Webster[5], W. D. Leslie[6], N. Harvey[7], C. Smith[8], J. R. Lewis[2]

[1]HealthPartners Institute Health Services Research, HealthPartners Inc, Bloomington, United States, [2]Edith Cowan University and University of Western Australia, Perth, Australia, [3]Flinders University, Adelaide, Australia, [4]Edith Cowan University, Perth, Australia, [5]Oxford University, Oxford, United Kingdom, [6]University of Manitoba, Winnipeg, Canada, [7]University of Southampton, Southampton, United Kingdom, [8]Edith Cowan University and University of Western Australia, ,

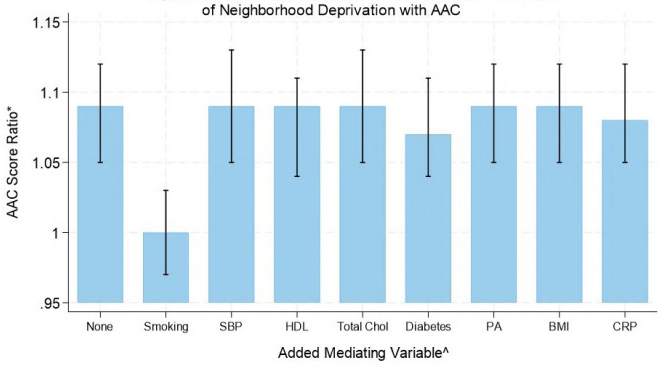
Objective: Residence in socioeconomically deprived neighborhoods (SDN) is associated with adverse health outcomes, and a constellation of neurohormonal/metabolic changes (allostatic load) that in turn causes premature tissue/organ aging and loss of physiologic resilience. We hypothesized that SDN is associated with abdominal aortic calcification (AAC), a marker of multisite atherosclerosis,assessed on bone density (DXA) lateral spine images (LSI).

Material and Methods: 35,493 UK Biobank enrollees with complete covariate data at baseline (mean [SD] age 54.9 [7.6] years, 49.3% female), who also had a DXA-LSI an average (SD) 9.7 (2.3) years later were included. AAC was scored using a validated algorithm developed by convolutional neural networks. Baseline Townsend Index was used to represent SDN and modeled as quintiles. We used exponential regression models to estimate the association of SDN with AAC score. Base model was adjusted for age, sex, and ethnicity. The attenuation of the association of SDN with AAC by potential mediators / confounders was then assessed by adding covariates singly and separately to the base model. Regression models were used to estimate the association of SDN with these potential mediators / confounders.

Results: In the base model, those in the poorest quintile had a 9% greater AAC score compared to those in the wealthiest quintile (**Figure**). Smoking was the sole potential mediator that attenuated this association. In an ordinal logistic model adjusted for age, sex, and ethnicity, SDN was associated with increase of smoking status (Odds Ratio for past vs never 1.69 [95% CI 1.58, 1.81]; current vs past 2.18 [95% C.I. 1.91, 2.49] highest vs lowest SDN quintile).

Conclusion: Residence in a poor SES neighborhood is associated with AAC, but its influence appears small and may be mediated by smoking status. These results are not generalizable to other societies that may have weaker or stronger gradients of socioeconomic neighborhood deprivation.

Figure: Effect of Potential Mediator Variables on Association of Neighborhood Deprivation with AAC



*Ratio of AAC Scores of Highest to Lowest Neighborhood Deprivation Quintile (light blue bars). Black capped lines are 95% confidence intervals

ANALYSIS FOR COMPRESSION RATE PROGRESSION IN OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURE

J. C. Lee[1], J. W. Soh[2]

[1]Soonchunhyang University Seoul Hospital, Seoul, South Korea, [2]Hanyang University Guri Hospital, Guri, South Korea

OBJECTIVE: To analyze whether there were any factors affecting the compression rate progression of osteoporotic vertebral compression fractures (OVCF) and also investigate the period when the compression rate progressed the most.

MATERIAL AND METHODS: Total 61 patients followed up more than 6 months were included in this study. The patient's age, gender, level of fracture, bone mineral density(BMD), body mass index(BMI), previous osteoporosis medication, initial compression rate, fracture location on vertebral body, and pelvic incidence were measured, and the correlation of the compression rate progression by more than 30% at the final follow-up was analyzed. Compression rates were measured at initial, 1 month, 2 months, 3 months, and final 6 months follow-up, then the progression of compression rate over time was analyzed, and the correlation with clinical results was also investigated. Statistical univariate analysis was performed for factors related to compression rate progression and multivariable Cox regression analysis was done. Compression rate progression according to time was analyzed

using a general linear model, and clinical outcomes were analyzed by paired t-test.
RESULTS: In univariate analysis, only when the initial compression rate was less than 30% was significantly high(p=0.001). In multivariable Cox regression analysis, it was analyzed as significant when the initial compression rate was less than 30%(p=0.015, Hazard ratio=3.103, 95% Confidence Interval 1.249-7.710). Also, the compression rate progressed over time, the most at 1 month of follow-up(p=0.0006). At the final follow-up, both VAS for back pain(p=0.034) and ODI(p=0.025) were significantly higher in the compression rate progression group.
CONCLUSIONS: An initial compression rate of less than 30% was associated with a higher correlation of compression rate progression, particularly within the first month after injury. Compression rate progression was correlated with poorer clinical outcomes in terms of pain and quality of life.

P724

TRENDS IN HIP FRACTURE INCIDENCE IN ENGLAND BEFORE, DURING, AND AFTER THE COVID-19 PANDEMIC (2014-2023)

J. Webster[1], R. Goldacre[1]

[1]Applied Health Research Unit, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom

Objective
To investigate recent trends in hip fracture incidence in England before, during, and after the COVID-19 pandemic.
Methods
An epidemiological population-based study was conducted of all first-time emergency hip fracture hospital admissions unrelated to high-energy trauma in adults aged ≥ 60 years using English national secondary care data with linked national death records from January 2014 to December 2023. Temporal trends in age-standardized incidence rates were investigated by sex using national mid-year population estimates. Joinpoint regression models with permutation tests were used to calculate monthly percent changes with 95% confidence intervals (MPCs, 95% CIs).
Results
From 2014 to 2023, there were 429,499 hip fracture admissions in women, and 187,566 in men. Age-standardised incidence rates steadily declined from 2014 to 2020, from a mean monthly rate of 20.1 to 17.6 cases per 100,000 men, and from 33.2 to 27.7 cases per 100,000 women (MPC in men: -0.17%, 95% CI: -0.23 to -0.11; MPC in women: -0.23%, 95% CI: -0.28 to -0.18). The direction of the trend changed in February 2021 in men and women, after which rates remained relatively flat (MPC for men: 0.14, 95% CI: -0.07 to 0.35; MPC for women: 0.13%, 95% CI: -0.05 to 0.31; p for slope change < 0.01 for both). By 2023, mean monthly incidence rates were 17.7 cases per 100,000 men and 28.2 cases per 100,000 women. The incidence of hip fracture was higher in women than in men (IRR 1.62, 95% CI: 1.61 to 1.64), but temporal trends were broadly consistent in both sexes.
Conclusion
This study highlights a downward trend in hip fracture incidence rates from January 2014 to February 2021 in England, followed by a sudden plateau from February 2021 onwards in men and women. Further investigation is needed to understand the cause of this change. Continued surveillance is needed to inform planning of emergency hip fracture care services and to measure the effectiveness of prevention strategies, particularly in the context of ongoing disruption and reorganisation of healthcare services in the UK.

EFFECT OF 3D PRINTING-ASSISTED MIPPO IN THE TREATMENT OF CLAVICLE FRACTURE

J. Wenchen[1]

[1]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Objective: To investigate the effect of 3D printing-assisted minimally invasive percutaneous plate osteosynthesis (MIPPO) in the treatment of clavicular fracture. ***Methods:*** Twenty-eight cases of clavicular fractures were randomly divided into two groups: 3D printing-assisted MIPPO group and MIPPO group, fourteen cases in each group. In the 3D printing-assisted MIPPO group, CT scan the healthy clavicle side before the operation to provide inverted image in the software in order to build the 3D printed physical model which is helpful in selecting the steel plate of appropriate length, whose local angle can also be adjusted and preset, whereas the MIPPO group only made a surgical plan based on imaging data. The incision length, bone fracture healing time, operation time, bleeding volume, fluoroscopy times, incidence of complications, Constant score, DASH score and Neer score were compared between two groups. ***Results*** Between 3D printing-assisted MIPPO group and MIPPO group, there was no significant difference in aspects of incision length [(7.71±1.32) cm VS. (8.04±1.41) cm], bone healing time [(2.9±0.2) months VS. (3.0±0.3) months], Constant scores (97.21±1.26) *vs.* (94.35±2.31), DASH scores (2.71±0.16) *vs.* (2.93±0.32) and Neer scores (93.5±3.1) *vs.* (91.2±2.7). There were significant differences in aspects of bleeding volume [(45.3±4.2) mL *vs.* (72.4±1.9) mL], operation time

[(40.2±6.3) min *vs.* (53.2±4.1) min], fluoroscopy times (3.4±1.2) *vs.* (6.2±1.9), rate of superficial infection around the incision (0% vs.7.146%) and incidence of internal implants protrusion (7.14% VS. 28.6%), $P < 0.05$. ***Conclusion*** 3D printing-assisted MIPPO has great significance in the treatment of clavicular fracture. It is helpful the doctor to select the appropriate length of anatomic plate before operation and to pre-bend and adjust it. It is also helpful the surgeon to clearly know the expected operation reduction and understand the expected effect. So as to shorten the operation time, reduce the amount of bleeding and reduce the number of fluoroscopy. It is worthy of clinical application.

P726

PATOS (PATIENT EDUCATION IN OSTEOPOROSIS): FEASIBILITY AND EFFECTIVENESS OF A DIGITAL PATIENT EDUCATION PROGRAM IN IMPROVING SELF-CARE IN PATIENTS WITH OSTEOPOROSIS - A PILOT STUDY

J. Wibault[1], A. Constantinou[2], Y. Lindbäck[3], A.-C. Grahn Kronhed[3], J. Forsberg[4], A. Spångeus[5]

[1]Department of Activity and Health in Linköping, and Department of Health, Medicine, and Caring Sciences, Linköping University., Linköping, Sweden, [2]Department of Activity and Health in Linköping, and Department of Health, Medicine and Caring Sciences, Linköping University., Linköping, Sweden, [3]Unit of Physiotherapy, Department of Health, Medicine and Caring Sciences, Linköping University., Linköping, Sweden, [4]Primary Health Care, Lillåns Healthcenter, Örebro, Örebro, Sweden, [5]Division of Diagnostics and Specialists Medicine, Department of Health, Medicine, and Caring Sciences, Linköping University., Linköping, Sweden

Objective: To assess the feasibility and effectiveness of a digital patient education program in improving self-care enablement, illness perception, perceived osteoporosis knowledge and self-care maintenance among patients with osteoporosis.
Material and methods: Thirty patients with osteoporosis participated in a digital patient education program. The program included eight modules covering key topics on osteoporosis knowledge and self-care maintenance (approximately 5 hours of e-learning) that participants completed at their own pace. Questionnaires were administered before and after 5 weeks. Outcome measures included the Patient Enablement Instrument (PEI), the Brief Illness Perception Questionnaire (BIPQ), and patient-reported ratings of perceived osteoporosis knowledge and self-care maintenance such as osteoporosis medication adherence, diet, exercise habits, fall prevention, and ergonomics. Results were analyzed using descriptive statistics and paired sample tests to evaluate changes in outcomes.
Results: All participants (90% women, mean age 70 ± 6.4, 27% with previous vertebral fractures) completed the program and expressed a high willingness to recommend it to others (83% "strongly recommend"). Content quality (mean score 4.3 ±0.6), and perceived benefits (mean score 4.1 ±1.1) of the program were rated highly on a 6-grade scale with a maximum score of 5. The mean PEI score (0-12) was 5.5 ±3.7, with 90% of the participants reporting improved understanding of the disease, and 77% reporting enhanced coping ability. BIPQ scores and perceived osteoporosis knowledge showed significant improvements (p< 0.001). Self-care maintenance also significantly improved (p<0.01) including regular practice of balance and weight-bearing exercises, and ergonomic adaptation in daily activities.
Conclusions: Participation in a digital patient education program improved self-care enablement, illness perception, perceived osteoporosis knowledge and self-care maintenance among patients with osteoporosis. Digital patient education programs may offer substantial benefits for patients with osteoporosis. Future research should explore the long-term effects of digital and traditional patient education programs on self-care maintenance and health-related quality of life in patients with osteoporosis. Additionally, combining patient education with supervised exercise interventions may enhance outcomes for some patients.

P727

SEX DIFFERENCES IN THE SUBJECTIVE PAIN PERCEPTION, FALL RISK AND FUNCTIONAL STATUS OF PATIENTS WITH KNEE OSTEOARTHRITIS

T. Tanaskovic[1], M. Isailovic[1], A. Cvetinovic[1], J. Krasic[1], M. Sili[1], J. Zvekic - Svorcan[2], I. Minakovic[3]

[1]University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia, [2]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [3]University of Novi Sad, Faculty of Medicine Novi Sad. Health Center "Novi Sad", Novi Sad, Serbia

Objective(s) To examine whether the knee osteoarthritis (OA) patients' subjective pain perception, fall risk, and functional status of the lower extremities are affected by their sex.
Material and Methods: This prospective cross-sectional study involved 50 individuals treated at the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia, in whom knee OA was diagnosed at least 3 years prior (VAS ≥ 5). Patients of both sexes were included and their age ranged from 60 to 75 years. The exclusion criteria were: metabolic disorders of the joints, inflammatory rheumatic disease, endoprothesis of the lower extremities, and history of lower-extremity fractures. Following the institutional Ethics Committee approval, all eligible patients signed an informed consent form. The VAS scale was administered to measure subjective pain perception, fall risk was assessed via the Morse Fall Scale (MFS), and functional status was evaluated using the Serbian version of the Lower Extremity Functional Scale (Srb-LEFS). All analyses were conducted using the SPSS ver. 24. As the aim was to conduct gender comparisons, t test for large independent samples was conducted.
Results: While the full sample (M = 69.06±4.98 years, 92% female) had a VAS score of 7.18±1.45, it was lower for men (6.75±2.22) relative to women (7.22±1.40), but the difference was not statistically significant (p=0.543). Men also had a significantly lower MFS score than women (6.25±12.50 vs. 33.48±20.08, p=0.011). Moreover, men had greater functional status of the lower ex-

tremities, as measured by the Srb-LEFS scale (47.00±17.22 vs. 35.83±13.40). However, this difference was not statistically significant (p=0.123).
Conclusion: As the risk of falling is statistically higher in women with knee osteoarthritis relative to men, this risk factor needs to be considered when developing personalized prevention strategies and designing sex-specific prediction tools for identifying high-risk patient profiles.

P728

THE INFLUENCE OF OCCUPATIONAL PHYSICAL DEMANDS AND TASK PERFORMANCE MODE ON THE FALL RISK AND THE FUNCTIONAL STATUS OF PATIENTS WITH KNEE OSTEOARTHRITIS

M. Isailovic[1], T. Tanaskovic[1], J. Krasic[1], A. Cvetinovic[1], M. Sili[1], J. Zvekic - Svorcan[2], I. Minakovic[3]

[1]University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia, [2]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [3]University of Novi Sad, Faculty of Medicine Novi Sad. Health Center "Novi Sad", Novi Sad, Serbia

Objective(s) To examine whether in patients with knee osteoarthritis (OA), the fall risk and the functional status differ in relation to the physical and postural demands of occupational tasks.
Material and Methods: This prospective cross-sectional study included 50 patients of both sexes aged 60–75 years that have suffered from knee OA for at least 3 years, with VAS ≥ 5 pain score, treated at the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia. The research was approved by the institutional Ethics Committee and all patients signed an informed consent form before completing a questionnaire comprising sociodemographic data, occupational task performance methods, Morse Fall Scale (MFS) for fall risk assessment, and cross-cultural validation of the Serbian version of the Lower Extremity Functional Scale (Srb-LEFS). Patients with inflammatory rheumatic disease, metabolic disorders of the joints, lower-extremity endoprosthesis, and prior lower-extremity fractures were excluded. Statistical package SPSS ver. 24 was used for all analyses.
Results: The average MFS and LEFS scores for the sample (M = 69.06 ± 4.98 years, 92% women) were 31.30 (SD = 20.87) and 36.72 (SD = 13.87), respectively. Fall risk was lower among individuals that mostly stand at work without bending down/lifting heavy loads (24.38; SD = 20.43) compared to those whose tasks involve bending/lifting loads (32.29; SD = 20.59). The former group had a higher average LEFS score (39.50; SD = 5.53) relative to the latter (35.58; SD = 14.06). However, neither difference was statistically significant (p = 0.597; p = 0.790).
Conclusion: Although the difference in work performance is not statistically significant, the fall risk is lower and the functional status is better in patients with knee OA whose occupation involves standing but does not require bending/lifting. Thus, strategies for mitigating the risk factors predisposing them to more pronounced knee OA are necessary.

P729

DISEASE ACTIVITY AND QUALITY OF LIFE OF PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING BIOLOGICAL THERAPY

M. Sili[1], J. Zvekic - Svorcan[2], J. Obradovic - Gajic[3], T. Jankovic[2], J. Aleksic[4], K. Boskovic[2]

[1]University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia, [2]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [3]Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [4]Railway Healthcare Center, Belgrade, Serbia

Objective: To examine the relationship between disease activity and quality of life in patients with rheumatoid arthritis (RA) treated with biological drugs.
Material and methods: With the approval of the Ethics Committee of the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia (14/01-1/1-25), a retrospective analysis of data spanning a 5-decade period pertaining to 39 RA patients that had received biological therapy was performed. General sociodemographic data, illness duration, biological drug (anti-TNF inhibitors) treatment length, Disease Activity Score (DAS28), and the Health Assessment Questionnaire (HAQ) index were analyzed using the SPSS ver. 24 commercial software.
Results: The average HAQ and DAS28 value for the sample (comprising 71.8% women) was 0.85 ± 0.51 and 3.30 ± 1.00, respectively. In terms of disease activity, 33.3% of respondents were in remission, 30.8% had low disease activity, 35.9% had moderate disease activity, and none had high disease activity. A statistically significant negative correlation between disease duration and DAS28 score (p = 0.043) and well as biological treatment length (p = 0.029) was noted. DAS28 = 4.35 ± 0.29 was obtained for patients with RA duration below 5 years, while those who have been ill for 6–10 years scored 2.80 ± 0.91. Similarly, DAS28 scores of 2.43 ± 0.73 and 3.50 ± 0.96 were attained by those receiving biological drugs for more than 5 years and up to 12 months, respectively. On the other hand, the correlation between disease activity and HAQ index was statistically significant and positive (r = 0.618, p < 0.01), suggesting that quality of life declines with greater disease activity.
Conclusion: In RA patients, disease activity declines with the biological therapy duration. However, higher disease activity is associated with worse quality of life.

P730

THE INFLUENCE OF MORNING STIFFNESS, PAIN, AND FATIGUE ON THE KEY GRIP STRENGTH IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Zvekic - Svorcan[1], A. Cvetinovic[2], J. Krasic[2], T. Jankovic[1], K. Boskovic[1], R. Krasnik[3]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [2]University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia, [3]University of Novi Sad, Faculty of Medicine Novi Sad. Institute of Child and Youth Health Care of Vojvodina, Novi Sad, Serbia

Objective: To examine the influence of morning stiffness, pain, and fatigue on the key grip strength in patients with rheumatoid arthritis (RA).

Material and methods: The sample for this prospective cross-sectional study comprised 56 RA patients of both sexes treated at the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia. After signing the informed consent form, the participants rated their hand pain intensity on the 0–10 VAS Visual Pain Scale and fatigue intensity on a 0–10 scale. The precision key grip strength (kg) was estimated using the Baseline-Mechanical Pinch Gauge dynamometer. The association between the VAS and fatigue scores and the key grip strength in both hands was tested through Spearman's correlation coefficient, while Using the Kruskal Wallis test was conducted to check whether there is a statistically significant difference between the morning stiffness duration and the key grip strength in both hands.

Results: The median VAS and fatigue scores for the sample (average age 63, 92.9% women, all right-handed) were Me=7.00 (IQR=2.0) and Me=7.00 (IQR=3.0), respectively. There was no statistically significant correlation between the VAS score and the key grip strength in the right (rho=-0.088, p>0.05) or the left hand (rho=-0.140, p>0.05). Similarly, no statistically significant correlation between the fatigue score and the key grip strength in either hand was established (right: rho=-0.259, p>0.05; left: rho=-0.163, p>0.05).On the other hand, morning stiffness duration was in a statistically significant relationship with the key grip strength of the right hand (p=0.008), as well as the left hand (p=0.001). Patients in whom morning stiffness lasts up to 30 minutes had the strongest key grip (right hand: Me=7.78, IQR=6.13; left hand: Me=8.75, IQR=5.63). Those with the longest morning stiffness (>60 min) had the weakest right-hand grip (Me=4.00, IQR=6.10; Me=3.16, IQR=5.83).

Conclusion: RA patients who have morning stiffness of longer duration have a weaker key grip in both hands, while pain and fatigue do not affect the key grip strength.

P731

REHABILITATION PROCESS AFTER TIBIA AND FIBULA FRACTURES IN ADOLESCENTS: A CASE REPORT

M. Stanic[1], R. Krasnik[1], J. Zvekic-Svorcan[2], A. Mikov[1], M. Kovacevic[3], D. Vuklis[3], D. Dedic-Novakovic[4], M. Kolundzic[5]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Institute of Child and Youth Health Care of Vojvodina, Novi Sad, Serbia, [2]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [3]University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia, [4]University of Novi Sad, Faculty of Medicine Novi Sad. Onkology Institute of Vojvodina, Sremska Kamenica, Novi Sad, Serbia, [5]Health Center Novi Sad, Novi Sad, Serbia

Fractures of both, tibia and fibula, in adolescents are common (5% of all fractures) and generally have good outcomes due to the high healing potential and bone remodeling ability in pediatric patients.

Case Report: A 16-year-old boy was injured in a traffic accident and diagnosed with distal tibia and fibula fractures. Five days after the injury, he underwent surgery (orthopedic repositioning and osteosynthesis). He was referred for outpatient rehabilitation, shortly after surgery, at the Clinic for Physical Medicine and Rehabilitation, Novi Sad, Serbia. Informed consent was obtained from the patient and his parents, with approval from the Ethics Committee (decision no: 3987-3/2024). Range of motion (ROM) was measured using a goniometer, and muscle strength was assessed weekly with the Manual Muscle Test (MMT). At the initial assessment, the patient used crutches and did not bear weight on the right leg. Swelling (1 cm) was present in the lower leg and foot, and thigh muscle atrophy (1 cm) was noted. ROM in the knee was normal, but only initial dorsiflexion and plantarflexion were possible in the ankle due to pain. The 6-week rehabilitation program included physical modalities (interferential therapy, paraffin therapy) and kinesiotherapy. Treatment goals included reducing pain and swelling, restoring ankle mobility, improving muscle strength, and reintegrating the patient into daily and sports activities. Initially, the patient was non-weight-bearing and used crutches. By the third week, partial weight-bearing (up to 30%) was allowed, with individual kinesiotherapy tailored to the patient's progress. At the end of 6 weeks, the patient was advised to return to daily activities and gradually resume sports, under guidance from a sports physician.

Conclusion: An individually tailored rehabilitation process after tibia and fibula fractures in adolescents leads to complete functional recovery and return to daily activities.

P733

INFLUENCE OF TEGOPRAZAN AND PROTON PUMP INHIBITORS ON BONE QUALITY AND FRACTURE RISK IN RHEUMATOID ARTHRITIS PATIENTS: INSIGHTS FROM BMD AND TBS ANALYSES

H.-A. Kim[1], J.-Y. Jung[1], M. J. Lim[2], Y.-A. Lee[3], J.-W. Kim[1], C.-H. Suh[1], Y. J. Choi[4]

[1]Ajou University School of Medicine/Department of Rheumatology, Suwon, South Korea, [2]College of Medicine, Inha University/Divison of Rheumatology, Department of Internal Medicine, Incheon, South Korea, [3]School of Medicine, Kyung Hee University/Divison of Rheumatology, Department of Internal Medicine, Seoul, South Korea, [4]Ajou University School of Medicine/Deparmtnet of Endocrinology and Metabolism, Suwon, South Korea

Background: Glucocorticoid-induced osteoporosis (GIO) poses a significant threat to rheumatoid arthritis (RA) patients undergoing long-term glucocorticoid therapy. Bone mineral density (BMD) and trabecular bone score (TBS) are essential tools for assessing bone quality and fracture risk. The effect of acid-suppressive therapies, including proton pump inhibitors (PPIs) and tegoprazan, on these bone parameters remains underexplored.
Objective: To evaluate the impact of tegoprazan and PPIs on bone quality and fracture risk in RA patients with GIO, with a focus on BMD and TBS changes.
Methods: This retrospective study involved RA patients treated with glucocorticoids and either tegoprazan or PPIs for at least three months. BMD and TBS were assessed using dual-energy X-ray absorptiometry (DXA), and osteoporotic fractures were confirmed via spinal radiographs. Multiple linear regression was conducted to analyze factors associated with annualized BMD percent change, and logistic regression was used to identify fracture risk factors.
Results: Among the 184 patients (92 in the tegoprazan group, 92 in the PPI group), baseline lumbar spine BMD was significantly higher in the tegoprazan group ($p<0.001$), but no significant differences were observed in TBS or femoral neck BMD. Multiple linear regression analysis indicated that tegoprazan had no significant effect on BMD changes ($\beta = -0.111$, $p = 0.505$ for lumbar spine; $\beta = -0.083$, $p = 0.556$ for femoral neck). However, the cumulative glucocorticoid dose during follow-up was a significant predictor of femoral neck BMD change ($\beta = -0.296$, $p = 0.046$). Logistic regression analysis revealed that cumulative glucocorticoid dose was also a significant risk factor for new-onset fractures (OR = 1.003, $p = 0.034$), but neither tegoprazan nor TBS changes showed significant associations with fracture risk in multivariate analysis.
Conclusions: This study highlights that tegoprazan does not significantly impact BMD or fracture risk compared to PPIs in RA patients with GIO. Cumulative glucocorticoid exposure remains a critical factor in both BMD reduction and fracture risk. Further prospective studies are needed to explore the long-term effects of tegoprazan on bone health.

P734

RECURRENT FRACTURES IN A YOUNG WOMAN: UNMASKING CUSHING'S DISEASE AND HYPERPROLACTINEMIA SECONDARY TO A FUNCTIONAL PITUITARY ADENOMA

K. A. Alnaqbi[1], A. K. Aljaberi[2]

[1]Rheumatology Division, Sheikh Tahnoon Medical City, Al Ain, United Arab Emirates, [2]Endocrinology Division, Sheikh Tahnoon Medical City, Al Ain, United Arab Emirates

Objective: To investigate the cause of recurrent bilateral metatarsal bones fractures and severe low bone mass in a 41-year-old Emirati woman with history of bariatric surgery, a one-year history of breast congestion and galactorrhea, and a 3-month of amenorrhea, hirsutism, and striae.
Materials and Methods: This patient was initially referred from the Orthopedic clinic to the rheumatology clinic for evaluation of osteoporosis. Comprehensive biochemical and hormonal profiling (vitamin D, PTH, prolactin, ACTH, cortisol, IGF-1), BMD assessment, FRAX evaluation, pituitary MRI, and histopathology were conducted to determine the underlying cause of osteoporosis.
Lab results showed severe vitamin D deficiency, hyperparathyroidism, and hyperprolactinemia, elevated ACTH and cortisol, and low IGF-1, consistent with pituitary dysfunction. BMD revealed levels severely below the age-expected range: L1-4 (0.947 g/cm², Z-score: -3.2), right femoral neck (0.777 g/cm², Z-score: -2.2), and left femoral neck (0.832 g/cm², Z-score: -1.8). FRAX indicated a 1.4% 10-year risk of major osteoporotic fracture and 0.3% for hip fracture. MRI and histopathology confirmed a corticotroph pituitary adenoma with Crooke's hyaline changes, consistent with Cushing's disease and hyperprolactinemia due to stalk compression. Symptoms resolved after transsphenoidal hypophysectomy and a short-term hydrocortisone replacement.
Results: Literature review revealed that Cushing's disease as a rare cause of secondary osteoporosis, with hypercortisolism increasing fracture risk. Hyperprolactinemia exacerbates bone loss via hypogonadism. Early diagnosis and surgical intervention improve outcomes.
Conclusion: Endocrine disorders like Cushing's disease and hyperprolactinemia should be considered in young patients with recurrent fractures. Early diagnosis and multidisciplinary management are crucial to prevent complications.

P735

A MULTIDISCIPLINARY CHALLENGE: RECURRENT FRACTURES, CUSHING'S SYNDROME, AND BREAST CANCER IN A 45-YEAR-OLD WOMAN

K. A. Alnaqbi[1], A. K. Aljaberi[2]

[1]Rheumatology Division, Sheikh Tahnoon Medical City, Al Ain, United Arab Emirates, [2]Endocrinology Division, Sheikh Tahnoon Medical City, Al Ain, United Arab Emirates

Objective: To investigate recurrent fractures and osteoporosis in a 45-year-old Pakistani woman referred for assessment of recurrent non-traumatic fractures.
Materials and Methods: The patient had diabetes mellitus, hypertension, anxiety, and a chronic thyroid cyst. She sustained six fractures: left and right metatarsal fractures (2020–2021) and left pubic ramus fractures (2020). Clinical findings included central obesity, oligomenorrhea, hand osteoarthritis, and telangiectasias. Normal tests included total ALP, corrected calcium, phosphorus, magnesium, prolactin and 24-hour urine catecholamines. Elevated morning serum cortisol, low ACTH, and unsuppressed cortisol on dexamethasone testing suggested Cushing's syndrome.
BMD was within the expected range for her age: L1-4 (1.078 g/cm², Z-score: -0.9), right femoral neck (0.944 g/cm², Z-score: -0.9), and left femoral neck (0.882 g/cm², Z-score: -0.9). FRAX indicated a 2.3% 10-year risk of major osteoporotic fracture and 0.3% for hip fracture.
SPECT-CT showed increased uptake in feet, ankles, wrists, and also in the pubic fractures site. CT revealed a left adrenal lesion suggestive of adenoma. She underwent left adrenalectomy and was started on hydrocortisone. Pathology suggested adrenocortical adenoma. After 2 years, she was diagnosed with metastatic breast cancer and treated with chemotherapy and denosumab.
Results: Literature review highlights that endogenous Cushing's Syndrome, often due to adrenal adenomas, is a significant cause of secondary osteoporosis and recurrent fractures. Hypercortisolism increases bone resorption and reduces bone formation, leading to fragility fractures. Early surgical intervention (adrenalectomy) improved hypercortisolism, but the emergence of metastatic disease necessitated integrated oncological management.
Conclusion: This case illustrates the imperative to evaluate for endocrine disorders, particularly Cushing's syndrome, in patients with recurrent fractures, even when BMD and FRAX scores appear reassuring. Multidisciplinary management is essential to address osteoporosis and associated comorbidities.
Disclosure and funding: None

P736

THE FIRST COMPARISON OF HIP FRACTURE INCIDENCE ACROSS 4 COUNTRIES IN AFRICA

C. L. Gregson[1], H. Wilson[1], A. Burton[1], M. K. Jallow[2], B. Trawally[3], L. S. Gates[4], T. Manyanga[5], J. Masters[6], R. A. Ferrand[5], M. Costa[6], K. Marenah[3], K. A. Ward[4]

[1]University of Bristol, Bristol, United Kingdom, [2]MRC Unit The Gambia @ London School of Hygiene and Tropical Medicine, Banjul, Gambia, [3]Department of Orthopaedics & Trauma, Edward Francis Small Teaching Hospital, Banjul, Gambia, [4]MRC Life-course Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [5]The Health Research Unit Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, [6]Oxford Trauma and Emergency Care, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Science, University of Oxford, Oxford, United Kingdom

Objectives: To determine age and sex specific hip fracture incidence rates in adults age ≥40 years in The Gambia, West Africa and compare with those from other African countries.
Methods: All hip fracture cases in adults aged ≥40 years, presenting to a hospital or traditional bone setter (TBS) in the study area over 2-years, were identified. Age- and sex- specific hip fracture incidence per 100,000 person-years were estimated using the 2024 Gambian Population census. Incidence estimates were compared between The Gambia, Zimbabwe[1], South Africa[2] and Botswana[3]. Future hip fracture numbers were estimated to 2054 using UN population projections.
Results: Over 2-years, 238 (67% female) patients, mean(SD) age 71.3(12.5) years, presented to hospital (197[82.8%]) or TBS (37[15.5%]). Most reported fragility fractures (217[91.2%]). Presentation >2 weeks after injury was common (70[29.4%]). Incidence rates in The Gambia were 28.0 and 56.2/100,000 person-years for men and women respectively. Hip fractures numbers are predicted to nearly quadruple, from 175 in 2024, to 656 in 2054.
Age-standardised hip fracture incidence rates were broadly comparable between The Gambia, Zimbabwe, Botswana, and the Black South African population (Figure-1). All countries see higher incidence in men than women until age >50 years. The highest incidence rates in women age 60-74 years were in The Gambia, and in women age >75 years in Zimbabwe.
Conclusions: These are the first hip fracture incidence data from West Africa. Fragility fractures in Gambian adults were common, indicative of age-associated osteoporosis. Across the 4 countries, hip fracture cases are predicted to at least double over coming decades; in The Gambia they will quadruple. Healthcare systems now need to pivot to provide fracture services for ageing populations.

INVESTIGATION OF THE CLINICAL RESPONSE OF ZOLEDRONIC ACID INJECTION AFTER 3- AND 5-YEARS TREATMENT COURSE IN POSTMENOPAUSAL OSTEOPOROSIS- A RETROSPECTIVE STUDY

K. Al Balushi[1], H. Al Harthi[1], D. Meenakshi[2]

[1]Khoula Hospital, Muscat, Oman, [2]National University of Science and Technology, Muscat, Oman

Background: Osteoporosis, characterized by bone fragility and increased fracture risk, is a global health concern. It affects millions of individuals with hip fractures, and the incidence is projected to rise substantially, especially in post-menopause women. The association between the duration of bisphosphonate therapy and the incidence of atypical fracture is still largely unknown, especially in long-term bisphosphonate therapy. Based on the above rationale, the present study aimed to assess and evaluate the long-term impact of zoledronic acid (ZA) treatment on bone mineral density (BMD) and fracture risk in Omani postmenopausal women after 3 & 5 years.

Objectives: To confirm the efficacy of ZA in maintaining BMD and reducing fracture risk over a longer duration than the standard 3-5 years treatment period among Omani women and to assess the safety profile of ZA.

Methodology: This is a retrospective observational study of the clinical response to ZA injection treatment at a tertiary care Trauma and Orthopaedic Centre in the Sultanate of Oman. Data was analyzed using SPSS-26 software. Continuous variables were described as mean, standard deviation (SD), median, and interquartile range (IQR). The Wilcoxon Signed Rank test with median and IQR was used for outcome variables showing non-normal distribution. Factors affecting the change in BMD outcome were assessed using independent samples (Kruskal-Walli's test). The significance level was considered at a p-value less than 0.05.

Results: A significant change in BMD at both hip and spine was observed, highlighting the effectiveness of the ZA treatment over a 2-year period. The BMD-hip increased from 0.578±0.099 g/cm2 at baseline to 0.596±0.102 g/cm2 after 2 years of treatment ($p < 0.001$) and BMD-spine, which increased significantly ($p < 0.001$) from a median of 0.619 to 0.699 g/cm2.

Conclusion: This study demonstrates the efficacy and safety of ZA in treating postmenopausal osteoporosis over a 3- and 5-year period. The results provide compelling evidence that ZA effectively reduces fracture risk and improves bone mineral density in this patient population. This study provides robust evidence supporting the use of ZA as an effective and safe treatment for postmenopausal osteoporosis.

BMD, Fragility fracture, Postmenopausal Osteoporosis, Zoledronic acid, Bisphosphonate.

P739

FACTORS AFFECTING MORTALITY AND QUALITY OF LIFE 1 YEAR AFTER SURGERY OF FRAGILITY HIP FRACTURES IN GREECE DURING THE ECONOMIC CRISIS

K. Alexiou[1], T. Karachalios[1], S. Varitimidis[1], K. Malizos[1]

[1]University of Thessaly, Larissa, Greece

Objective: Hip fractures are associated with a lower quality of the patient's life, increased morbidity and mortality. The primary aim of this study is to identify risk factors of mortality at twelve months after surgery for hip fracture and furthermore include the evaluation of functional outcomes and quality of life at the same period.

Material and Methods: Prospectively collected data from 597 patients with hip fractures that were treated in the tertiary hospital, and another 147 patients that were treated in a secondary hospital were available. The perioperative data were collected from medical charts and interviews. Functional Assessment Measure score, Short Form-12 and mortality were recorded at 12 months. Patients and surgery variables identified that were associated with increased mortality. Included all patients above 65 years of age, that were admitted to hospital with a fragility or geriatric hip fracture. Pathological and high energy fractures were excluded. All surgeries were performed from or under the supervision of fourteen trauma surgeons.

Results: In-hospital mortality was 2.4%. Mortality for the whole cohort was 19.4% at one year. In the tertiary hospital mortality was 18.3%, while in the secondary it was 23.0%. Functional outcome at one year was similar to preoperative status, even though their level of physical function dropped after the hip surgery and slowly recovered. From the variables tested BMI < 25, age > 80, CCI > 6, time to surgery > 48 hours, ASA ≥ 3, use of anti-coagulants and male sex was associated with increased mortality.

Conclusion: The study cannot affect or modify the treatment management of hip fractures which is based on early surgery. Nonetheless, it could possibly detect high risk patients so appropriate management is initiated early.

Keywords: hip fractures; mortality; functional outcome; time to surgery

BERTOLOTTI SYNDROME – HIDDEN CAUSE OF LOWER BACK PAIN

S. Delezan[1], L. J. Drazic[2], K. Boskovic[1], J. Zvekic - Svorcan[1], T. Tasic[1], N. Bastaja[1], T. Bjeletic[1]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [2]Special Hospital for Rheumatic Diseases, Novi Sad, Serbia

Objectives: Differential radiological evaluation in a female patient with lower back pain syndrome (LBPS) with a focus on Bertolotti syndrome (BS). BS is characterized by the presence of a lumbosacral transitional vertebra, in the form of an enlarged transverse process of the fifth lumbar vertebra (greater than 19 mm), with a tendency toward pseudoarticulation or fusion with the sacrum, with or without compromise of the nerve roots. Based on the presence of pseudoarthrosis, BS is classified into four groups according to the Castellvi classification, with two subgroups: A (unilateral) and B (bilateral).
Material and Methods: A 76-year-old female patient presents with chronic pain in the hips and lower back. Radiographs of the pelvis in the AP lying position were performed on a Philips DuraDiagnostic F30 machine. Ethical approval (No. 14/01-2/1-25, 13.01.2025.) was obtained from the ethics committee of the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia, and the patient signed an informed consent form.
Results: An oval bony formation, approximately 30 mm in size, is positioned para-vertebral and suprasacral on the left side of the fifth lumbar vertebral body. This formation could belong to the transverse process of the fifth lumbar vertebra or an extension of the lateral side of the first sacral vertebra. The above-described findings may indicate Bertolotti syndrome type IIIa, according to the Castellvi classification, based on the absence of pseudoarthrosis.

Conclusion: The pelvic X-ray raises suspicion of Bertolotti syndrome. The patient has been referred for a CT scan of the lumbar spine to confirm the definitive diagnosis.

P741

GLUCOCORTICOID - INDUCED OSTEOPOROSIS IN A PATIENT WITH SJÖGREN'S SYNDROME – CASE REPORT

S. Delezan[1], S. Mandic[2], K. Bjelic[3], B. Erdeljan[4], J. Zvekic - Svorcan[1], T. Jankovic[1], K. Boskovic[1]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [2]University of Novi Sad, Faculty of Medicine Novi Sad. Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia, [3]University of Novi Sad, Faculty of Medicine Novi Sad. Health Center Novi Sad, Novi Sad, Serbia, [4]Special Hospital for Rheumatic Diseases, Novi Sad, Serbia

Objective: Case report of a patient suffering from Sjögren's syndrome (SS) with iatrogenic osteoporosis and multiple fractures caused by glucocorticoids (GCs).
Material and Methods: A 62-year-old female patient was hospitalized at the Special Hospital for Rheumatic Diseases in Novi Sad due to osteoporosis and multiple fractures. Clinical, radiological (DXA), basic laboratory and bone metabolism marker tests were performed. Ethical approval (No. 14/02-1/1-25, 27.01.2025.) was obtained from the ethics committee of the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia, and the patient signed an informed consent form.
Results: The first symptoms, including dryness of the eyes and mouth, difficulty swallowing, joint pain, and swelling of the neck lymph nodes, appeared in 2003. This coincided with laboratory confirmation of leukopenia and anemia, and the diagnosis of primary SS was made. Glucocorticoid therapy was initiated. In 2010, the patient's symptoms worsened, presenting as acute polyarthritis with morning stiffness. Antimalarials and GCs were introduced into the treatment regimen. Due to inadequate clinical response, methotrexate was added to the therapy but was soon discontinued due to leukopenia and anemia. Treatment continued with antimalarials and GCs. In 2019, an attempt to discontinue GC therapy led to an exacerbation of symptoms. Due to anemia, a pathohistological examination of a bone marrow biopsy was performed, which revealed hypoplastic changes and osteoporosis. In late 2013, after a fall, the patient sustained pathological fractures of Th6 and Th7 vertebra. In 2019, a fracture occurred at Th12 vertebra, followed by a fracture of the fourth finger of the right hand in 2020, and a fracture of L3 vertebra in 2024. Recent laboratory results for bone markers show moderate activity of bone structure breakdown, while the DXA scan suggests osteopenia. The ESSDAI score is 20 and the ESSPRI score is 8.33. Despite prolonged use of antimalarials and GCs, adequate disease control has not been achieved. In November 2024, sulfasalazine was replaced with azathioprine.
Conclusion: Although an attempt was made to de-escalate GC therapy due to osteoporosis, there are currently no effective therapeutic options. The patient will be reevaluated for more modern treatments for osteoporosis and SS.

P742

OSTEAOATHRITIS IN STROKE PATIENTS - THE IMPACT ON REHABILITATION TREATMENT AND HEALTH-RELATED QUALITY OF LIFE

D. Simić-Panić[1], K. Bošković[1], A. Knežević[1], S. Pantelinac[1], D. Popović[1], L. Subić[2], S. Tomašević-Todorović[2]

[1]Medical Faculty of Novi Sad, University of Novi Sad, Novi Sad, Serbia, Novi Sad, Serbia, [2]Medical Rehabilitation Clinic, University Clinical Center of Vojvodina, Novi Sad, Serbia, Novi Sad, Serbia

Objective: Osteoarthritis has been identified as a potential risk factor for stroke, as well as potential hinderance for stroke rehabilitation. The aim of this study was to determine the prevalence of osteoarthritis among stroke patients and compare health-related quality of life (HRQoL) and rehabilitation outcome between patients with and without osteoarthritis.
Material and Methods: This research was designed as a prospective cross-sectional study. A total of 150 stroke patients were consecutively recruited at the Medical Rehabilitation Clinic, Clinical Center of Vojvodina, Serbia. The presence of osteoarthritis of the hip or knee was determined at the beginning of the rehabilitation treatment using clinical evaluation and radiographic findings. At the end of the treatment, health-related quality of life (HRQoL) was determined by means of the Medical Outcomes Study 36-item Short Form (SF-36). Functional status was evaluated using Barthel index (BI). Multiple regression analysis was performed to determine the factors affecting the HRQoL of the stroke group.
Results: The overall prevalence of osteoarthritis in stroke patients was 25.56%. A significantly higher prevalence was registered in female patients (38.26%) compared to male patients (17.67%). The mean role physical score of the group of patients with osteoarthritis was lower than in the group of patients without osteoarthritis (17.86% vs. 25.17%). Osteoarthritis was associated with significantly lower BI at discharge and prolonged hospital stay.
Conclusion: Osteoarthritis impairs recovery from stroke and negatively impacts health-related quality of life (HRQoL) in stroke patients. Therefore, these patients require longer lengths of stay for inpatient medical rehabilitation. Osteoarthritis needs to be considered when planing the rehabilitation treatment for stroke patients.

EFFECTS OF RESISTANCE TRAINING ON TIBIAL STRUCTURE IN POSTMENOPAUSAL WOMEN: THE REPROOF STUDY

O. Caliskan[1], E. A. Marques[2], R. L. Duckham[3], M. Ó Breasail[4], B. Ahmad[1], J. P. Folland[1], K. Brooke-Wavell[1]

[1]Loughborough University, Loughborough, United Kingdom, [2]University of Kalba, Kalba, United Arab Emirates, [3]Deakin University and University of Melbourne, Melbourne, Australia, [4]Monash University, Melbourne, Australia

Objective High-load conventional resistance training (CRT) is recommended to prevent bone loss. Ballistic resistance training (BRT) maximises power by explosively lifting light/moderate loads. This study investigated the effects of CRT and BRT, relative to control (CON), on tibial structure in postmenopausal women.
Methods The Resistance Exercise Programme on Risk of Osteoporosis and Osteoarthritis in Females (REPROOF) trial, randomised healthy postmenopausal women (>4 years) into BRT, CRT, or CON. The BRT and CRT involved supervised resistance training with hack squats and calf raises twice weekly for 8 months, with training loads of 20-50% and 60-80% 1-repetition maximum, respectively. Peripheral quantitative computed tomography (Stratec XCT2000L, voxel size 0.5mm, slice thickness 2 mm) was used to scan at 66% of the left tibia length. Cortical volumetric BMD (vBMD), thickness, and circumferences were analysed, and the BoneJ plug-in for ImageJ analysed mass/density distribution around the centre of bone mass (polar distribution) and through the bone cortex (radial distribution) (figure 1A). Paired t-tests and ANCOVA with baseline values as covariates assessed within-group and between-group comparisons, respectively.
Results Of 109 randomised participants, 76 (27 BRT, 26 CRT, 23 CON, mean age 63.1±3.7) completed the training programme and had available scans. The mean training adherence was ~98% in both groups. When adjusted for baseline values, there was a significant increase in cortical vBMD (mean difference: 3.18 (CI:0.05,6.31)) mg/cm^3, P=0.047), and a decrease in cortical thickness (mean difference: 0.07 (CI:-0.13,-0.01, mm P=0.033) in the CRT relative to CON. This was due to a greater percentage increase in endosteal (1.7%, P=0.012) than pericortical circumference (0.8%, P=0.034) in the CRT group. Local cortical mass increased by 1.3% in the anterior-lateral tibia region in CON (P=0.034) only. CRT significantly increased pericortical radial density distribution by 0.3% (P=0.045) with no change at the endo- and mid-cortical distribution. No significant structural adaptations were observed in the BRT group compared to CON.

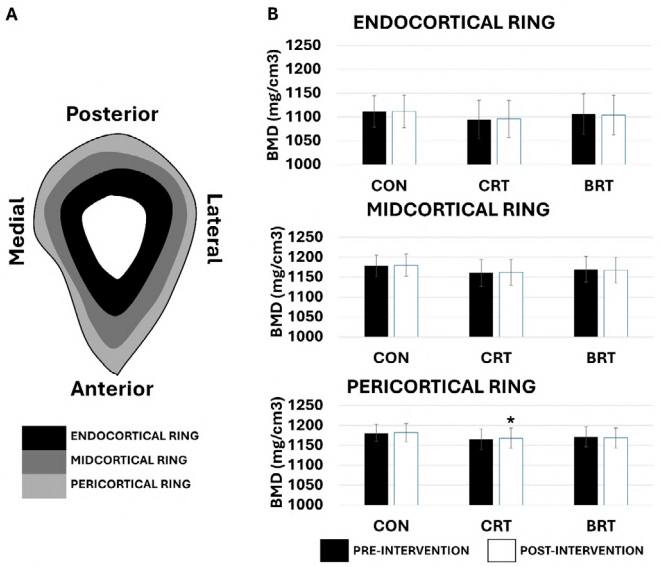

Figure1: A) regions of interest B) Mean±SD cortical BMD (g/cm3)
*post different from pre-intervention P<0.05

Conclusion CRT produced greater structural adaptations than BRT and CON, involving cortical expansion and increased vBMD, particularly in the pericortical ring at the mid-tibia shaft. This adaptation may increase strength in bending, which would be expected to reduce fracture risk.

P744

BONE MINERAL DENSITY IN ADULTS WITH DOWN'S SYNDROME: A CROSS-SECTIONAL STUDY IN A BRAZILIAN SAMPLE

K. Chrisostomo[1], A. Fedrigo[2], T. Skare[3], G. Levandoski[3], N. Oliveira[2], R. Nisihara[2]

[1]Federal University of Parana - Department of Tocogynecology, Curitiba, Brazil, [2]Federal University of Parana - Internal Medicine Post Graduate, Curitiba, Brazil, [3]Mackenzie Evangelical School of Medicine Parana - Department of Medicine, Curitiba, Brazil

Background
We aimed to investigate the relationship between bone mass in a sample of Brazilian individuals with Down's syndrome (DS) and handgrip strength, body mass index (BMI), and physical exercise.
Methods
Dual-energy X-ray absorptiometry was used to analyse bone mass in 26 individuals with DS (8 men and 18 women, mean age 30.7 ± 10.3 years). Weight and height were measured to calculate BMI, handgrip strength was assessed using a Jamar dynamometer®, and physical activity levels were classified using the International Physical Activity Questionnaire (IPAQ).
Results
In this sample, 2/15 (13.3%) individuals aged 18 to 29 years had low BMD in the spine; 2/8 (25%) of those aged 30 to 39 years also had low BMD in the spine, and 2/3 (66.6%) of those aged ≥40 years had low BMD in the femur. Significant correlations were observed between handgrip strength and femoral neck Z-score in women (P = 0.02) and between BMI and femoral neck Z-score in men (P = 0.04). All other correlations were not statistically significant (P > 0.05).
Conclusions
Brazilian patients with Down's syndrome showed a high prevalence of low bone mass. Traditional factors such as muscle strength, BMI, and physical activity appear to have minimal influence on bone mineral density in this population.

P745

DIFFERENT DOSE OF VITAMIN D SUPPLEMENTATION AND ITS EFFECTS ON OSTEOPOROSIS PATIENTS IN LATVIA: A 5-YEAR RETROSPECTIVE STUDY REAL-WORLD DATA AT THE RIGA EAST UNIVERSITY HOSPITAL (REUH)

K. E. Berzina[1], I. Rasa[1]

[1]Riga East University Hospital, Rīga Stradiņš University, Latvian Osteoporosis and Bone Metabolic Diseases Association, Riga, Latvia

Objectives. Osteoporosis is a condition that causes bones to become weak and porous. Vitamin D may help with osteoporosis because of its role in bone growth and remodelling. If a person with osteoporosis regularly obtains adequate amounts of vitamin D, it can help promote calcium absorption, which is essential for good bone health and is associated with a lower risk of fractures. This research aims to investigate patients with osteoporosis in Latvia, focusing on their intake of supplements and the effects of those supplements.
Materials and Methods. A retrospective study analyzed data from 505 unique osteoporosis patients treated at REUH, all treated in one centre. Data were collected from 2020 to 2024 and analyzed using IBM SPSS 29.0.
Results. Of 505 patients with a mean age of 68.3±9.4SD years, 90.3% (n=456) were female, 37.6% (n=190) of patients have had fractures, of which 74.7% (n=142) occurred before they started osteoporosis therapy. Calcium supplements 500mg were taken by 82.4% (n=416) daily. Vitamin D by 89.3% (n=451). The prescribed vitamin D doses ranged from 1000IU daily to 50000IU weekly. 18.6% (n=8) of patients who had fractures while receiving osteoporosis treatment had vitamin D levels below 30±0.1ng/ml, compared to only 11.8% (n=40) of all other patients. In general, 12.2% (n=53) of patients had vitamin D levels below 30±0.1ng/ml, which dropped to 5.3% (n=24) after one year of adequate supplementation. The largest average increase in vitamin D level over a year was observed in patients who received 8000IU per day, with a 45% increase noted for 32 patients. The most prescribed dose of vitamin D was 4000IU (n=101), which increased levels by 11.4% in a year. Lower vitamin D doses, 1000IU to 2000IU were less effective, with increases below 0.6% or even decreases.
Conclusion. The study found that most patients with osteoporosis take calcium and vitamin D daily. Vitamin D is generally taken in appropriate doses that maintain adequate blood levels.

P746

BONE MINERAL DENSITY, TRABECULAR BONE SCORE AND HIP STRUCTURAL ANALYSIS IN CHRONIC GLUCOCORTICOID USERS ATTENDING A TERTIARY CENTRE IN SOUTHERN INDIA

K. E. Cherian[1], N. Kapoor[1], V. Paul[1]

[1]Christian Medical College Vellore, VELLORE, India

Objectives: Glucocorticoids (GC) are used for various chronic medical conditions and is one of the most abused drugs in India. Despite widespread GC use, there is lack of knowledge among physicians regarding assessment and management of glucocorticoid induced osteoporosis(GIO). This study was performed to assess bone mineral density(BMD), trabecular bone score(TBS) and hip structural analysis(HSA) in chronic steroid users.
Material and Methods: An observational study done over eight years. Details of patients were obtained through archived medical records. Bone biochemical parameters and densitometric variables that included bone mineral density(BMD), trabecular bone score(TBS) and hip structural analysis(HSA) were assessed by a DXA(Hologic Horizon) scanner.
Results: A total of 74 subjects (56 females, 45/56 postmenopausal) with a mean(SD) age and BMI of 49.5(12.5) years and 29.0(6.9) kg/m^2 were studied. Vitamin D deficiency was present in 33/74(44.6%) of subjects. Fifteen subjects (20.3%) had sustained fragility fractures. At baseline, the prevalence of osteoporosis/low bone mass at neck of femur and lumbar spine was 24/74(32.4%) and 34/74(45.9%) respectively. Degraded trabecular microarchitecture as defined by a TBS<1.200 was present in 32/74(43.2%) of the subjects. Among those with normal BMD at the lumbar spine, 13/40(32.5%) had a low TBS. Buckling ratio(BR) at the narrow(NN) neck > 10 was seen in 57/74 (77%) of subjects. Among subjects with normal BMD at the femoral neck, 33/50 (66%) had a BR at NN >10, which indicates high fracture risk.
Conclusion: GIO continues to be prevalent among steroid users. TBS and HSA may confer additional benefit regarding bone health, not conveyed by conventional BMD assessment in chronic glucocorticoid users.

P747

UTILITY OF FRAXPLUS® IN PREDICTING RADIOGRAPHIC PREVALENT VERTEBRAL FRACTURES IN IN RURAL SOUTHERN INDIA - A CROSS-SECTIONAL STUDY

K. E. Cherian[1], J. Cherian[2], V. Paul[1]

[1]Christian Medical College Vellore, VELLORE, India, [2]Christian Hospital Ambilikkai, VELLORE, India

Objectives: The prevalence of vertebral fractures in urban postmenopausal women in India is about 30 - 35%. Dual Energy X-Ray Absorptiometry (DXA) is not widely available in India. In this cross-sectional study we aimed to identify the prevalence of vertebral fractures in rural postmenopausal women and to assess the utility of FRAXplus® in them.
Material and Methods: This was a cross-sectional study done over six months in 150 postmenopausal women presenting to the Medicine and Endocrinology Outpatient Department in a secondary care hospital in rural India. FRAX®, and FRAXplus® (where appropriate) were used for assessment of fracture risk along with X-ray of the thoraco-lumbar spine to identify vertebral fractures (Genant classification). The sensitivity and specificity of FRAXplus® for predefined Indian thresholds and new cut-offs were studied.
Results: The mean (SD) age of the patients was 66.1(6.5) years. The prevalence of moderate to severe vertebral fractures was 34%. Forty-four subjects had FRAX- MOF cut-off ≥ 10.5 and 57 had FRAX-HF cut-off ≥ 3.5. Fifty percent (n=22) of subjects with high FRAX-MOF and 49 % of high FRAX-HF had moderate to severe prevalent radiographic vertebral fractures. FRAXplus® correction was utilized in 34 Subjects (23%) for falls (n-=30) and glucocorticoids(N=4). On ROC analysis (Table 1, Figure 1), FRAXplus®-MOF score cutoff of 10.5 had a sensitivity of 45% and specificity of 73%. A cut-off of 6 had a sensitivity of 80% and 40% specificity for FRAXplus®-MOF and cutoff of 1.5 for FRAXplus®-HF had a sensitivity of 76% and 40 % specificity.
Conclusion: FRAXplus® may be a useful tool in predicting prevalent vertebral fractures in postmenopausal women in a resource limited setting and may be used to guide treatment.

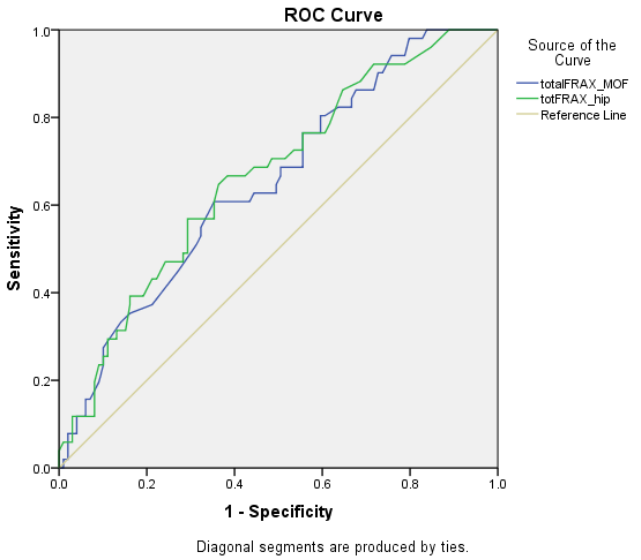

Figure 1: ROC curve of FRAXplus® in predicting vertebral fractures

Test	AUC	95% CI	P-value
FRAXplus MOF	0.653	0.563-0.743	0.003
FRAXplus hip	0.700	0.578-0.758	0.001

Table 1: AUC of FRAXplus® in predicting prevalent vertebral fractures

WOMEN WITH GRAVES' DISEASE HAVE DERANGED PROXIMAL HIP GEOMETRY, TRABECULAR BONE SCORE AND BODY COMPOSITION PARAMETERS: A CASE-CONTROL STUDY FROM SOUTHERN INDIA

K. E. Cherian[1], N. Kapoor[1], V. Paul[1]

[1]Christian Medical College Vellore, VELLORE, India

Objectives: While it is well known that hyperthyroidism is associated with decreased bone mineral density, other DXA-derived indices such as proximal hip geometry and body composition parameters have not been well studied in India. The present study was undertaken to comprehensively assess DXA-derived parameters in premenopausal women aged 25-45 years, and to compare these matched female controls.

Materials and Methods: A case-control study done over a period of one year. DXA-derived parameters such as bone mineral density (BMD), trabecular bone score (TBS), hip structural analysis (HSA), body composition and bone biochemical parameters were assessed.

Results: Forty-one premenopausal subjects with hyperthyroidism and 74 age and BMI matched controls were recruited. The mean (SD) ages of cases and controls were 34.5(6.3) and 33.8(5.2) years respectively. The bone turnover markers (C-terminal telopeptide of type 1 collagen and N-terminal pro-peptide of type 1 procollagen) were significantly higher among cases as compared to controls (P<0.001). The BMD at lumbar spine(LS), neck of femur (NOF) and trabecular bone score were significantly lower in cases when compared to controls (p<0.05). Several parameters of proximal hip geometry at all 3 sites were impaired in subjects with Graves' disease as compared to controls (Table 1). A significantly greater proportion of cases had sarcopenia when compared to controls (27% versus 1.4 %; p<0.001)

Conclusion: In rural premenopausal subjects from southern India, with hyperthyroidism, a comprehensive assessment utilizing BMD, TBS and HSA may be used for a holistic evaluation of bone fragility.

EXPLORING THE BMD-TBS-BSI PARADOX IN PATIENTS WITH END-STAGE KIDNEY DISEASE – AT BASELINE, ACROSS THE TRANSPLANT TRANSITION AND BEYOND: A PROSPECTIVE STUDY

K. E. Cherian[1], S. Sundar Raj[1], N. Kapoor[1], V. Paul[1]

[1]Christian Medical College Vellore, VELLORE, India

Objectives: Much remains unknown with regards changes in densitometric indices following renal transplant in Asians with end-stage kidney disease(ESKD). This prospective study aimed to comprehensively assess bone health in renal transplant recipients at baseline and at 3, 12, and 48-months post-transplant.
Material and Methods: A prospective study in which consecutive patients with ESKD scheduled for renal transplant were recruited. Evaluation included renal and bone biochemical parameters and densitometric indices such as bone mineral density (BMD), trabecular bone score (TBS) and the bone strain index (BSI) at baseline, and at 3, 12, and 48-months post-transplant.
Results: A total of 53 patients(Females =15) were recruited. The mean (SD) age was 33.9(10.3) years. A repeated measures ANOVA showed that the mean BMD at the total hip and distal forearm showed an improving trend; the lumbar-spine BMD did not significantly differ during the period of follow-up. However, the TBS showed a significant decline from baseline to 4 years (P=0.001). The BSI of the lumbar spine increased progressively, indicating a higher tendency to fracture(Figure 1). Incident vertebral fractures occurred in 3 patients in the first year. Concentrations of parathormone, creatinine, phosphate, C-terminal telopeptide of type 1 collagen and N-terminal telopeptide of type 1 procollagen differed significantly between time points (P < 0.01).
Conclusion: This prospective study in renal transplant recipients showed BMD at all sites to be stable. Paradoxically, the TBS and BSI continued to deteriorate. Incorporating TBS and BSI in addition to conventional BMD assessment in renal transplant recipients is required to gain insights into the qualitative aspects of bone strength.

P750

BONE FRAGILITY IN ACROMEGALY – HOW DO DENSITOMETRIC INDICES PERFORM? A CASE CONTROL STUDY FROM INDIA

K. E. Cherian[1], N. Kapoor[1], V. Paul[1]

[1]Christian Medical College Vellore, VELLORE, India

Objectives: While growth hormone (GH) is a bone anabolic hormone, its persistent elevation is associated with increased bone turnover and deterioration of bone health. Bone fragility in individuals with acromegaly is not well studied in India. This study was undertaken to assess the performance of various densitometric indices in assessing bone health in patients treated for acromegaly.
Materials and Methods: A case-control study in which individuals with a GH-secreting pituitary adenoma, operated in the last ten years were recruited over a period of two years. Bone mineral parameters and densitometric indices including bone mineral density (BMD), prevalent vertebral fractures, trabecular bone score (TBS), hip structural analysis (HSA) and bone strain index (BSI) were studied.
Results: A total of 50 subjects operated for acromegaly were recruited at a median duration of 3 (1-10) years post-surgery and compared with 53 controls. The mean (SD) age of the cases and controls were 40.2 (11.9) and 40.5 (11.9) years respectively. The BMD at the neck of femur and forearm were significantly higher in cases. While the lumbar spine BMD was not significantly different between cases and controls, the TBS was significantly lower among cases as compared to controls (Table 1). The prevalence of vertebral fractures was higher among cases (34%) as compared to controls (17%); P=0.04. Parameters of hip structural analysis was enhanced in cases; BSI was not significantly different between the two groups.
Conclusion: Prevalent vertebral fractures and trabecular bone score may be better indices of bone fragility in individuals with acromegaly as compared to bone mineral density as a standalone measure.
Table 1: Comparison of BMD and TBS between cases and controls

Parameters	Cases (N-50) Mean±SD	Control (N-53) Mean±SD	P-value
Femoral Neck BMD (g/cm^2)	0.849±0.123	0.770±0.144	0.013
Lumbar Spine BMD (g/cm^2)	0.995±0.135	0.990±0.169	0.893
Forearm BMD (g/cm^2)	0.740±0.698	0.697±0.100	0.047
Trabecular Bone Score	1.301±0.090	1.344±0.090	0.023

TBS-ADJUSTED T-SCORES AND BONE STRAIN INDEX PRESENT A NEW PARADIGM IN EVALUATING BONE FRAGILITY IN INDIAN POSTMENOPAUSAL WOMEN: A CROSS-SECTIONAL STUDY

K. E. Cherian[1], N. Kapoor[1], V. Paul[1]

[1]Christian Medical College Vellore, VELLORE, India

Objectives: Trabecular Bone Score (TBS) has been incorporated as an input variable in FRAX to improve fracture risk prediction. An alternate approach for using TBS in clinical practice was recently proposed based on a risk-equivalent offset adjustment to bone mineral density (BMD) T-scores. Bone Strain index (BSI) is a novel densitometric tool that indicates the level of strain inside the bone. This study was undertaken to assess the utility of the TBS-adjusted BMD T-scores and BSI in prevalent vertebral fractures in Indian postmenopausal women.

Materials and Methods: A cross-sectional study in which 560 community dwelling postmenopausal women aged over 50 years were recruited. Bone biochemical parameters and densitometric indices such as bone mineral density (BMD), trabecular bone score (TBS), prevalent vertebral fractures and bone strain index were assessed. TBS-adjusted BMD T-scores were computed from previously described formulae.

Results: The mean (SD) age of the study participants was 59.4(6.8) years. Prevalent moderate-severe vertebral fractures was present in 165/560 (29.4%) of individuals. Among the DXA-derived indices at the lumbar spine, the odds of prevalent vertebral fractures was highest with TBS-adjusted lumbar spine T-score (OR=1.8; 95% CI: 1.2-2.6) followed by lumbar spine BSI (OR=1.5; 95% CI=1.0-2.1) and unadjusted lumbar spine T-score (OR=1.4; 95% CI: 0.9-2.0). The sensitivity for detection of prevalent vertebral fractures was highest with the femoral neck BSI followed by the TBS adjusted T-scores at the lumbar spine and BSI at the lumbar spine. and (Table 1).

Conclusion: TBS-adjusted BMD T-scores and BSI had a higher sensitivity in detecting prevalent vertebral fractures and may be a new paradigm in assessing bone fragility in Indian postmenopausal women, not captured by standalone BMD measurements.

Table 1: Performance of various densitometric indices in deetecting prevalent vertebral fractures

Parameter	Sensitivity (%)	Specificity (%)	Positive predictive value (%)	Negative predictive value (%)
LS BMD T-score	46.1	62.5	33.9	75.7
FN BMD T-score	36.9	81.5	45.5	75.5
TBS adjusted LS BMD T-score	54.5	60.5	36.5	76.1
TBS adjusted FN BMD T-score	41.2	75.1	40.9	75.4
High LS BSI	53.9	56.4	34.1	74.5
High FN BSI	58.7	53.9	34.7	75.8

T-score cut-off: ≤ minus 2.5

BSI cut-off: ≥ 1.68

Disclosures: None

OSTEOPOROSIS TREATMENT INDICATION AFTER RECENT FRACTURE: IMPORTANCE OF INDEX FRACTURE SITE – A RESTROSPECTIVE COHORT STUDY

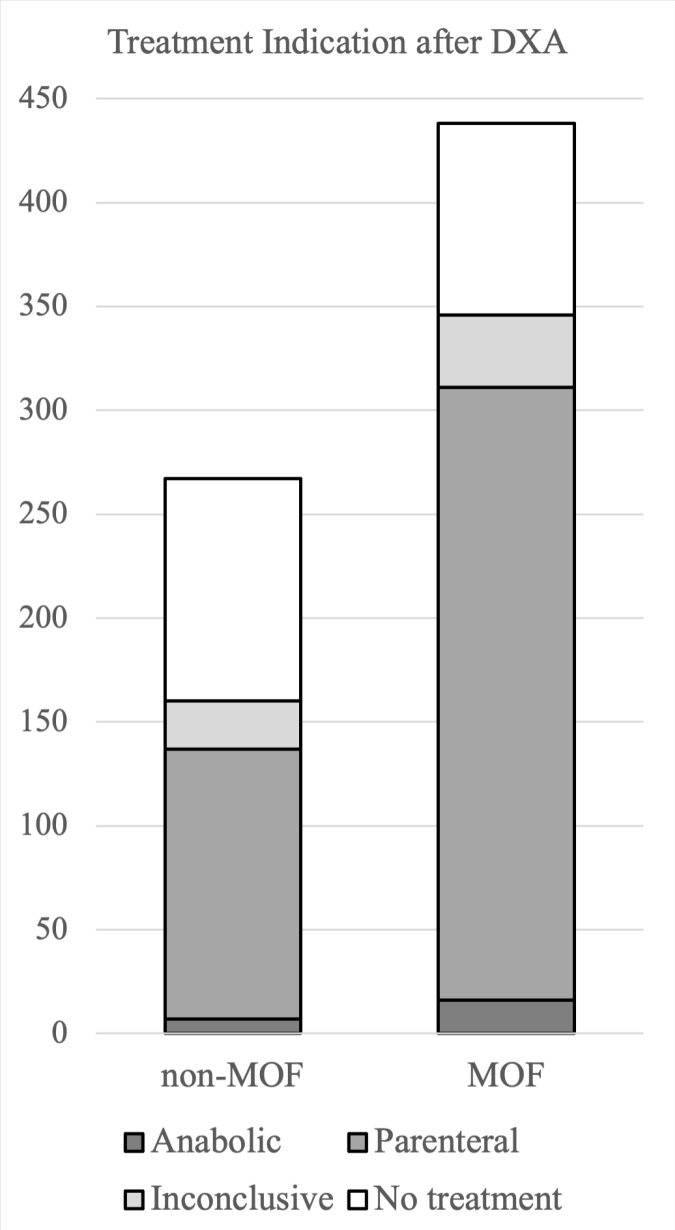
C. Florberger[1], M. Lorentzon[1], J. Merina[2], E. Bertholds[2], H. Litsne[1], K. F. Axelsson[1]

[1]Geriatric Medicine, Institute of Medicine, Sahlgrenska Academy, Gothenburg University, Mölndal, Sweden, [2]Osteoporosis Center, Skaraborgs Hospital, Skövde, Sweden

Background: Fracture Liaison Services (FLS) identify patients with recent fractures and after investigation provide treatment to prevent subsequent fractures. Traditionally, many services has been limited to include only Major Osteoporotic Fractures (MOF, i.e. fractured vertebrae, hip, proximal humerus, wrist, and pelvis). However, recent studies have found that recent fractures at other bone sites are also associated with increased risk for subsequent fracture. This study aimed to compare key characteristic, fracture risk factors and indication for osteoporosis treatment in patients with a recent non-MOF to patients with recent MOF after being included in an FLS at Skaraborg Hospital in Skövde, Sweden.

Methods: Patients with a bone mineral density (BMD) measurement between December 2023 and May 2024, with a recent fracture and 50 years or older were included (N=705). The patients' age, sex, FRAX risk factors, FRAX-score, BMD, trabecular bone score, vertebral fracture (VF) assessment identified VFs, and physician issued osteoporosis treatment recommendation after the FLS evaluation were collected. Differences non-MOF vs MOF were analyzed using t-test, chi-square tests and standardized mean differences. The odds ratio (OR) for receiving a recommendation (yes/no) to provide the patient with osteoporosis medication was calculated using logistic regression non-MOF vs MOF, with

increasing levels of adjustment for confounders.
Results: There were high rates of osteoporosis treatment indication in both non-MOF (51%) and MOF (71%) patients, and corresponding low numbers needed to screen to identify 1 patient with osteoporosis treatment indication, in both non-MOF (1.95) and MOF patients (1.41). There were similar characteristics and risk profiles in both non-MOF and MOF patients with osteoporosis treatment indication.
Conclusion: Patients with recent non-MOF and MOF should all be included in secondary prevention programs, since the proportions with treatment indications are high regardless of fracture category.



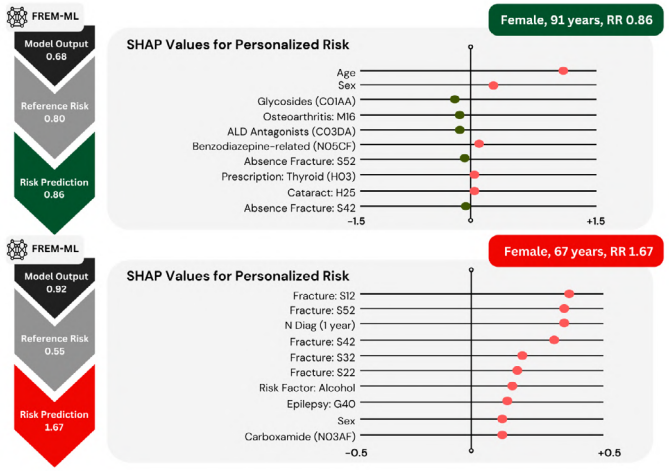
P753

INTRODUCING FREM_ML: MACHINE LEARNING FOR AUTOMATED IDENTIFICATION OF INDIVIDUALS AT HIGH IMMINENT FRACTURE RISK IN GENERAL PRACTICE

M. Rietz[1], J. C. Brønd[2], S. Möller[3], J. Søndergaard[4], B. Abrahamsen[3], K. H. Rubin[3]

[1]Research Unit OPEN, Department of Clinical Research, University of Southern Denmark and Division of Clinical Physiology, Department of Laboratory Medicine, Karolinska Institutet, Odense, Denmark, [2]Research Unit for Exercise Epidemiology, Department of Sports Science and Clinical Biomechanics, Centre of Research in Childhood Health, University of Southern Denmark, Odense, Denmark, [3]Research Unit OPEN, Department of Clinical Research, University of Southern Denmark, Odense, Denmark, [4]Research Unit for General Practice, Department of Public Health, University of Southern Denmark, Odense, Denmark

Objective
To innovate the Danish Fracture Risk Evaluation Model (FREM) using machine learning to better predict the imminent (one-year) risk of major osteoporotic fractures (MOFs) in the Danish population ≥45 years
Material and Methods
The $FREM_{ML}$ Dropouts meet multiple Additive Regression Tree (DART) boosting algorithm was trained and validated using complete registry data extracted for the Danish population ≥45 years without previous osteoporosis diagnoses or osteoporosis-related treatment (N=2,472,912). Predictors of MOFs (2022), automatically extracted for the 15-year lookback period (2007-2021), included hospital diagnoses, filled medication prescriptions, days since last redemption of fall- and osteoporosis-specific risk medication, and markers of polypharmacy and multi-morbidity. Model outputs were evaluated in the context of explainable artificial intelligence (AI). Risk prediction outputs were backed by SHapley Additive exPlanations (SHAP) values
Results
$FREM_{ML}$ displayed an overall area under the curve (95%CI) of 0.77 (0.76, 0.77) – making it superior to previous versions of FREM. While age and sex were the most relevant predictors of MOF events, advanced feature engineering, including temporal information, contributed to model performance. Importantly, SHAP values allowed for the clinical interpretation of predicted relative risks considering age and sex. Two case examples are shown in Figure 1: a 67-year-old female at elevated risk and a 91-year-old female at lower risk compared to a female of the same age.
Figure 1: Case Examples



Conclusion

The open-source FREM$_{ML}$ boosting model, enhanced by explainable AI, provides an effective decision-support tool for identifying individuals at high imminent risk of fractures, supporting physicians in deciding who to refer for dual-energy X-ray absorptiometry. By incorporating age- and sex-specific thresholds, this system offers a promising approach to improving primary detection of osteoporosis and preventing fractures in an aging population

P754

RELATIONSHIP BETWEEN FASTED GLYCATED HEMOGLOBIN (HBA1C) AND TRABECULAR BONE SCORE ADJUSTED FOR TISSUE THICKNESS (TBS OSTEO, VERSION 4)

M. Swainson[1], K. Hind[1], G. Gatineau[2], M. Davies[3], M. De Gruttola[3], D. Hans[2]

[1]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom, [2]CHUV, University of Lausanne, Lausanne, Switzerland, [3]Medimaps Group, Geneva, Switzerland

Objective:

Trabecular bone score (TBS) is a validated index of bone microarchitecture, used alongside bone mineral density (BMD) to enhance the assessment of bone health and fracture risk. Previous studies demonstrate associations between TBS, type 2 diabetes and glycemic control, but TBS version 3, adjusted for body mass index (BMI), may not fully account for increased central adiposity. The new TBS version 4 adjusts for tissue thickness, addressing this limitation. Therefore, this study compares TBS v3 and v4 in their relationships with glycated hemoglobin (HbA1c), a marker of glycemic control.

Methods:

In this single center study, 111 male and female (65%) participants (mean age: 50.8±9.5 years) received dual-energy X-ray absorptiometry scans (GE iDXA) of the lumbar spine to derive TBS and BMD, and the total body, for visceral fat. Fasting blood samples were collected during the same visit and analysed for HbA1c.

Results:

The mean values for the cohort were: HbA1c, 35.4±3.1 mmol/mol (range: 28.0–45.0); BMI, 25.4±3.8 kg/m² (range: 19.1–36.7); TBS v3, 1.41±0.1 (1.12–1.63); and TBS v4, 1.38±0.1 (1.11–1.62). TBS v3 and v4, but not BMD, were negatively correlated with age. No significant correlations were observed between BMI or tissue thickness, for either TBS version, whereas BMD was positively associated with BMI. Furthermore, no associations were observed between BMD and HbA1c. In contrast, both TBS v3 and v4 were negatively associated with HbA1c ($P < 0.01$).

Conclusion:

The negative associations between TBS, derived using both v3 and v4 software, and HbA1c suggest that poorer glycemic control is linked to reduced bone quality, as reflected in lower TBS values. In contrast, no such relationship was observed with BMD. Mechanistically, hyperglycemia may impair bone quality by driving the accumulation of advanced glycation end-products in collagen, which weakens trabecular integrity. These findings underscore the value of TBS, offering insights beyond those provided by BMD.

	Lumbar Spine BMD	TBS version 3, BMI adj.	TBS version 4, Tissue Thickness adj.
Age	-0.134	**-0.472***	**-0.427***
Body Mass Index	**0.272***	0.106	-0.05
Tissue Thickness	0.179	-0.08	-0.11
Glycated Hemoglobin	-0.03	**-0.261***	**-0.247***

ADVANTAGES OF USING BIOACTIVE GLASS 60S IN PATIENTS WITH DIAPHYSEAL BONE DEFECTS CAUSED BY BLAST INJURIES

V. Chornyi[1], O. Burianov[1], M. Bazarov[1], V. Poniatovskyi[2], A. Kusyak[3], K. Honchar[1], B. Hurskyi[1]

[1]Department of Traumatology and Orthopedics Bogomolets National Medical University, Kyiv, Ukraine, [2]Department of microbiology and parasitology with the basics of immunology Bogomolets National Medical University, Kyiv, Ukraine, [3]Institute of Surface Chemistry National Academy of Sciences in Ukraine, Kyiv, Ukraine

Objective: Filling diaphyseal bone defects in patients with blast injuries is a challenging problem often complicated by infectious processes. Bioactive materials, particularly bioactive glass 60S, are used in accordance with the Masquelet technique, which provides prolonged local antimicrobial effects, rapid material remodeling, and bone tissue consolidation. This study compares the effectiveness of bioactive glass 60S with calcium-based materials,

which are the standard for defect replacement.
Materials and Methods: The bioactivity of Cu-doped bioactive glass 60S was studied in vitro in SBF Kokubo solution using SEM-EDX, FTIR, XRD, and ICP-AES methods. The study included 45 patients with gunshot fractures and diaphyseal bone defects ranging from 5 to 7 cm (mean size: 6.2 ± 1.1 cm), confirmed through radiographic and CT imaging. The patients were divided into two groups: the main group (n=21) received bioactive glass 60S, while the control group (n=24) was treated with calcium-based materials. Treatment outcomes were assessed at 12 and 18 months using radiographic examinations and the Lane-Sandhu scale, where 3 points indicate active consolidation and 4 points indicate complete consolidation and material remodeling.
Results: Bioactive glass 60S demonstrated high bioactivity and ion exchange activity, promoting the formation of a hydroxyapatite layer and the remodeling of the material into bone tissue. It exhibited pronounced antimicrobial activity against *Ps. aeruginosa* and *Kl. pneumoniae* but no effect against *St. aureus*. Recurrences of infectious processes occurred in one patient (4.76%) from the main group after 3 months and in two patients (8.33%) from the control group after 22 and 30 days postoperatively; these patients were excluded from further analysis. After 12 months, 45% of patients (9 of 20) in the main group achieved complete consolidation (4 points), while 55% (11 patients) showed partial consolidation (3 points). At 18 months, all patients in the main group achieved complete consolidation (4 points). In the control group, after 12 months, only 27.3% of patients (6 of 22) achieved complete consolidation, while 72.7% (16 patients) demonstrated partial consolidation (3 points). At 18 months, 59% of control group patients (13 individuals) achieved 4 points, while 41% (9 patients) remained at 3 points.
Conclusions: Cu-doped bioactive glass 60S demonstrates high bioactivity, facilitates rapid bone tissue consolidation, and provides prolonged antimicrobial effects, particularly against gram-negative microorganisms. It surpasses calcium-based materials in tissue remodeling speed and effectively reduces the risk of infection recurrence. The use of bioactive glass 60S is a promising approach for treating diaphyseal bone defects in patients with blast injuries.

P756

APPLICATION OF VDMT TECHNIQUE IN PATIENTS WITH LOWER LIMB AMPUTATION DUE TO MINE-EXPLOSION INJURIES

O. Smyk[1], O. Burianov[1], K. Honchar[1]

[1]Department of Traumatology and Orthopedics Bogomolets National Medical University, Kyiv, Ukraine

Relevance: The formation of peripheral nerve neuromas is a common cause of chronic pain in the late postoperative period among patients with limb amputations. The standard approach to nerve management is distal nerve resection. According to recent data, the use of the VDMT technique prevents neuroma formation, facilitates early prosthetic fitting, and reduces the need for repeated surgical interventions.
Materials and Methods:
From 2022 to 2024, 46 patients with lower limb stumps after amputation due to mine-explosion injuries, with pain syndrome and ultrasound-confirmed peripheral neuromas were included in the study. Pain levels were assessed using the Visual Analog Scale (VAS). All patients underwent surgical treatment. Patients were divided into two groups: the main group (n=23), who underwent peripheral nerve management with the VDMT technique, and the control group (n=23), who underwent distal nerve resection. Pain reassessment was conducted 3 and 6 months after surgery.
Results: Pain levels in both groups were evaluated using the VAS, with a preoperative mean score of 7.91 ± 1.15. At 4 months, the mean VAS score for the main group was lower (2.95 ± 0.64) compared to the control group (3.17 ± 0.80), the t-test showed difference was not statistically significant ($t = -1.03$, $p = 0.309$). At 6 months, the mean VAS score for the main group (2.23 ± 0.60) was significantly lower than that of the control group (5.79 ± 0.87), with a highly significant result ($t = -16.15$, $p < 0.001$), indicating much better pain relief in the main group. Ultrasound re-evaluation at 6 months revealed recurrent peripheral neuromas in 10 patients (43.47%) in the control group, while none were detected in the main group.
Conclusion: The VDMT technique effectively prevents neuroma formation in patients with limb amputations, reduces pain levels, and decreases the recurrence rate of neuromas. This improves patients' quality of life, accelerates prosthetic fitting, and reduces the need for repeat surgeries.
Keywords: limb amputation, VDMT technique, neuroma, post-amputation pain, stump neuroma, symptomatic neuroma, pain neuroma, Visual Analog Scale (VAS).

P757

COMPARATIVE PAIN INTENSITY BETWEEN FIRST AND SECOND STAGE BILATERAL TOTAL KNEE ARTHROPLASTY

K. Iamthanaporn[1], A. Wiwatboworn[1], P. Wanasitchaiwat[1], P. Purngpiputtrakul[1], V. Yuenyongviwat[1]

[1]Department of Orthopedics, Faculty of Medicine, Prince of Songkla University, Hatyai, Thailand

Background: Total knee arthroplasty (TKA) is a common surgical procedure for managing end-stage knee osteoarthritis, particularly in patients requiring bilateral intervention. Staged bilateral TKA is often performed to minimize risks. Previous studies suggest increased postoperative pain after the second stage, but findings remain inconsistent.
Methods: A retrospective analysis was conducted on 175 patients who underwent staged bilateral TKA. Pain scores, opioid consumption, and length of hospital stay were recorded for each stage. Patients were categorized by the interval between surgeries (<6 months, 6–12 months, and >12 months). Statistical analysis employed linear mixed-effects models and subgroup comparisons.

Results: Pain levels were not significantly different between the first and second TKA stages. Opioid consumption was comparable across both stages. Subgroup analysis based on the inter-surgery interval revealed no significant pain differences between the groups. Sensitivity analysis supported these findings, although a minor reduction in pain after the second stage was observed.
Conclusions: This study suggests no significant difference in postoperative pain between the first and second stages of staged bilateral TKA. Pain outcomes were consistent across different inter-surgery intervals, offering flexibility in scheduling the second procedure. These findings may inform clinical decision-making for pain management in staged bilateral TKA.
Keywords: knee osteoarthritis, staged bilateral TKA, postoperative pain, opioid consumption, surgical interval

P758

MUSCLE METABOLISM IN PATIENTS WITH TRAUMATIC SPINAL CORD DISEASE

N. Kaladze[1], K. Kaladze[1], O. Poleshchuk[1], K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: The purpose of this study was to study the condition of muscle tissue in patients with traumatic spinal cord disease, depending on the duration and level of spinal cord injury.
Methods: We examined 90 male patients suffering from traumatic spinal cord disease, aged 26-45 years, with varying duration of illness. Lesions of the cervical spine were found in 18, thoracic spine in 22, and lumbar spine in 50 patients. Together with conventional research methods, the number of CD3 lymphocytes was determined using immunophenotyping, the content of TNF-α and myoglobin in blood serum was studied by enzyme immunoassay, and the ELISA myoglobin test, which is designed to quantify the concentration of myoglobin in human blood serum as a marker of muscle tissue damage.
RESULTS: A reflection of the severity of metabolic disorders in skeletal muscles is the level of myoglobin, which corresponds to the clinical picture of suffering and its systemic manifestations, the correlations of myoglobin with TNF-α and CD3 indicators in the thoracic region and partially in patients with lumbar spine lesions and are most commonly found in patients with cervical lesions. The dependence of myoglobin levels on the duration of the disease is obvious, and its highest values were observed in patients in the first year of suffering, which were more often associated with altered TNF-α and CD3 values and a decrease in its level in subsequent years of the disease.
Conclusion: in patients with traumatic spinal cord disease, there is a violation of the trophism of skeletal muscles, manifested by an increased level of myoglobin, which is associated with a deterioration in the oxygen supply to tissues, leading to the development of tissue hypoxia. The severity of developing disorders depends on the level of spinal cord damage and the duration of the disease and is caused by concomitant disorders of the systemic order in the patient's body due to the preservation and maintenance of inflammatory activity of the process and the development of endothelial dysfunction.

P759

ADEQUATE DAIRY CONSUMPTION AMONG THE GENERAL POPULATION: FINDINGS FROM A TELEPHONE SURVEY IN SOUTHERN TEHRAN

Y. Azizpour[1], S. Akbarpour[1], K. Karimi[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Adequate dairy consumption, along with other contributing factors, can help prevent and manage osteoporosis while promoting overall health. The aim of this study was to investigate the prevalence of sufficient dairy intake among residents of southern Tehran in 2023.
Materials and Methods: A population-based telephone survey was conducted among individuals aged 18 years and older in three primary regions of southern Tehran, Iran. Participants reported their weekly dairy product consumption by indicating the number of days they consumed dairy products and the number of servings on one of those days. Two or more servings of dairy per day were classified as sufficient. A total of 1,311 individuals were selected using stratified random sampling with probability proportional to size (PPS). The data were analyzed using chi-square tests and t-tests.
Results: Out of the participants, 1,170 (89.2%) had low dairy intake, while 141 (10.8%) had sufficient intake. Specifically, 105 females (13.2%) and 36 males (6.9%) met the recommended intake levels ($p < 0.001$). Among participants under 65 years of age, 135 (10.8%) consumed enough dairy, whereas only 6 individuals (9.4%) aged 65 years and older met the recommended intake ($p = 0.715$). In terms of residency, 125 urban individuals (10.7%) and 16 rural individuals (10.9%) had adequate dairy consumption ($p = 0.957$). Average dairy intake was significantly higher among females ($p = 0.035$), younger individuals ($p = 0.039$), and urban residents ($p < 0.001$).
Conclusion: The findings indicate that residents of southern Tehran frequently have inadequate dairy intake. To improve overall nutritional status and health outcomes, there is an urgent need for public health interventions aimed at addressing these dietary deficiencies.
Key words: Dairy products, Prevalence, Telephone survey, Tehran

P760

HEALTHY LIFESTYLE BEHAVIORS AND RISK OF FALLS AMONG THE ELDERLY POPULATION IN IRAN: A NATIONWIDE CROSS-SECTIONAL STUDY

K. Karimi[1], F. Nemati[2], S. Mozafari[3], N. Rezaei[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]School of public health, Tehran University of Medical Sciences, Tehran, Iran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: The purpose of the study is to assess the relationship between healthy lifestyle and occurrence of falls among elderly people.
Methods: Data for this secondary analysis study came from the STEPS 2021 survey conducted in Iran. Individuals aged 60 years and older who responded who answered to question about fall events in the past 12 months were included in the study population. Fall history was assessed using a question and the lifestyle score was calculated based on several components, including tobacco use, alcohol consumption (AC), diet, body mass index (BMI) and physical activity (PA). Each component was initially scored on a scale 0 to2 points (except AC, which was scored as 0 or 1). the scores for these components were the summed to create the overall healthy lifestyle index (HLI). The HLI scores were categorized into tertiles and classified as poor, moderate and good HLI for tertiles 1,2 and 3. Chi-square and logistic regression were used to assess the odds of falls across the different HLI subgroups.
Results: Among, 3383 older participants with a mean age of 72.9 ±0.10 years, 4.8 (n=149) percent reported experiencing a fall event in the last year. Fall events were more prevalent among participants with unhealthy lifestyles (5.5 percent) compared to those with healthy lifestyle (3.5 percent). Logistic regression analysis indicated that participants with good and moderate healthy lifestyles had a lower risk of falls compared to those with unhealthy lifestyles, after adjusting for age, sex, and comorbid chronic diseases (OR=0.60, p=0.07 and OR=0.77, p=0.291, respectively).
Conclusion: The results of the study indicate that elderly population with healthier lifestyles had a lower odd of falls events in the past year compared to those with unhealthy lifestyles. These results emphasize that the promotion of healthy lifestyle behavior may be considered a potential strategy in reducing fall events and related risks among the elderly.
Keywords: life style, activity, fall, elderly, Iran

P761

THE ASSOCIATION BETWEEN DIETARY HABITS AND FALL RISK IN THE ADULT IRANIAN POPULATION: A NATIONAL CROSS-SECTIONAL STUDY

K. Karimi[1], S. Salehi[2], S. Ghorbani[3], N. Rezaei[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [3]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran

Objective: To investigate the association between falls in the past 12 months and dietary habits in the Iranian population aged 18-60 years, defined as adults.
Methods: A cross-sectional analysis was conducted using data from the 2021 Iran STEPS survey. Fall events in the past year were measured with a question from 21525 participants (56.3% female). Dietary habits were assessed using the score calculated from the principal component analysis (PCA) of the items in the questionnaire related to macronutrient intake and eating habits, including: daily meal and snake, breakfast, diary and its types, fruits, vegetables, meat, processed meat, sweated drinks, fish, whole grains, and nuts. The dietary habits score was divided into tertiles, with a higher score indicating healthier habits. In addition to demographic variables such as age, sex, and employment status, BMI and the comorbidity of chronic diseases were adjusted in Multivariable logistic regression.
Result: According to the survey results, 433 participants (mean age; 39.13±0.17) reported a fall event in the last year (2.0%; 95%CI [2.3-2.6] of those under 60 years of ages). Regarding dietary habits, the majority of those who fell had an unhealthy dietary pattern (37.3; 95%CI [32.5-42.5] compared to 31.8% and 30.8% with a partially healthy and healthy dietary pattern, respectively (p=0.122). Logistic regression, adjusting for age, sex, BMI and comorbidity of chronic diseases showed that people with healthy and partially healthy dietary patterns had a 25% and 20% lower risk of falling compared to those with unhealthy dietary patterns (OR=0.75; 95%CI [0.58-0.98] and OR=0.80; 95%CI [0.62-1.02], respectively).
Conclusion: Unhealthy dietary habits are associated with a higher occurrence of falls in individuals under 60 years of age. It seems that consuming a healthy diet and maintaining healthy nutritional habits, such as reducing sugar and salt intake and increasing the consumption of vegetables and fruits, can reduce the risk of falls in the younger population.

P762

FREQUENCY OF FALLING IN THE PAST YEAR IN PEOPLE OVER 50 YEARS OLD

V. Mohseni[1], K. Karimi[2], N. Fahimfar[1], M. Sanjari[1], A. Ostovar[1], B. Larijani[3]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran , Iran, [2]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [3]Endocrinology and Metabolism Research Center Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran , Iran

Background: Falling is a significant public health issue among older adults, globally as approximately one-third of older adults experience a fall annually. This study aimed to estimate the annual rate of falling among older adults aged ≥ 50.
Methods: This cross-sectional descriptive investigation included participants who were referred to the bone densitometry clinic in Tehran, Iran. Data concerning falls in the previous year, hypertension, diabetes, cardiovascular disease, the use of anticonvulsant medications over the past year, and the individual's eligibility for osteoporosis treatment were collected through telephone interviews.
Results: The mean age (SD) of the 425 participants was 64.7 (7.1) years, of which 373 (87.7%) were women. Of the study population, 210 (49.4%) aged over 65 years and 223 (52.5%) and 87 (20.5%) had osteopenia and osteoporosis, respectively. During the one year, 95 (22.3%, 95%: 18.6-25.6) falls were recorded. The annual prevalence (95% confidence interval) of falls in women, men, persons <65 years and persons ≥65 years was estimated to be 23.6% (19.5 – 28.2), 13.7% (6.4 – 26.1), 21.3% (16.3 – 27.4) and 23.3% (18.3 – 29.5), respectively. People taking diabetes medication reported a higher prevalence of falls in the last year (55 (27.23%) compared to other groups 40 (17.9%). However, the analysis showed that bone mineral density categories were not significantly associated with the occurrence of falls in the last year (p-value: 0.320). In addition, the data showed that the prevalence of falls in the past year was more common in people eligible for osteoporosis medication compared to those who were not eligible for this medication treatment (26.5% vs. 20.7%, p-value: 0.20), although the difference was not statistically significant.
Conclusion:
Given the high frequency of falls and low bone mineral density in older adults who attend bone densitometry units, fall risk assessment and fall prevention education can help reduce fractures in this high-risk population.

ADHERENCE TO OSTEOPOROSIS TREATMENT AMONG THE CLINICAL POPULATION

K. Karimi[1], N. Fahimfar[2], M. Sanjari[2], E. Nasli-Esfahani[3], A. Ostovar[2], B. Larijani[4]

[1]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran , Iran, [3]Diabetes Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran , Iran, [4]Endocrinology and Metabolism Research Center Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran , Iran

Objective: To illustrate the status of candidates for osteoporosis treatment, the referral to a physician, the prescription of osteoporosis medications, and adherence to treatment among individuals referred to a clinic for bone mineral density (BMD) assessment
Methods: Data were collected from participants≥50 years who attended a clinic in Tehran, Iran, for BMD measurements. The demographic data and BMD status were reviewed from their medical records. The FRAX score was calculated using the required data. Individuals with at least one of the following criteria were eligible to start OP treatment: 1) osteoporosis with T-score≤-2.5 in either total hip, femoral neck or spine, 2) osteopenia with -1≤T-score<-2.5 and a history of minor-trauma fracture , 3) a FRAX score ≥3 or ≥20 for hip and major osteoporotic fractures, respectively. The data on osteoporosis management were collected through a telephone interview.
Result: Of the 425 participants with an average age of 64.7±7.1 years, 117 individuals (27.5%,95%CI: 23.4-31.9) were eligible for osteoporosis treatment. Regarding BMD result,18 (15.4%:9.8-23.2) candidates had osteoporosis and (52.9%:43.8-61.9) had osteopenia. Of the candidates for treatment, 110 (94.2% individuals(were referred to a physician. Of the 110 referred subjects, medication was prescribed for 95 (86.3%) patients. Regarding adherence to treatment, only 79 (83.1%) of those who had received a treatment prescription had taken the medication regularly. If we consider the entire eligible population for treatment, the adherence rate is lower, at 67.5%.
Conclusion: The study results showed that one in three patients eligible for osteoporosis treatment does not adhere to treatment properly. Considering the long duration of treatment, patient education and counseling seems essential.
Key word: osteoporosis, adherence, treatment, BMD

Objective
Osteoporosis screening is important for early diagnosis and intervention. The Fracture Risk Assessment (FRAX) tool is widely used to estimate fracture risk and guide clinical decisions. This study was conducted with the aim of evaluating the accuracy of FRAX for the osteoporosis screening.
Method
The target population of this study was Iranian women aged 50 years and older. This study was conducted in Hamedan province. Before starting the study, invitations to participate in the study were disseminated in the public communication channels. Participants with informed consent to participate who had inclusion criteria and lacked exclusion criteria were included in the study. The required data for FRAX risk calculations were collected with questionnaires, and Dual-energy X-ray Absorptiometry (DXA) method using the GE Lunar device was used to determine bone mineral density (BMD) as the gold standard test. The t-score in at least total hip, femoral neck, or spine under -1 classified as osteopenia and under -2.5 classified as osteoporosis. The diagnostic accuracy of the FRAX score was evaluated as a quantitative variable and assessed by the Receiver Operating Characteristic (ROC) curve.
Results
In total, 995 females over 50 years were included in this study. The mean age of participants was 71.59±6.25 years, and the mean BMI of participants was 26.98±4.78 kg/m². The ROC analysis for evaluation of osteoporosis showed good to excellent discriminatory performance across all variables. The area under the curve (AUC) for detecting osteoporosis in the spine, femoral neck, total hip, and detecting in at least one of these areas was 0.74, 0.93, 0.89, and 0.79, respectively. In addition, FRAX showed high discriminatory performance for evaluating osteoporosis or osteopenia in the spine, femoral neck, total hip, and detecting the condition in at least one of these areas, with AUCs of 0.73, 0.91, 0.88, and 0.88, respectively.
Conclusion
The results of this study showed that FRAX has good to excellent discriminatory performance for detecting osteoporosis and osteopenia, with the highest accuracy observed in the femoral neck and total hip regions.
Keywords: Fracture Risk Assessment Tool, osteoporosis, screening, diagnostic accuracy, osteopenia.

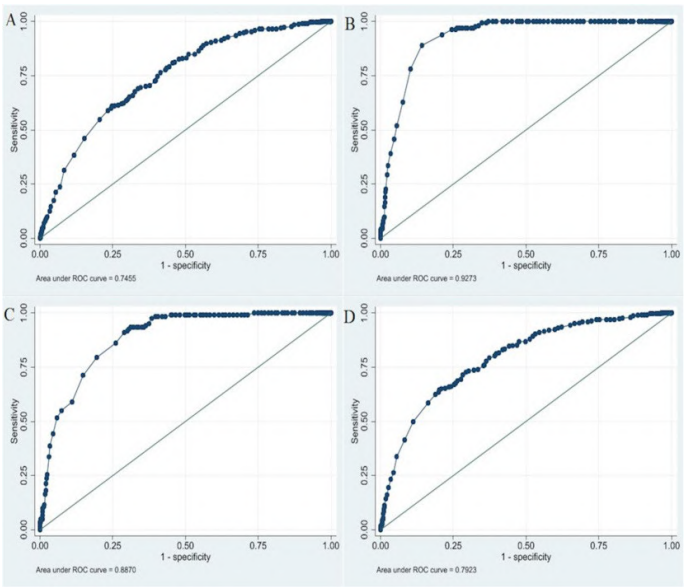

Figure 1: Receiver Operating Characteristic (ROC) curve of FRAX in detecting osteoporosis in A: spine, B: femoral neck, C: total hip, and D: detecting in at least one of these areas.

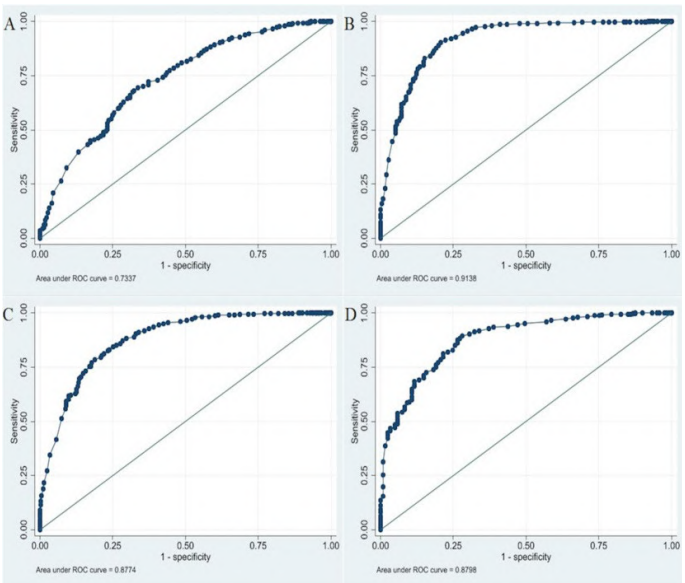

Figure 2: Receiver Operating Characteristic (ROC) curve of FRAX in detecting osteopenia/osteoporosis in A: spine, B: femoral neck, C: total hip, and D: detecting in at least one of these areas.

REHABILITATION OF A PATIENT WITH SARCOPENIA ON THE BACKGROUND OF MOTOR DISORDERS DUE TO STROKE: THE CLINICAL CASE

K. Kuznetsov[1], L. Marchenkova[1], T. Konchugova[1]

[1]Federal State Budgetary Institution "National Medical Research Center for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russia

Background. Rehabilitation of patients with secondary sarcopenia on the background of motor disorders due to stroke is difficult due to the lack of knowledge of this problem.
Objective: to describe the experience of complex rehabilitation of a patient with sarcopenia on the background of a stroke using a complex rehabilitation method with the use of electrostimulation and robotic mechanotherapy with biological feedback (BF).
Description of the clinical case. In April 2024 a man of 65 years old applied for physical rehabilitation with a diagnosis early recovery period of ischemic stroke in the right carotid basin dated 12.12.2023, right-sided moderate spastic hemiparesis, moderate sensory aphasia. The patients complaints were marked weakness and numbness in the lower extremities, fatigue, difficulty moving, inability to stay upright for a long time. Clinical examination revealed general condition of moderate severity, blood pressure 150/90 mmHg, clinical and biochemical blood tests and general urinalysis within the reference values. Sarcopenia risk assessment for the SARC-F questionnaire score was 5 points, the results of the Up and go test was 25 seconds. The lean mass index according to DXA was 1.8 that corresponds to sarcopenia. According to testing data on a robotic complex Con-Trex the maximum extension force (MEF) of the right leg was 548 N, the average extension force (AEF) of the right leg was 383 N and the average extension power (AEP) of the right leg was 19 Watts. The walking speed according to the results of sensory treadmill ergometer measurement was about 21 steps per minute.
The 15-day rehabilitation program included daily group therapeutic wait bearing physical exercises in a gym, medical massage of the lower extremities, laser therapy for the neck-collar zone, occipital protuberance zones and cubital veins, electrical stimulation of the of the back and lower extremities muscles with sinusoidal modulated currents with carrier frequency 2000 Hz and modulation frequency of 25-30 Hz, robotic mechanotherapy with a BF for targeted training of lower extremities and back muscles. Patients condition after completion of 15-day rehabilitation was satisfactory. The Up and go test takes 20 seconds that is motor function has improved. There was a moderate increase in muscle strength: MEF of the right foot increased up to 739 N, AEF of the right leg – up to 3506 N and AEP of the right leg – up to 29 Watts. The walking speed rise up to 35 steps per minute.
Conclusion. The clinical case demonstrates the effectiveness of a complex rehabilitation program includes electrostimulation and robotic mechanotherapy with BF combined with basic non-medicamentous methods in rehabilitation of man with sarcopenia due to stroke.

P766

RESULT OF TOTAL KNEE ARTHROPLASTY IN PRE-OPERATIVE ADREANAL INSUFFICIENCY PATIENTS

K. Kwangkyoun[1]

[1]University of konyang, Daejeon, South Korea

The purpose of this study is to investigate to effect of adrenal insufficiency on the results of TKA.
Materials and Methods: A total of 189 patients (89 knees) treated with TKA from April, 2022 to December, 2022 were enrolled in this study. Levels of serum cortisol and adrenocorticotropic hormone (ACTH) were checked preoperatively. Hydrocortisone 50~75 mg was injected to adrenal insufficient group at 7:00 AM and 4:00 PM on operative day and the following day. We evaluated the range of motion, the knee society knee score and function score at preoperatively and 2 years follow up, and compared the results between non-adrenal insufficiency group (NAI) and adrenal insufficiency group (AI).
Results: Cortisol and ACTH levels were reduced in 36 of 89 patients. All of 85 patients of low cortisol level do not stimulated in ACTH stimulation test. In the adrenal insufficiency group, the knee society score (KSS) improved from 49.8 to 86.8 and the knee society functional score (KSFS) from 42.6 to 89.5 at 2 years follow up. In the control group KSS rose from 51.9 to 84.3 and KSFS from 49.4 to 88.6 during the same period. In adrenal insufficient patients, there were no postoperative complication to include mortality, infection, periprosthetic fracture except skin lesions during operation or postoperatively. There was a case of rupture of quadriceps tendon on the 10th postoperative day which was treated with primary repair.
Conclusion: Based on our study, there was no increased operative and postoperative complications except skin lesions and 1 case quadricepse tendon rupture in patients with adrenal insufficiency group.

THE ASSOCIATION BETWEEN KNEE OSTEOARTHRITIS AND FRACTURE RISK IN WOMEN AGED 50 AND OLDER: A POPULATION-BASED COHORT STUDY

S. Lee[1], K. J. Kim[2], S. J. Kwon[3], K. M. Kim[3]

[1]Department of Internal Medicine, Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, South Korea, [2]Department of Internal Medicine, Korea University College of Medicine, Seoul, South Korea, [3]Division of Endocrinology, Department of Internal Medicine, Yongin Severance Hospital, Yonsei University College of Medicine, Yongin, South Korea

Objective
Osteoarthritis (OA) and osteoporosis are prevalent disorders in elderly women, sharing common risk factors such as menopause and aging. Research on the relationship between these conditions showed variable associations depending on the specific site

of osteoarthritis. Previous studies on knee OA—the most common form of OA— showed higher bone mineral density compared to those without. However, the relationship between knee OA and fracture risk still controversial; these inconsistent results may be due to differences in the demographic and clinical characteristics of the study populations. Our study aims to address this gap by focusing on Asian women aged 50 and above.

Material and methods

We used cohort data from the National Health Insurance Service of Korea between 2010 and 2018. Women aged 50 and older, without prior OA before 2010, or conditions such as cancer, rheumatoid arthritis, and with available body mass index (BMI) data, were included. Patients with knee OA were matched at a 1:2 ratio with non-knee OA participants based on age, BMI, and the index year using propensity score matching.

Results

49,198 patients with knee OA were compared with 98,396 non-knee OA controls. The mean age of the study population was 61.9±9.6 years, and the mean BMI was 23.4±2.8kg/m^2. During an average of 9.1 years follow-up, knee OA groups had a 21% higher fracture risk compared to the non-knee OA group, with a significantly higher risk in the first two years after diagnosis. Walking exercise, the use of osteoporosis medication, and calcium or vitamin D supplements were associated with a reduced risk of fractures than the non-use groups (p for interaction <0.05).

Conclusion

Knee OA was associated with an increased risk of fractures in women aged 50 and over, particularly shortly after diagnosis. Walking exercise and the use of osteoporosis medications might be beneficial. Further research is needed, but early management of osteoporosis in knee OA patients could be beneficial.

P768

BILATERAL TOTAL KNEE ARTHROPLASTY WITH THE CORI ROBOTIC SYSTEM: A PROSPECTIVE STUDY

K. Makridis[1], S. E. Zourntou[1]

[1]IASO THESSALIAS, LARISSA, Greece

Objectives: In the literature, there is a debate regarding the performance of bilateral total knee arthroplasty in one surgery. The purpose of the study was to analyze the clinical and radiological results after bilateral knee arthroplasty with the CORI robotic system.

Material and Methods: 50 patients underwent bilateral total knee arthroplasty (1 surgery) using the CORI robotic system. The range of pain improvement, accuracy of mechanical axis correction, range of motion, time to return to activities, and any complication were analyzed. Clinical evaluation was performed using the OXFORD KNEE score, pain was assessed with the VAS scale, and quality of life was assessed with the SF-12. Radiological evaluation consisted of plain radiographs.

Results: There were a total of 33 women (66%) and 17 men (34%), with a mean age of 72.5 years (range 47-82). Patients were mobilized within 10.5 hours (range 8-13 hours) after surgery and the mean hospital stay was 3 days (range 2-4 days). There was a significant improvement in pain and functional status immediately postoperatively, while the restoration of the mechanical axis was complete. Only 2 patients (4%) were transfused. Patients' overall quality of life was significantly better for both SF-12 parameters. All patients returned immediately to their homes without the need for further physical therapy.

Conclusions: The CORI robotic system can provide excellent functional and clinical results even when performing bilateral total knee arthroplasty in 1 operating session. Specialized experience is required, in order to apply all the advantages of robotics and achieve the optimal result while minimizing the risk of complications.

P769

FIXATION OF PERTROCHANTERIC FRACTURES WITH THE TRIGEN INTERTAN NAIL: TIPS AND TRICKS

K. Makridis[1], S. E. Zourntou[1]

[1]IASO THESSALIAS, LARISSA, Greece

Objectives: The purpose was to describe the characteristics of the implant and the specific technical aspects and how they may affect the outcome and minimize the risk of perioperative complications.

Material and Methods: From 2019 to 2022, 58 patients with an intertrochanteric or subtrochanteric hip fracture underwent surgery by a single orthopaedic surgeon. The TRIGEN INTERTAN intramedullary nail was used for fracture fixation (short nail for the intertrochanteric and long for the subtrochanteric). The overall walking scores included the Parker mobility score. Hip functional scores included the LEFS (lower extremity function score), and HOOS (hip dysfunction and osteoarthritis outcome score). Hip joint reconstruction scores included the objective Harris hip and the subjective Oxford-12 scores. The SF-12 and EuroQol- 5D questionnaires were used to evaluate quality of life. Any postoperative (either medical or surgical) complications, hip re-fracture rate and mortality rate at 6 months and 12 months were also recorded. T – student and chi-square tests were performed using the SPSS 22.0 statistical software.

Results: There were 36 females (62%) and 22 males (38%), with a mean age of 80.9 years (range 69 to 92 years) and a mean BMI of 27.2 (range 20.5 to 32.5). Mean values of walking, hip functional, hip reconstruction and quality of life scores were progressively improved within 1 year after surgery. No major complications were recorded. There were no cases with hardware failure. The overall mortality rate at 1 year was 9.6%.

Conclusion: The TRIGEN INTERTAN nail offers a stable fixation either the short or the long device is used. Its flexibility provides an easy insertion to the bone once the correct entry point is set. The dual lag screw of the femoral neck give absolute stability and strong compression of the fracture minimizing the risk of any hardware failure.

P770

TOTAL KNEE ARTHROPLASTY WITH THE CORI ROBOTIC SYSTEM: A PROSPECTIVE STUDY

K. Makridis[1], S. E. Zourntou[1]

[1]IASO THESSALIAS, LARISSA, Greece

Objectives To analyze the robotic technique with CORI and to evaluate the clinical and radiological postoperative results. **Material & Methods** 120 patients underwent total knee arthroplasty using the CORI robotic system. The pain improvement, accuracy of mechanical axis correction, range of motion, time to return to activities, and any complication were analyzed. Clinical evaluation was performed using the OXFORD KNEE score, pain was assessed with the VAS scale, and quality of life was assessed with the SF-12. Radiological evaluation consisted of plain radiographs. **Results** There were a total of 79 women (65.8%) and 41 men (34.2%), with a mean age of 71 years (range 59-83). Patients were mobilized within 6.5 hours (range 5-10 hours) after surgery and the mean hospital stay was 2 days (range 1-3 days). There was a significant improvement in pain and functional status immediately postoperatively, while the restoration of the mechanical axis was complete. No patient was transfused. Patients' overall quality of life was significantly better for both SF-12 parameters. All patients returned immediately to their homes without the need for further physical therapy. **Conclusion** CORI robotic system can provide excellent functional and clinical results even immediately postoperatively. The restoration of the mechanical axis and the kinematics of the knee is absolutely accurate, blood loss is minimal, balancing of the soft tissues is ideal and the postoperative pain is less.

P771

EXPLORING THE IMPORTANCE OF VITAMIN D SCREENING IN OLDER ADULTS WITH CHRONIC ILLNESSES: EVIDENCE FROM VLORE, ALBANIA

K. Malaj[1], F. Kamberi[1]

[1]University of Vlore "Ismail Qemali", Scientific Research Centre for Public Health, Faculty of Health, Vlora, Albania

Objective: Vitamin D plays a crucial role in calcium absorption, bone health, and immune function, and its deficiency can exacerbate these chronic conditions. In Vlore, as with many Mediterranean regions, exposure to sunlight is vital for Vitamin D synthesis, but lifestyle changes, limited sun exposure, and dietary patterns can affect this balance. This study aimed to evaluate the vitamin D levels in a random sample of older adults with chronic health conditions from Vlore, Albania, who were undergoing routine laboratory blood tests. The focus was on understanding the prevalence of vitamin D deficiency and its potential impact on their health.
Materials and Methods: Between March and August 2023, a total of 150 vitamin D assessments were conducted at NOVIDAL-AB, a private laboratory in Vlore. The study sample consisted of 90 women and 60 men, with participants primarily aged 65 and above. In addition to the blood tests, participants were surveyed regarding their use of vitamin D supplements and any symptoms they experienced that could be related to vitamin D deficiency.
Results: Among the 150 participants, 78 exhibited vitamin D levels below 30 ng/ml, which is considered insufficient for optimal health. The most commonly reported symptoms included muscle cramps, joint pain, and general fatigue, which are known to be associated with low vitamin D levels. The average age of participants was 65 years, and a significant majority indicated that they were not using vitamin D supplements regularly, suggesting a potential gap in preventive healthcare practices.
Conclusions: The findings indicate that a substantial portion of the older adult population in this sample has inadequate vitamin D levels, placing them at increased risk for various health complications, including weakened immune function and musculoskeletal disorders. This study underscores the urgent need for greater awareness and education on the importance of vitamin D, especially for older adults with chronic conditions, and highlights the potential benefits of routine vitamin D supplementation as part of health management for this demographic.

P772

PREVALENCE AND PREDICTORS OF SECONDARY HYPERPARATHYROIDISM AND ITS RELATIONSHIP TO BMD IN PATIENTS ATTENDING A BONE HEALTH CLINIC

K. Mcsherry[1], A. Carroll[1], R. Lannon[1], N. Maher[1], N. Fallon[1], G. Steen[1], C. O'Carroll[1], K. Mccarroll[1], D. Fitzpatrick[2]

[1]Bone Health Unit, St James's Hospital, Dublin, Dublin, Ireland, [2]Mater Misrecordiae University Hospital, Dublin, Dublin, Ireland

Objectives. Secondary hyperparathyroidism (SHPT) leads to bone loss, especially at cortical sites such as the hip and forearm. It can also blunt the response to antiresorptive treatment. We aimed to identify the prevalence of SHPT in patients attending our bone health clinic and examine its predictors and relationship to bone mineral density (BMD).
Materials and Methods. We identified patients from our clinic who had hyperparathyroidism (PTH>65 pg/ml). Those with serum calcium (>2.5 mmol/l) and eGFR < 30 min /ml were excluded to avoid primary hyperparathyroidism or elevated PTH due to advanced renal disease. We explored effects of vitamin D status (25(OH)D), renal function (eGFR), sex and body mass index (BMI) on SHPT in multinomial regression. We also examined for differences in lumbar and total hip BMD due to SHPT.
Results: 2298 patients identified, mean age 67.4 years, 82.7% female. Overall, 9.6% had SHPT. In a subsample (n=1911), SHPT was predicted by 25(OH)D < 30 nmol/l (OR 5.3, CI 3.6 – 7.8, p=0.0001), 25(OH)D 30 – 50nmol/l (OR 2.2, CI 1.5 – 3.3, p=0.001), GFR 30 – 60 ml/min (OR 2.6, CI 1.7 – 3.9, p=0.0001), BMI>30 (OR 3.0, CI 2.0 – 4.6, p=0.001) and older age (p=0.002). In a subsample (n=1677), BMD at the hip was lower (0.735 vs 0.765 g/cm, p=0.012) in those with versus without SHPT but there was no difference at the spine.

Conclusion. One in ten patients had SHPT which was associated with lower hip BMD (-3.9%). The biggest predictor was vitamin D deficiency with 25(OH)D (30 – 50 nmol/l) also doubling the risk. Other independent predictors were eGFR 30 – 60 ml/min, obesity, and older age. Similar predictors of SHPT have been found in other studies. The mechanism of the relationship between higher PTH and obesity remains unclear. Findings highlight the importance of maintaining adequate vitamin D levels to prevent SHPT and bone loss at the hip.

P773

THE OBESITY PARADOX – AN INCREASED RISK OF VERTEBRAL AND ANKLE FRACTURES IN OBESITY

K. Mcsherry[1], A. Carroll[1], R. Lannon[1], N. Maher[1], N. Fallon[1], G. Steen[1], C. O'Carroll[1], D. Fitzpatrick[2], K. Mccarroll[1]

[1]Bone Health Unit, St James's Hospital, Dublin, Dublin, Ireland, [2]Mater Misrecordiae University Hospital, Dublin, Dublin, Ireland

Objectives. Higher body mass index (BMI) is associated with greater bone mineral density (BMD) though the relationship between BMI and non-hip fracture risk is complex. We aimed to investigate the association between BMI and vertebral and ankle fractures in patients at our bone health clinic.
Materials and Methods. Patients identified from our clinic database. The association between vertebral and ankle fractures and BMI was explored in multinomial regression adjusting for age, sex and then lumbar spine or hip BMD. BMI (kg/m^2) was categorised as low (<18.5), normal (18.5 – 24.9), overweight (25 – 29.9) and obese (>30.0) with the reference group being normal.
Results. There were a total of 4813 and 787 patients in the respective vertebral and ankle fracture groups for which data was available. An increased risk of vertebral fracture (OR 1.37, CI 1.16 – 1.63, p<0.001) was found in those who were obese. In a subsample (n=4546) the risk remained after adjusting for lumbar spine BMD (OR 1.57, CI 1.30 – 1.80, p<0.001). There was also an increased risk of ankle fracture in obesity (OR 2.61, CI 1.57 – 4.34, p<0.001) which remained in a subsample (n=666) after adjusting for total hip BMD (OR 2.52, CI 1.46 – 4.38, p=0.001).
Discussion. Obesity irrespective of BMD was associated with an increased risk of fracture at the ankle (2.5 times higher) and vertebrae (57% higher) as reported elsewhere. Altered gait and greater ankle impact on falling in obese adults may explain this. Higher vertebral fracture risk in obesity may be due to greater loading forces on the spine, deterioration in vertebral micro-architecture and increased bone marrow fat content.

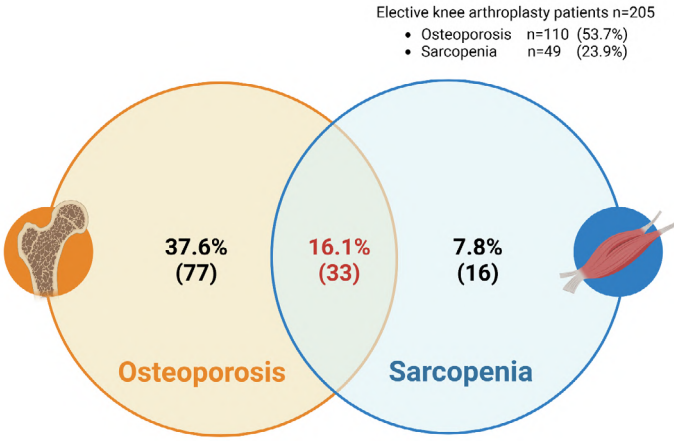
P774

HIGH PREVALENCE OF OSTEOPOROSIS AND SARCOPENIA IN PATIENTS UNDERGOING KNEE ARTHROPLASTY

K. Mekariya[1], P. Bhumiwat[1], E. Vanitcharoenkul[1], P. Chotiyarnwong[1], A. Unnanuntana[1]

[1]Department of Orthopaedic Surgery, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Objective: With the global shift toward an aging population, age-related conditions such as osteoporosis, sarcopenia, and osteoarthritis are becoming increasingly prevalent. In patients undergoing knee arthroplasty (KA), osteoporosis has been shown to increase the risk of periprosthetic fractures, while sarcopenia is associated with a higher incidence of postoperative medical complications and blood transfusion. Despite their clinical importance, data on the prevalence of these conditions in KA patients remain limited. We aimed to determine the prevalence of osteoporosis, sarcopenia, and osteosarcopneia in patients undergoing KA.
Material & Methods: This cross-sectional study enrolled patients who underwent elective primary total knee arthroplasty and unicompartmental knee arthroplasty at a single tertiary care hospital. Risk factors and previous treatment for osteoporosis were collected. All patients were evaluated for 25-hydroxyvitamin D level, bone mineral density, skeletal muscle mass, grip strength, and the 5-time Chair Stand test. Osteoporosis and sarcopenia were diagnosed according to the World Health Organization definition and the Asian Working Group for Sarcopenia 2019 criteria, respectively.
Results: A total of 205 patients were included (mean age 70.2 ± 7.9 years; 86.3% female). The prevalence of osteoporosis, sarcopenia, and osteosarcopenia was 53.7%, 23.9%, and 16.1%, respectively. Notably, only 22.7% of subjects with osteoporosis had received anti-osteoporosis medication prior to surgery, and less than half of KA patients (41.5%) had received calcium and vitamin D supplementation. Additionally, one-third of patients (36.6%) were found to have vitamin D deficiency (<20ng/ml).
Conclusions: There is a high prevalence of osteoporosis and sarcopenia in patients with advanced knee osteoarthritis undergoing KA, with 16% of these patients diagnosed with osteosarcopenia. However, the treatment rate remains surprisingly low; less than a quarter of the indicated patients received osteoporosis medication before the surgery. Considering the increasing number of KA globally, it is essential to integrate comprehensive assessments of bone and muscle health into the preoperative evaluation process. Early diagnosis, timely treatment, and preoperative optimization for osteoporosis and sarcopenia should be prioritized to improve surgical outcomes and long-term musculoskeletal health in this aging population.



P775

THE EFFECT OF INITIAL AND SUBSEQUENT DENOSUMAB OR ZOLEDRONATE APPLICATIONS ON BIOCHEMICAL PARAMETERS IN PATIENTS WITH PRIMARY HYPERPARATHYROIDISM

K. Mlekus Kozamernik[1], L. Ležaić[2], M. Hočevar[3], T. Kocjan[1]

[1]UMC Ljubljana/Department of Endocrinology Diabetes and Metabolic Diseases, Ljubljana, Slovenia, [2]UMC Ljubljana/Department of Nuclear Medicine, Ljubljana, Slovenia, [3]Institute of Oncology/Surgery, Ljubljana, Slovenia

Objective: The reduction in serum calcium (S-Ca) after the initial dose of denosumab is greater compared to subsequent doses in patients with GFR of < 30 ml/min/1.73m^2 and osteoporosis. We investigated if antiresorptive therapy had a similar time-related effect on S-Ca and other biochemical parameters in patients with primary hyperparathyroidism (PHPT) and GFR of > 30 ml/min/1.73m^2.

Methods: We analyzed data from our ongoing randomized trial on osteoporotic postmenopausal women with PHPT who are being treated with either denosumab 60 mg sc every six months (DMAB group) or with zoledronate 5 mg iv once a year (ZOL group) (ClinicalTrials.gov Identifier NCT04085419). Here, we compare S-Ca, intact parathyroid hormone (iPTH), and bone turnover markers following initial and subsequent zoledronate or denosumab application.

Results: We enrolled 40 females with PHPT and osteoporosis (aged 73.0 (7.8 SD) years; 22.6 (10.0) years from menopause; BMI 27.77 (5.1) kg/m^2; GFR 91.7 (25.7) ml/min/1.73m^2). After randomization, 20 women received denosumab (DMAB group) and 20 zoledronate (ZOL group). The changes in S-Ca at six months (6M) intervals in DMAB group were insignificant after initial and after subsequent applications. 6M after the first zoledronate application, S-Ca was significantly lower (ZOL Δ S-Ca 6M -0.06 (0.09); p=0.014 mmol/L), but it remained unchanged 6M after the second application. An iPTH level increased significantly in both groups at 6M (DMAB Δ iPTH 6M 31.84 (100.29); p=0.009, ZOL Δ iPTH 6M 36.39 (43.02); p=0.015 ng/L), but it decreased insignificantly after subsequent applications. Bone turnover markers decreased significantly at 6M in both groups (DMAB Δ CTX 6M -0.77 (0.407); p<0.001; ZOL Δ CTX 6M -0.534 (0.429); p<0.001 µg/L; DMAB Δ P1NP 6M -64.03 (30.39); p<0.001; ZOL Δ P1NP 6M -49.06 (27.88); p<0.001 µg/L; DMAB Δ BAP 6M -18.15 (8.72); p<0.001; ZOL Δ BAP 6M -13.02 (6.8)p<0.001 µg/L), but remained low and unchanged thereafter.

Conclusion: In our cohort of postmenopausal females with PHPT and osteoporosis, the initial application of either denosumab or zoledronate had a greater effect on serum calcium and other bone-related biochemical parameters than subsequent applications.

P776

FILLING GAPS IN TELEREHABILITATION: VALIDATING REMOTE SYNCHRONOUS AND ASYNCHRONOUS ASSESSMENTS OF PERFORMANCE-BASED OUTCOMES

K. Mullen[1], Z. Boos[1], L. Muhammad[2], M. K. Alshahrani[1], D. Pinto[1]

[1]Marquette University, Milwaukee, United States, [2]Northwestern University, Evanston, United States

Objective: This study assessed the agreement between three methods of performance-based outcome data collection for the 4-Meter Walk (4MW), Timed Up and Go (TUG), and Five-Repetition Sit-to-Stand (5XSTS) tests.

Materials and Methods: Fifty-eight participants were randomized into six groups, completing assessments in different sequences for in-person, remote synchronous, and remote asynchronous assessments of the 4MW, TUG and 5XSTS. In-person assessments served as the gold standard and were repeated five times to capture natural variability of the assessment; remote assessments were performed twice. Participants self-timed remote assessments. Participants were supervised in the remote synchronous assessment and were unsupervised during the remote asynchronous assessment. Agreement was analyzed using the extended Bland-Altman method accounting for repeated measurements, with limits of agreement (LOA) calculated as the mean difference ± 1.96 standard deviations.

Results: Participants were on average 40 years old (range 19–86), confident using technology (97%), held at least a bachelor's degree (83%), managed a medical condition (40%), and managed at least one active pain complaint (12%). After excluding three statistical outliers, remote synchronous and asynchronous assessments agreed with in-person assessments across all outcomes, with no significant differences in timing. Including outliers, agreement was observed only for the 4MW. Asynchronous TUG demonstrated the largest mean bias (3.31 seconds, 95% CI [2.62, 4.01]). Agreement diminished for tasks requiring more time to complete. Notably, the three outliers were among the study's oldest participants.

Conclusion: Telerehabilitation is a viable management approach. This study shows that in-person, remote synchronous, and asynchronous methods of assessing performance-based outcomes are interchangeable for most participants but require further vali-

dation among older adults. This may have reflected the dual-task nature of the remote assessments. Our findings support the use of select performance-based assessments in virtual environments among most participants studied. This research addresses critical gaps in remote physical performance assessment as health providers transition to greater use of telehealth.

P777

PHOTOTHERAPY WITH POLARIZED POLYCHROMATIC LIGHT IN THE TREATMENT OF ODONTOGENIC PERIOSTITIS

S. G. Bezrukov[1], A. A. Gavrilenko[1], L. A. Filippova[1], K. N. Kaladze[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To increase the effectiveness of the treatment of odontogenic periostitis by including phototherapy with polychromatic polarized light in the complex of local treatment.
Methods: We observed 40 patients with acute purulent odontogenic periostitis, who were divided into two groups: the main and the control (20 people each). All patients underwent periosteotomy using the standard technique with and without removal of the causative tooth, and were prescribed generally accepted general therapy. In the control group, after periosteotomy, the wound was washed daily with an aqueous solution of antiseptic. UHF currents were used as a physiotherapeutic agent. In the main group, after opening the subperiosteal abscess, the wound was also sanitized with a chlorhexidine solution, followed by applying a Sanguiritin dressing for 15 minutes, after which Emalan gel was applied to the postoperative wound. In addition, in the main group, local exposure procedures were performed with a Bioptron lamp using polychromatic polarized light. The polarized light beam was used externally in the projection of the wound, directing it at an angle of 90 ° to the skin surface at a distance of 3-5 cm, the exposure time was 6 minutes, 8 procedures, daily.
Results: Clinical observations have shown that, it was found that the intensity of recovery processes in the wound was higher in patients in the main group, the severity of general and local inflammatory reactions decreased faster, early cleansing of the postoperative wound from purulent-necrotic contents was noted, treatment times were reduced, and the risk of developing local complications of an infectious and inflammatory nature was reduced.
Conclusion: With local exposure to polychromatic polarized light of the Bioptron lamp, in the complex treatment of patients with acute purulent odontogenic periostitis, which has a local anti-inflammatory, anti-edematous, anesthetic, reparative-regenerative effect, contributes to a more rapid subsidence of inflammation symptoms, activation of regenerative reactions, reduction of the treatment time of patients, which allows using this method in surgical dental practice, both for treatment and for the prevention of postoperative complications of an infectious-inflammatory nature.

P778

XENOGENIC TRANSPLANT OSTEOBIOL DERMA IN SINGLE-STAGE IMPLANTATION AND AUGMENTATION OF SOFT TISSUES AFTER TOOTH EXTRACTION

L. A. Filippova[1], A. A. Gavrilenko[1], K. G. Bom[1], K. N. Kaladze[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: Purpose. To evaluate the effectiveness of the xenogeneic transplant Osteobiol Derma for soft tissue augmentation with one-stage implantation based on clinical, cytological and radiological examination methods.
Methods: We examined 10 patients aged 30 to 50 years, of both sexes, with defects in dental arches, without somatic pathology. The one-stage dental implantation operation was performed under local anesthesia. The tooth was removed, maximally preserving the inter-root septum, bone walls and alveolar bottom. The implants were installed according to the protocol for the introduction of a one-stage surgical intervention. To replace the bone spaces between the socket wall and the implant, the bone plastic material Gen-os osteobiol was placed. A resorbable xenogeneic membrane Osteobiol Derma was placed over the introduced bone material and the installed implant, under the soft tissue flap, and fixed with guide sutures.
Results: The postoperative period was uneventful. The clinical and cytological data indicate the intensity of reparative processes in the wound. According to the X-ray examination, after 3 months the bone defect was mostly formed by newly formed bone tissue that had undergone maturation. The resorption of the preparation occurred gradually, the restoration of the bone tissue defect was of the type of complete healing. All this made it possible to obtain good preservation and stabilization of the transplant in full and led to successful rehabilitation of the implant.
Conclusion: The use of the resorbable xenogeneic membrane Osteobiol Derma in one-stage implantation is an effective method for stabilizing the protection of the bone transplant, as well as a support for the growth of epithelial tissue, which does not require removal. Atraumatic execution, high biocompatibility, gradual resorption and vascularization, in turn, are key factors in clinical success and a good aesthetic result and allow us to recommend the use of this method in wide clinical practice.

P779

ON THE ISSUE OF INCREASING THE EFFECTIVENESS OF TREATMENT OF TRAUMATIC OSTEOMYELITIS OF THE MANDIBLE

S. G. Bezrukov[1], G. G. Roganov[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To increase the effectiveness of treatment of patients with traumatic osteomyelitis of the mandible by including Bestim in the treatment complex.
Methods: A total of 58 patients with traumatic osteomyelitis of the lower jaw were examined and treated. All patients were divided into 2 groups: control (27 people) and main (29). All patients with traumatic osteomyelitis of the lower jaw received traditional complex treatment, according to indications they were given immobilization of the lower jaw and traditional drug postoperative therapy. In the main group, in addition to traditional therapeutic treatment, patients received Bestim (intramuscularly, once a day, No. 5-7).
Results: All patients with traumatic osteomyelitis of the lower jaw before the start of treatment had clinical and radiological signs characteristic of a purulent-destructive post-traumatic process that developed in the mandibular bone. Significant changes were demonstrated by the general immunity indicators: IgA decreased by 39% ($p < 0.01$), and IgM by 24.7% ($p < 0.05$), which indicated the presence of disorders in the general immunity system. These results also indicated the presence of moderate initial local and general inflammatory reactions, metabolic hypoxia and chronic immunodeficiency in patients. The dynamics of the restoration of immunogram indicators was of particular importance for us, since it allowed us to judge the level of effectiveness of sequestrectomy and the quality of elimination of secondary immunodeficiency developing in patients with traumatic osteomyelitis of the lower jaw. In the main group, normalization of IgM, IgG indicators was recorded on the 10th day of therapy, and IgA - on the 21st day of therapy. In the control group, the restoration of the digital values of the studied indicators was recorded at a later date.
Conclusion: The inclusion of an immunomodulator and antioxidant in the treatment complex for patients with traumatic osteomyelitis of the lower jaw significantly increases its effectiveness. This is evidenced by earlier periods of restoration of immunological parameters of the blood (on the 7th-14th day, in the control - on the 14th-21st), a decrease in the number of local complications (by 28.4%) and relapses of the disease (by 7.7%).

P780

EFFECTIVENESS OF COLLAGEN D6 PHONOPHORESIS IN REHABILITATION OF CHILDREN WITH TEMPOROMANDIBULAR JOINT DYSFUNCTIONS

K. N. Kaladze[1], N. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To conduct a study of the effectiveness of including phonophoresis with the medicinal gel collagen D6 c Gel THERAPY (GUNA, Italy) in the rehabilitation complex of patients with distension diseases of the TMJ.
Methods: We examined and treated 30 children aged 16-18 years with distension diseases of the TMJ, of which 20 patients received a rehabilitation complex: a sparing unloading diet, jellied dishes, jelly, cheeses, seafood, enriched with vitamins E, B, C, Mg; therapeutic physical training, postisomeric relaxation; massage of the collar zone; Phonophoresis of D6 collagen with a therapeutic gel in the area of both TMJs using the technique we developed. Phonophoresis technique of D6 collagen with Gel THERAPY: the medicinal mixture of D6 with Gel THERAPY was applied to the skin in the area of the TMJ, including adjacent tissues and the projection of the masticatory muscles. The effect was achieved with a 1 cm2 emitter, frequency of 880 kHz, intensity of 0.4 W/cm2, pulsed 10 ms or continuous mode. The duration of exposure to the joint was 3 minutes, the course of treatment consisted of 12 daily procedures. The control group consisted of 10 patients similar in gender, age, and clinical data. Their rehabilitation complex included ultrasound using the same technique instead of phonophoresis of D6 collagen, the contact medium being lanolin oil.
Results: After the treatment, patients in both groups noted the disappearance or significant reduction of pain during exercise. Limited joint mobility was noted by only 1 /10%/ patient in the control group. Joint instability was noted by 1 patient in the main group and 3 patients in the control group. The "click" symptom persisted in 2 patients in the main group and 4 in the control group. The study of the results of the study using the TMJ Assessment Scale showed that the improvement in patients in the main group after collagen phonophoresis was manifested not only by the disappearance of pain, but also by improved joint function and decreased instability; the score was 9.5±1.49, ($P<0.001$). The result in patients in the control group after treatment was 12.4±2.35 ($P>0.2$).
Conclusion: The study showed a positive effect of D6 collagen phonophoresis with Gel THERAPY on the main pathogenetic links of distension diseases of the temporomandibular joint.

P781

REGIONAL HEMODYNAMICS IN PATIENTS WITH LOWER JAW FRACTURES USING PHYSIOPHARMACOTHERAPY

K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1], S. A. Khamidova[2], S. Kulanthaivel[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Tashkent State Pedagogic Univ. named after Nizami, Tashkent, Uzbekistan, [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Study the recovery period in patients with lower jaw fractures and the effect of bioresonance therapy and a combination of bioresonance therapy and Osteogenon on the fracture consolidation process and regional hemodynamics in the fracture zone.

Methods: We observed 120 male patients with lower jaw fractures, aged 18 to 58 years. The patients were divided into 3 groups, with 40 people in each group.

All patients first underwent splinting of bone fragments with a splint-bracket with hook loops according to Tigerstedt method. The teeth were set in the bite and fixed with rubber traction.

Bioresonance therapy was carried out according to the following method: on the 2nd day, the BRS device was applied to the collar zone according to the standard method. For the effect, nozzle No. 3 was used, mode 1, the exposure time was from 3 to 5 minutes, the duration at each position was 10-30 seconds, for 3-4 days. From the 5th day, not only the collar zone was affected, but also the area of the projection of the fracture of the lower jaw through the skin. Gradually, the force (mode 3) and the exposure time (up to 12 minutes) were increased, the course of treatment was 10 procedures.

Osteogenon (ossein-hydroxyapatite complex), used mainly for the prevention and treatment of systemic osteoporosis. The course of treatment with the drug is 2 tablets 2 times a day for 14 days.

In group III, treatment was carried out according to the generally accepted method (splinting, anti-inflammatory therapy, e.p. UHF).

The treatment efficiency was assessed based on clinical and morphological data and the results of the functional examination method (rheography) after immobilization and 2 weeks after the start of treatment. Rheograms were assessed based on 11 main parameters, taking into account arterial and venous circulation. The rheography data of 15 healthy people aged 16 to 60 years served as a control. Electrodes were applied according to the method of N.B. Laskova (Laskova N.B., 1973) bipolarly. Rheographic curves were subjected to qualitative and quantitative analysis with subsequent mathematical processing according to Student.

Results: Upon admission, patients in all 3 groups had edema and swelling of soft tissues due to trauma, and a combination of edema and hematomas. Almost all patients had displacement of bone fragments of the lower jaw. Impaired regional circulation was noted for all main indicators in 89% of patients. There was a decrease in the rheographic index, relative volumetric pulse, an increase in the relative β index, a decrease in the catacrotic angle, which indicated a violation of both arterial and venous blood flow.

Later, after the treatment, in patients of groups I and II, who were simultaneously treated with bioresonance stimulation and a complex of bioresonance stimulation and Osteogenon, traumatic edema and hematomas decreased and disappeared earlier than in patients of group III.

Conclusion: Thus, complex treatment of mandibular fractures with the inclusion of bioresonance therapy and Osteogenon contributes to earlier fusion of mandibular fragments, restoration of working capacity and functional indicators.

P782

APPLICATION OF BIORESONANCE THERAPY IN LOWER JAW FRACTURES

K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1], S. A. Khamidova[2], S. Kulanthaivel[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Tashkent State Pedagogic Univ. named after Nizami, Tashkent, Uzbekistan, [3]Naarayani Multispeciality Hospital, Erode, India

Objective: According to the standpoint of rheographic indices of local blood flow, to assess the effect of BRT on local blood flow and the rate of bone regeneration in patients with lower jaw fractures based on radiographic data, as well as the nature and number of inflammatory complications.

The aim of this study is to substantiate the possibility of stimulating osteogenesis and the development of inflammatory phenomena by the effect of bioresonance therapy (BRT) and sorbent tissue in the complex treatment of patients with lower jaw fractures.

Methods: The method for conducting bioresonance therapy for a lower jaw fracture was as follows: after fixation of the bone fragments of the lower jaw with a metal splint, a bracket with Tigerstedt hook loops. On the second day of treatment, the collar zone was exposed to the BRT device using the standard technique. Mode "3" was used for the exposure, the exposure time was from 3 to 5 minutes. The duration at each position was 10-30 seconds. The same exposure was carried out on days 3 and 4. From the 5th day, not only the collar zone was affected, but also the fracture area through the skin. Gradually increasing (mode "3") the force and time of exposure (up to 12 minutes).

Results: During bioresonance therapy, we did not observe any complications in patients. The formation of primary bone callus was observed radiologically on the 6-7th day after the fracture. Clinical consolidation of the fracture was observed on the 24th day. After the bioresonance therapy session, the patients underwent a rheographic study of the perimaxillary soft tissues. An increase in hemodynamics was observed in the fracture zone, which accordingly has a positive effect on the rate of formation of primary bone callus and clinical consolidation of the fracture of the lower jaw. We did not encounter any inflammatory complications when using bioresonance therapy.

Conclusion: Increased local hemodynamics has a positive effect on the course of formation of primary bone callus, accelerates its formation, which accordingly leads to earlier clinical consolidation of the fracture, and prevents the occurrence of inflammatory complications.

P783

EFFECTIVENESS OF PHYSIOTHERAPY AND PHARMACOTHERAPY IN TREATMENT OF LOWER JAW FRACTURES

K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1], S. Kulanthaivel[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: The aim of this work was to study the structural and functional state of bone tissue in patients with lower jaw fractures and the effect of bioresonance therapy and a complex of bioresonance therapy and Osteogenon on the process of fracture consolidation and bone tissue remodeling processes.
Methods: 80 male patients with lower jaw fractures, aged from 18 to 58 years are observed. All patients first underwent splinting of bone fragments with a splint-bracket with hook loops according to Tigerstedt. Bioresonance therapy was carried out according to the following technique: on the 2nd day, the collar zone was exposed to the BRS device according to the standard technique. The force (mode 3) and exposure time were gradually increased; the treatment course was 10 procedures. Osteogenon (ossein-hydroxyapatite complex), used mainly for the prevention and treatment of systemic osteoporosis. The course of treatment with the drug is 2 tablets 2 times a day for 14 days. In group III, treatment was carried out according to the generally accepted method. The study of the structural and functional properties of bone tissue was studied using an “Achilles+” ultrasound densitometer, which recorded the following parameters: broadband ultrasound attenuation, ultrasound propagation velocity, bone density index.
Results: A study of the initial data on the structural and functional properties of bone tissue in patients with a mandible fracture revealed that 40 (50%) of them had osteopenic syndrome, manifested in a decrease in the level of SRU, SHOU and IP. These changes had a high degree of reliability, compared with the norm. After the treatment, densitometric indices in patients of groups I and II increased significantly, most pronounced in patients of group II, who were simultaneously treated with bioresonance stimulation and osteogenon. In patients of group III, the parameters under study remained within the normal range, but tended to decrease. structural and functional properties of bone tissue were more pronounced in group II. Thus, we noted the greatest therapeutic effect in the group of patients with osteopenic syndrome, who underwent combined treatment with bioresonance stimulation causing intensification of microcirculation and metabolic processes in the tissues of the mandibular region, and osteogenon having a dual effect on bone tissue metabolism: a stimulating effect on osteoblasts and an inhibitory effect on osteoclasts, which is accompanied by an increase in calcium absorption.
Conclusion: The use of bioresonance stimulation helps to improve the structural and functional properties of bone tissue and mineral metabolism. The greatest effect on the restoration of the structural and functional properties of bone tissue is achieved by the combined use of bioresonance stimulation and Osteogenon.

P784

ASSESSMENT OF FACTORS ASSOCIATED WITH LOW MUSCLE MASS IN WOMEN WITH RHEUMATOID ARTHRITIS

R. Mnevets[1], K. Ostrovskyy[2], S. Kulanthaivel[3]

[1]ESC Institute of Biology and Medicine of Taras Shevchenko National University of Kyiv, Kyiv, Ukraine, [2]Pharmaceutical Product Development, Warsaw, Poland, [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Purpose of the study is determining the incidence of sarcopenia (SP) and factors associated with low muscle mass in a cohort of women with rheumatoid arthritis (RA).
Methods: 87 women aged 40-75 years with confirmed RA underwent dual-energy X-ray absorptiometry of the lumbar spine, proximal femur, and whole body to determine bone mineral density (BMD) in standard areas and to quantify muscle mass. The appendicular muscle mass (AMM) was determined as the sum of the muscle mass of the arms and legs, and the appendicular muscular index (AMI) was determined as the ratio of AMM to the square of the height, with AMM<15 kg and/or AMI<6 kg/m^2 considered criteria for decreased muscle mass. Muscle strength was assessed using hand dynamometry and the "Stand up from a chair" test. The functional state of the muscles was determined by the walking speed at 4 m, the "Stand up and go" test and the total score of the short set of physical fitness tests (SAT OFF). AP was diagnosed according to the criteria of the European Working Group on Sarcopenia in Older People (EGGSOP2, 2018). Based on the correlation analysis, the associations between muscle mass and clinical, anamnestic and laboratory data were studied.
Results: Probable spondylosis (based on decreased muscle strength) was found in 80 (92%) of the examined women. Demonstrable spondylosis (decreased muscle strength in combination with low AMM and/or AMI) was detected in 20 (23%) patients, with 9 (10%) of them having decreased functional state of muscles, which allowed diagnosing severe spondylosis in these women. Comparative analysis showed that patients with RA and demonstrable spondylosis, compared with women without spondylosis, had a longer duration of RA (p=0.006), lower BMI (p=0.0001), more often took glucocorticoids (p=0.04), and had lower BMD in the femoral neck and proximal femur as a whole (p=0.049 and p=0.009, respectively).
Conclusion: According to the results of correlation analysis between AMM, AMI, and clinical laboratory data, which revealed that AMM directly correlated with BMI (r=0.58), methotrexate dose (r=0.26), serum uric acid and creatinine concentrations (r=0.56 and r=0.33, respectively), BMD in all measurement areas (r from 0.36 to 0.5), and inversely correlated with the cumulative dose of glucocorticoids. In addition to the above parameters, AMI also inversely correlated with the duration of RA (r=-0.32) and the number of falls in the previous year (r=-0.24).

P785

ANALYSIS OF THE FREQUENCY OF SEROLOGICAL MARKERS TO THE CAGA HELICOBACTER PYLORI ANTIGEN IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS

R. Mnevets[1], K. Ostrovskyy[2], S. Kulanthaivel[3]

[1]ESC Institute of Biology and Medicine of Taras Shevchenko National University of Kyiv, Kyiv, Ukraine, [2]Pharmaceutical Product Development, Warsaw, Poland, [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Numerous epidemiological and clinical studies conducted in various regions and countries of the world indicate an extremely wide and widespread distribution of Helicobacter pylori in the human population. It should be taken into account that the incidence of Helicobacter infection throughout the world is not decreasing and remains at a fairly high level. The reason for this is the epidemiological features of the infection – a relatively high probability of contracting Helicobacter pylori in childhood in the family, during invasive research methods in healthcare institutions, late diagnosis of the disease, etc. To date, it has been established that infection with bacteria leads to a variety of clinical manifestations. Helicobacter pylori causes not only the development of gastritis and peptic ulcer disease, but can also be accompanied by extragastric manifestations. In particular, helicobacteriosis can contribute to the development of osteoporosis. Thus, the aim of this study was to study the frequency of registration of total antibodies to the CagA antigen of Helicobacter pylori in women with postmenopausal osteoporosis.

Methods: 520 postmenopausal women were examined. The indicators of the age of the examined patients were 62 years, and the duration of the postmenopausal period was 13 years. The studies included osteodensitometry (DEXA method) and blood serum testing for specific class M antibodies and total antibodies (IgA, IgM, IgG) to the CagA Helicobacter pylori antigen (enzyme-linked immunosorbent assay) in all patients.

Results: It was found that in the group of women with postmenopausal osteoporosis (n=151), positive serological tests for total antibodies to the CagA Helicobacter pylori antigen were recorded in 29.1% of cases. The frequency of detection of the above-mentioned specific antibodies in the group of women with osteoporosis significantly (p=0.049) exceeded the similar indicator established in the combined group of healthy women and patients with osteopenia (20.6%). The frequency of positive tests for class M antibodies to the CagA antigen of Helicobacter pylori (4.8%) did not show an association with the state of bone tissue in postmenopausal women (p=0.951).

Conclusion: The studies conducted have established an increased frequency of Helicobacter pylori infection in women with postmenopausal osteoporosis compared to individuals characterized by either normal bone tissue or osteopenia (p=0.049). The obtained results require clarification in further studies.

P786

PREOPERATIVE MUSCLE MASS AFFECTS PREOPERATIVE LOW BACK PAIN SCORE AND IMPROVEMENT OF SCIATICA IN PATIENTS WITH LUMBAR CANAL STENOSIS

K. Sachiyo[1], K. Ayumu[1], K. Tomohisa[1], U. Ken[1]

[1]Department of Orthopedic Surgery, Kitasato University Medical Center, Kitamotoshi, Japan

Introduction: LSS causes lower back pain, lower extremity pain and numbness, lower muscle weakness, and gait disturbance, resulting in decreased physical function. Only a few studies have evaluated the relationship between muscle mass and the outcome of LSS surgery.

Aim: The aim of this study was to investigate the relationship between preoperative muscle mass and clinical outcomes in patients with LSS who underwent surgical treatment.

Materials and Methods: A total of 86 patients were included in the current study. We evaluated skeletal muscle mass using bioelectrical impedance analysis and calculated the skeletal muscle mass index (SMI), corrected by the square of height. The following indices were measured before and 3 weeks after each operation: Visual analogue scale (VAS) scores for lower back pain, lower extremity pain, and lower extremity numbness. The recovery rate for each score following surgery was also evaluated. In order to assess the impact of muscle mass on the clinical score of LSS surgery, the patients were divided into two groups (sarcopenia group and non-sarcopenia group).

Results: The pre-operative VAS score for lower back pain was significantly higher in the sarcopenia group compared with the non-sarcopenia group ($p<0.05$). Although there was no statistical difference in the VAS score for lower extremity pain before surgery between the two groups, the recovery rate in this score was significantly higher in the non-sarcopenia group ($p <0.05$).

Conclusion: This study showed that some preoperative low back pain scores were worse in the sarcopenia group compared with those in the non-sarcopenia group. In addition, there was less improvement in lower extremity pain following surgery in the sarcopenia group compared with the non-sarcopenia group. These findings indicated that preoperative muscle mass may affect preoperative low back pain score and the improvement in sciatica in patients with lumbar canal stenosis. The preoperative physical therapy for low muscle mass might be effective for LSS surgery.

BIOCHEMICAL AND PATIENT-REPORTED OUTCOMES IN PATIENTS WITH TUMOUR-INDUCED OSTEOMALACIA TREATED AND NOT TREATED WITH BUROSUMAB

M. Zanchetta[1], K. Dahir[2], E. Imel[3], T. Carpenter[4], K. Sandilands[5], S. Sader[6], Z. Li[7], B. Johnson[8], S. Jan de Beur[9]

[1]Instituto de Diagnósticoe Investigaciones Metabólicas, Buenos Aires, Argentina, [2]Department of Endocrinology, Vanderbilt University Medical Center, Nashville, TN, United States, [3]Departments of Medicine and Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States, [4]Yale University School of Medicine, New Haven, CT, United States, [5]Kyowa Kirin International, Galashiels, United Kingdom, [6]Ultragenyx Pharmaceutical Inc., Novato, CA, United States, [7]Kyowa Kirin Inc., Princeton, United States, [8]Kyowa Kirin International, Marlow, United Kingdom, [9]University of Virginia, Charlottesville, VA, United States

Objectives: Tumour-induced osteomalacia (TIO) is an ultra-rare condition caused by tumours secreting fibroblast growth factor 23 (FGF23), resulting in chronic hypophosphataemia, and consequent severe musculoskeletal morbidities, pain, fatigue, and impaired physical function. Burosumab, a fully human monoclonal antibody which targets FGF23, is indicated for treatment of TIO where tumours cannot be localised or curatively resected. This study aimed to compare biochemical and patient-reported outcomes (PROs) in patients with TIO treated and not treated with burosumab in a real-world setting.

Methods: The TIO Disease Monitoring Program (DMP, NCT04783428) is a 10-year prospective, multicentre, observational study enrolling patients with TIO across the US and Latin America. This is a descriptive study of biochemical outcomes and PROs assessed at the time of DMP enrolment (baseline), stratified according to burosumab treatment status at enrolment.

Results: Of the 21 patients with TIO enrolled, 11 (52.4%) were treated with burosumab at baseline, for a median (IQR) duration of 4.1 (6.2) years. Burosumab-treated patients had higher median serum phosphorus, lower alkaline phosphatase and higher $1,25(OH)_2D$ levels compared to those not treated with burosumab. Median Brief Pain Inventory Short Form (BPI-SF) and Brief Fatigue Inventory Short Form (BFI-SF) worst scores were lower in the burosumab-treated group, indicating lower symptom severity, while median PROMIS Physical Function (PROMIS-PF) and Short-Form Six-Dimension (SF-6D) scores were higher, indicating better functioning and health-related quality of life.

Table 1. Patient characteristics, biochemistry and PROs.

Characteristic	Burosumab at enrolment (n=11)	No burosumab at enrolment (n=10)
Age (years)*	54.2 (12.5)	45.2 (26.9)
Male **	5.0 (45.5)	3.0 (30.0)
Time since diagnosis (years)*	8.6 (14.5)	1.1 (4.2)
Serum phosphorus (mg/dL) *	3.5 (1.4)	1.9 (1.5)
ALP (U/L) *	105.0 (58.0)	156.0 (156.0)
$1,25(OH)_2D$ (pg/ml) *	55.4 (70.0)	28.7 (28.8)
BPI-SF (worst) *	4.0 (4.0)	7.5 (3.5)
BFI-SF (worst) *	3.0 (5.0)	4.0 (5.7)
PROMIS-PF*	41.4 (11.5)	38.9 (11.9)
SF-6D*	0.68 (0.18)	0.64 (0.22)

** Median(IQR); ** N(%)*

Conclusion(s): At the time of enrolment, the TIO DMP shows favourable biochemical outcomes and PROs in TIO patients treated with burosumab versus those not treated with burosumab.

Disclosures: The TIO DMP (NCT04783428) is sponsored by Kyowa Kirin and Ultragenyx. Kyowa Kirin funded this analysis.

CALCIUM AND VITAMIN D INTAKE IN RELATION TO OSTEOPENIA AND OSTEOPOROSIS RISK IN PATIENTS WITH CELIAC DISEASE

K. Skoracka[1], M. Michalak[2], A. E. Ratajczak-Pawłowska[3], A. M. Rychter[4], A. Zawada[3], A. Dobrowolska[3], I. Krela-Kaźmierczak[3]

[1]Department of Gastroenterology, Dietetics and Internal Diseases, Poznan University of Medical Sciences, Clinical Hospital of Poznan, Poznań, Poland, [2]Department of Computer Science and Statistics, Poznan University of Medical Sciences, Poznań, Poland, [3]Department of Gastroenterology, Dietetics and Internal Medicine, Poznan University of Medical Sciences, Clinical Hospital of Poznan, Poznań, Poland, [4]Department of Gastroenterology, Dietetics and Internal Diseases, Poznan University of Medical Sciences, 60-355 Poznan, Poland, Poznań, Poland

Objective: One of the most common complications of celiac disease (CD) is a low bone mineral density (BMD) which is due to several factors, including impaired absorption of calcium (Ca) and vitamin D (vit. D). This study aimed to find association between BMD and dietary intake of Ca and vit. D in CD patients.

Materials and Methods: A total of 60 participants under 50 years of age were recruited from the outpatient clinic with 40 people with CD following gluten-free diet (GFD) and 20 people following traditional diet in the control group (CG). BMD, T-score, and Z-score of the lumbar spine (L1-L4) and femoral neck (FN) were assessed using the Lunar DPX-Plus device (Lunar Inc., Madison, WI, USA). Participants were asked to follow their usual diet to assess intakes of Ca and vit. D by 4-day food records analysed (Diet 6.0, Poland). The percentage coverage of recommended intakes (RDA) between the two groups and differences in BMD in the groups with RDA<100% and RDA>100% were assessed. Blood samples were collected. Finally, an appropriate statistical analysis was carried out.

Results: CD patients presented lower BMD, T-score, and Z-score at the FN and L1-L4 than CG. No differences in Ca (769.13 vs. 884.52 mg/d) and vit. D (2.28 vs. 3.06 mg/d) intakes were ob-

served between CD patients and CG. However, participants in both groups did not meet the RDA for Ca (77.84 vs. 88.85% RDA) and vit. D (17.35 vs. 20.42% RDA). Patients not meeting RDA of Ca had differences in body mass (60.46 vs. 67.5 kg), FN BMD (0.98 vs. 1.08), and FN T-score (-0.43 vs. 0.32) between CD patients and CG, but no differences were observed in the group meeting RDA of Ca. None of participants met RDA for vit. D but patients with CD had higher vit. D concentrations than CG (41.51 vs. 28.88 ng/dl), whereas no differences were observed in Ca (5.11 vs. 5.29 mg/dl).

Conclusions: CD patients have high risk of low BMD and their diet is deficient in Ca and vit. D. Given the direct involvement of Ca and vit. D in bone metabolism, it is imperative to emphasise the importance of dietary Ca intake and vit. D supplementation in patients with CD. The elevated vit. D concentrations observed in patients with CD may be attributed to the fact that CD patients were under outpatient care at our clinic, where the supplementation of vit. D and, if necessary, Ca is recommended.

ASSOCIATION BETWEEN BODY COMPOSITION PARAMETERS AND BONE MINERAL DENSITY IN PATIENTS WITH CELIAC DISEASE

K. Skoracka[1], M. Michalak[2], A. E. Ratajczak-Pawłowska[3], A. M. Rychter[3], A. Zawada[3], A. Dobrowolska[3], I. Krela-Kaźmierczak[3]

[1]Department of Gastroenterology, Dietetics and Internal Diseases, Poznan University of Medical Sciences, Clinical Hospital of Poznan, Poznań, Poland, [2]Department of Computer Science and Statistics, Poznan University of Medical Sciences, Poznań, Poland, [3]Poznan University of Medical Science, Department of Gastroenterology, Dietetics and Internal Medicine, Clinical Hospital of Poznan, Poznań, Poland

Introduction: Celiac disease (CD) has been linked with increased susceptibility to osteoporosis; therefore, the aim of the study was to explore association between body composition parameters and bone mineral density (BMD) in a group of patients with CD.

Methods: This study covered 76 participants: 56 adults—47 women and 9 men—mean age 39 years, and 20 healthy controls—16 women and 4 men, mean age 38 years recruited from the outpatient clinic. Densitometry of the lumbar spine (L1–L4) and femoral neck (FN) was conducted with Lunar DPX-Plus device (Lunar Inc., Madison, WI, USA). Body composition was measured by bioimpedance analysis (BIA) method (TANITA MC-980 MA, Tanita, Tokyo, Japan) to the nearest 0.01 kg. Finally, appropriate statistical analysis was carried out.

Results: CD patients presented lower BMD, T-score, and Z-score at the FN and L1-L4 than CG. We found osteopenia in the FN in 19.65% of patients and in L1–L4 in 26.79% of the patients. One patient displayed evidence of osteoporosis in the L1–L4 region, while two patients (3.57%) exhibited similar findings in the FN. There were no significant differences between body mass, fat-free mass (FFM), muscle mass, % of fat mass, basal metabolic rate (BMR), and body mass index (BMI) between CD patients and CG. Significant positive correlations were observed between BMD and body mass, FFM, muscle mass, and BMR for both L1–L4 and the FN, and BMI and BMD of the L1–L4. There was no relationship between BMD and % of fat mass in either group.

Conclusions: In conclusion, despite a higher incidence of osteopenia and osteoporosis in CD patients, there are no significant differences in body composition between the two groups, but participants with lower body weight, FFM, muscle mass, and BMR were more likely to have a reduced BMD what can be explained by the direct mechanical stimulation of bone by muscle, which promotes osteogenesis. Since there were no correlations between BMD and % of fat mass, we suppose that adipose tissue may have a negative impact on BMD if present in excess due to the possible low-grade inflammation generated. It seems worthwhile to explore the possibility of body composition testing with BIA as a potential indicator of increased risk of bone disease in the CD population.

DOES COEXISTENCE OF CELIAC DISEASE WITH TYPE 1 DIABETES AND INFLAMMATORY BOWEL DISEASE INCREASE THE RISK OF LOW BONE MINERAL DENSITY?

K. Skoracka[1], A. Zawada[1], M. Marciniak[2], M. Michalak[3], A. E. Ratajczak-Pawłowska[1], A. M. Rychter[1], A. Dobrowolska[1], I. Krela-Kaźmierczak[1]

[1]Department of Gastroenterology, Dietetics and Internal Diseases, Poznan University of Medical Sciences, 60-355 Poznan, Poland, Poznań, Poland, [2]Department of Gastroenterology, Dietetics and Internal Diseases, Poznan University of Medical Sciences, Clinical Hospital of Poznan, Poznań, Poland, [3]Department of Computer Science and Statistics, Poznan University of Medical Sciences, Poznan, Poland, Poznań, Poland

Objective: Autoimmune diseases are more frequently observed in celiac disease (CD) than in the healthy population. Taking this into account, the aim of this study was to assess whether patients who in addition to CD are diagnosed with inflammatory bowel disease (IBD) or type 1 diabetes (DM1) have a higher risk of low bone mineral density (BMD).

Materials and Methods: A total of 100 people (80 women and 20 men) with CD were recruited from the outpatient clinic. Based on the medical records, patients were divided into groups: group A - patients with CD, group B - patients with CD and IBD, group C - patients with CD and DM1. BMD, T-score, and Z-score of the lumbar spine (L1-L4) and femoral neck (FN) were assessed using the Lunar DPX-Plus device (Lunar Inc. Madison, WI, USA). Finally,

an appropriate statistical analysis was carried out.
Results: Sixteen percent of the patients had comorbid IBD and 10% of the patients had DM1, so the patients were divided into the following groups: 74 patients were classified in group A, 16 in group B and 10 in group C. The mean age of the patients was 40.3 years. There were statistically significant differences in body weight (57.3 vs. 73.2 kg) and BMI between group B and C patients (20.5 vs. 24.1 kg/m2). There were no significant statistical differences between the groups with regard to age, disease duration, FN BMD, FN T-score, FN Z-score, L1-L4 BMD, L1-L4 T-score, and L1-L4 Z-score. In the overall study group, 43% of patients had low BMD, of which 32% had osteopenia and 11% had osteoporosis. Osteopenia was present in 33.78% of patients in group A, 18.75% in group B and 40% in group C, while osteoporosis was present in 10.8% of patients in group A, 1.25% in group B and 1% in group C. Reduced BMD at the FN was present in 12.33% of patients in group A, 6.67% of patients in group B and 33.33% of patients in group C, and at L1-L4 in 23.61% of patients in group A, 28.57% of patients in group B and 10% of patients in group C, although these differences were not statistically significant.
Conclusions: Patients with CD have high risk of low BMD, but there is no difference in the prevalence of reduced BMD when IBD or DM1 cooccur. Further studies, including larger and equally sized groups, are needed to determine whether autoimmune comorbidities increase the risk of low BMD in patients with CD.
Disclosures: None Disclosed.

CORRECTION OF BONE INJURY WITH MORPHOLINII THIAZOTAS

K. Fomina[1], K. Stadnik[1], A. Tadevosyan[1], N. Mosyagina[2]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia, Lugansk, Russia, Lugansk, Russia, [2]FSBEI HI ST. LUKA LSMU of MOH of Russia, Lugansk, Russia

Objective: The aim of the study was to investigate the possibilities of Morpholinii thiazotas as a corrector of bone injury.
Material and methods: An experimental study was conducted on 90 rats weighing 220-250 g. The animals were divided into three groups. The first group was a control, and the second was a group with bone trauma, in which rats had a hole made in the proximal metaphysis of both tibia with a dental drill. The third group consisted of rats that received daily intraperitoneal injection of a solution of Morpholinii thiazotas in dosage 117 mg/kg. The observation terms were 1, 7, 15, 30, and 60 days after the injury. The objects of the study: the pituitary gland and the pineal gland, which were studied at the organ, tissue, cellular and subcellular levels of organization using modern morphological research methods.
Results: Changes were found in the central parts of the endocrine system in the groups after bone injury, confirming the stages of fracture healing. In group of animals who received Morpholinii thiazotas, results were obtained indicating accelerated recovery and stabilization of pituitary and pineal structures at the final stage of consolidation of damaged bones. The administration of the drug increases the rate of recovery of the micro- and ultrastructure of the endocrine glands. The drug stimulates the synthetic activity of the glands without disrupting their structural organization and cell damage. Morpholinii thiazotas potentiates metabolic processes and, through stimulation of protein synthesis and acceleration of regeneration processes, has a positive effect on bone tissue repair.
Conclusions: The indirect effect of Morpholinii thiazotas on the central links of the endocrine system can affect the hypothalamic-pituitary axis, contributing to the coordination of regenerative processes and the body's adaptation to traumatic injuries.

OSTEOARTHRITIS IN PATIENTS WITH RHEUMATOID ARTHRITIS: THE ROLE OF COMORBID PATHOLOGY AND PHARMACOTHERAPY

A. R. Babaeva[1], K. T. Mirakhmedova[2], E. V. Kalinina[1], V. P. Goloskova[1], K. S. Solodenkova[3]

[1]Volgograd State Medical University, Volgograd, Russia, [2]Tashkent Medical Academy, Department of Propaedeutics of Internal Diseases No. 1, Tashkent, Uzbekistan, [3]Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russia

The aim of our study was to analyze the frequency of osteoarthritis (OA) registration in patients (pts) with rheumatoid arthritis (RA) and to assess the role of cardiometabolic comorbidity, as well as antirheumatic therapy on the OA development.
Materials and methods. 107 hospital pts with RA: 20 (18.7%) men and 87 (81.3%) women aged 30 to 83 years (mean age 59.4 ± 4.6 years). All underwent a standard examination to verify RA, OA, cardiovascular (hypertension, coronary heart disease, heart failure) and metabolic (diabetes mellitus, obesity) pathology. A comparison of the comorbid pathology frequency and the nature of antirheumatic therapy was made in groups of pts with RA and OA combination and without concomitant OA.
Results. OA was diagnosed in 46 (43%) pts with RA, which was regarded as a secondary process. There were 7 men (15.2%) and 39 women (84.2%) in the group 1 (RA with OA), aged 46 to 83 years, the average age was 69.4±5.2 years. Five (10.9%) pts with secondary OA underwent joint replacement surgery (knee or hip joint). The frequency of cardiometabolic pathology in the group 1: hypertension - in 44 pts (95.7%), coronary heart disease - in 6 (13.0%), CHF - in 8 (17.4%) patients, obesity - in 28 (60.9%), type 2 diabetes - in 8 (17.4%). The group 2 (RA without OA) included 61 pts (57%), 13 men (21.3%) and 48 women (78.7%) aged 30 to 75 years, the average age was 54.3±4.9 years. The comorbid pathology spectrum was as follows: hypertension - in 42 (68.9%) pts, coronary heart disease - in 2 (3.3%), CHF - in 2 (3.3%), obesity - in 6 (9.8%), type 2 diabetes - in 3 (4.9%). In group 1, 44 (95.7%) pts received GC at an average dose of 6.5±1.2 mg/day in terms of prednisolone. All pts received DMARDs: methotrexate - 37 pts (80.4%), sulfasalazine - 5 (10.9%), leflunomide - 4 (8.7%).

In group 2, 32 pts (85.2%) received GC at an average dose of 3.2 ± 0.9 mg/day in terms of prednisolone. All pts received DMARDs: methotrexate - 55 (90.2%), sulfasalazine - 4 (6.6%), leflunomide - 2 (3.3%). Groups 1 and 2 differed significantly in terms of average age (t=2.14, p<0.05), frequency of cardiovascular and metabolic pathology (χ^2>4.0, p<0.05), and average dose of GC (t=2.2, p<0.05)

Conclusion. A combination of RA and OA was observed in 46% of hospital patients. An association of OA with age, the presence of cardiovascular and metabolic comorbidity, and long-term use of GC at a dose of more than 5 mg in terms of prednisolone was established.

P793

CLIMATE CHANGE AWARENESS AND HEALTH BEHAVIOURS RELEVANT FOR MUSCULOSKELETAL OUTCOMES: FINDINGS FROM THE HERTFORDSHIRE COHORT INTERGENERATIONAL STUDY

K. Waidyaratne[1], E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom

Objective

Climate change is commonly reported by the media, leading to widespread discussion especially among younger adults. We hypothesized that this may result in lifestyle changes relevant to musculoskeletal health in young adults, specifically changes of active transport uptake and switching to a plant-based diet. We conducted a qualitative study to consider this further.

Materials and methods

We recruited 9 participants: 6 men and 3 women aged between 18 and 41 years old, from the Hertfordshire Cohort Intergenerational Study. Semi-structured qualitative interviews that considered awareness of climate change and lifestyle measures that had been adopted were conducted on Microsoft Teams. Interviews were recorded and transcribed verbatim. Thematic analysis was conducted using Braun and Clarke's approach.

Results

All respondents in our sample were educated to degree level. Several participants reported moving toward a plant-based diet, citing environmental concerns as a major reason behind this, although some did report other health benefits, including reduced risk of bowel cancer. Changes in physical activity were driven more commonly by practical concerns, specifically whether respondents had access to good public transportation, although some respondents did allude to the health and climate impact of active transport.

Conclusion

Several participants interviewed reported health behaviours that might impact their musculoskeletal health, especially peak bone mass acquisition. These data are now being assessed in a larger quantitative study. Further work in other populations, including older adults, is now warranted.

METHOTREXATE MAINTENANCE AND CLINICAL OUTCOMES AFTER TWO YEARS OF BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS: INSIGHTS FROM A TUNISIAN COHORT

K. Zribi[1], S. Rahmouni[1], K. Zouaoui[1], M. Abbes[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]University Hospital La Rabta, Rheumatology Department, Tunis, Tunisia, Tunis, Tunisia

Background:

Biologic therapies (BT) have revolutionized rheumatoid arthritis (RA) management, yet access remains limited in low- and middle-income countries like Tunisia, highlighting the need for optimized methotrexate (MTX) use. While EULAR recommends maintaining MTX in RA patients, real-world data may differ.

Objectives:

To describe MTX maintenance, dose adjustments, discontinuations, and their associations with clinical outcomes two years after BT initiation.

Methods:

We conducted a retrospective, single-center study at La Rabta University Hospital, Tunis, including RA patients meeting the 2010 ACR/EULAR criteria and treated with BT. MTX doses and Disease Activity Score 28 - C-Reactive Protein (DAS28-CRP) scores were collected at BT initiation and after two years. Statistical analyses included Wilcoxon signed-rank, Student's t-test, and logistic regression.

Results:

Fifty RA patients (72% female, mean age 59 ± 12.6 years) were included. Most were ACPA-positive (86%) and had structural damage (98%). The mean disease duration at BT initiation was 7.6 ± 8.5 years. BT included TNF-α inhibitors (68%), CD20 inhibitors (22%), and IL-6 inhibitors (10%).

At BT initiation, all received MTX (mean 16.2 ± 3.65 mg). After two years, 10 patients (20%) discontinued MTX due to adverse effects, while 40 continued: 5% increased, 65% decreased, and 30% maintained the same dose. The mean MTX dose significantly decreased to 11.2 ± 6.4 mg ($p < 10^{-3}$). DAS28-CRP improved from 5.8 ± 0.8 to 4.5 ± 1.4 ($p < 10^{-3}$). MTX dose reduction was associated with lower DAS28-CRP scores (p = 0.02, OR = 6.8) and TNF-α inhibitor use (p = 0.02, OR = 7.5). Other factors showed no significant association.

Conclusion:

After two years, 80% of RA patients maintained MTX, with most reducing doses without compromising BT efficacy. These findings align with EULAR recommendations [1].

P795

CORTICOSTEROID OUTCOMES AFTER TWO YEARS OF BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS

R. Safa[1], K. Zribi[2], M. Abbes[2], K. Zouaoui[2], S. Rekik[2], S. Boussaid[2], H. Sahli[2]

[1]University Hospital La Rabta, Rheumatology Department, Tunis, Tunisia,, Tunis, Tunisia, [2]University Hospital La Rabta, Rheumatology Department, Tunis, Tunisia, Tunis, Tunisia

Background:
Biologic therapies (BT) have revolutionized rheumatoid arthritis (RA) management, improving disease control and a potential corticosteroid (CS) sparing effect.
Objectives:
To assess CS dose changes after two years of BT in RA patients.
Methods:
This retrospective study included RA patients from La Rabta University Hospital, Tunisia. Oral CS doses, expressed in prednisone equivalents (p.e), and Disease Activity Score 28 - C-Reactive Protein (DAS28-CRP) scores were recorded at BT initiation and after two years. Wilcoxon signed-rank and Student's t-tests were used for comparisons, with $p<0.05$ considered significant.
Results:
We included 50 RA patients, mainly female (72%; female-to-male ratio = 2.6). The mean age was 59 ± 12.6 years. Among them, 86% were anti-citrullinated protein antibodies (ACPA)-positive and 98% had structural damage. The mean disease duration at the time of BT initiation was 7.6 ± 8.5 years. BTs used included TNF-α inhibitors (68%), CD20 inhibitors (22%), and IL-6 inhibitors (10%).
At BT initiation, 49 patients were prescribed CS with a mean dosage of 7.9 ± ± 2.6 mg [5-15] (p.e): 14 patients (28.6%) received 5mg (p.e), 12 patients (24.5%) received a dose between 5 and 10 mg (p.e) and 23 patients (46.9%) received a dose ≥10 mg (p.e).
After two years of BT, 19 patients (38%) had the same CS doses, only one had higher doses, and 30 patients (60%) had lower doses. 10 patients (20%) were CS- free. The mean CS dose decreased to 5.6 ± 3.6 mg (p.e) after two years ($p<10^{-3}$).
Similarly, the mean DAS28-CRP score improved significantly from 5.8 ± 0.8 at BT initiation to 4.5 ± 1.4 after two years of BT ($p<10^{-3}$).
Age, gender, ACPA-positive status, structural damage, disease duration at the time of BT initiation, CS dose at BT initiation, DAS at BT initiation and type of BT were not statistically associated with CS decrease.
Conclusion:
BT enables significant CS tapering while maintaining disease control in RA patients. Future research should explore predictive factors for improved treatment strategies.

P796

HOW RELIABLE ARE THE ADRAR AND MAC KENNA INDICES IN DIAGNOSING OSTEOMALACIA? INSIGHTS FROM A RETROSPECTIVE STUDY

K. Zribi[1], S. Boussaid[1], M. Hassayoun[1], S. Rahmouni[1], K. Zouaoui[1], M. Abbes[1], S. Rekik[1], H. Sahli[1]

[1]University Hospital La Rabta, Rheumatology Department, Tunis, Tunisia, Tunis, Tunisia

Background:
Osteomalacia is a rare metabolic bone disorder characterized by defective mineralization, leading to increased bone fragility and diffuse musculoskeletal pain. Its nonspecific presentation makes diagnosis challenging. The Adrar and Mac Kenna indices have been proposed to aid diagnosis.
Objectives:
To describe the clinical, biological, and radiological features of osteomalacia and assess the diagnostic utility of the Adrar and Mac Kenna indices.
Methods:
We conducted a retrospective study of 45 patients hospitalized for osteomalacia between 2002 and 2022. Clinical symptoms (bone pain, muscle weakness, gait disturbances), biological parameters (calcium, phosphate, parathyroid hormone, 25-OH vitamin D, alkaline phosphatase, urinary calcium), and radiological findings (bone translucency, Looser-Milkmann lines, fractures) were analyzed. Adrar (≥25) and Mac Kenna (≥35) indices were calculated. Statistical analyses included chi-square tests and Pearson/Spearman correlations, with $p<0.05$ considered significant.
Results:
The mean age was 46.4±16.8 years (range: 14–70), with a female predominance (73%). Hypocalcemia (66.7%), hypophosphatemia (64.4%), and elevated alkaline phosphatase (93.3%) were common. Parathyroid hormones were elevated in 62.2%, and vitamin D deficiency was present in 84.5%. Radiological findings included bone translucency (91%), Looser-Milkmann lines (40%), and bone deformities (40%). Vitamin D deficiency was the leading cause (36%).
Significant correlations were found between bone pain and urinary calcium ($p=0.05$), muscle weakness and serum calcium ($p=0.04$), and gait disturbances with phosphate ($p=0.01$), alkaline phosphatase ($p=0.02$), urinary calcium ($p=0.01$), and vitamin D ($p=0.03$). Fractures were associated with low serum calcium ($p=0.01$), and bone deformities correlated with hypocalcemia ($p=0.01$).
The Adrar and Mac Kenna indices demonstrated high diagnostic reliability, with mean scores of 50.88±15.85 and 59.81±10.09, respectively. Both identified 97.8% of cases, with strong concordance ($p<10^{-3}$), confirming their diagnostic utility.
Conclusion:
A comprehensive diagnostic approach integrating clinical, biological, and radiological assessments is essential for osteomalacia. The Adrar and Mac Kenna indices are reliable tools for confirmation, enabling early intervention to prevent complications. Further research is needed to optimize long-term management strategies.

P797

ASSOCIATION BETWEEN COOKING OIL FUME EXPOSURE AND BONE MINERAL DENSITY AMONG POSTMENOPAUSAL WOMEN IN TAIWAN: A CROSS-SECTIONAL STUDY

K.-E. Huang[1], Y.-S. Chuang[2], Y.-T. Lin[2]

[1]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, [2]Department of Family Medicine, Kaohsiung Medical University Hospital. Center for Big Data Research, Kaohsiung Medical University. Research Center for Precision Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan

Objective

Exposure to air pollutants is increasingly recognized as a potential risk factor for impaired bone health (1). As cooking oil fumes (COF) represent a primary source of indoor air pollution, this study aimed to investigate the relationship between COF exposure and bone mineral density (BMD) among postmenopausal women in Taiwan.

Materials and Methods

This cross-sectional study included 5,283 postmenopausal women with regular cooking habits from the Taiwan Biobank between December 2008 and February 2020. Participants with a history of hormone replacement therapy were excluded. For general screening purpose, BMD was assessed using quantitative ultrasonography (QUS) of the calcaneus. COF exposure amount was quantified by multiplying the frequency of cooking (times per week) by the duration (years). Participants were categorized into higher and lower exposure groups based on the median exposure level. Multiple linear regression models were used to assess the association between COF exposure and BMD.

Results

The mean BMD was significantly lower in the higher exposure group (n=2,644) compared to the lower exposure group (n=2,639) (-1.03 ± 1.44 vs. -0.80 ± 1.45, p<0.0001). However, the multiple linear regression showed no significant association between higher COF exposure and BMD (β=0.07, 95% CI: -0.05 to 0.18, p=0.2683) after adjusting for potential confounders, including age, BMI, marital status, cigarette smoking, second-hand smoke exposure, tea drinking habits, exercise habits, diabetes, chronic kidney disease, duration and cause of menopause, cooking method, cooking fuel type, cooking oil type, and the use of a cooking hood.

Conclusion

This study found no significant association between COF exposure and BMD as measured by QUS in postmenopausal women. Further longitudinal studies are warranted to validate this finding and clarify the long-term impact of COF exposure on bone health.

P798

NUTRITIONAL PROFILE IN OLDER PEOPLE WITH LOW BONE MINERAL DENSITY: PILOT NUTRITIONAL STUDY

L. A. Lacoski[1], T. Tsuani[1], B. O. Alfonso[1], M. L. Da Silva[1], A. L. Coutinho[1], O. De Matos[1]

[1]Federal University of Technology-Parana, Curitiba, Brazil

Objective: The objective of this study was to evaluate the nutritional profile of elderly people with low bone mineral density and physical performance, as a predictor for the increased risk of fractures due to falls in the older adults.
Methods: The cross-sectional pilot study consisted of 45 elderly people (35 female and 10 male) with a mean age of 67.7±5.9 years, assessed with low bone mineral density. Dual energy x-ray absorptiometry (DXA) was used to evaluate total mass, total lean mass (TLM), appendicular skeletal mass (ASM/H²), body mass index (BMI) and bone mineral density (BMD). For physical performance gait speed (GST) was used; Three-day food record and data were processed by DietBox software for nutritional analysis. The results were presented with descriptive analysis.
Results: We found mean BMI classifying overweight, 27 people with low muscle mass, 19 with low performance test in chair stand and gait speed tests (42.2%). Of the total, only two people had normal calcium intake. Table 2 presented high values of calories and sugar, while dietary fiber, minerals such as calcium and magnesium presented low daily intake in almost the entire sample; Vitamin D also showed very low values.
Conclusion: We conclude that inadequate intake of mineral and other nutrients may be the cause of bone fragility in the sample evaluated. We also consider that the fact that the majority of the sample presented low physical performance, increases not only the risk of falls, but also of fractures due to bone fragility.

P799

TREATMENT AND REHABILITATION OUTCOMES IN OSTEOARTHRITIS PATIENTS WITH COMORBID CONDITIONS

L. Ametova[1], A. Useinova[1], V. Kaliberdenko[1], I. Bykovskiy[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To evaluate the effectiveness of comprehensive treatment and rehabilitation in patients with osteoarthritis (OA) combined with chronic obstructive pulmonary disease (COPD).
Materials and Methods: The study included patients with stage I-II OA combined with moderate to severe (stage 2-3) COPD. Of these, 20 patients had knee OA, 12 had polyosteoarthritis, and 10 had hip OA. Clinical-functional, radiological, and biochemical (ALT, AST, bilirubin, C-reactive protein (CRP)) assessments were conducted. Pulmonary function tests (PFTs) and peak flowmetry (PFM) data were analyzed. Magnetic resonance imaging (MRI) or computed tomography (CT) scans were performed as needed. Patients received individually tailored programs of ultraviolet

irradiation, ultra-high-frequency microwave therapy, extremely high-frequency therapy, magnetotherapy, or laser therapy. Against the background of basic COPD treatment, patients received a chondroprotector containing chondroitin sulfate and herbal extracts as a symptom- and structure-modifying slow-acting drug for 6 months (2 tablets twice daily, 5-10 minutes before meals).
Results and Discussion: During treatment, dyspnea decreased from 2.9±0.29 to 1.3±0.15 points and cough from 2.5±0.14 to 1.2±0.16 points. Regression of these symptoms occurred alongside a reduction in physical findings, weakness, sweating, and improvement in the overall condition of patients. PFM data revealed an increase in bronchial patency (from 305.6±21.9 to 343.4±23.1 L/min). Positive dynamics were observed in PFT and clinical-biochemical parameters. Inflammatory manifestations in the bronchopulmonary system decreased or resolved, correlating with laboratory indicators (CRP, leukocytes, ESR, sputum). Starting from the first month of treatment, patients reported a reduction in pain and other clinical signs of OA, with the most significant changes observed in the knee OA group. Pain during movement, measured on a visual analog scale (VAS), decreased from 70.7±11.2 to 31.7±3.8 mm by the third month of observation. In the same group, a significant reduction in resting pain (VAS) was observed, from 32.3±6.7 to 11.5±3.2 mm. The Lequesne Functional Index (LFI) in this group decreased from 6.5±1.1 to 4.15±0.39. In the polyosteoarthritis group, pain during movement (VAS) decreased from 72.5±26.7 to 28.9±6.7 mm by the third month (resting pain decreased from 30.4±7.1 to 13.4±4.2 mm; LFI decreased from 6.5±1.36 to 4.5±0.51). In patients with hip OA, pain during movement decreased from 81.0±10.1 to 37.9±6.8 mm, and resting pain decreased from 30.3±6.4 to 22.2±5.1 mm. LFI also decreased from 6.8±1.23 to 5.2±0.51. A significant decrease in pain index (VAS) during movement and at rest was observed in all three groups after 3 months of treatment. LFI decreased in all three groups after four weeks of chondroprotector intake, with the most significant decrease in the knee OA group. The chondroprotector allowed for a reduction in the dose or complete discontinuation of traditional nonsteroidal anti-inflammatory drugs (NSAIDs). Three months after the start of therapy, 21% of patients took NSAIDs as needed, while 79% discontinued them. Treatment of OA with comorbid conditions is a complex process targeting the pathogenetic mechanisms of the diseases. The anti-inflammatory properties of the chondroprotector components favorably influence the course of both diseases. Proper organization of rehabilitation measures is crucial for patients with comorbid pathology. Functional status, pain syndrome, range of motion in the joints, severity of dyspnea, motivation level, and smoking status are considered when selecting OA patients with COPD for rehabilitation. Objectification of the functional state shows that certain success can be achieved in patients with varying severity of OA and COPD The baseline rehabilitation potential should characterize the patient's capacity to utilize multifactorial mechanisms for restoring impaired health and normalizing various forms of life activity. The combined use of modern pharmacotherapy and rehabilitation can improve exercise tolerance in comorbid patients and positively influence the outcomes of the final stage of joint and pulmonary rehabilitation. Therapeutic exercises are a cornerstone of medical rehabilitation programs for patients with OA and COPD. This is due to the corrective influence of therapeutic exercises on the biomechanics of movement and respiration, improvement of bronchial patency, acceleration of the resolution of the inflammatory process, and increase in pulmonary function reserves. Available physiotherapy methods for OA and COPD include ultraviolet irradiation, ultra-high-frequency therapy (UHF), inductothermy, microwave therapy in the centimeter and decimeter ranges, extremely high-frequency therapy (EHF), amplipulse therapy, and magnetotherapy. All these methods reduce inflammatory manifestations in the joints and bronchi, improve joint mobility and bronchial patency, decrease exudative reactions in the lung parenchyma, exert a bacteriostatic effect, and provide an immunomodulatory effect. Acupuncture, electroacupuncture, laser acupuncture, and acupressure can also be incorporated. Laser radiation has an anti-inflammatory effect, increases the body's reactivity, and improves blood rheological properties. Clinical manifestations of this effect include resolution of inflammation, including synovitis, and reduction of bronchial mucosa edema. Hirudotherapy (leech therapy) can be widely used in the outpatient rehabilitation phase. The use of combined chondroprotectors in the treatment of patients with OA in combination with COPD leads to a faster reduction in pain, shorter hospital stays, and restoration of daily activity. The obtained results demonstrate the effectiveness of combined chondroprotectors in OA therapy and the possibility of their use in general medical practice. In addition to physical rehabilitation, all patients are recommended to perform breathing exercises for 20 minutes 2-3 times a day, including the following exercises: pursed-lip breathing, resistance exhalation, breathing in a bent position with a forward lean, and diaphragmatic breathing exercises.
Conclusions: For patients with OA and COPD, combined joint and pulmonary rehabilitation programs are recommended to improve quality of life, increase exercise tolerance, and reduce the severity of clinical symptoms. Modern treatment and rehabilitation of OA with COPD aims not only to reduce pain and improve the functional state of the affected organs but also to slow the progression of the disease through the complex use of non-pharmacological and pharmacological methods, contributing to a reduction in disability and improvement in the quality of life of patients.

P800

SEASONAL VARIATIONS IN VITAMIN D3 IN PATIENTS WITH OSTEOPOROSIS

L. Ametova[1], V. Kaliberdenko[1], E. Kulieva[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The body's supply of endogenous cholecalciferol (vitamin 25(OH) D3) depends on age, gender and a number of other parameters, and also changes significantly throughout the year depending on the season. However, the question of practical recommendations regarding the timing of the administration of vitamin D preparations depending on the time of year remains open to discussion.
The aim of the study was to study the fluctuations in vitamin D levels in patients with osteoporosis (OP) depending on the season.

Materials and methods. We studied the level of vitamin 25 (OH) D3 in 396 patients (mean age 54.07 ± 11.32) diagnosed with OP/osteopenia, including 376 (94.95%) women and 20 (5.05%) men. There were 245 patients with a history of fractures, and 151 patients without fractures. All patients underwent dual-energy X-ray absorptiometry on a Lunar DPX device. The diagnosis of OP was made based on the clinical guidelines Osteoporosis-2021 approved by the Ministry of Health of the Russian Federation. The level of vitamin 25 (OH) D3 was determined using a kit for enzyme-linked immunosorbent assay 25-OH Vitamin D ELISA. Results. The maximum levels of average 25(OH)D3 values were observed in June (90.38 nmol/l), and the minimum value in January (50.85 nmol/l, p<0.001). During July-November, the average values of vitamin D level were 65.94-73.89 nmol/l (the differences are statistically insignificant). In order to identify the number of patients requiring drug prophylaxis of hypovitaminosis D, we calculated the number of patients with vitamin D deficiency. We found that during the year, the majority of patients have a deficiency of this indicator. The highest percentage of patients with vitamin D deficiency was observed in April and May (16.67 and 12.24%, respectively). In the period from June to September, the incidence of hypovitaminosis was significantly lower and amounted to 1.92–3.7%. Despite the fact that the lowest average 25(OH)D3 values are observed in January and December, there were no patients with a deficiency of this indicator in these months. We also studied the relationship of 25(OH)D3 with the age of patients. We found that with increasing age of patients, a gradual decrease in the level of 25(OH)D3 in the blood is observed (r = - 0.099, p = 0.049). Conclusions. We found significant seasonal fluctuations in 25(OH)D3 in the examined group of patients. The influence of the seasonal factor on the level of vitamin D was proven using statistical analysis methods. No statistically significant differences were found in the average levels of vitamin D in the summer months, accompanied by high solar activity (July-August) and autumn (September-November). This fact can be explained by the short time spent outdoors on hot summer days, which does not contribute to sufficient production of endogenous 25(OH)D3. Based on the results identified, it is recommended to carry out prevention of vitamin D deficiency. For the population of the Volgograd region, prevention should be carried out from September to May, in accordance with international recommendations. This is especially important for older patients.

P801

EVALUATION OF THE REMOTE RESULTS OF COMPREHENSIVE REHABILITATION OF PATIENTS WITH VERTEBRAL FRACTURES AGAINST THE BACKGROUND OF OSTEOPOROSIS WITH THE INCLUSION OF MECHANOTHERAPY AND INTERACTIVE BALANCE THERAPY WITH BIOLOGICAL FEEDBACK

L. Ametova[1], A. Useinova[1], V. Kaliberdenko[1], I. Bykovskiy[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Relevance. Rehabilitation of patients with vertebral fractures (VF) against the background of osteoporosis (OP) requires a personalized approach and the use of modern low-traumatic methods of restorative medicine. According to Svensson H.K. et al. (2017), personally selected physical exercise programs for patients with VF against the background of OP with varying degrees of evidence affect motor functions, pain, quality of life, pain level and fear of falls. However, the data are ambiguous and sometimes contradictory. According to Genev I.K. et al. (2017), despite numerous options for non-drug treatment of compression VF against the background of OP, there is currently no consensus on the management of patients with these fractures. Objective: to evaluate the effectiveness of a new rehabilitation complex in the long-term period in patients with VF against the background of OP, including mechanotherapy and interactive balance therapy with biofeedback. Material and methods. The study included 120 patients aged 40-80 years with at least one PP at the ThIV-LV level dating from 4 to 12 weeks and bone mineral density (BMD) values in the LI-LIV segment or femur ≤ -2.0 according to the T-score. Patients in group 1 received a new physical therapy complex for 20 days with the inclusion of mechanotherapy technologies with biofeedback (patent No. 2709843, state registration date December 23, 2019), which included: 1) 10 sessions on a group of exercise machines with biofeedback to increase back muscle strength; 2) 10 sessions of interactive balance therapy on an unstable platform with biofeedback; 3) 15 group hydrokinesitherapy sessions in fresh water in a therapeutic pool with an instructor to increase muscle strength and improve coordination; 4) 15 group sessions of therapeutic gymnastics in the gym with the duration, using the modified and adapted for patients with OP Gorinevskaya-Drewing method. Patients of group 2 (comparison group) were prescribed a set of 15 group sessions of hydrokinesitherapy and 15 sessions of therapeutic gymnastics according to the Gorinevskaya-Drewing method (without the use of mechanotherapy methods with biological feedback). Functional tests and the level of back pain were assessed after 70 days, 6, 12 and 24 months, BMD by bone densitometry was studied after 12 and 24 months. Results and discussion. The level of back pain in group 1 was 2.5 [0; 3.0] points after 6 months (p = 0.005 compared with the initial level), 1.0 [0; 1.0] points after 12 months (p=0.003 compared to baseline; p=0.0009 compared to group 2) and 1.5 [0; 2.0] points after 24 months (p=0.038 compared to baseline). In group 2, at similar stages, the pain intensity was, respectively, 3.0 [0; 3.0] points (p=0.006 compared to baseline), 3.0 [0.5; 3.0] points (p=0.022) and 2.5 [0; 3.0] points (p=0.041). In group 1, on the 70th day and subsequently at all stages of remote observation, the time to complete the "Stand up and go" test was significantly lower than before the start of rehabilitation (p<0.05). In group 2, improvement in the results of this test was noted only after 6 and 12 months from the start of rehabilitation (p<0.05). In group 1, a statistically significant increase in BMD in the lumbar spine segment LI-LIV by 1.82% [-1.17; 5.48] was noted after 12 months

(p=0.045) and by 3.24% [-1.41; 12.8] after 24 months (p=0.038). Also in the main group, after 24 months, an increase in BMD in the femoral neck by 2.45% [-2.23; 10.6] was noted (p=0.029). No significant dynamics of densitometric indicators were recorded in group 2, either after 12 or 24 months (p>0.05). Probably, the main factor that influenced this result was the different proportion in the groups of patients who received pathogenetic drug therapy for OP - bisphosphonates or denosumab during the observation period. The proportion of such patients who received basic therapy for OP in group 1 was 39/47 (83.0%) after 12 months and 18/21 (85.7%) after 24 months, in group 2 - 21/43 (48.8%, p = 0.0006 compared with group 1, Pearson χ2) and 9/16 (56.3%, p = 0.046 compared with group 1, Pearson χ2). Obviously, patient monitoring after a fracture by a health care professional, close interaction and contact between the doctor and the patient significantly increase the degree of adherence not only to medical rehabilitation procedures, but also to drug treatment for OP. In this aspect, the role of personal control by a physician in physical and rehabilitation medicine, his participation in patient education and monitoring of the correct implementation of the recommended treatment is extremely important.
Conclusions: In patients with PP against the background of OP, the use of a new rehabilitation method with the inclusion of mechanotherapy and interactive balance therapy with biofeedback is associated with rapid regression of pain syndrome and with an increase in the motor activity of patients, and also increases adherence to OP therapy, which contributes to an increase in BMD in the spine after 12 and 24 months, and in the femoral neck after 24 months. A 20-day complex, including training on exercise machines with biofeedback and interactive balance therapy against the background of group therapeutic exercise classes in the gym and in the pool is recommended for the 2nd stage of medical rehabilitation of patients with osteoporosis in periods from 4 to 12 weeks after clinical compression PP.

P802

HIGH RISK OF FRACTURES AMONG RESIDENTS OF THE RUSSIAN FEDERATION

L. Ametova[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: to determine the frequency of high risk of major osteoporotic fractures (MOF) among residents aged 50 years and older in different regions of the Russian Federation. Material and methods: The study included 13,941 women (average age 61.5 ± 9.8 years) (stratified samples of cities in 7 federal districts (FD)) and 4,077 men (average age 61.9 ± 10.2 years) (stratified samples in 5 FDs). Participants were surveyed using the risk factors questionnaire included in FRAX®, on the basis of which the absolute ten-year risk of MOF was calculated without entering data on bone mineral density of the femoral neck. A high risk was considered to be a FRAX® value above the Russian age-dependent threshold for therapeutic intervention. Results: FRAX® indicators for major MOF were significantly higher in women compared to men, regardless of the region of residence. The highest FRAX® values were found in women in the Far Eastern Federal District (15.0% [10.0, 23.0], (Me [Q25, Q75]), and the lowest in women in the Volga Federal District (11.0% (7.8, 16.0)) (p < 0.001). Among men, this indicator was higher in residents of the Northwestern Federal District (6.3% [4.4, 10.0]), and the lowest, as well as among women, in the Volga Federal District (4.6% [4.2, 8.1]) (p < 0.001). Among all survey participants, 31% of women had FRAX® values corresponding to a high risk of AKI, while among men, only 5% of respondents reached the threshold of therapeutic intervention. An increase in the number of women with FRAX® values above the threshold of therapeutic intervention was noted depending on the age of the surveyed: from 23% at the age of 50-59 years old to 51.3% at the age of 80 years and older. No such pattern was obtained for men: most often, a high risk of fractures was determined at the age of 50-59 years (7.8%), and in other age groups it was slightly more than 3%. A high risk of fractures was more often detected among female residents of the Far Eastern Federal District (38.5%), the Ural Federal District (34.8%), the Siberian Federal District (33.7%) and the Central Federal District (32%) compared to representatives of the Volga Federal District (24%) and the Southern Federal District (25.8%) (p <0.001). Among men, individuals with high fracture risk were more common in the Northwestern Federal District (10.2%) and the Ural Federal District (8.8%) compared to those living in other regions of the country (p<0.001), the frequency of high FRAX® among men in the Volga Federal District (4.4%), Central Federal District (3.6%) and Siberian Federal District (2.8%) did not differ statistically (p>0.05). Conclusion: 31% of women and 5% of men aged 50 years and older had a high fracture risk according to the FRAX® algorithm. High fracture risk was determined more often in women in the Far Eastern, Siberian, Ural and Central Federal Districts than in other regions, and in men in the Northwestern and Ural Federal Districts.

P803

EVALUATION OF VITAMIN D METABOLISM IN PATIENTS WITH CUSHING'S DISEASE IN RESPONSE TO TREATMENT WITH COLECALCIFEROL AT A DOSE OF 150,000 IU

L. Ametova[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: to evaluate vitamin D metabolism in patients with Cushing's disease (CD) compared to healthy individuals during a bolus load of cholecalciferol.
Materials and methods: the main group included 30 adult patients with active CD, the control group included 30 healthy volunteers matched for age, gender and BMI. All participants received a single dose (150,000 IU) of aqueous cholecalciferol solution orally. Blood vitamin D metabolites (25(OH)D3, 25(OH)D2,1,25(OH)2D3, 3-epi-25(OH)D3 and 24,25(OH)2D3), free 25(OH)D, vitamin D-binding protein (DBP) and parathyroid hormone (PTH), as well as blood and urine biochemical parameters were determined before and on days 1, 3 and 7 after cholecalciferol administration.

Results: In patients with CCD, 25(OH)D3 levels were similar to those in healthy individuals throughout the study ($p > 0.05$), but higher 25(OH)D3/24,25(OH)2D3 ratios were observed ($p < 0.05$). They also had lower baseline free 25(OH)D ($p < 0.05$) despite comparable DBP levels ($p>0.05$) and lower albumin levels ($p < 0.05$). 24-hour urinary free cortisol correlated with baseline 25(OH)D3/24,25(OH)2D3 ratio ($r = 0.36$, $p < 0.05$). The increase in 25(OH)D3 by day 7 after taking cholecalciferol in patients with ICD was similar in the presence and absence of obesity and did not correlate with BMI ($p > 0.05$), unlike the control group. Conclusions. In general, patients with ICD had consistently higher 25(OH)D3/24,25(OH)2D3 ratios, indicating reduced 24-hydroxylase activity. Altered activity of the main enzyme of vitamin D catabolism in patients with ICD may influence the effectiveness of cholecalciferol treatment. The observed difference in baseline levels of free 25(OH)D is not entirely clear and requires further study.

P804

ASSESSMENT OF QUALITY OF LIFE INDICATORS IN PATIENTS WITH FRACTURES OF THE PROXIMAL FEMUR AND IN INDIVIDUALS WITHOUT FRACTURES

L. Ametova[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective. To assess the quality of life of patients with proximal femur fractures.
Materials and methods. The quality of life was studied in 173 women and 46 men aged 50 years and older with hip fractures sustained with minimal trauma. The control group consisted of 150 women and 50 men aged 50 years and older without a history of hip fractures. A total of 419 people were included in the study. The quality of life of patients with proximal femur fractures was assessed using the QOL questionnaire: SF-36. Results. It was found that among the scales characterizing the physical component of health, statistically significant differences between the groups were obtained for the indicators of physical functioning - 9.46% ($p = 0.002$) and role functioning due to physical condition - 11.2% ($p = 0.001$). There were no statistically significant differences between the groups in terms of general health and pain intensity (3.85% and 1.16%, respectively) ($p> 0.05$). For the scales that make up the mental component of health, statistically significant differences between the groups were found for the mental health indicator of 4.4% ($p=0.03$) and the role functioning indicator due to emotional state of 6.5% ($p=0.006$). The social functioning indicator did not differ significantly between the groups and amounted to 1.85% ($p=0.26\%$). In the group with hip fractures, the vital activity scale indicator was 2.92% higher than in the group without fractures, however, no statistically significant differences were found between the groups ($p=0.12$). There were no statistically significant differences in the physical and psychological health components (3.91% and 2.38%, respectively) ($p> 0.05$). Conclusions. Thus, in the group of individuals with hip fractures, quality of life indicators were reduced to a greater extent and in most parameters than in the group of individuals without fractures.

P805

OSTEOPOROTIC FRACTURE INCIDENCE AND 10-YEAR FRACTURE RISK IN PATIENTS WITH SYSTEMIC SCLERODERMA

V. Kaliberdenko[1], L. Ametova[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: to determine the incidence of fragility fractures in patients with systemic sclerosis (SSc) and to calculate the 10-year risk of new major osteoporotic fractures. Materials and methods: The study included 230 patients with SSc according to the ACR/EULAR 2013 criteria: 180 (78.3%) women (110 (61.1%) postmenopausal) and 50 (21.7%) men (33 (66%) over 50 years). The median age was 54.0 [42.0; 61.0] years, the median disease duration was 7.0 [3.25; 12.0] years. For postmenopausal women and men over 50 years, the risk of major osteoporotic fractures was calculated using the FRAX tool, as a result of which patients were divided into low, intermediate or high risk groups. Patients with moderate risk underwent dual-energy X-ray absorptiometry of the femoral neck (FE) and FRAX was recalculated with inclusion of the FE T-score value. Results and discussion: Low-energy fractures in the anamnesis were present in 59 (25.6%) patients: vertebral fractures - in 27 (15.0%) women and 8 (16.0%) men, peripheral fractures - in 31 (17.2%) women and 2 (4.0%) men, of which 9 (5.0%) women and 1 (2.0%) man had both vertebral and peripheral fractures. Among all patients, only 1 (2.0%) man had a fracture of the proximal femur. FRAX calculation showed that 36 (25.2%) patients (12 (10.9%) women and 24 (72.7%) men) had a low risk of osteoporotic fractures, 60 (41.9%) patients (51 (46.4%) women and 9 (27.3%) men) had an average risk. The high-risk group included 47 (42.7%) women and no men. After recalculating FRAX with the inclusion of the SB T-score in individuals with an average risk, 9 (8.2%) women and 2 (6.0%) men were in the high-risk group, 14 (12.7%) women and 1 (3.0%) man were in the very high-risk group, and 34 (30.9%) women and 6 (18.2%) men were in the low-risk group. 6 (18.2%) men and 3 (2.7%) women with a history of fragility fractures had low risk according to FRAX, but they should also be considered as high-risk patients. Conclusions: 59 (25.6%) patients with SSD had fragility fractures. The incidence of vertebral and peripheral fractures did not differ in women. Vertebral fractures were significantly more common among men. High risk of osteoporotic fractures was significantly more common in women (66.4%) compared to men (27.3%).

P806

PSORIATIC ARTHRITIS WITH SEVERE MUSCULOSKELETAL MANIFESTATIONS AND ERYTHRODERMIC PSORIASIS. SUCCESSFUL TREATMENT WITH IV AND SC INFLIXIMAB

P. Athanassiou[1], C. Kalinou[2], L. Athanassiou[3], N. Koukosias[1], S. Mitsoulis[1], I. Kostoglou-Athanassiou[4], G. Kaiafa[5], C. Savopoulos[5]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece, [2]Dermatology Unit, St. Paul's Hospital, Thessaloniki, Greece, [3]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece, [4]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece, [5]First Department of Propaedeutic Medicine, AHEPA University General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Psoriatic arthritis is a systemic autoinflammatory disease which may be accompanied by psoriasis. Psoriatic arthritis is accompanied by musculoskeletal manifestations. A very rare form of psoriasis is erythrodermic psoriasis. Erythrodermic psoriasis represents a rare variant of psoriasis and accounts only for 1-2% of psoriasis patients. It is characterized by erythema and scaling affecting almost the whole of body surface, namely 75-90% of it. Patients may present with systemic symptoms, such as pruritus, fever, chills, dehydration, joint pain, fatigue and lymphadenopathy. Triggers for this rare variant of psoriasis are severe emotional stress and a preceding illness.

The aim was to describe the case of a female patient who presented with psoriatic arthritis, severe musculoskeletal manifestations and erythrodermic psoriasis, which was managed successfully by topical treatment and IV followed by SC administration of infliximab.

A female patient, aged 41 years, suffering from psoriatic arthritis with severe musculoskeletal manifestations presented with diffuse erythema and scaling affecting almost the whole of body surface and systemic symptoms. The patient reported severe emotional stress within the previous week. The patient had a fever in spikes, fatigue and arthralgias.

Topical preparations were applied to treat the skin erythema and scaling. Antibiotics were administered along with intravenous fluids and prednisolone. Infliximab IV was administered and the patient improved significantly. Subsequently, SC infliximab was given.

Psoriatic arthritis, a systemic autoinflammatory disease with musculoskeletal manifestations, may be accompanied by psoriasis. The case of a patient is described herein who presented with erythrodermic psoriasis in the context of psoriatic arthritis with musculoskeletal manifestations following severe emotional stress. Infliximab was administered along with topical treatment with significant improvement. Biological agents have revolutionized the treatment of erythrodermic psoriasis and have offered hope in the management of this rare and severe form of psoriasis, which in this case was observed in the context of psoriatic arthritis.

P807

DOSE MATTERS: A COMPARISON OF 5,000 IU AND 50,000 IU VITAMIN D SUPPLEMENTATION

M. G. Ghasaboghlyan[1], L. B. Baghdasaryan[1], V. M. Mukuchyan[2], A. G. Jaghinyan[1]

[1]Vardanants Medical Center for Innovative Medicine, Yerevan, Armenia, [2]National Institute of Health in Armenia, Yerevan, Armenia

Background: Vitamin D is a steroid hormone essential for calcium homeostasis, bone health, and numerous physiological processes, including immune function and inflammation. Vitamin D deficiency (<20 ng/mL) and insufficiency (20–30 ng/mL) are common and associated with various health risks. Effective repletion of vitamin D levels is crucial, but the optimal dosing strategy remains debated. Adherence to daily supplementation may also influence outcomes.

Objective: The purpose of this study is to compare the efficacy of two vitamin D supplementation regimens: 5,000 IU daily and 50,000 IU weekly in rapidly increasing serum vitamin D levels in patients with deficiency and insufficiency, while also evaluating adherence and convenience of weekly versus daily dosing.

Methods: A total of 800 patients (ages 25–50) with documented vitamin D deficiency or insufficiency were enrolled and randomized into four groups:

- Group 1 (n=200): Vitamin D 5,000 IU daily (deficiency group).
- Group 2 (n=200): Vitamin D 50,000 IU weekly (deficiency group).
- Group 3 (n=200): Vitamin D 5,000 IU daily (insufficiency group).
- Group 4 (n=200): Vitamin D 50,000 IU weekly (insufficiency group).

Serum 25(OH)D levels were measured at baseline, 6 weeks, and 12 weeks. Adherence was assessed using patient diaries and pill counts. Patients were educated on the importance of consistent supplementation.

Results: At 6 weeks, both 50,000 IU groups (Group 2 and Group 4) showed a faster and more significant rise in serum 25(OH)D levels compared to the 5,000 IU groups. By 12 weeks, Group 2 (50,000 IU weekly, deficiency) achieved a mean serum level of 36 ng/mL (±5), while Group 1 (5,000 IU daily, deficiency) reached 28 ng/mL (±6). Similarly, Group 4 (50,000 IU weekly, insufficiency) achieved a mean level of 40 ng/mL (±8), while Group 3 (5,000 IU daily, insufficiency) reached 30 ng/mL (±5). Adherence was higher in the weekly dosing groups (Groups 2 and 4) compared to the daily dosing groups (Groups 1 and 3), with 92% of patients completing the weekly regimen versus 78% for daily dosing.

Conclusion: Weekly supplementation with 50,000 IU of vitamin D is not only more effective for rapidly increasing serum vitamin D levels but is also more convenient, leading to better adherence compared to daily 5,000 IU dosing. These findings suggest that 50,000 IU weekly is a superior option for repleting vitamin D levels in both deficient and insufficient patients, particularly in real-world settings where adherence is a concern.

P808

TERIPARATIDE IN A HEMODIALYSIS PATIENT WITH HIGH TURNOVER BONE DISEASE AND MULTIPLE FRACTURES: A CASE REPORT

L. B. Brunerova[1]

[1]Department of Medicine, Faculty Hospital Kralovske Vinohrady, Prague, Czechia

Objetive: Chronic kidney disease (CKD)–induced osteoporosis represents one of the skeletal components of chronic kidney disease–mineral and bone disorder (CKD–MBD) associated with a 3-5 fold increased fracture risk. Its management faces several challenges, since some anti-osteoporotics are contraindicated or the data for their use is limited. Successful use of teriparatide has been reported in patients with low turnover bone disease and in hypercalcemia associated with adynamic bone disease. Here, a case of an elderly female patient with CKD stage 5 on hemodialysis and multiple fractures due to high turnover bone disease treated with teriparatide is presented.

Case Presentation:

A woman (born 1941) with polycystic kidney disease had been treated for postmenopausal osteoporosis without fractures with bisphosphonates since 2007 for 6 years. After 5 years of drug holidays with significant BMD decrease, denosumab 60 mg every 6 months was initiated and increased lumbar BMD after 2 years. Meanwhile, CKD progressed to dialysis. Despite prevention, transient episodes of hypocalcemia-induced hyperparathyroidism after each administration of denosumab were observed. In 2019, serum calcium and PTH significantly increased (2.82 mmol/l and 35 pmol/l respectively) and a hyperplasia of upper right parathyroid gland was suspected based on MIBI. The patient refused surgical treatment, thus cinacalcet 30 mg daily was initiated, resulting in normal calcemia (2.54 mmol/l) and a decrease in PTH (23 pmol/l). In 2021, DXA revealed significant decrease in BMD in the proximal femur, and CT confirmed multiple compressive fractures of Th12, L1, and L2. With the patient's approval, teriparatide 20 µg daily was administered, leading to a significant increase in lumbar BMD after 2 years without any new fractures, and normalization of calcemia (with consequent withdrawal of cinacalcet). After termination of teriparatide, ibandronate 3 mg i.v. was administered every three months. The patient died after 11 months due to cardiovascular complications.

Conclusions: Teriparatide also appears to be effective and safe in high turnover CKD-MBD (with tertiary hyperparathyroidism well controlled on cinacalcet), complicated by multiple vertebral fractures.

P809

STRUCTURAL DAMAGE AND CORTICOSTEROID DOSES IN RHEUMATOID ARTHRITIS: IS THERE A LINK?

R. Dhahri[1], I. Oueslati[1], L. Ben Ammar[1], H. Ben Ayed[1], K. Amri[2], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital, Rheumatology departement, Tunis, Tunisia, [2]Military Hospital, Orthopedics departement, Tunis, Tunisia

Introduction:

Corticosteroids play a significant role in the management of rheumatoid arthritis (RA). They control inflammation and provide protection against structural progression.

Objective:

This study aims to evaluate the structural damage in patients with RA and the corticosteroid doses they receive, in order to determine if there is a link between the two.

Methodology:

Consecutive patients with rheumatoid arthritis according to the ACR/EULAR 2010 criteria were enrolled. Socio-demographic data, daily doses of corticosteroids, and cumulative doses were recorded. Structural damage was assessed using the Sharp score, which evaluates the presence of erosions in 17 joint sites and joint narrowing at 18 sites in the hands. A score from 0 to 5 was given for each joint based on the severity of the erosions (total erosion score: 0–170). A score from 0 to 4 was given for joint narrowing (total narrowing score: 0–144). The total score is 448.

Results:

A total of 70 patients were included, with a sex ratio of 0.27 (15 men and 55 women). The average age was 55 ± 13 years, and the mean disease duration was 104.3 ± 102 months. Cs-DMARDs were prescribed to 64 patients (91.4%), and b-DMARDs were prescribed to 21 patients (30%).

Sixty-five patients (92.9%) were receiving systemic corticosteroids, with an average daily dose of 19.6 ± 13.8 mg and an average cumulative dose of 4.8 g ± 1.2 g. The mean Sharp score was 28.17 ± 3. There was no correlation between the Sharp score and the daily dose of corticosteroids ($r = 0.043$, $p = 0.728$), nor with the cumulative corticosteroid dose ($r = 0.137$, $p = 0.381$).

Conclusion:

This study suggests that the structural effect of corticosteroids is not dose-dependent.

Given their protective structural effects and their dose-dependent adverse effects, it is necessary to prescribe corticosteroids at the lowest effective dose.

P810

PULMONARY INVOLVEMENT IN RHEUMATOID ARTHRITIS: A DESCRIPTIVE STUDY

R. Dhahri[1], I. Oueslati[1], L. Ben Ammar[1], H. Ben Ayed[1], I. Mejri[2], T. Znegui[2], Z. Moatamri[2], M. Aloui[3], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital, Rheumatology departement, Tunis, Tunisia, [2]Military Hospital, Pneumology departement, Tunis, Tunisia, [3]Military Hospital, radiology departement, Bizerte, Tunisia

Introduction:
Pulmonary involvement in rheumatoid arthritis (RA) is common and is associated with significant morbidity and mortality. Early diagnosis is essential.
objective:
This study aims to assess pulmonary involvement in RA from clinical, spirometric, radiographic, and computed tomography (CT) perspectives.
Methods:
Consecutive RA patients, diagnosed according to the ACR/EULAR 2010 criteria, were enrolled. A comprehensive respiratory evaluation, including clinical, radiographic, spirometric, and computed tomography assessments, was performed.
Statistical analysis was carried out using SPSS software.
Results:
A total of 70 patients were included, with a sex ratio of 0.27 (15 men and 55 women). The mean age was 55 ± 13 years, the mean disease duration was 104.3 ± 102 months, and the mean DAS28-ESR score was 3.5 ± 1.4. RA was seropositive in 62 cases (88.6%), erosive in 54 patients (77.1%), and deforming in 24 patients (34.3%).
Dyspnea was reported by 11 patients (15.7%). Two patients (2.9%) reported a cough, and three patients (4.2%) had crackles on lung auscultation.
Chest X-ray revealed interstitial lung disease (ILD) in 5 cases (7.1%). Spirometry showed a mean FEV1 of 98 ± 14%, a mean vital capacity (VC) of 95 ± 12%, and a median FEV1/FVC ratio of 101 ± 11%. Four cases (5.7%) of restrictive syndrome were noted.
Thoracic CT demonstrated abnormalities in 24 patients (34.3%), distributed as follows: reticulations in 10 patients (14.3%), distortion in 3 patients (4.3%), septal thickening in 9 patients (12.9%), traction bronchiectasis in 11 patients (15.7%), honeycombing in 7 patients (10%), consolidation in 2 patients (2.9%), ground-glass opacity in 13 patients (18.6%), PINS in 6 patients (8.6%), UIP in 2 patients (2.9%), and rheumatoid nodules in 16 patients (22.9%).
Conclusion:
This study suggests that pulmonary involvement in RA is common, primarily characterized by rheumatoid nodules and ground-glass opacity. The most frequent abnormalities are observed on chest CT, whereas chest X-ray and spirometry appear to be less sensitive.

P811

IMPACT OF AGE AND GENDER ON DISEASE SEVERITY AND PULMONARY INVOLVEMENT IN RHEUMATOID ARTHRITIS

R. Dhahri[1], I. Oueslati[1], L. Ben Ammar[1], H. Ben Ayed[1], I. Mejri[2], T. Znegui[2], Z. Moatamri[2], M. Aloui[3], M. Slouma[1], I. Gharsallah[1]

[1]Military Hospital, Rheumatology departement, Tunis, Tunisia, [2]Military Hospital, Pneumology departement, Tunis, Tunisia, [3]Military Hospital, radiology departement, Bizerte, Tunisia

Introduction:
Rheumatoid arthritis (RA) is a chronic inflammatory disease that predominantly affects women, especially during the peri-menopausal period. While typically diagnosed in middle-aged adults, its presentation and progression in the elderly can differ significantly.
objective:
This study aims to evaluate the impact of age and gender on disease severity, structural damage, and pulmonary involvement in RA.
Methodology:
Consecutive patients diagnosed with RA according to the 2010 ACR/EULAR criteria were recruited. Socio-demographic, clinical, and para-clinical data were recorded. Statistical analysis was performed using SPSS software.
Results:
A total of 70 patients were included, sex ratio was 0.27 (15 men and 55 women). The mean age was 55 ± 13 years, mean disease duration was 104.3 ± 102 months, and mean DAS28-ESR score was 3.5 ± 1.4. RA was seropositive in 62 cases (88.6%), erosive in 54 patients (77.1%), and deforming in 24 cases (34.3%). The mean Sharp score was 28.17 ± 3.
Thoracic CT revealed abnormalities in 24 patients (34.3%), distributed as follows: reticulations in 10 patients (14.3%), distortion in 3 patients (4.3%), septal thickening in 9 patients (12.9%), traction bronchiectasis in 11 patients (15.7%), honeycombing in 7 patients (10%), consolidation in 2 patients (2.9%), ground-glass opacity in 13 patients (18.6%), PINS in 6 patients (8.6%), UIP in 2 patients (2.9%), and rheumatoid nodules in 16 patients (22.9%).
This study showed that men had significantly higher Sharp scores (32± 7 versus 19±2, p=0.36) and DAS28-ESR (4.8±2 versus 3.1±1, p=0.025) compared to women. On the other hand, there was a significantly higher prevalence of pulmonary involvement in elderly patients compared to younger patients (p=0.023).
Conclusion:
Male gender is associated with worse prognostic outcomes in terms of disease activity and structural damage, while elderly age serves as a risk factor for pulmonary involvement in RA.

P812

THE ROLE OF TRABECULAR BONE SCORE IN PATIENTS WITH HIGH BONE MASS BY DXA

L. Canterle Dal Osto[1], R. Mendonça da Silva Chakr[1], O. A. Monticielo[1], R. Machado Xavier[1], P. M. Spritzer[1], T. Muniz Fighera[1]

[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Objective: Reports of high bone mass (HBM) on routine DXA scanning are relatively common in clinical practice. The goal of this study is to compare a group of HBM individuals with a control group, assessing TBS and osteoarthritis rates differences between groups. Material and Methods: A database of DXA scans performed from 2019 to 2024 in a tertiary center in South Brazil was searched for patients with HBM, defined as femur or lumbar spine Z-score of ≥ 2.5. A control group with Z-score ≤ 2.5 matched by age, sex, BMI and ethnicity was adopted, being both groups assessed for evident signs of osteoarthritis in DXA scans. Results: 792 exams from 493 individuals revealed 65 individuals with HBM, from which 63 were paired with controls. Most patients were women (64.3%) and caucasian (93.7%), with median age and BMI of 71 years-old and 27.9kg/m2, respectively. Femoral neck and L1-L4 lumbar spine BMD was significantly different between groups (0.867 vs 1.003g/cm2; p<0.001; 1.078 vs 1.445g/cm2; p=0.000), as well as Z-score (0.1 vs 1.2; p<0.001; 0.1 vs 3.1; p=0.000), but L1-L4 TBS did not differ between groups (1.354 vs 1.376; p=0.246). TBS was poorly correlated with hip and lumbar BMD in both groups, and such correlation was significant only in the control group (r=0.243; p=0.05; r=0.337; p=0.007; respectively). Signs of evident osteoarthritis were evenly distributed between groups in both lumbar and hip sites (χ2=0.9; p=0.392; χ2=0.2; p=0.684, respectively). Conclusion: An important artifact in bone imaging, osteoarthritis did not seem to be significantly different for patients with HBM, suggesting that other factors may play a role in the process. A complementary tool to assess bone health, TBS seems not to be different in patients with HBM, remaining suitable for such patients in bone global assessment. Acknowledgments: INCT Hormônios e Saúde da Mulher, FIPE/HCPA.

P813

OSTEOPOROSIS AND OSTEOARTHRITIS IN ANKYLOSING SPONDYLITIS LINKED TO CHLAMYDIA TRACHOMATIS

L. Chislari[1], A. Lobiuc[2], E. Russu[3], L. Groppa[1]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Moldova, [2]"Stefan cel Mare" University, Suceava, Romania, [3]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "TimofeiMosneaga" Republican Clinical Hospital, Chisinau, Moldova

Background:
Chlamydia trachomatis is a known trigger for ankylosing spondylitis (AS) and other forms of seronegative spondyloarthritis (SpA). Its role in systemic bone complications, including osteoporosis (OP) and osteoarthritis (OA), is underexplored. This study investigates the clinical, diagnostic, and bone health impacts of *Chlamydia trachomatis* in AS, with a focus on osteoporosis and osteoarthritic changes.

Objectives:
To evaluate osteoporosis prevalence and osteoarthritic changes in patients with AS associated with *Chlamydia trachomatis*, using molecular diagnostics and advanced imaging techniques.

Methods:
From 2015 to 2021, 138 SpA patients were examined at "Timofei Moșneaga" Republican Clinical Hospital. *Chlamydia trachomatis* monoinfection was confirmed in 87 patients (63%) using PCR. Subgroups included axial AS (n=21), peripheral SpA (n=34), and mixed SpA (n=32). Bone health assessments included DXA scans for osteoporosis and imaging (X-ray, MRI) for OA. Clinical and laboratory evaluations (CRP, ESR, HLA-B27) were also conducted.

Results:

- **Osteoporosis prevalence:** OP was most prevalent in axial AS (42.9%), linked to high inflammatory activity (CRP: 37.2 mg/L). Peripheral SpA showed lower OP rates (17.6%), with milder inflammation (CRP: 3.3 mg/L).
- **Bone Mineral Density (BMD):** Lumbar spine and femoral neck BMD were significantly reduced in AS patients (T-score: -2.7 ± 0.3). Mixed SpA displayed intermediate BMD loss (T-score: -2.4 ± 0.4).
- **Osteoarthritic changes:** Sacroiliac joint OA was present in 100% of axial AS cases, with knee OA in 61.9%. Mixed SpA exhibited less OA progression compared to peripheral SpA, despite higher polyarthritis rates (82.3%).
- **Molecular findings:** *Chlamydia trachomatis* DNA was detected in 89.7% of synovial fluid samples, indicating pathogen persistence and its role in inflammation-induced bone and joint damage.

Conclusions:
Chlamydia trachomatis exacerbates bone health deterioration in AS, increasing the risk for osteoporosis and osteoarthritis. Early DXA screening and targeted anti-inflammatory treatments are crucial for mitigating these complications. Molecular diagnostics and imaging play essential roles in optimizing care for *Chlamydia trachomatis*-associated AS.

P814

OSTEOPOROSIS IN PATIENTS WITH AXIAL SPONDYLITIS AND INFLAMMATORY BOWEL DISEASE

L. Chislari[1], A. Lobiuc[2], E. Russu[3], L. Groppa[1]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Moldova, [2]"Stefan cel Mare" University, Suceava, Romania, [3]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "TimofeiMosneaga" Republican Clinical Hospital, Chisinau, Moldova

Background:
Axial spondylitis (AxS) is a chronic inflammatory condition affecting the axial skeleton, with common extra-articular manifestations, including osteoporosis (OP) and inflammatory bowel disease (IBD). Chronic inflammation and immune dysregulation in AxS contribute to systemic bone loss, making osteoporosis a significant comorbidity. Understanding the intersection of AxS, OP, and IBD is essential for improving clinical outcomes.
Objectives:
This study aimed to evaluate the prevalence of osteoporosis in AxS patients, assess its correlation with disease activity, inflammatory markers, and IBD, and explore the impact of chronic inflammation on bone mineral density (BMD).
Methods:
A prospective observational study included 257 AxS patients (ASAS criteria) over two years. Of these, 13 (5.1%) were diagnosed with IBD (Crohn's disease, ulcerative colitis, or indeterminate colitis). Comprehensive assessments included demographic, clinical, and laboratory evaluations, DXA scans for BMD, and disease activity indices (BASDAI, CRP, ESR). Statistical analysis was performed using SPSS v22.0, with $p<0.05$ indicating significance.
Results:
Osteoporosis was identified in 37.4% of AxS patients, with a higher prevalence in those with IBD (61.5% vs. 35.1%, p=0.012). Patients with IBD exhibited greater reductions in lumbar spine BMD (T-score: -2.8 ± 0.4) compared to those without IBD (T-score: -2.3 ± 0.5). Elevated CRP and ESR levels were associated with increased OP risk, reflecting the role of systemic inflammation. Disease duration correlated with OP prevalence, with rates rising from 22.5% in patients with <5 years of AxS to 49.1% in those with ≥10 years. Multivariable analysis identified IBD (OR=2.9; p=0.038) and prolonged AxS duration (OR=1.6; p=0.042) as significant predictors of OP.
Conclusions:
Osteoporosis is a prevalent and underrecognized comorbidity in AxS patients, particularly in those with concurrent IBD. Chronic inflammation and prolonged disease duration are key contributors to bone loss. These findings underscore the need for routine DXA screening and early anti-inflammatory interventions in AxS management to mitigate osteoporosis risk and improve patient outcomes. Enhanced collaboration between rheumatologists and gastroenterologists is crucial for addressing the complex interplay between AxS, IBD, and osteoporosis.

P815

OBESITY IS RELATED TO POORER FUNCTIONAL OUTCOMES AMONG INDIVIDUALS WITH RADIOGRAPHIC KNEE OSTEOARTHRITIS: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], F. Laskou[1], F. Kirkham-Wilson[1], G. Bevilacqua[1], N. R. Fuggle[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objective
Osteoarthritis is the most common joint condition, with obesity an established risk factor. Although osteoarthritis patients are advised to maintain a healthy weight, this is often challenging, especially when pain limits activity. We examined relationships between obesity and functional outcomes in older community-dwelling adults with radiographic knee osteoarthritis.
Material and Methods
We studied 101 men and 115 women, aged 71-80 years, from the UK Hertfordshire Cohort Study. Participants completed a questionnaire that ascertained information on health-related quality of life (EuroQol-5D) and pain according to the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Knee radiographs were taken and classified according to Kellgren and Lawrence (K&L) criteria; analysis was restricted to individuals with radiographic knee osteoarthritis (K&L score ≥2 on either knee). Balance, walking and chair rise scores were assigned, depending on performance, and used to derive the Guralnik physical performance score. Binary and ordinal logistic regression were used to examine obesity status in relation to functional outcomes after adjustment for age and sex.
Results
Prevalence of obesity (BMI≥30kg/m^2) was 26.7% among men and 44.3% among women. Odds of having a higher Guralnik score were lower among obese participants compared to those who were not obese ($p<0.001$). Being obese was associated with greater odds of reporting at least some problems in the following EuroQol domains compared to those who were not obese: mobility (odds ratio [95% CI]: 4.73 [2.52, 8.85], $p<0.001$); self-care (3.40 [1.44, 8.02], p=0.005); usual activities (4.38 [2.31, 8.30], $p<0.001$); and pain (2.27 [1.24, 4.15], p=0.008). Obesity was also related to increased odds of having a WOMAC pain score > 0 (2.21 [1.24, 3.95], p=0.007).
Conclusions
These findings highlight the strong relationships between obesity and functional outcomes in community-dwelling older people with radiographic knee osteoarthritis, and reinforce the need for support to achieve appropriate weight management.

P816

ASSESSMENT OF THE RISK OF VERTEBRAL FRACTURES AND THEIR INCIDENCE IN POSTMENOPAUSAL PATIENTS WITH RHEUMATOID ARTHRITIS

M. Bojadzioska[1], F. Gucev[1], M. Nikolovska-Kotevska[1], L. Damjanovska-Krstic[1], A. Karadzova-Stojanovska[1], S. Vidinikj[1], S. Pavlova[1], E. Sandevska[1], D. Spasovski[1], B. Osmani[1], S. Petrova[1], A. Vasilevska[1], L. Xhemaili-Jakupi[1], R. Vejseli[2]

[1]University Clinic of rheumatology, Medical Faculty, University "Sts.Cyril and Methodius", Skopje, R.N.Macedonia, Skopje, Republic of North Macedonia, [2]Medical Faculty, University "Sts. Cyril and Methodius", Skopje, R.N.Macedonia, Skopje, Republic of North Macedonia

Objective

The incidence of vertebral fractures and their association with the activity, duration of the disease, therapeutic modality, lifestyle, and functional impairments.

Material and methods

This is a cross-sectional analytical study that includes 150 patients with an established diagnosis of definitive RA according to the ACR (American College of Rheumatology) criteria from 1987, treated on an outpatient and inpatient basis at the University Clinic of Rheumatology in Skopje between 2019-2021. The subjects are females aged 50-80 years, postmenopausal women with a menopause duration of ≥ 2 years. We include patients who have not previously been treated with bisphosphonate therapy. All subjects with RA were treated with nonsteroidal anti-inflammatory drugs (NSAIDs) and/or disease-modifying antirheumatic drugs (DMARDs) and corticosteroids (CS).

Results

The prevalence of vertebral fractures (VF) in postmenopausal patients with RA is 54.6%. Among 58 patients, VF with grade 2 reduction is 31.3%, mild fracture is 18.0%, and severe fracture is 5.3%. In patients due to CS therapy, there is an increased occurrence of VF, smoking is one of the significant risk factors (p>0.05), along with the duration and activity of the disease, while increased BMI reduces the risk of developing these fractures. In patients with vertebral fractures, osteopenia is registered in 51.2%, normal findings in 28.0%, and osteoporosis in 19.3%. There is a statistically significant association between osteopenia and normal findings versus vertebral fractures (Pearson Chi-square: 4.0793, df=1, p=.043412), as well as between osteoporosis and normal findings versus vertebral fractures (Pearson Chi-square: 4.7127, df=1, p=.029940)

Conclusions

RA represents a risk factor for the development of osteoporosis and increases the risk of vertebral and non-vertebral fractures in postmenopausal patients with RA. This risk is proportional to the reduction in weight, duration, and activity of the disease.

P817

VERTEBRAL FRACTURES IDENTIFIED ON LATERAL DXA IMAGES USING DEEP NEURAL NETWORKS PREDICT INCIDENT FRACTURES IN OLDER WOMEN

L. Johansson[1], V. Wåhlstrand[2], J. Alvén[2], I. Häggström[2], M. Lorentzon[3]

[1]Sahlgrenska University Hospital, Mölndal, Sweden, [2]Chalmers University of Technology, Gothenburg, Sweden, [3]Institute of Medicine, University of Gothenburg, Mölndal, Sweden

Objective: The aim of this study was to examine if vertebral fractures (VFs) identified on lateral DXA-images, using deep neural networks [1], predict incident fractures to a comparable degree of manually annotated vertebral fracture assessments (VFAs).

Material and Methods: 2,831 women from the SUPERB study were included in this study. VFs (mild to severe) were diagnosed from DXA by VFA or by the novel deep learning method XVFA[1]. Due to image quality, manually annotation was possible for 30,589 vertebrae, while XVFA used all visible vertebrae (n=37,123). Incident fractures were x-ray verified. Cox regression models were used to assess the association between VFs and incident fractures, with adjustments for clinical risk factors and femoral neck BMD.

Results: During 8 years of follow-up 683 and 1,310 women were identified as having any VF when analyzed manually or by XVFA, respectively. Women with any VF verified by the manual method or by XVFA had 327 (47.9%) and 539 (41.1%) any fracture, respectively. With the manual annotation method women with any VF had 70% increased risk of any fracture compared to women without VF. With the XVFA method, women with any VF had 42% increased risk of any fracture, compared to women without VF. These associations remained in adjusted models in both methods (Table 1).

Conclusion: Both methods for identification of VFs, the novel XVFA and manually annotated VFAs, predicted incident fractures.

1.V Wåhlstrand Skärström, L Johansson, J Alvén, M Lorentzon, I Häggström, *Explainable vertebral fracture analysis with uncertainty estimation using differentiable rule-based classification.* https://doi.org/10.48550/arXiv.2407.02926, 2024.

Table 1. Associations between VF identified by VFA manually or by XVFA and fracture risk in older women.

	VF identified manually		VF identified by XVFA	
	No VF n=2148	Any VF n=683	No VF n=1521	Any VF n=1310
Any fracture				
No. (%)	698 (32.5)	327 (47.9)	486 (32.0)	539 (41.1)
HR (95% CI)				
Adjusted for age, height, weight	1 [Reference]	**1.70 [1.49-1.94]**	1 [Reference]	**1.42 [1.26-1.61]**
+ clinical risk factors	1 [Reference]	**1.58 [1.38-1.81]**	1 [Reference]	**1.34 [1.18-1.52]**
+ FN BMD	1 [Reference]	**1.47 [1.29-1.68]**	1 [Reference]	**1.28 [1.13-1.45]**

Associations were examined using cox regression model. Hazard Ratios (HR) and 95% confidence intervals (CI) are presented. XVFA = explainable VFA (a model developed by deep learning).

EFFICIENCY OF DENOSUMAB TREATMENT IN MEN WITH OSTEOPOROSIS

L. K. Kilasonia[1], N. K. Kirvalidze[1], T. R. Rukhadze[1], M. T. Tsagareli[2], L. L. Lagvilava[3]

[1]"Tbilisi Heart and Vascular Clinic" Ltd , Rheumatology Department /Tbilisi/ Georgia, Tbilisi, Georgia, [2]National Institute of Endocrinology / Tbilisi /Georgia, Tbilisi, Georgia, [3]Georgian National Association of Osteoporosis / Tbilisi /Georgia, Tbilisi, Georgia

Osteoporosis in men is gaining more and more relevance in the world, and there is a reason for this. - Every third man over 50 develops osteoporotic hip fracture. - The World Health Organization (WHO) has announced the so-called "demographic tsunami" which means an increase in the number of men over 60 in the world's population by 2050 (from 200 million in 2020 to 900 million in 2050). The latter will lead to an increase in the frequency of age-related chronic diseases, with Osteoporosis playing a leading role among them.

The problem of osteoporosis in men is also determined by their infrequent referral to a doctor, infrequent diagnosis and the absence of "men's anti-osteoporosis treatment guidelines", which the IOF rightly calls "discrimination". - Based on the above, we do not have sound medical evidence about the effectiveness of anti-osteoporosis drugs in men.

In the presented work, we aimed to study the effectiveness of denosumab (Prolia) treatment in men with osteoporosis. Treatment was given to 250 men diagnosed with osteoporosis, in which 2 age groups were represented. Group 1 (110 patients aged 35-55), Group 2 (aged 60-80). Patients were diagnosed using a dual-energy X-ray absorption densitometer (Lunar Prodigy) – (T and Z score). Denosumab treatment lasted 3 years - 60 mg The drug was administered subcutaneously once every 6 months. The dynamics of the indicators in the treatment process are given in the table:

Indicators	Group 1 Patient N#92 (T-score)	Group 2 Patient N#100 (T-score)
Before treatment	-3.1+-0.015	-2.9+-0.015
After treatment	-2.6+-0.16	-2.9+-0.15
Beeief	P<0.001	P<0.05

Results:

- Studies have shown that the average number of BMD in a group of young men is lower than in older patients.
- The effect of treatment with denosumab in the 1st group of subjects (35-55) is significantly higher than in older patients.
- No serious side effects were detected during treatment.
- The use of denosumab in men with osteoporosis is characterized by high efficacy and a high safety index

P819

25(OH)D LEVEL AND PREVALENCE OF RISK FACTORS FOR VITAMIN D DEFICIENCY/ INSUFFICIENCY

L. Kezhun[1], V. Skrebets[1]

[1]Educational establishment "Grodno State Medical University", Grodno, Belarus

Objective: To assess the level of 25(OH)D in blood plasma and the prevalence of risk factors for the development of vitamin D deficiency/insufficiency.

Materials and methods: A total of 60 patients were examined, the average age was 57 (38; 65) years, of which 31.7% (n=19) were men and 68.3% (n=41) were women. The level of 25(OH)D in plasma was determined by the enzyme immunoassay. A questionnaire survey method was used to identify risk factors for vitamin D deficiency/insufficiency: exposure to sunlight in the summer months and / or visits to the solarium, the use of sunscreens, intake of vitamin D-containing drugs, consumption of products containing vitamin D, omega-3 fatty acids, calcium. Statistical processing of the obtained results was carried out using the program “STATISTICA 10.0”.

Results: The level of 25(OH)D in the blood plasma of patients averaged 17.6 (13.7; 22.2) ng/ml, and was optimal in 9,2% of the examined subjects, 25(OH)D insufficiency was revealed in 28,8% and deficiency in 62% of the subjects. The 25(OH)D level in the blood plasma of women was 17.6 (13.7; 22.4) ng/ml, while in men it was – 17.2 (14.3; 20.2) ng/ml, no differences were found between the examined patients (p> 0.05).

The results of the questionnaire revealed low adherence to tanning among the subjects, amounting to 83.4%, non-visitation of solarium – 100%, insufficient intake of preparations containing vitamin D – 60% and calcium with vitamin D – 76.7% in both sexes, no differences were found (p>0.05). Men intake of preparations containing vitamin D less often (p£0.05), compared to women (10,5% versus 53,7%, respectively).

Conclusion: A high prevalence of risk factors for vitamin D deficiency/insufficiency as well as 25(OH)D level in blood plasma was revealed, which amounted to 83,4% and 90,8%, respectively.

P820

PHYSICIANS’ MANAGEMENT APPROACH TOWARDS PATIENTS WITH NON-TRAUMATIC MUSCULOSKELETAL COMPLAINTS

L. Kharrat[1], S. Ben Dhia[1], D. Ben Nessib[1], F. Majdoub[1], D. Kaffel[1], H. Ferjani[1], K. Maatallah[1], W. Hamdi[1]

[1]Mohamed Kassab Institute of Orthopeadics, Department of Rheumatology, Manouba, Tunisia

Objective

To describe physicians’ management approach towards patients who consult for non- traumatic musculoskeletal complaints.

Methods
We performed a cross-sectional survey from September 2023 until January 2024 using Google Forms, including physicians of several specialties. We did not include rheumatologists and non-clinical specialists. We collected data on the socio-demographic background of medical doctors and those regarding their diagnostic and therapeutic approach towards patients with non-traumatic musculoskeletal complaints.

Results
A total of 105 physicians participated in the survey. Most of them were females (80%). The mean age was 30.2±3.4 years.
Mean clinical experience was 4±2.1 years. Training in rheumatology during medical studies was performed by 63% of the physicians, with a mean duration of 2.5±1.5 months [0.5-6 months]. In their daily practice, 40% of the physicians saw fewer than 5 patients per week with non-traumatic musculoskeletal complaints, 30.5% saw 5 to 10, 10.5% saw 10 to 20, and 12.4% saw more than 20 patients per week.
Physicians requested complementary exams in the following cases: inflammatory osteoarticular pain in 42.9% of the cases (n=45), intense pain in 29.5% of the cases (n=31), resistance to treatment in 41% of the cases (n=43), presence of associated general symptoms in 41.9% of the cases (n=44), if the patient had multiple pain sites in 14.3% of the cases (n=15), and only if a medical emergency was suspected in 1% of the cases (n=1). Six physicians (5.7%) requested complementary exams for every patient and 29.5% did not request any tests and referred the patient to a rheumatologist (n=31).
As for therapeutic approaches, 68.6% of physicians always prescribed symptomatic treatment to relieve pain (n=72), 10.5% only prescribed treatment after tests' results (n=11), and 26.7% did not prescribe treatment and referred the patient to a rheumatologist (n=28).
The prescribed treatments depending on whether the complaint was mechanical or inflammatory are detailed in **Table 1**.
Table 1: Prescribed treatments in mechanical and inflammatory musculoskeletal pain

	Mechanical musculoskeletal pain	Inflammatory musculoskeletal pain
Acetaminophen	87.6% (n=92)	74.3% (n=78)
Weak opioids	19% (n=20)	21% (n=22)
Non-steroidal anti-inflammatory drugs	43.8% (n=46)	58.1% (n=61)
Corticosteroids	1.9% (n=2)	7.6% (n=8)
Muscle relaxants	23.8% (n=25)	6.7% (n=7)
Phytotherapy	5.6% (n=6)	3.8% (n=4)
Icing	28.6% (n=30)	35.2% (n=37)
Topical analgesics	51.8% (n=61)	64.8% (n=68)

Conclusion
Our study noted that most of non-rheumatologist physicians consistently prescribed symptomatic treatment for pain relief in patients with non-traumatic musculoskeletal complaints. They were motivated to run diagnostic tests especially in case of inflammatory pain, resistance to treatments, or in presence of associated general symptoms.

P821

APPROACHES TO URATE-LOWERING TREATMENT IN MULTIMORBID PATIENTS WITH EARLY GOUT

L. Khimion[1], O. Burianov[2], S. Danyliuk[1], T. Sytiuk[1], N. Kicha[1], O. Yashchenko[1]

[1]Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine, [2]Bogomolets National Medical University, Kyiv, Ukraine

Introduction. Patients with gout and hyperuricemia have an increased number of comorbid diseases, compared to population level, which may affect the efficacy and safety of urate-lowering therapy (ULT).
Objective. To determine the frequency of comorbid pathology in multimorbid patients with early gout, the effecy and safety of ULT (allopurinol,febuxostat).
Materials and methods. The study was conducted in Kyiv and Kyiv region in 2024., involved patients who were diagnosed with gout for the first time, consulting by GP/traumatologist/rheumatologist, with joint pain syndrome duration for up to 3 months. All patients underwent a comprehensive clinical, laboratory and instrumental examinations; retrospective analysis of medical records was done also to identify comorbid pathologies. Patients who had already started urate-lowering treatment (ULT), had GFR <60 ml/min, ALT and/or AST >3 ULN at the initial examination, had secondary hyperuricemia were not enrolled. After signing the informed consent, patients were prescribed ULT - either allopurinol or febuxostat with subsequent dose titration as needed. Assessment of the effecacy and safety of ULT was performed at 1, 3, and 6 months visits.
Results. The study included 112 patients (aged 37-62 years, women – 18.69%). Comorbid diseases/pathologies were detected in all patients (64.08% - diagnosed with arterial hypertension, 63.19% - dyslipidemia, 61.4% - overweight/obesity, 54.29% - MAFLD; 52.51% - osteoarthritis, 36.49% - gastrointestinal diseases, 34.71% - GFR 60-89 ml/min., 18.69% - CHD, 15.13% prediabetes/T2DM, 15.13% - nephrolithiasis; other pathology - 10.68%). The average number of established comorbid pathologies in 1 patient was 4.1±1.02, most patients received/needed their pharmacologic treatment. Analysis of the efficacy and safety of allopurinol and febuxostat over the next 6 months showed higher efficacy (in terms of speed and stability of achieving target serum uric acide (UA) level) in febuxostat group with the same level of registered adverse events in both groups. The most frequently registered AE was an increase in the level of ALT and/or AST, which was associated with a greater number of comorbid diseases and the presence of MAFLD.
Conclusions. In multimorbid patients with early gout febuxostat demonstrates higher efficacy in achieving target serum UA levels compared to allopurinol. Increased ALT and AST levels during ULT are associated with higher comorbidities index and MAFLD.

P822

METHOD FOR INCREASING THE ULTRASONIC CONDUCTIVITY OF SKULL BONE TISSUE IN PATIENTS WHO ARE PLANNED TO BE TREATED WITH MAGNETIC RESONANCE IMAGING-GUIDED FOCUSED ULTRASONIC IMAGING

L. Kuzina[1]

[1]State Budgetary Healthcare Institution Children's Polyclinic 6 Ufa, Ufa, Russia

The invention relates to medicine, namely to endocrinology and neurosurgery, and can be used to treat patients with altered ultrasound conductivity of bone tissue who are planned to be treated with magnetic resonance imaging-guided focused ultrasound (MR-FUS) The MR-FUS method is most often used to treat movement disorders such as Parkinson's disease, dystonia, and essential tremor. This method is an aid to standard neurosurgical interventions, primarily due to its non-invasiveness [Elias WJ et al., 2016; [Leinenga G. et al., 2016]. The method is based on two technologies – high-intensity focused ultrasound (HIFU) and MRI. Using heating or cavitation at a variable distance from the sensor, HIFU can cause selective thermal coagulation in a clearly defined volume [Chang W. 2016]. The error in the destruction of brain tissue with this method is extremely small and averages 0.50–0.75 mm, varying depending on the technical characteristics of the selected equipment. Skull density ratio (SDR) is the ratio between the average Hounsfield units of bone marrow and cortical bone, affecting energy transmission through the skull. Skull bone tissue affects the distortion of the trajectory of acoustic waves in the brain. The velocity of each ultrasound beam varies differently depending on its path through the skull. This results in ultrasound waves not constructively converging at the focus, changing the shape or location of the focus. These phase aberrations are currently clinically corrected using computed tomography (CT) images to calculate delays from individual transducer elements based on the geometry of the imaged skull and estimates of the speed of sound ratios in Hounsfield units (HU) [U. Vyas et al., 2016]. Skull density is then calculated and, depending on it, starting points are individually selected for calibration of MR-FUS helmets. It follows that one of the limitations for performing MR-FUS is the density of the skull bone tissue, which is expressed by the coefficient of ultrasound conductivity of bone tissue (CUBT) less than 0.35. According to various authors, the empirical criterion of CUBT for thalamotomy in MR-FUS is 0.35 [Wang TR. et al., 2018, Chang WS. et al., 2019]. The arsenal of solutions to the problem associated with low CUPT is very limited, which in turn leads to numerous refusals to perform operations using focused ultrasound. The closest analogue of the invention is a method for treating patients with a reduced ultrasound conductivity coefficient of the skull bone tissue using an oral form of a bisphosphonate, namely alendronic acid (Alendronate) at a dose of 35 mg once a week for 3-9 months, described by the Japanese in 2019 [Yamamoto K. et al. The Efficacy of Bisphosphonate to Increase the Skull Density Ratio of MRI-guided Focused Ultrasound Candidates with Brain Disorders //ARCHIVOS DE MEDICINA. - 2019. - Vol. 10. - No. 2. – P. 293. (PDF) Efficacy of a bisphosphonate for increasing the skull density coefficient in candidates for MRI-guided focused ultrasound examination with brain diseases (researchgate.net)]. The disadvantages of the prototype include the following: a longer preparation period for MR-FUS, lower efficiency in the form of reduced absorption from the gastrointestinal tract, poor tolerability, lower adherence to the therapy, an increase in the cost of using the drug once a week, concomitant therapy is not reflected, which is regarded as its absence. The objective of the invention is to develop a method for increasing the ultrasound conductivity of the bone tissue of the skull for further surgical interventions in patients using MR-FUS in a short time and with a safer method. The technical result of using the invention is a significant increase in the skull UCCT in patients with an initial UCCT of less than 0.35, achieving the threshold value necessary for thalamotomy with MR-FUS.

The proposed method for increasing the ultrasound conductivity of the cranial bone tissue is carried out as follows. The patient for whom MR-FUS is planned undergoes CT of the cranial bones to determine the UPCCT, as well as laboratory tests for ionized calcium and vitamin D. If the coefficient is less than 0.35, the patient is administered Bonviva (Ibandronic acid) 3 mg intravenously by bolus over 15-30 seconds once every 3 months, Aquadetrim (Cholecalciferol) at a dose of 1500-5500 IU per day and Calcium D3 Nycomed (Calcium carbonate + Cholecalciferol) at a dose of 500 mg + 200 IU 2 times a day. The course of treatment is 3-6 months. After 3 months, the patient undergoes a repeat CT of the cranial bones on the same device and with the same program to assess the ultrasound conductivity coefficient of bone tissue, and laboratory tests for vitamin D and ionized calcium. If the cranial CUPCT increases by more than 0.35, the patient is referred for surgery using focused ultrasound. If there is no effect after 3 months, treatment is continued for up to 6 months. The drug Bonviva (Ibandronic acid) is actively used in the treatment of various forms of osteoporosis. The mechanism of action of Bonviva does not disrupt the mineralization of bone tissue when prescribed in therapeutic doses for the treatment of osteoporosis and does not affect the process of replenishment of the osteoclast pool. The selective effect of Bonviva (ibandronic acid) on bone tissue is due to its high affinity for hydroxyapatite, which makes up the mineral matrix of bone. It dose-dependently inhibits bone resorption and does not directly affect the formation of bone tissue. Reduces the increased rate of bone turnover, which leads to an overall progressive increase in bone mass, a decrease in bone collagen breakdown indices (concentrations of deoxypyridinoline and cross-linked C- and N-telopeptides of type I collagen) in urine and serum, the incidence of fractures and an increase in bone mineral density (BMD).

Three surfaces are responsible for the processes of ultrasound wave reflection (during MR-FUS): the outer and inner plates and the bone marrow itself. During therapy with Bonviva (Ibandronic acid), the porosity of the skull bone tissue, mainly the cortical layer, decreases due to an increase in the degree and homogeneity of bone matrix mineralization. A decrease in porosity leads to an increase in ultrasound conduc-

tivity and the removal of one of the limitations for MR-FUS. According to International and Russian guidelines for the treatment of osteoporosis, the optimal therapeutic dosage of Bonviva (ibandronic acid) is 3 mg 3 ml in a syringe, which is administered intravenously for 15-30 seconds at a frequency of 1 time in 3 months [J Orthop Surg Res. July 9, 2024; RCT 2021]. Using the proposed method, 7 patients with CUPT less than 0.35 were treated. The average age of patients was 54.5±13.5 years. During the therapy, an increase in the KUPCT was revealed in patients (Table 1).

Table 1

Changes in the ultrasound conductivity coefficient of bone tissue during therapy

№ Full name Age Gender UPC before therapy UPC after therapy

1. Ch.O.G. 61 F 0.34 0.41
2. S.I.A. 51 M 0.34 0.38
3. M.E.A 41 M 0.30 0.41
4. K.A.M. 54 M 0.34 0.42
5. B.H.S. 66 M 0.33 0.41
6. P.A.V 60 M 0.31 0.38
7. P.N.M. 68 M 0.32 0.43

The differences in the KUPCT before and after therapy using the proposed method were statistically significant (Table 2).

Table 2

Average KUPCT values before and after the therapy

KUPCT before therapy KUPCT after therapy P

m±s 0.32±0.025 0.40±0.057 <0.0001

Thus, it follows from the presented data that as a result of the therapy using the claimed method, it was possible to achieve the threshold value necessary for performing thalamotomy with MR-FUS.

The essence of the invention is explained by the following examples.

Example 1. Patient M.E.A., 41 years old, with the main diagnosis: torsion dystonia, characterized by abnormal muscle contractions in the right leg, both arms (more than the right) and neck. The patient underwent CT of the skull bones, which showed low bone density of the skull: CT-CT 0.30. The patient's plasma vitamin D level was 17 ng / ml, ionized calcium 1.17 mmol / l. By decision of the endocrinologist and neurosurgeon, after additional examination and exclusion of contraindications, treatment was prescribed according to the proposed method: Bonviva (ibandronic acid) 3 mg intravenously bolus for 15-30 seconds once every 3 months, Aquadetrim at a dose of 5000 IU per day and Calcium D3 Nycomed at a dose of 500 mg + 200 IU 2 times a day, the course of treatment was 3 months. After 90 days of therapy, a repeat computed tomography of the skull bones was performed, the CCT was 0.41, the plasma vitamin D level was 43 pg/ml, ionized calcium 1.14 mmol/l, which would have allowed this patient to undergo the planned surgical intervention, which he did not attend due to personal circumstances.

Example 2. Patient Ch.O.G., 61 years old, with the main diagnosis: Essential tremor, a family case, involving the upper limbs and head. Severe impairment of social and everyday adaptation. The patient underwent CT of the skull bones, which showed low density of the skull bones: KUPCT 0.34. The plasma vitamin D level in this patient was 45 ng/ml, ionized calcium 1.14 mmol/l. By decision of the multidisciplinary team (endocrinologist, neurosurgeon, neurologist and cardiologist), after additional examination and exclusion of contraindications, treatment was prescribed according to the proposed method: Bonviva (ibandronic acid) 3 mg intravenously bolus over 15-30 seconds once every 3 months, Aquadetrim at a dose of 1500 IU per day and Calcium D3 Nycomed at a dose of 500 mg + 200 IU 2 times a day, the course of treatment was 4.5 months. After 90 days of therapy, the patient was unable to undergo a repeat CT scan of the skull bones (due to personal circumstances), which was ultimately performed 1.5 months later than stated, that is, 4.5 months after the start of treatment. After 135 days of therapy, a repeat CT scan of the cranial bones was performed, the CT scan was 0.41, the plasma vitamin D level was 56 pg/ml, and ionized calcium was 1.12 mmol/l, which allowed this patient to undergo the planned surgical intervention, namely, unilateral noninvasive thalamotomy of the ventral intermediate nucleus of the thalamus on the left using focused ultrasound under MRI control. After the surgery, almost complete regression of neurological symptoms caused by the underlying disease was noted, which significantly affected the patient's quality of life.

Example 3. Patient P.N.M., 68 years old, with the main diagnosis: Parkinson's disease, rigid-tremor form, mainly in the right limbs, stage 3 according to Hen Yar. The patient underwent CT of the cranial bones, which noted low bone density of the cranial bones: CT scan 0.31. The plasma vitamin D level in this patient was 10 ng/ml, ionized calcium 1.19 mmol/l. By decision of the multidisciplinary team (endocrinologist, neurosurgeon, neurologist and cardiologist), after additional examination and exclusion of contraindications, treatment was prescribed according to the proposed method: Bonviva (ibandronic acid) 3 mg intravenously bolus over 15-30 seconds once every 3 months, Aquadetrim at a dose of 5500 IU per day and Calcium D3 Nycomed at a dose of 500 mg + 200 IU 2 times a day, the course of treatment was 6 months. Three months after the CT scan, the required CTUCCT of 0.34 was not achieved, so the early treatment was continued, and after another three months of therapy, a repeat CT scan of the skull bones was performed, the CTUCCT was 0.43, the plasma vitamin D level was 47 pg/ml, ionized calcium 1.15 mmol/l. Then the patient underwent surgery - non-invasive thalamotomy with focused ultrasound under MRI control. Follow-up observation of the patient demonstrates regression of the neurological manifestations of the underlying disease.

P823

ROLE OF NAIL BED CAPILLAROSCOPY IN PATIENTS WITH UNDIFFERENTIATED ARTHRITIS AND RAYNAUD'S PHENOMENON

L. L. Korsunskaya[1], A. N. Zakharova[1], E. R. Zagidullina[1], N. G. Nikolashina[1], S. Kulanthaivel[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: Undifferentiated arthritis (UDA) is arthritis (oligo-, polyarthritis) in which the criteria of any specific disease are not met

at the present time. Excessive spastic reaction of digital arteries and cutaneous vessels against the background of the Raynaud's phenomenon (RP) when exposed to cold or emotional stress. RP has two variants: primary and secondary. Primary RP occurs in 90% of cases and is not a sign of a serious disease. Secondary RP is one of the manifestations of systemic autoimmune pathology, most often systemic sclerosis (SSc), but can also occur in other systemic connective tissue disorders (SCTD) such as systemic lupus erythematosus, rheumatoid arthritis, mixed connective tissue disease (MCTD) and others. Nail bed capillaroscopy (NBC) is a study of the nail fold or capillary bed and vascular circulation using a special device - a capillaroscope, which has a device for fixing the finger and a light source. NBC is a safe and non-invasive method for differential diagnosis of primary and secondary RP. According to this, the aim of the study is the capillaroscopic picture in patients with UDA in combination with RP.

Methods: A total of 33 patients with UDA in combination with risk factors were examined: 25 women (75.7%) and 8 men (24.3%) aged 25 to 40 years (mean age 30.4 ± 4.6 years), average duration of arthritis 3.7 ± 2.3 months. Anamnesis, examination and complete clinical examination of patients were performed. All patients had arthritis in at least 1 joint, which was verified by ultrasound examination of the joints. All patients underwent NBC, laboratory and immunological studies (immunoblot to determine the spectrum of autoantibodies).

Results: Primary risk factors were detected in 21 patients (63.6%), including 16 women and 5 men. Secondary risk factors were detected in 12 patients (36.4%), in 9 women and 3 men. Of these, scleroderma changes were detected in 9 patients (27.3%) (6 women and 3 men), and connective tissue disease (CTD) in 3 (9.1%) patients. NBC together with immunological diagnostics allowed us to establish the diagnosis of one or another CTD in 11 patients for the first time.

Conclusion: NBC can significantly help in the diagnosis and differential diagnosis of patients with NDA in combination with FR. NBC is the "gold standard" in the diagnosis of patients with RP.

P824

ASSESSMENT OF THE CONTRIBUTION OF URATE-LOWING THERAPY TO THE CORRECTION OF METABOLIC AND LIPID DISORDERS IN HYPERURICEMIA

L. L. Korsunskaya[1], A. N. Zakharova[1], E. R. Zagidullina[1], N. G. Nikolashina[1], S. Kulanthaivel[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: The association of hyperuricemia (HU) with metabolic and cardiovascular disorders has been well studied and proven. The positive effect of urate-lowering therapy on blood pressure, pathological remodeling of the heart, endothelial function, kidneys and a number of other positive effects have been determined for patients with gout. However, the feasibility of prescribing uricostatics to patients with asymptomatic HU (AHU) is not so obvious and continues to be studied. The purpose of the study: to assess the contribution of urate-lowering therapy to limiting the progression of metabolic and lipid disorders in patients with purine metabolism disorders.

Methods: A retrospective analysis of data from 37 of 406 initially selected medical records of patients was performed, followed by statistical processing of the data (STATISTICA 12). The selection criteria were: the presence of GU confirmed during 3 or more hospitalizations over 4 years (2020 – 2024).

Results: The study group consisted of 18 patients with AGU and 19 patients with gout (mean age 67.8 ± 13.8 years). Men predominated in both subgroups and had significantly higher uric acid (UA) levels ($p < 0.001$). AGU was 2.6 times more common in men, and gout 5.3 times more common than in women. In patients with gout, the absolute values of UA levels by year were subject to significant fluctuations due to irregular uricostatic therapy, which was received by 16 of 19 patients. The target uric acid level according to hospital records was achieved in only one case. In the subgroup with AGU, uricostatic therapy was not prescribed. The initial (2017) uricemia indicators and the degree of its severity did not have reliable differences in the AGU and gout subgroups. By 2020, an increase in the severity of GU was noted in both subgroups, however, with AGU, the increase in uricemia was almost 2 times higher than in the gout subgroup ($p < 0.05$). The average values of TC, LDL and TG in the subgroup with AGU did not undergo significant changes over 4 years, while in the subgroup of patients with gout there was a reliable decrease in all three indicators ($p < 0.05$). With an initial blood glucose level without reliable differences between the subgroups, after 4 years a statistically significant increase was determined with AGU ($p < 0.001$). In the gout subgroup, the glycemia level did not differ significantly from the 2017 values. Of the associated pathologies, the most frequently noted were kidney damage (AGU n = 9 (50%), gout n = 13 (68%)), hypertension and obesity. Evaluation of the treatment of patients with gout and AGU from the standpoint of prescribing drugs with a potential effect on purine metabolism did not demonstrate significant differences in the subgroups, which made it possible to consider the above reliable differences with a high probability as the effect of uricostatic therapy.

Conclusion: For patients with persistent purine metabolism disorder, regardless of the presence or absence of gout symptoms, HU progression over time and a wide range of associated pathology are characteristic. Uricostatic therapy in the subgroup of patients with gout demonstrated not only a positive effect on limiting the increase in uricemia, but also had a reliable synergistic effect on the correction of lipid and carbohydrate metabolism, in contrast to patients with AGU without the appointment of uricostatics. Positive effects were determined even without achieving target values of UA and atherogenic lipids. In the future, it is planned to expand the study group using multivariate analysis to clarify the presented data.

P825

CORRELATION OF EFFECTIVENESS OF ANTI-OSTEOPOROSIS TREATMENT WITH D - HORMONE INDICATORS IN PERIPHERAL BLOOD

L. K. Kilasonia[1], L. L. Lagvilava[2], N. K. Kirvalidze[2], T. R. Rukhadze[2], G. A. Aladashvili[1]

[1]"Tbilisi Heart and Vascular Clinic" Ltd, Tbilisi, Georgia, [2]National Georgian Association of Osteoporosis, Tbilisi, Georgia

We live in an era of vitamin D3 hormone deficiency. A large part of the population, especially women, often without a diagnosis and a doctor's recommendation, arbitrarily take vitamin D3 treatment. The world medical community has long agreed that vitamin D3 is directly involved in the process of bone formation. D3 medicinal forms have been created in the form of pills, and injections, with different doses - although many questions remain unanswered:
- Does the amount of vitamin D3 in the blood affect the development of osteoporosis?
- Does the dose of vitamin D3, and the duration of administration affect the course of osteoporosis and, most importantly, the effectiveness of anti-osteoporosis treatment?
Here, we tried to offer answers to these questions. 65 female patients aged 38-70 were under observation. Osteoporosis was diagnosed by dual energy absorption densitometry (Lunar Prodigy) using T and Z-score. Quantitative research on vitamin D3 was done in the blood of all patients before treatment and every 6 months. Treatment of patients lasted for 2 years. All patients with postmenopausal osteoporosis received zoledronic acid (60 mg) once a year - intravenously for two years.
Two groups of women suffering from postmenopausal osteoporosis were separated according to vitamin D3 levels. Group 1 (35 patients) - whose D3 level was < 30 ng/l. Group 2 (30 patients - vitamin D3 levels below 20ng/L.) In patients of both groups, treatment was started in October 2022- (first injection) The 2nd injection was given intravenously in October 2024
Results:
1. Patients of the first group received 4000-10000 IU of vitamin D3 along with anti-osteoporosis treatment. - once a day (according to the vitamin D3 index).
2. Subjects in the second group of patients received 10,000-20,000 IU according to their vitamin D3 levels. 1 tablet of vitamin D3 per day (with control once every 6 months).

- 67% of women with postmenopausal osteoporosis in the study have vitamin D3 deficiency.
- No correlation was found between low levels of vitamin D3 and the incidence of vertebral fractures. The increase in BMD indicators (T-score) was expressed in the 2nd group of patients where there were significantly reduced parameters of vitamin D3 and received high doses of vitamin D3.
- It is likely that the effectiveness of antiresorptive treatment is related to the doses and duration of vitamin D3 received.

A MULTI-BIOMARKER COMPRISING FECAL CALPROTECTIN (FCPT), BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF), FIBROBLAST-GROWTH FACTOR-21 (FGF-21) AND IRISIN OUTPERFORMS SINGLE BIOMARKERS IN THE DIAGNOSIS OF SARCOPENIA IN COMMUNITY-DWELLING PERSONS

L. Lapauw[1], L. Vermeiren[2], L. Vercauteren[1], N. Amini[1], J. Dupont[1], S. Dalle[3], K. Koppo[4], M. Derrien[5], J. Raes[5], E. Gielen[1]

[1]KU Leuven, Department of Public Health and Primary Care, division of Gerontology and Geriatrics, Leuven , Belgium, [2]KU Leuven, Faculty of Medicine, Leuven, Belgium, [3]University of Antwerp, Department of Rehabilitation and Physiotherapy, Antwerp, Belgium, [4]KU Leuven, Department of Movement Sciences, Leuven , Belgium, [5]KU Leuven, Department of Microbiology, Immunology and Transplantation, Leuven , Belgium

Objectives: This study aimed to develop a sarcopenia biomarker in community-dwelling persons (≥ 65 years) reflecting gut and non-gut related factors underlying its etiology. Materials and methods: This exploratory, cross-sectional study includes 156 older adults (53♂/103♀, median age 73 years) of whom 59 have EWGSOP2-defined sarcopenia. Serum myokines (irisin, myostatin, IGF-1, FGF-21 and BDNF) and the intestinal inflammatory marker fCPT were determined via ELISA. Muscle mass and function were evaluated by appendicular lean mass, handgrip strength, 5-time chair stand time (CST), gait speed and the Short Physical Performance Battery (SPPB). Correlations (Spearman; point-biserial, ρ), multivariate linear and logistic regressions were calculated for associations between sarcopenia, muscle mass, function and biomarkers. Receiver operating characteristics of Areas Under the Curve (AUC) were determined for diagnostic accuracy. Significance was set at $p<0.05$. Results: BDNF was lower in persons with sarcopenia ($p = 0.008$), correlated negatively with sarcopenia ($p = 0.004$) and significantly decreased the odds of sarcopenia (OR:0.99; 95% CI (0.99989;0.99999)) after adjusting for age and sex. fCPT associated positively with 5-time CST after correcting for age and sex ($p = 0.022$), implying that higher intestinal inflammation was associated with worse lower limb strength. Persons with low intestinal inflammation (fCPT < 50 µg/g) walked faster than those with high intestinal inflammation (fCPT ≥ 200 µg/g) ($p = 0.006$). BDNF (AUC:0.63; sensitivity 53%; specificity 71%) significantly diagnosed sarcopenia in the entire cohort. Only in men, additionally to BDNF, fCPT (AUC:0.77; sensitivity 100%; specificity 48%) diagnosed sarcopenia. A multi-biomarker with fCPT, BDNF, irisin and FGF-21 (AUC:0.71; sensitivity 64%; specificity 58%) outperformed myostatin ($p = 0.011$), irisin ($p = 0.037$), IGF-1 ($p = 0.024$) and FGF-21 ($p = 0.042$) alone, but not BDNF ($p = 0.3327$) or fCPT ($p = 0.1843$) in sarcopenia diagnosis. Conclusions: BDNF lowers the OR of sarcopenia, although with limited clinical relevance. A multi-biomarker panel sig-

nificantly outperforms specific single markers to detect sarcopenia. These findings warrant further investigation in larger cohorts, assessing additional (non-)myokine markers to identify the 'optimal' multi-biomarker in diagnosis of sarcopenia. Disclosures: The authors declared no competing interests.

P827

EFFECT OF GUT MICROBIOTA ALTERING INTERVENTIONS ON SARCOPENIA OR ITS DEFINING PARAMETERS IN OLDER ADULTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Lapauw[1], N. Amini[1], E. Switsers[2], J. Dupont[1], L. Vercauteren[1], M. Derrien[3], J. Raes[3], E. Gielen[1]

[1]KU Leuven, Department of Public Health and Primary Care, division of Gerontology and Geriatrics, Leuven , Belgium, [2]KU Leuven, Faculty of Medicine, Leuven, Belgium, [3]KU Leuven, Department of Microbiology, Immunology and Transplantation, Leuven , Belgium

Objectives: We aimed to investigate effects of gut microbiota (GM) altering interventions to assess their therapeutic potential on sarcopenia or its parameters (muscle strength, mass and physical performance). Interventions of interest were diets, prebiotics (non-digestible foods promoting bacterial growth), probiotics (supplementation with live bacteria) or synbiotics (a combination of the latter two). Materials and methods: A protocol was preregistered on PROSPERO (CRD42022347363). Six databases and one registry were searched. Mono-interventions on diet, pre-, pro or synbiotics in populations of mean age ≥50 years were included. Standardized mean differences (SMD) and 95% confidence (CI) were computed using a randomized-effects model if heterogeneity was > 50%. Sensitivity and meta-regression analyses were performed to identify sources of heterogeneity and potential modulators, respectively. Risk of bias (RoB) 2 and Risk Of Bias In Non-randomized Studies (ROBINS)-I tools were used to assess randomized and non-randomized interventions respectively. Results: 51 studies were included in the qualitative analysis, of which 30 were on several diets, 11 on prebiotics, 9 on probiotics and one on synbiotics, totaling 4205 participants (58% ♀). 44 and 7 studies were at high and moderate RoB, respectively. Of 51 studies, 33 were included in the quantitative analysis. Probiotics (SMD: 0.68; 95% CI [0.30; 1.06]) and increased intake of fruits and vegetables significantly improved muscle strength (SMD: 0.88; 95% CI [0.38; 1.37]). The former intervention also improved physical performance (SMD: 0.69; 95% CI [0.41; 0.96]). Additionally, energy-restricted high-protein diets improved physical performance estimates (SMD: 0.77; 95% CI[0.01; 1.52]). However, when for one study the physical performance test was replaced by gait speed test, findings were no longer significant. Conclusions: Increased fruits and vegetables intake and probiotics improve muscle strength. Also, the latter intervention and energy-restricted high-protein diets improve physical performance. Included studies were heterogeneous in terms of study duration, included population and tools used to assess sarcopenia (parameters). Further investigation in more uniformly designed longitudinal studies is warranted to estimate the effect of GM altering interventions on sarcopenia. Disclosures: The authors declared no competing interests.

P828

EVALUATION OF THE EFFECTIVENESS OF COMPLEX IMPACT OF SHOCKWAVE THERAPY AND PULSED LOW-FREQUENCY ELECTROSTATIC FIELD IN SANATORIUM TREATMENT OF PATIENTS WITH CHRONIC SHOULDER PAIN

S. Pavlovsky[1], L. Marchenkova[2], T. Konchugova[2], M. Nikitin[1]

[1]A clinical research branch "Vulan" sanatorum and resort complex of Federal State Budgetary Institution "National Medical Research Centre for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Gelendzhik, Russia, [2]Federal State Budgetary Institution "National Medical Research Center for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russia

Introduction. The relevance of the study is due to the widespread prevalence of chronic pain in the shoulder joint, including among people of working age, as well as the insufficient effectiveness of standard therapy for patients with degenerative-dystrophic joint diseases.

Objective: development and scientific substantiation of a new complex physiotherapeutic method for treating patients with chronic pain in the shoulder joint, increasing the effectiveness of spa treatment in this category of patients.

Methods. The study was conducted in a comparative aspect on three randomized groups of patients with chronic shoulder pain (30 people in each). In the 1st group, standard spa treatment was carried out, in the 2nd group, patients additionally received 3 procedures of shock wave therapy (SWT) once a week, in the 3rd group, in addition to SWT, patients additionally received 8 effects of a pulsed low-frequency electrostatic field (PLFEF). The results were assessed before treatment and on the 15th day of spa treatment.

Results. In the compared groups, statistically significant changes in the Swanson activity index were found after treatment, with an advantage in the main group ($p<0.001$). When analyzing the amplitude of extension and flexion in the shoulder joint before treatment, it was not possible to establish statistically significant differences between the groups ($p>0.05$). After treatment, a reliable significant dynamics of both of these indicators was noted in all three groups ($p<0.001$), but after treatment, significant intergroup differences in these indicators were revealed: in the main and control groups they were better than in the comparison group ($p<0.001$). When assessing the pain index according to the ICF after treatment, significant differences were found compared with the initial level in all three groups ($p<0.001$), but the pain level was lower than in the comparison group ($p=0.031$).

Conclusion. The combined effect of SWT and PLFEF against the background of basic spa treatment in patients with chronic pain

in the shoulder joint contributes to a more significant analgesic effect, an increase in the range of active movements in the shoulder joint and an increase in the patient's activity level in everyday life compared to standard spa treatment.

P829

THE EFFECTIVENESS OF VIRTUAL REALITY AND MECHANOTHERAPY TECHNOLOGIES IN THE REHABILITATION OF PATIENTS AFTER SURGICAL TREATMENT OF HIP FRACTURES AGAINST THE BACKGROUND OF OSTEOPOROSIS

L. Marchenkova[1], D. Otvetchikova[1], V. Vasileva[1], E. Ryabkov[1]

[1]Federal State Budgetary Institution "National Medical Research Center for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russia

Background. The primary goal of rehabilitation measures after hip fracture surgery against the background of osteoporosis is to reduce the likelihood of disability and death, which is highest in the first months after the hip fracture.
Objective. To develop, scientifically justify, and study the effectiveness of virtual reality and mechanotherapy technologies in the rehabilitation of patients after surgical treatment of hip fractures against the background of osteoporosis.
Methods. The study included a total of 98 patients aged 59 to 84 years who underwent osteosynthesis or hip joint replacement due to osteoporotic hip fractures within 6 to 12 weeks before inclusion in the study.
Results. The study results indicate that the new medical rehabilitation complex contributes to an increase in the total Harris score (p=0.034) and maximum hip extension strength (p=0.041) after 12 days, improvement in walking speed and biomechanics - increasing the step length of the right leg after 12 days (p=0.036) and reducing step width after 60 days (p=0.22), rapid regression of pain syndrome, and improved physical functioning.
Conclusion. In patients with osteoporosis who have undergone surgical treatment for proximal femoral fractures, the new medical rehabilitation complex with mechanotherapy technologies, virtual reality, and training on a sensory treadmill with biofeedback function, compared to the standard rehabilitation complex, contributes to a shorter recovery time for hip joint function.

P830

THE EFFICACY OF LONG-TERM TREATMENT WITH CALCIMIMETICS OF CKD PATIENTS ON HEMODIALYSIS WITH SECONDARY HYPERPARATHYROIDISM

L. Martynyuk[1], T. Malska[1]

[1]Ternopil National Medical University, Ternopil , Ukraine

Objective. Despite much is known about mineral and bone disorders (MBD) in chronic kidney disease (CKD), the treatment of such patients remains a difficult clinical problem. The aim of the study was to evaluate the effect of long-term calcimimetic therapy (LTCT) of secondary hyperthyroidism (SHPT) in CKD patients on hemodialysis.
Materials and methods. A single-center prospective cohort study included 46 patients CKD 5D stage receiving hemodialysis treatment at least 3 months. We examined were 25 (54.3%) men and 21 (45.7 %) women, aged 55.25 ± 13.34 years. All patients received standard treatment with phosphate binders, active metabolites of vitamin D in individual doses to achieve target levels of Ca and P. 30 patients in group of LTCT received additionally cinacalcet in individual dose 30-90 mg according to iPTH level up to two years. Results obtained in group of LTCT treatment were compared with those on standard therapy – 16 oatients. Laboratory assessments included analysis of iPTH, alkaline phosphatase (AP), serum Ca and P before and after one and two years of therapy. Statistical data were obtained by usage of SPSS program, v. 21 with statistical significance determined at the level of p <0.05.
Results. In patients with SHPT who received LTCT treatment significant decrease of iPTH level took place after 1 year of treatment compared to starting level. (p=0.031) After 2 years of cinacalcet therapy this process became more prominent (p<0.0001). In group of standard background therapy after1 and 2 years there was not significant changes in iPTH level compared to starting levels (p>0.05) . Simultaneously it was established significant decrease of P (p=0.0001); Ca (p=0.001) after 1 year, and after 2 years (p=0.0001) of LTCT ; and significant decrease of ALP (p=0.001) only after 2 years of long-term use of cinacalcet. In group of LTCT target levels of iPTH according to KDIGO 2017 recommendations were achieved in 80.0% of patients with SHPT. It was accompanied by a significant decrease in the frequency of fractures which did not occurred during 2 years in group of LTCT compared with group of standard treatment showing incidence of hip fracture in 4 (25 %) during 2 years. There were no side effect of long term cinacalcet therapy during 2 year period.
Conclusions. Long-term therapy of SHPT with calcimimetics showed safety and a significant decrease in iPTH, accompanied by a decrease of P, Ca, AP levels, and prevention of hip fracture during 2 years.

P831

THE EXPEDIENCY OF ONLINE EDUCATION FOR PATIENTS WITH GOUT

L. Masadov[1], S. Lezhenina[2], N. Shuvalova[3], E. Guryanova[4]

[1]Hospital Istiklop, Dushanbe, Tajikistan, [2]Chuvash State University by I. N. Ulianova, Cheboksary, Russia, [3]Chuvash State Pedagogical University by I. Y. Yakovlev, Cheboksary, Russia, [4]Postgraduate Doctors' Training Istitute, Cheboksary, Russia

Objectives. To analyze the possibility of using online learning as a method of preventing gout.
Materials and methods. The study was conducted in Turkmenistan with the participation of 50 patients who underwent online training on gout from October 2023 to October 2024. At the end of the training period, all patients filled out a questionnaire that

included 22 questions divided into two blocks: Block I — general questions about age, gender, bad habits and frequency of exacerbations, block II — assessment of the usefulness of information and the desire to continue training on a 5-point scale. An open-ended question was also asked about the greatest impressions of online learning.
The training took place on the Spherum platform, lasted 1 year and included 20 lectures and 3 practical classes. The results were analyzed using Statistical Analysis Software 17.0. Statistical significance was processed using Analysis of Variance analysis.
Results. Block I. In the first block, it was found that the number of patients under the age of 40 was 16% (8 people), 20% (10 people) under the age of 50, 26% (13 people) under the age of 60, and 38% (19 people) over the age of 60. 70% of the respondents are men. 54% of the patients had bad habits, while only 14% knew about gout in their relatives. More than half of the respondents noted at least one exacerbation of the disease over the past year.
Block II. In block II, 82% of the participants learned about new risk factors for gout, including the effect of medications on uric acid levels. 56% realized the need for lifestyle adjustments, including proper nutrition, weight maintenance, and physical activity. 98% of the respondents expressed a desire to continue their studies. Most of the participants noted that the interesting side of online learning is the opportunity to communicate with like-minded people, share experiences and receive psychological support.
Conclusion. Online learning can be successfully used as a method of preventing gout. Communication in a group of like-minded people helps to improve the prevention of gout and allows you to receive timely support and start treatment of exacerbations.

P832

HOW TO PREVENT THE DEVELOPMENT OF GOUT?

L. Masadov[1], N. Shuvalova[2], S. Lezhenina[3], E. Guryanova[4]

[1]Hospital Istiklop, Dushanbe, Tajikistan, [2]Chuvash State Pedagogical University by I. Y. Yakovlev, Cheboksary, Russia, [3]Chuvash State University by I. N. Ulianova, Cheboksary, Russia, [4]Postgraduate Doctors' Training Istitute, Cheboksary, Russia

Objectives. To evaluate the effect of physical activity and nutrition on the frequency of gout attacks.
Materials and methods. The study was conducted in Turkmenistan from December 2021 to December 2023. The participants were 90 patients with gout who had a history of the disease for more than 5 years. The average age was 52.2 ± 2.9 years (62 men and 28 women). The patients were divided into two groups: experimental and control, with 45 people each. The experimental group visited the pool twice a week for 40 minutes and did physical therapy with gym poles once a week for 30 minutes, and also followed a diet of up to 1800 kcal/day. The control group led a normal lifestyle. To evaluate the results, a questionnaire was conducted, which focused on the frequency of gout attacks. The questionnaire contained the following questions:
1. Have you had a gout attack in the last two years? (yes/no)
2. Have you had a gout attack in the last year? (yes/no)
3. Was there any deterioration during the course of the disease (seizures became more frequent)? (yes/no)
The results were processed in Statistical Analysis Software17.0. Statistical significance was processed using Analysis of Variance analysis
Results. In the experimental group, 31 patients (69%) had not experienced gout attacks in the last two years, 13 patients (29%) had not experienced attacks in the last year, and only 1 (2%) noted a worsening. In the control group, 42 patients (93%) reported an increased frequency of seizures, while only 3 patients (7%) indicated no seizures over the past year.
Conclusion. Preventing the development of gout is associated with lifestyle changes such as going to the pool, exercising, and following a diet of up to 1800 kcal/day. As a result, 69% of the patients in the experimental group had not experienced gout attacks in the last two years

P833

EFFECTION OF DIGITAL ORTHOPEDIC TECHNOLOGY ASSISTED MIPPO IN THE TREATMENT OF PROXIMAL TIBIOFIBULAR FRACTURE

L. Meng[1]

[1]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Abstract: ***Objective*** To investigate digital orthopedic technology assisted MIPPO in the treatment of proximal tibiofibular fracture. ***Methods*** 32 cases of proximal tibiofibular fractures were randomly divided into two groups: digital orthopedic technology assisted MIPPO group and MIPPO group, 16 cases in each group. Digital orthopedic technology assisted MIPPO group use Minmics software to simulate reduction and fixation before operation, and to determine the surgical protocol. MIPPO group's operation plan was determined according to the imaging data. The incision length, operation time, bleeding volume, fluoroscopy times, hospitalization time, first healing rate of the wound, good rate of functional reduction, good rate of Johner-Wruhs and the healing time of the fracture were compared between two groups. ***Results*** Compared to digital orthopedics technology assisted MIPPO group and MIPPO group, there were no significant difference in aspects of incision length (12+1.21cm *vs.* 13.1+1.41cm), wound healing rate (100% *vs.*100%), Johner-Wruhs excellent rate (98.1% *vs.* 98.2%), fracture healing time (3.1+0.2m *vs.* 3.3+ 0.7m). There were significant differences in aspects of bleeding volume (50.21±3.1mL *vs.* 78.2±2.7mL), operation time (46.2±2.1min *vs.* 67.2±2.1min), fluoroscopy times (6.2±3.41*vs.*10.2±2.1), hospitalization time (8.2±.1.9d *vs.*11.2±2.1d), excellent rate of fracture reset function (98.4% *vs.* 84.2%), P < 0.05. ***Conclusion*** According to patient's condition, digital technology assisted MIPPO could develop the best surgical plan, shorten operation time, reduce bleeding volume and fluoroscopy times, improve fracture reset function rate, it is worthy of clinical application.

P834

INCIDENCE OF OSTEOPOROSIS VERTEBRAL FRACTURES IN THE GERIATRIC PATIENTS OF EASTERN SIBERIA (RUSSIAN FEDERATION)

L. Menshikova[1], Y. U. Bazhenova[1], V. Pustozerov[1], M. Menshikov[1]

[1]Irkutsk State Medical Academy of Postgraduate Education, Irkutsk, Russia

Objective: Vertebral fractures are markers of osteoporosis. There is often a late diagnosis of fractures, severe pain and poor quality of life in the elderly.

Aim to study the frequency of osteoporotic vertebral fractures (VF), we formed a random sample of 420 Irkutsk residents aged 60 years and older.

Metods: In order to recruit men and women equally in six age groups, the sample was stratified by gender and age: 210 men and 210 women, 35 people in each age group (60-64 years old, 65-69 years old, 70-74 years old, 75-79 years old, 80-84 years old, 85 years old and older). 369 people participated in the study. The responsiveness of the sample was 87.9%. All the subjects (369 people: 184 women and 185 men) were examined using a «PHILIPS» device according to the standard procedure. The average age for women was 73.01±7.1 years, for men – 72.5±8.7 years. To identify the degree of correspondence between two different methods for assessing vertebral deformities (the semi-quantitative Genant method and the quantitative Felsenberg method), "kappa" statistics were used for all members of the sample.

Results: During the visual assessment of spondylograms using the H. Genant method, 4,522 vertebrae were analyzed, which accounted for 98.8% of the total number of vertebrae studied (145 vertebrae did not participate in the analysis due to pronounced projection changes). A 20% decrease in any of the vertebral body heights was detected in 94 people (40 men and 54 women), which was 25.5% (21.6% in men and 29.3% in women). Vertebral deformities were 1.4 times more common in women than in men ($p < 0.05$). The average age of individuals in the group with vertebral fractures was higher than in the group without deformities in both women (79.8±5.81 in the group with fractures and 71.4±6.9 in the group without fractures) and men (79.2±6.08 and 72.5±7.03, respectively), $p<0.05$. Osteoporotic deformities of the vertebrae were detected in 85 (23.6%) people, amounting to 18.3% in men and 28.9% in women ($p < 0.01$). The prevalence of vertebral fractures increased with age. Thus, at the age of 60-64, the incidence of osteoporotic fractures was 6.7 % fractures accounted for 6.7% in women and 3.4% in men. In the 65-69 age group: 10 and 6.7%, in the 70-74 age group 19.4 and 13.3%; in the 75-79 age group 33.3 and 19.4%, and in the 80-84 age group 46.7 and 30%, respectively. The maximum frequency of fractures was determined in people 85 years of age and older: 58.6% of women and 36.7% of men had deformities of the vertebrae. In general, the incidence of osteoporotic vertebral fractures in both sexes of the older age groups of the Irkutsk population, detected using the semi-quantitative H. Genant method, was 102.8 per 100,000 population. The lowest frequency of vertebral fractures was found at the age of 60-64 years – 15.8 per 100,000 in women and 12.8 per 100,000 in men, increasing with age, reaching maximum rates in the group of 85 years and older – 721.7 per 100,000 in women and 1469 per 100,000 in men ($p < 0.05$) At the next stage, the spondylograms of 360 people (180 women and 180 men) were examined using the quantitative morphometric method. At the next stage, the spondylograms of 360 people (180 women and 180 men) were examined using the quantitative morphometric Felsenberg method. A quantitative assessment of the shape of 4,522 vertebrae was performed. 101 (28%) patients: 61 (33.9%) women and 40 (22.2%) men had 226 deformed vertebrae (134 in women and 92 in men).

Conclusion: A study of the frequency of vertebral fractures in elderly and senile Irkutsk residents revealed high rates in both sexes, increasing with age.

P835

DENOSUMAB FOR THE TREATMENT OF OSTEOPOROSIS IN HONG KONG CHINESE WOMEN: COMPLIANCE, EFFICACY AND ADVERSE EVENTS

L. Ming Chu[1]

[1]Hong Kong Orthopaedic and Osteoporosis Center for Treatment and Research, Hong Kong, Hong Kong SAR China

Objectives

To study the followings for denosumab in treating Chinese women with osteoporosis:

- Efficacy in increasing bone mineral density
- Compliance to treatment
- Adverse events

Material and methods

Six hundred and fifty-five postmenopausal women with osteoporosis or osteopenia with major risk factors, or fracture history were recruited. Subjects were treated by Denosumab injection every 6 months. Bone mineral density (BMD) was measured by Dual X-Ray densitometry (DEXA). Subjects were followed up for 5 years.

Results

A total of 655 subjects were recruited in the whole study for compliance, and 283 subjects participated in the DEXA study. The BMD increase is shown in the table. The percentage increase was comparable to international trials e.g. The Freedom Study. The compliance dropped quite rapidly and was 49% for the fifth injection; and 15% for the 11 injections.

No osteoporosis of the jaw nor atypical femoral fracture were observed. One patient developed skin reaction which led to discontinuation of treatment.

Conclusion

Denosumab is a safe and efficacious drug for treating osteoporosis in Chinese women. Efforts should be made to increase long term compliance.

Percentage change (mean±SD) in BMD at the total hip and total spine

	1st year 6 months after 2nd injection (N=283)	3rd year 6 months after 6th injection (N=144)	5th year 6 months after 10th injection (N=63)
Total hip			
BMD (gm/cm^2)	0.730±0.094	0.738±0.098	0.736±0.096
Percentage change from baseline	2.69±2.55	4.90±3.20	6.99±3.68
Total spine			
BMD (gm/cm^2)	0.832±0.100	0.838±0.091	0.860±0.091
Percentage change from baseline	4.33±4.18	7.20±5.31	10.08±7.09

P836

SIX-MINUTE WALK TEST PERFORMANCE CORRELATES WITH TRABECULAR BONE SCORE IN A GROUP OF OLDER SARCOPENIC WOMEN

L. Moussi[1], R. El Hage[1]

[1]University of Balamand/Department of Physical Education, Kelhat, El-Koura, Lebanon

Aim: The main aim of the current study was to explore the relationship between the performance in the Six-minute walk test (6MWT) and trabecular bone score (TBS) in a group of older sarcopenic women.
Methods: A total of 36 women whose ages range from 60 to 82 years participated in this study. The participants were recruited from multiple cities in north Lebanon. In addition, the participants underwent multiple clinical and physical tests including DXA scan, 6MWT, handgrip and vertical jump test. The participants were diagnosed as sarcopenic based on the skeletal muscle mass index results (<5.5 kg/m^2) and handgrip test (<20 kg) as determined by the requirements of EWGSOP to diagnose sarcopenia. In addition, L1-L4 TBS scores were recorded for each individual by DXA. Associations between clinical characteristics and TBS were given as Pearson correlation coefficients. Multiple linear regression analysis models were used to test the relationship of TBS with 6MWT performance/vertical jump/physical activity level and age.
Results: There was a significant correlation between the 6MWT performance and the L1-L4 TBS (r=0.42; p=0.01). In addition, a significant correlation was present between L1-L4 TBS and vertical jump height (r=0.35; p=0.03). Moreover, L1-L4 TBS presented a significant correlation with physical activity level (r=0.38; p=0.02). Age presented a significant positive correlation with 6MWT performance (r= 0.33; p= 0.04), physical activity level (r= 0.32; p= 0.05) and L1-L4 TBS (r= 0.35; p= 0.033). However, age did not present a significant correlation with vertical jump height (r= -0.11; p= 0.51). Moreover, the positive association between L1-L4 TBS and 6MWT remained significant after controlling for age. In addition, the positive association between L1-L4 TBS and vertical jump remained significant after controlling for age.
Conclusion: The present study suggests that the performance in the 6MWT and vertical jump level are significant independent predictors of L1-L4 TBS in older sarcopenic women.

P837

A RETROSPECTIVE CLAIMS DATA ANALYSIS ON HEALTHCARE RESOURCE UTILIZATION OF PATIENTS TREATED WITH ROMOSOZUMAB IN GERMANY

L. Grotenrath[1], H. D. Pannen[2], M. Hadwiger[3], L. Möckel[2]

[1]GWQ ServicePlus AG, Gesellschaft für Wirtschaftlichkeit und Qualität bei Krankenkassen, Düsseldorf, Germany, [2]UCB Pharma, Monheim am Rhein, Germany, [3]GWQ ServicePlus AG, Gesellschaft für Wirtschaftlichkeit und Qualität bei Krankenkassen, Hamburg, Germany

Objective
This study aimed to describe patient characteristics and costs associated with romosozumab treatment in Germany.
Material and Methods
This was a retrospective analysis of German statutory sick funds data covering a population of 6.3 million insured persons. Costs (inpatient, outpatient, medication) were calculated in patients with ≥1 pharmacy dispensation of romosozumab (index = date of 1st dispensing) and who were observable 2 years prior and up to 2 years after index.
Results
138 female romosozumab patients were included in the analysis. They had suffered 310 recorded fractures in the year prior to index. In those observable for at least 1 year (n=71) after index, the mean total costs per patient were 11,109 [SD 13,314; median 8,033] EUR (inpatient: 5,834 [SD 8,343; median 2,181] EUR / outpatient: 1,801 [SD 1,732; median 1,420] EUR / medication: 3,473 [SD 9,220; median 770] EUR) within the year prior 1st romosozumab dispensation and 18,630 [SD 24,470; median 12,215] EUR (inpatient: 2,425 [SD 4,269; median 0] EUR / outpatient: 1,803 [SD 1,551; median 1,313] EUR / medication: 14,403 [SD 24,025; median 9,653] EUR) within the first year after index.
In patients with 2 years of follow-up (n=22) the mean total costs per patient decreased substantially within the second year after index compared to the pre-index mean total costs (Fig.). Inpatient costs were approx. 4.5 and 10 times lower in the second year after index compared to the year 2 years and the last year prior to index, respectively.
Within the first and second year after index 50% and 75% of patients were not admitted to hospital, respectively.
Conclusion
Total patient costs in the year before and the year after starting romosozumab were similar despite the additional cost of the medication. During the second year after 1st romosozumab administration total patient costs reduced to levels lower than those before starting romosozumab. In addition, inpatient costs were lower within the two years after index than the costs in the last and the year 2 years before index.

ASSOCIATION OF ANGIOPOIETIN-LIKE PROTEIN TYPE 6 WITH HYPERTENSION IN PSORIATIC ARTHRITIS PATIENTS

L. N. Shilova[1], V. A. Aleksandrov[2], N. V. Golovina[1], A. V. Aleksandrov[2], R. A. Grekhov[2]

[1]Volgograd State Medical University, the Department of Hospital Therapy, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, VolgogradState Medical University, Volgograd, Russia

Purpose of the study:
To determine associations between serum angiopoietin-like proteins (Angptl) of different types and arterial hypertension (AH) in psoriatic arthritis (PsA) patients.
Materials and Methods.
The content of serum Angptl types 3, 4 and 6 patients was studied in 45 PsA by enzyme immunoassay (in 60% of cases metabolic syndrome was diagnosed, in 42.2% the presence of AH was confirmed).
Results and Discussion.
An intergroup comparison of Angptl levels in patients with/without arterial hypertension was performed (Table).
Table. Content of Angptl types 3,4 and 6 in PsA patients depending on AH

Indicators	Patients with AH (n=19)	Patients without AH (n=26)
Angptl3, pg/mL	1103 ± 319	1059 ± 372
Angptl4, pg/mL	436 ± 210	349 ± 133
Angptl6, pg/mL	5,64[4,3;7,0]	4,03[3,6;6,0] #

Note: # – p<0.05.
Angptl 3 and 4 types were not significantly different in groups of PsA patients with and without arterial hypertension (p>0.05), but a significant increase of Angptl6 in PsA patients in the presence of arterial hypertension was clearly demonstrated (M-WUtest, p=0.015). The effect of arterial hypertension on the content of different types of Angptl in the presence of metabolic syndrome (MS) was also demonstrated only for Angptl6 (p=0.044).
Conclusions.
Therapeutic strategies for PsA with MS targeting Angptl6 may be beneficial for patients with hypertension and possibly reduce cardiovascular risk.

P839

EVALUATING FRAX CORRECTIONS IN PREDICTING OSTEOPOROSIS TREATMENT RECOMMENDATIONS IN TYPE 2 DIABETES MELLITUS : A PILOT STUDY IN INDIA

L. Nagendra[1], S. Bhattacharya[2], S. Mondal[3], S. Avarebeel[4], Y. S. Ravikumar[5], H. Basavana Gowdappa[5], M. Chandran[6], M. Hiligsmann[1]

[1]Department of Health Services Research, Care and Public Health Research Institute, Maastricht University, Maastricht, Netherlands, [2]Department of Endocrinology, Indraprastha Apollo Hospitals, Sarita Vihar, Delhi, India, [3]Department of Endocrinology, NRS Medical College, Kolkata, India, [4]Department of Geriatrics, JSS Medical College, Mysore, India, [5]Department of General Medicine, JSS Medical College, Mysore, India, [6]Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore General Hospital, Singapore, Singapore

Objective: The study aimed to evaluate the effectiveness of unadjusted FRAX, the 10-year age adjustment, and the rheumatoid arthritis (RA) input as proxy in predicting osteoporosis treatment recommendations for patients with type 2 diabetes mellitus (T2DM), compared to bone mineral density (BMD) based thresholds outlined in guidelines.
Materials and methods: We recruited 100 participants with T2DM from two tertiary care centers in India for a prospective pilot study. FRAX scores without BMD were calculated for all participants. Adjusted FRAX scores without BMD were derived by increasing the age by 10 years and by adding the RA input as adjustments for T2DM. The scores were mapped onto an Indian risk stratification model of low, medium and high risk based on validated FRAX thresholds.(1) All participants underwent BMD testing, and treatment recommendations were determined based on the American Diabetes Association guidelines (fragility fracture or T-score ≤ -2.0). Prediction rates of the two corrections were compared.

Results: The study cohort consisted of 61% women with a mean age of 66.53 ± 9.43 years. Key characteristics included a mean BMI of 25.67 ± 5.17 kg/m², mean HbA1c of 8.69 ± 2.75%, and mean diabetes duration of 13.15 ± 10.09 years, with 15% reporting fragility fractures. The mean T-scores were -1.27 ± 1.37 at the femoral neck, -0.96 ± 2.04 at the lumbar spine, and -1.7 ± 2.0 at the distal one-third radius. Correct treatment recommendations were identified in 86.9% of cases using unadjusted FRAX, in 90.2% with the 10-year age increase input, and in 97.8% with the RA input (Table 1).
Conclusion: In this pilot study, the inclusion of RA input to FRAX was the best correction, leading to the identification of more individuals with T2DM who met the recommended treatment thresholds for osteoporosis. The RA input FRAX correction might emerge as the most suitable tool for predicting fracture risk in T2DM in resource-constrained regions. Larger studies are warranted to validate these findings and explore clinical implications.

Table 1 : Predictive ability of FRAX corrections in T2DM

	FRAX without BMD (n=100)			FRAX adjusted Age value increment 10 years (n=94)			FRAX adjusted RA input to FRAX (n=100)		
Indication for treatment (as per ADA guidelines)	*High risk*	*Medium risk*	*Low risk*	*High risk*	*Medium risk*	*Low risk*	*High risk*	*Medium risk*	*Low risk*
Yes (n = 46)	6	26	14	19	18	4	19	26	1
No (n = 54)	1	24	29	9	41	3	4	47	3

Risk stratification into high, medium, and low risk, respectively, based on validated FRAX thresholds for India
Treatment recommendations for
- High Risk : May be treated without BMD measurement
- Medium Risk : Measure BMD
- Low Risk : Measurement of BMD or treatment not required

The predictive ability was considered accurate if the treatment recommendation was "yes" and the patient was classified in the high risk or medium risk category

P840

PREVALENCE AND IMPACT OF GONARTHROSIS AND SPONDYLOARTHROSIS IN A COHORT OF PATIENTS WITH FIBROMYALGIA

L. Polino[1], T. L. Rodriguez Araya[1], A. Arias Gassol[1], X. Torres Mata[1]

[1]Rheumatology Department, Hospital Universitari Clinic, Barcelona, Spain

Objectives: To evaluate the prevalence of gonarthrosis and spondyloarthrosis in a cohort of patients with fibromyalgia and the impact of their presence on these patients after multidisciplinary treatment.
Methods:A retrospective study assessed the prevalence of gonarthrosis and spondyloarthrosis in fibromyalgia patients (ACR 1990 + ACR 2010) treated in our Fibromyalgia Unit who have undergone multidisciplinary treatment for 12 months. We collected data on pain (VAS), fatigue, and functionality (FIQ) before and after 12 months of multidisciplinary treatment, comparing patients with and without these comorbidities.
Results:630 fibromyalgia patients (96% women, mean age 48.4 years) were included. 156 had spondyloarthrosis, 26 had gonarthrosis, and 14 had both comorbidities. Patients with spondyloarthrosis showed a reduction in pain (VAS from 6.5 to 3.6), fatigue (VAS from 6.33 to 4.2), and FIQ scores (from 60.5 to 33.5). Those with gonarthrosis had similar improvements (pain VAS from 6.4 to 3.3, fatigue VAS from 6.2 to 4.3, FIQ from 61.2 to 32.2). Patients with both comorbidities showed pain reduction (VAS from 6.8 to 3.4), fatigue reduction (VAS from 6.8 to 4.4), and improvement in FIQ (from 61.1 to 32.6). In the 434 patients with only fibromyalgia, pain decreased from 6.5 to 3.5, fatigue from 6.6 to 4.1, and FIQ from 60.7 to 32.5.
Conclusions: The presence of gonarthrosis, spondyloarthrosis, or both does not seem to significantly affect the EVA scales for pain and fatigue or functional capacity in patients diagnosed with fibromyalgia according to both ACR 1990 and 2010 classification criteria, and who are undergoing specialized multidisciplinary treatment. The presence of gonarthrosis and spondyloarthrosis does not appear to influence the intensity and extent of generalized hyperalgesia in patients with fibromyalgia. Multidisciplinary treatment for fibromyalgia, even when the patient has gonarthrosis and spondyloarthrosis, remains crucial for the overall clinical improvement of the disease.

P841

INTEGRATED MULTI-OMICS AND MACHINE LEARNING APPROACHES REVEAL THE CHARACTERISTICS OF MACROPHAGES IN POSTMENOPAUSAL OSTEOPOROSIS AND IDENTIFY SMAD7 AS A KEY REGULATOR

L. Qianning[1], C. Weishen[1]

[1]The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

INTRODUCTION: Postmenopausal osteoporosis (OP) is a chronic bone disease characterized by low bone mineral density and microstructural deterioration. While early research focused on inhibiting osteoclast activity, recent perspectives highlight the interaction of bone resorption and formation. Given that macrophages serve as precursors to osteoclasts and secret cytokines that stimulate osteoblasts, they may be promising for identifying new dual-effect drug targets. In this study, we employed multi-omics and machine learning methods to investigate the molecular characteristics of macrophages in OP and identify some novel drug targets. We suggest that this research will help understand the OP's molecular mechanisms and assist the development of new

therapies.

METHODS: We integrated 6 scRNA-seq samples and 12 bulk RNA-seq samples as a discovery cohort to identify potential drug targets. Additionally, we utilized 20 paraffin tissue samples and 20 bulk RNA-seq samples for validation. Differential gene expression analysis was performed on the scRNA-seq data, while Weighted Gene Co-expression Network Analysis (WGCNA) was utilized to analyze the bulk RNA-seq data. Furthermore, we employed Lasso regression and Support Vector Machine (SVM) models to identify core genes. Subsequently, we performed Protein-Protein Interaction (PPI) analysis, cellular communication inference, differentiation trajectory analysis, and network pharmacology analysis based on the identified genes.

RESULTS: In the discovery cohort, we observed a significant difference in the proportion of macrophages **(Fig.1A)**. We identified a module correlated with macrophages and detected the differentially expressed genes **(Fig.1B-C).** The KEGG enrichment analysis revealed that these differential genes were significantly enriched in ferroptosis-related pathways **(Fig.1D)**. Additionally, the core genes identified in the PPI network showed a significant correlation with ferroptosis (**Figure 2A-B**). Moreover, machine learning techniques identified four core genes, with Smad7 emerging as the most critical, demonstrating a strong connection in the validation cohort (**Figure 2C-D**). Finally, we validated the expression of Smad7 and the differential proportions of macrophages in paraffin-embedded tissues using immunohistochemical staining.

DISCUSSION: In conclusion, we first detected a significant difference in the proportion of macrophages in osteoporosis, along with identifying differentially expressed genes. Enrichment analysis and the PPI network indicated that these genes were highly correlated with ferroptosis mechanism, which may help explain the varying distribution of macrophages. Machine learning approaches further identified several novel targets, with Smad7 emerging as the most significant and promising regulator in the validation cohort. Our findings provide novel insights for targeted treatments for OP, while also contributing to the understanding of the underlying molecular mechanisms.

P842

THE DUAL IMPACT OF CHRONIC LOW BACK PAIN ON PHYSICAL AND MENTAL HEALTH: INSIGHTS FROM A QUALITY OF LIFE ASSESSMENT

L. R. Rouached[1], M. A. Ayachi[1], N. G. Gharbi[1], S. B. Boudeen[1], A. B. T. Ben Tekaya[1], I. M. Mahmoud[1], R. T. Tekaya[1], O. S. Saidane[1], L. A. Abdelmoula[1]

[1]Charles Nicolle Hospital, Tunis, Tunisia

Objective: To assess the impact of chronic low back pain on patients' quality of life.

Methods: A cross-sectional study was conducted on 124 patients consulting for chronic low back pain. Quality of life was assessed using the SF-36 score, which evaluates both the physical component summary (PCS) and the mental component summary (MCS).

Results: The study included 124 patients, predominantly male (sex ratio: 4.4), with a mean age of 53.3 ± 13 years (range: 15–80 years) and an average duration of low back pain of 6.69 ± 4.67 years (range: 1–20 years).

The **PCS** had a mean score of 41.41 ± 17.94 (range: 11.5–87.5), with impairments observed in 46.8% of patients. Among the physical domains, *physical functioning* (D1) was moderately affected (58.08 ± 26.52), while *role limitations due to physical health* (D2) and *bodily pain* (D3) showed severe impairments with mean scores of 20.95 ± 35.71 and 20.94 ± 37.66, respectively. *General health perception* (D4) scored 41.12 ± 19.55.

The **MCS** had a mean score of 41.92 ± 20.74 (range: 10.75–94), with impairments in 46% of patients. E*nergy levels* (D5) were relatively preserved (53.03 ± 24.28), also *social functioning* (D6) scored 59.09 ± 33.03. In contrast, *emotional role limitations* (D7) and *mental health* (D8) were moderately affected, with scores of 43.56 ± 24.65 and 49.14 ± 8.89, respectively.

Conclusion: Chronic low back pain significantly affects patients' quality of life, with notable impairments in both physical and mental domains. These findings emphasize the need for comprehensive management strategies targeting both aspects to improve patient outcomes.

P843

THE ROLE OF PAIN INTENSITY AND CLINICAL FEATURES IN THE QUALITY OF LIFE OF CHRONIC LOW BACK PAIN PATIENTS

L. R. Rouached[1], M. A. Ayachi[1], N. G. Gharbi[1], S. B. Boudeen[1], A. B. T. Ben Tekaya[1], I. M. Mahmoud[1], R. T. Tekaya[1], O. S. Saidane[1], L. A. Abdelmoula[1]

[1]Charles Nicolle Hospital, Tunis, Tunisia

Objective: To analyze the impact of low back pain characteristics on the quality of life in patients with chronic low back pain.
Methods: A cross-sectional study was conducted including patients consulting for chronic low back pain. The studied parameters included disease duration, pain type (nociceptive, neuropathic assessed by the DN4 scale), radicular pain (sciatica, cruralgia), clinical characteristics (spinal syndrome, stiffness, antalgic posture), and neurological signs. Quality of life was assessed using the SF-36 score, covering both physical and mental components.
Results: The study included 124 patients, predominantly male (sex ratio: 4.4), with a mean age of 53.3 ± 13 years and a mean disease duration of 6.69 ± 4.67 years. The mean pain intensity, assessed by the Visual Analog Scale (VAS), was 6.3 ± 1.87. Neuropathic pain (median DN4 score: 2 [0-5]) was identified in 57 patients (46%). Of these, 84 patients (68%) reported radicular pain: 7% had L3 cruralgia, 45% had L5 sciatica, and 48% had S1 sciatica. Impulsive pain was reported by 35%. Spinal syndrome was present in 91.9%, spinal stiffness in 75% and 70.2% had radicular syndrome. Neurological disorders were found in 8.9% of patients, including 8.1% with sensorimotor deficits and 6.5% with vesicourethral dysfunction.
Physical component (PCS) impairment was associated with higher VAS scores (6.8 vs. 5.9; p=0.018) and more frequent spinal syndrome (98% vs. 80%; p=0.004). Cruralgia was more frequent in the non-impaired PCS group (29% vs. 9%; p=0.034). No significant difference was found for disease duration, neuropathic pain, or sciatica.
Impaired mental component summary (MCS) scores were associated with higher VAS scores (7 ± 1.5 vs. 5.5 ± 1.9; p=0.002), more frequent impulsive pain (44% vs. 19%; p=0.045), and increased spinal stiffness (81% vs. 57%; p=0.035)
Conclusion: Pain intensity and clinical characteristics, such as spinal syndrome and stiffness, have a significant impact on the quality of life of patients with chronic low back pain. These findings underscore the need for a targeted management approach that addresses both the physical and mental aspects of the condition to improve patients' well-being.

P844

FUNCTIONAL DISABILITY AND QUALITY OF LIFE IN CHRONIC LOW BACK PAIN

L. R. Rouached[1], M. A. Ayachi[1], N. G. Gharbi[1], S. B. Boudeen[1], A. B. T. Ben Tekaya[1], I. M. Mahmoud[1], R. T. Tekaya[1], O. S. Saidane[1], L. A. Abdelmoula[1]

[1]Charles Nicolle Hospital, Tunis, Tunisia

Objective: To explore the correlation between the functional impact of chronic low back pain (CLBP) and quality of life.
Methods: A cross-sectional study was conducted on 124 patients consulting for chronic low back pain. The functional impact of CLBP was assessed using the Oswestry Disability Index (ODI), a validated tool for measuring functional disability. Quality of life was evaluated using the SF-36 questionnaire, which assesses both the physical component score (PCS) and mental component score (MCS)
Results: A total of 124 patients were included, predominantly male (sex ratio: 4.4), with a mean age of 53.3 ± 13 years (range: 15–80 years) and a mean duration of CLBP of 6.69 ± 4.67 years (range: 1–20 years). The mean ODI score was 42.7 ± 19.6 (range: 0–92%). Regarding disability levels, 15.3% of patients had minimal disability, 21% had moderate disability, 44.4% had severe disability, 17.7% had very severe disability, and 1.6% had total disability. A significant association was found between the degree of functional disability and the physical component score (PCS).
None of the patients in the group with an impaired SF-36 physical component score (PCS) were free of disability, compared to 30% in the non-impaired PCS group (p<0.001). Moderate disability was significantly more frequent in the impaired PCS group (67% vs. 30%, p<0.001), while severe and very severe forms were exclusively observed in this group (10% and 2%, p<0.001). Moreover, patients with an impaired SF-36 mental component score (MCS) exhibited significantly greater functional disability (p<0.001). Similarly, the degree of functional disability was significantly associated with the mental component score (MCS) (p<0.001) (table1)

OSDI	PCS impaired	PCS not impaired	P	MCS impaired	MCS not impaired	p
No disability	0%	30%	<0.001	2%	24%	**<0,001**
Mild disability	21%	40%		16%	52%	
Moderate disability	67%	30%		75%	10%	
Severe disabilit	10%	0%		5%	14%	
Very severe disability	2%	0%		2%	0%	

Conclusion: The functional impact of chronic low back pain is significantly associated with reduced quality of life, affecting both physical and mental health. These findings emphasize the need for a comprehensive management approach that addresses both the physical and psychological aspects of the condition.

P845

THERIPARATIDE AND VERTEBRAL PAIN

L. Rivero Gonzalez[1], M. Castro[2]

[1]Rehabilitacion hospital insular de Gran Canaria, , Spain, [2]Agaldar centro medico Gran Canaria, , Spain

Theriparatide is a drug used in the treatment of osteoporosis that has been shown to have positive effects in reducing vertebral pain and improving the quality of life in osteoporotic patients. A prospective longitudinal observational study carried out in the rehabilitation service of the Insular Hospital of Gran Canaria evaluated 30 patients with osteoporosis and vertebral pain treated with teriparatide. The results indicated a significant decrease in pain and an improvement in the quality of life of these patients

P846

ANTI-RESORPTIVE THERAPY FOR PREGNANCY- AND LACTATION-ASSOCIATED OSTEOPOROSIS

L. S. Abboskhujaeva[1], N. M. Alikhanova[2]

[1]Republican Specialized Scientific-and-Practical Medical Centre of Endocrinology named after academician Yo.Kh.Turakulov under the Ministry of Health of the Republic of Uzbekistan, Tashkent, Uzbekistan, [2]Institutes of Health and Strategic Development. Tashkent, Uzbekistan, Tashkent , Uzbekistan

Objective: To evaluate the outcomes of treatment for pregnancy- and lactation-associated osteoporosis.
Materials and Methods: The study included 27 women aged 18-40 years diagnosed with pregnancy- and lactation-associated osteoporosis.
Results: All women were advised to stop breastfeeding immediately after the diagnosis of PLO and received individualized osteoporosis treatment, including bone-anabolic and anti-resorptive medications. All patients were administered 1000 mg of calcium and 800 IU of vitamin D3 daily. The 12-month treatment outcomes included the following indicators: blood markers of bone metabolism and bone mineral density (BMD).
After one year of therapy, the patients reported significant reductions in back pain and no new clinical vertebral fractures. Blood calcium and phosphorus levels remained relatively unchanged. There was a significant increase in average vitamin D levels (pre-treatment: 18.4±7.93 ng/ml; post-treatment: 29.1±17.1 ng/ml, p=0.002).
Parathyroid hormone (PTH) levels decreased but were not statistically significant (pre-treatment: 56.7±40.9 pg/ml; post-treatment: 38.4±19.9 pg/ml; p=0.05).
The β-CrossLaps levels, elevated before treatment (0.91±0.99 ng/ml), significantly decreased after treatment (0.40±0.41 ng/ml, p=0.02).
Alkaline phosphatase levels significantly declined during therapy (pre-treatment: 114.6±27.4 U/L; post-treatment: 38.99±31.7 U/L; p=0.01).
Osteocalcin levels also decreased significantly (pre-treatment: 132.9±66.1 ng/ml; post-treatment: 49.7±37.4 ng/ml; p=0.0001).
BMD increased by 10.9% in the lumbar spine, by 5.1% and 4.1% in the left and right femoral bones, and by 6.3% and 5.9% in the neck of the left and right femur, respectively.
Conclusion: Anti-resorptive therapy, combined with cessation of breastfeeding and supplementation with calcium and vitamin D, appears to reduce severe back pain, significantly increase BMD, and help prevent further vertebral fractures.

P847

TBS AND BSI DO NOT DIFFER BETWEEN PRIMARY HYPERPARATHYROIDISM AND PRIMARY OSTEOPOROSIS PATIENTS WITH SIMILAR FRACTURE RISK

A. Pusterla[1], F. Fraire[1], L. Sauro[1], N. Sagone[1], F. Bioletto[1], A. M. Berton[1], M. Procopio[1], M. Barale[2]

[1]Division of Endocrinology, Diabetology and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy, [2]Division of Oncological Endocrinoly, Departmente of Medical Sciences, University of Turin, Turin, Italy

Premise: Primary hyperparathyroidism (PHPT) is characterized by chronic excessive PTH secretion, leading to hypercalcemia. Key features include osteopenia and increased fracture risk. DXA remains the gold standard for evaluating bone mineral density (BMD) and quality using Trabecular Bone Score (TBS) and Bone Strain Index (BSI).
Objective: To evaluate BMD, TBS, and BSI in PHPT and identify differences from primary osteoporosis (PO) based on disease severity and fragility fracture predictors.
Methods: This cross-sectional case-control study compared 87 consecutive hypercalcemic PHPT patients, including symptomatic (hypercalcemic crises, clinical fractures, renal colic) and asymptomatic cases, with 173 PO patients. Vertebral fracture assessment and DXA were performed in PHPT (lumbar spine, femur, and radius) and PO (lumbar spine and femur) to detect asymptomatic fractures and calculate BMD, T-score, TBS, and BSI.
Results: In this study, 70% of PHPT patients were asymptomatic, though 54% had complications (osteoporosis, morphometric fractures, or kidney disease). PHPT patients, including asymptomatic cases, had a higher prevalence of osteoporosis (68%, 95% CI 58–78) and lower total femoral BMD (0.7±0.13) compared to PO patients (47%, 40–55; 0.8±0.14). Fragility fracture prevalence was similar between PHPT and PO (26%, 17–36 vs. 29%, 22–36). No differences in TBS or BSI were observed between PHPT and PO, but both were significantly worse in fractured versus non-fractured PHPT patients (TBS: 1.13±0.1 vs. 1.23±0.1; BSI: 2.93±0.98 vs. 2.42±0.59, p<0.05). Multivariate analysis showed that PTH and age were independent predictors of bone loss (especially femoral and radial T-scores) in PHPT, while BMI and age negatively impacted TBS (p<0.01).
Conclusions: PHPT, even in its asymptomatic form, is linked to a higher prevalence of osteoporosis and predominant cortical bone damage. While TBS and BSI do not distinguish PHPT from PO, they are valuable for predicting fracture risk in PHPT. Combining traditional DXA with TBS and BSI is essential for more accurate

fracture risk assessment and therapy selection in PHPT.

P848

AIR POLLUTION EXPOSURE AND BONE HEALTH: IDENTIFYING CRITICAL WINDOWS OF SUSCEPTIBILITY IN THE DANISH COPSAC2010 BIRTH COHORT

L. Scheepers[1], A. C. Binter[2], M. Guxens[2], J. Stokholm[3], F. Johnston[1], C. E. Pederson[3]

[1]Menzies Institute for Medical Research, Hobart CBD, Australia, [2]IS Global Barcelona, Barcelona, Spain, [3]COPSAC, Herlev and Gentofte Hospital, University of Copenhagen, Copenhagen, Denmark

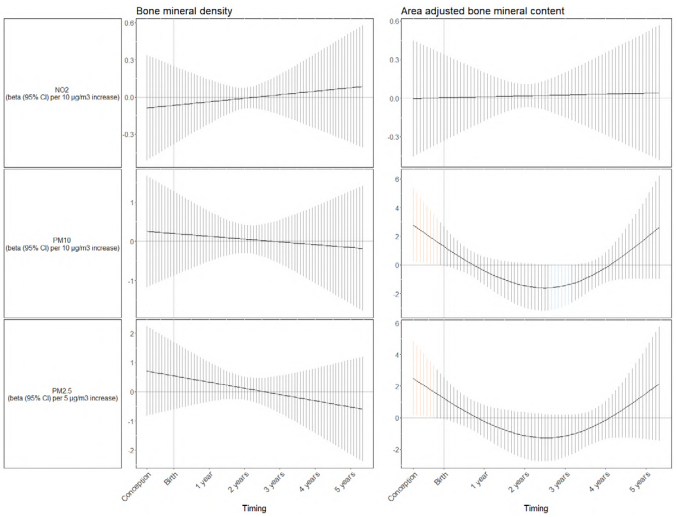
Objective: We aimed to identify periods of susceptibility to air pollution in early life in relation to bone health outcomes at age six years.

Material and Methods: We used data from the $COPSAC_{2010}$ study, an ongoing population-based mother-child cohort in Denmark (n=700). We modelled daily ambient air pollution concentrations of nitrogen dioxide (NO_2) and particulate matter with a diameter of ≤2.5 and ≤10 µm ($PM_{2.5}$ and PM_{10}) at the home addresses during pregnancy and childhood, using the Danish Eulerian Hemispheric Model (DEHM)–urban background model (UBM)–Danish Air Pollution and Human Exposure Modelling System (AirGIS) model system. Bone mineral density (BMD) and area-adjusted bone mineral content (aBMC) were measured by dual-energy x-ray absorptiometry (DXA) at age six. We performed distributed lag non-linear modelling (DNLM) adjusted for several socioeconomic characteristics to assess the associations between air pollution and bone health and identify windows of susceptibility.

Results: In total, 518 children were included. We identified a window of susceptibility for PM_{10} exposure between 2.8 to 3.2 years of age with aBMC (-9.0; CI -17.9 to -0.1 per 10 µg/m3 increase in PM_{10}). In sex-stratified analyses, associations for both $PM_{2.5}$ and PM_{10} with aBMC followed similar trends, but were only statistically significant in boys, and not in girls. Also, we identified a positive association between PM_{10} and $PM_{2.5}$ from conception to ~ 7 months of gestation with aBMC (e.g., 14.4; CI 0.7 to 28.2 per 5 µg/m3 increase in $PM_{2.5}$) (**Figure**). Nevertheless, all associations dissapeared after correction for multiple testing.

Conclusion: We observed conflicting evidence regarding the impact of air pollution during pregnancy and early childhood on bone health outcomes at age six. We showed a protective effect during pregnancy, while, around 3 years of age may represent a critical period for negative effects on bone health, particular in boys.

Funding: All funding received is listed at www.copsac.com, including funding provided by the Health Effects Institute, a Walter A. Rosenblith New Investigator Award, the Lundbeck Foundation, and from the Danish Ministry of Health, Council for Strategic Research, and the Capital Region Research Foundation.



Blackline represents the beta estimate of the association between the exposure at each specific lag (1 month) and the outcome. Vertical grey, blue, and orange lines represent 95% confidence interval (CI) and indicate no divergence from the null, significant divergence from negative association, and significant divergence from positive association, respectively. Darker blue and orange colors indicate associations after correction for multiple testing (p-value < 0.025).

Objectives

To demonstrate the clinical equivalence in efficacy and compare the pharmacodynamics (PD), safety, and immunogenicity of proposed denosumab biosimilar RGB-14-P and reference denosumab (RD) in postmenopausal women with osteoporosis.

Materials and Methods

Participants were randomised 1:1 to subcutaneous RGB-14-P or RD 60 mg every 6 months, on Day 1 and Week (W) 26. At W52, a subset of participants on RD were re-randomised 1:1 to RGB-14-P or RD. Primary endpoints: Percentage change from baseline (%CfB) in lumbar spine (LS) bone mineral density (BMD) at W52 and area under the curve (AUC) of %CfB serum C-terminal telopeptide of type 1 collagen (sCTX) to W26. Secondary endpoints: %CfB in total hip (TH), LS and femoral neck (FN) BMD at W26 and W52, and vertebral and non-vertebral fragility fractures at W52. Results reported to W52 (EudraCT 2020-006017-38).

Results

Of 1210 screened participants, 473 were randomised (RGB-14-P n=242; RD n=231). Both primary endpoints were met: %CfB in LS BMD at W52 was equivalent between arms (**Figure**), and the geometric mean ratio in the AUC of %CfB in sCTX concentration was 1.01 (95% CI 0.98–1.05; p=0.494). Secondary endpoints were also met, with no statistical differences in %CfB in LS at W26, or TH and FN BMD at W26 and W52 (**Figure**). There was no meaningful difference in the incidence of vertebral (RGB-14-P, 1.7%; RD, 3.5%) or non-vertebral (RGB-14-P, 1.7%; RD, 4.3%) fragility fractures at W52. Anti-drug antibody incidence was <1% in both arms. Percentage of participants with ≥1 treatment-related treatment-emergent adverse event (TEAE) was similar between arms (RGB-14-P, 14.9%; RD, 13.9%); the most frequent TEAE was hypocalcaemia (RGB-14-P, 6.6%; RD, 6.9%). Percentage of participants with severe TEAEs was low (RGB-14-P, 3.3%; RD, 3.5%).

Conclusion

RGB-14-P demonstrated equivalent efficacy, pharmacodynamics, immunogenicity and safety with RD in postmenopausal women with osteoporosis.

METHODS OF EARLY DIAGNOSIS OF BONE REMODELING DISORDERS AND PREDICTION OF OSTEOPOROSIS DEVELOPMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Sivordova[1], J. Polyakova[1], E. Papichev[1], Y. Akhverdyan[1], B. Zavodovsky[1]

[1]Federal State Budgetary Institution «Zborovsky Research Institute of Clinical and Experimental Rheumatology», Volgograd, Russia

Bone tissue is metabolically active and remodeling processes are constantly taking place in it. Under normal conditions, resorption and synthesis processes are balanced in healthy bone. In patients with rheumatoid arthritis (RA), this balance is disturbed, the activity of resorptive processes begins to prevail over the construction of new bone, which can lead to the development of secondary osteoporosis (OP). It is known from clinical practice that the most effective way to preserve bone quality is early and even preventive therapeutic intervention, which allows timely prevention of bone tissue destruction. In this regard, the search for markers for early prediction of bone metabolism disorders in RA is an urgent scientific task. Objective: to assess the diagnostic significance of indicators affecting bone metabolism, for the purpose of early prediction of osteoporosis (OP) development in patients with RA. Materials and methods. The study included 88 women suffering from RA, aged 21 to 81 years. RA was diagnosed according to the ACR/EULAR criteria, 2010. The average age of patients was 47.51±9.63 years. The average duration of the disease was 7.92±5.21 years. Within the framework of the study, the ELISA test was used to determine the level of 25-OH vitamin D, the specific sequence of type I collagen and its degradation products using commercial kits. The diagnostic value of the studied parameters was determined by constructing ROC curves. Study results. When studying the diagnostic value of the level of 25-OH vitamin D, it was shown that the study of this marker in patients with RA has high prognostic significance in predicting the development of OP. The area under the ROC curve was 0.696. The diagnostic decision point was the level of 25-OH vitamin D 58.741 ng/ml. When using this cutoff point, the specificity of the method was 95.45%, the specificity was 37.88%. Evaluation of the role of the N-terminal propeptide of type 1 procollagen (P1NP) level showed that it is also a valuable diagnostic marker of AP in RA. The area under the ROC curve is 0.785. The diagnostic decision point is 50.225 ng/ml (the specificity of the method was 71.21%, the sensitivity was 81.82%). Determination of the C-telopeptide of type I collagen by constructing ROC curves showed that in the diagnosis of AP in RA, the indicator has good quality (the area under the curve is 0.595), the diagnostic decision point is 0.988 ng/ml. The sensitivity of the method was 36.36%, the specificity was 90.91%. Conclusions. Thus, the level of P1NP, C-telopeptide of type I collagen and 25-OH vitamin D have high diagnostic value and can be used for early diagnosis of bone metabolism disorders in RA and

for predicting the development of osteoporosis in patients with RA.
Keywords: rheumatoid arthritis, osteoporosis, bone remodeling markers.

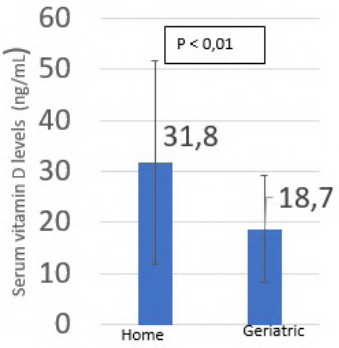
Primary Care Medicine. University of Barcelona., Barcelona, Spain

Objective To compare vitamin D levels in the osteoporotic population living in nursing homes versus those living at home, with similar functional capacity.
Material and methods Observational, cross-sectional, and descriptive study over a period of 12 months, between December 2022 and November 2023. The study was carried out in primary care health centers in Spain. Patients were selected from their electronic medical records, and the following inclusion criteria were met: > 49 years of age with a diagnosis of osteoporosis confirmed by bone densitometry (T-score ≤ -2.5 SD in femoral neck) and/or fragility fracture. Patients with other pathologies that alter bone mass were excluded.
To evaluate predictive factors, clinical and lifestyle variables are analyzed by applying multiple regression analysis. Based on the data obtained, a comparative sub-analysis was carried out between patients who lived in nursing homes versus those who live at home with similar functional capacity (Barthel index > 60 points). A total of 185 patients from nursing homes throughout Spain were included and compared with a group similar in age, sex and place of residence.
Results
The mean age of the patients was about 71.7 (±9.9) years and 91.5% of them were women. Mean serum vitamin D level (31.8 ng/mL) in outpatients compared to 18. 7 ng/mL of institutionalized patients.



There is a difference between the two of -41.2%. Of the institutionalized patients, there was a 23% lower exposure to sunlight. And 37% of them had greater skin pathology that interacted with the absorption of vitamin D.
Conclusions.
Those patients living in nursing homes had lower levels of vitamin D.

DISCONTINUATION AND NON-PUBLICATION OF OSTEOARTHRITIS CLINICAL STUDIES: A CROSS-SECTIONAL ANALYSIS OF 10,686,401 PATIENTS

M. A. Abdelsalam[1], H. M. Hafez[2], M. T. Lasheen[3], B. E. Badwy[3], O. El-Sedafy[3], A. M. Hafez[4], O. S. El-Sayed[5], M. A. Ali[3], M. R. Awad[1], M. S. Hamza[6]

[1]Rheumatology and Rehabilitation Dept., Faculty of Medicine, Misr Univ. for Science and Technology, Giza, Egypt, [2]Faculty of medicine, October 6th University, Giza, Egypt, [3]Faculty of medicine, Misr university for science and technology, Giza, Egypt, [4]Faculty of medecine, Damietta university, Damietta, Egypt, [5]Faculty of Medicine, Zagazig University, Zagazig, Egypt, [6]Orthopedics department, Faculty of Medicine, Misr University for Science and Technology, Giza, Egypt

Objective:
Osteoarthritis (OA) is rising at an alarming rate, affecting millions worldwide and threatening mobility, independence, and quality of life. High-quality evidence is essential to guide clinical decision-making and ensure the best patient outcomes. The discontinuation and non-publication of clinical studies are major contributors to research waste and incomplete data synthesis in evidence-based medicine.This study aims to assess the prevalence, characteristics, and publication history of OA clinical studies and investigate the causes for their non-publication or discontinuation.
Methods:
We searched OA-related clinical trials registered in ClinicalTrials.gov using NCT identifiers up to January 2, 2025. We excluded the last 24 months to account for ongoing peer reviews. Studies were considered discontinued if terminated, withdrawn, or sus-

pended and unpublished if their results were not available in a peer-reviewed journal. Data on gender, age, study type, funding, intervention, enrollment, and location were extracted. Multiple logistic regression analyzed characteristics linked to unpublished or discontinued trials.

Results:

A total of 3828 study were included, devided into 2715 (70.92%) completed, 425 (11.1%) discontinued, and 687 (17.9%) classified as of unknown status. Completed and discontinued studies were analysed, comprising 2588 interventional studies 538 observational studies. Among these, 425 were discontinued, with 9.4% of them being published despite being discontinued, and 34.8% of unknown studies were also found published. Also, almost half (47.8%) of completed studies remained unpublished. Logistic regression analysis revealed that studies funded by non-industry sources had significantly lower odds for completion compared to those funded by industry (Odds Ratio (OR) = 0.4, 95% CI [0.326, 0.513], p < 0.001). as for publication, behavioral intervention were significantly more likely to be published compared to device intervention (OR = 2.346, 95% CI: 1.594 to 3.451, p < 0.001), enrollment sizes >100 were more likely to be published than those <100 (OR = 0.575, 95% CI: 0.479 to 0.690), and non-indusrty studies were more likely to be published than industry (OR = 0.409, 95% CI: 0.326 to 0.513).

Conclusion: OA clinical studies are frequently discontinued or left unpublished, exposing participants to potential harm without benefit. This not only poses challenges in recruiting for future trials but also leads to the inefficient utilization of limited time and financial resources in medical research. Enrollment size and Funding type are the main predictors of unpublished studies.

P853

DISCONTINUATION AND NON-PUBLICATION OF KNEE OSTEOARTHRITIS CLINICAL STUDIES: A CROSS-SECTIONAL ANALYSIS OF 1,560,030 PATIENTS

M. A. Abdelsalam[1], H. M. Hafez[2], O. El-Sedafy[3], M. T. Lasheen[3], B. E. Badwy[3], R. J. Barakat[3], A. A. Mohamed[3], A. M. Hafez[4], O. S. El-Sayed[5], M. A. Mannaa[2], M. A. Ali[3], M. R. Awad[1], A. N. Bayoumy[6]

[1]Rheumatology and Rehabilitation Dept., Faculty of Medicine, Misr Univ. for Science and Technology, Giza, Egypt, [2]Faculty of medicine, October 6th University, Giza, Egypt, [3]Faculty of medicine, Misr university for science and technology, Giza, Egypt, [4]Faculty of medecine, Damietta university, Damietta, Egypt, [5]Faculty of Medicine, Zagazig University, Zagazig, Egypt, [6]Faculty of medicine, Al-Azhar University for Boys, Cairo, Egypt

Objective: Knee Osteoarthritis (KOA) affects millions worldwide, with prevalence rates escalating from 19.2% in individuals under 50 to 54.1% in those over 70, emphasizing the need for effective treatments and prevention. Despite the numerous clinical studies targeting KOA, many remain unpublished or discontinued, Limiting the advancement of medical knowledge and patient care. This study aims to assess the prevalence, characteristics, and publication history of KOA clinical studies and investigate the reasons for their non-publication or discontinuation.

Methods: We conducted a comprehensive search of ClinicalTrials.gov for KOA studies up to December 12, 2024. Studies completed within the last two years were excluded to account for ongoing peer review processes. Published trials were determined through their NCT identifiers. We collected and analyzed data on gender, age, study type, funding, intervention, enrollment, and location were extracted. Multiple logistic regression analyzed characteristics linked to unpublished or discontinued trials.

Results: A total of 2,614 registered studies on knee osteoarthritis were reviewed, divided into 1,871 (71.58%) completed, 258 (9.87%) discontinued, and 485 (18.55%) classified as unknown. Completed and discontinued studies were analysed, encompassing 1,821 (85.7%) interventional studies and 303 (14.3%) observational studies. Among these, 258 were discontinued, with 10.4% of them being published despite being discontinued, and 35.4% of unknown studies were also found published. Logistic regression analysis indicates that studies funded by industry were twice as likely to be completed compared to studies funded by non-industry sources (Odds Ratio (OR) = 2.018 (95% Confidence interval (CI): 1.476 to 2.759, p < .001). Regarding publication, Studies with a procedure intervention were significantly less likely to be published compared to studies with behavioral interventions (OR = 0.424, 95% CI: 0.2532 to 0.711, p = 0.001), Studies with > 100 participants were significantly more likely to be published than those with < 100 participants (OR = 2.314, 95% CI: 1.7470 to 3.066, p < .001), and Observational studies were significantly less likely to be published than interventional studies (OR = 0.531, 95% CI: 0.3520 to 0.800, p= 0.002).

Conclusion: KOA clinical studies are frequently discontinued or left unpublished, exposing participants to potential harm without benefit. Enrollment size and study designs are the main predictors of unpublished studies. Regulatory bodies and journals should enforce stricter policies to ensure timely publication of results and minimize research waste.

P854

EFFICACY OF INTRA-ARTICULAR HYALURONIC ACID INJECTION FOR NONSURGICAL MANAGEMENT OF CARPOMETACARPAL OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

M. A. Abdelsalam[1], O. S. El-Sayed[2], A. Al-Najjar[3], M. R. Awad[1], M. S. Hamza[4]

[1]Rheumatology and Rehabilitation Dept., Faculty of Medicine, Misr Univ. for Science and Technology, Giza, Egypt, [2]Faculty of Medicine, Zagazig University, Zagazig, Egypt, [3]Faculty of medicine, Al-Azhar University, Gaza, Palestinian Territories, [4]Orthopedics department, Faculty of Medicine, Misr University for Science and Technology, Giza, Egypt

Objective: Carpometacarpal osteoarthritis (CMC OA) is a painful

condition affecting 21% of hand OA patients. Various treatment modalities have been explored to reduce pain and improve function, including intra-articular injections of hyaluronic acid (HA). However, the effectiveness of HA in managing CMC OA remains a topic of debate.

Methods: We conducted a systematic search across multiple databases, including PubMed, Cochrane Library, Web of Science, and Scopus from inception till February 1, 2024. We included randomized clinical trials evaluating the efficacy of HA in CMC OA. The main outcome was pain at rest measured by visual analogue scale (VAS). We stratified the outcome into short-term (after 1 month) and medium-term (after 3 months) follow-up and long-term (after 6 months) follow-up. We used Rayyan for identifying duplicates, title, abstract and full-text screening and Review Manager (RevMan) software V.5.3.5 for data analysis.

Results: This systematic review and meta-analysis incorporates data from nine studies, of which seven were included in the main outcome analysis, encompassing a total of 1,070 patients diagnosed with CMC osteoarthritis. The primary objective was to evaluate the efficacy of HA treatment across multiple outcome measures. The VAS for pain relief served as the primary endpoint, demonstrating a significant improvement with HA treatment in short-term (standardized mean difference [SMD] = -0.32, 95% confidence interval [CI]: [-0.52 to -0.12]) and medium-term (SMD = -0.56, 95% CI: [-0.81 to -0.31]) follow-up and long-term (SMD = -0.29, 95% CI: [-0.54 to -0.04]) follow-up than the control groups. However, for grip strength, the analysis did not reveal a statistically significant difference (SMD = 0.18, 95% CI: [-0.17 to 0.52]). Similarly, HA treatment had no significant impact on tip pinch strength (SMD = -0.23, 95% CI: [-0.58 to 0.11]).

Conclusion: Intra-articular HA injections provide pain relief in CMC OA, as evidenced by improvements in VAS scores. However, grip strength and tip pinch strength did not show significant differences. Further research and larger randomized controlled trials are warranted to validate these findings.

P855

MY SHOULDER HURTS, WHAT SHOULD I DO? A SYSTEMATIC REVIEW AND BAYESIAN NETWORK META-ANALYSIS OF DIFFERENT INJECTABLES IN GLENOHUMERAL OSTEOARTHRITIS

M. A. Abdelsalam[1], A. Alsaeed[2], H. Abdelrahman[2], R. Refaat[3], M. Tarek[4], A. Al-Najjar[5], M. S. Hamza[6]

[1]Rheumatology and Rehabilitation Dept., Faculty of Medicine, Misr Univ. for Science and Technology, Giza, Egypt, [2]Rheumatology and Rehabilitation Dept, Faculty of Medicine, Mansoura University, Mansoura, Egypt, [3]Faculty of medicine, Ahfad University for Women, Khartom, Sudan, [4]Faculty of medicine, Al-Azhar University for Boys, Cairo, Egypt, [5]Faculty of medicine, Al-Azhar University, Gaza, Palestinian Territories, [6]Orthopedics department, Faculty of Medicine, Misr University for Science and Technology, Giza, Egypt

Objective: Glenohumeral Osteoarthritis (GH OA) significantly impacts joint function and quality of life. Various intra-articular injectable treatments, including hyaluronic acid (HA), corticosteroids (GCs), platelet-rich plasma (PRP), and bone marrow aspirate (BMA), aim to alleviate these symptoms. This systematic review and Bayesian network meta-analysis aims to compare their efficacy in alleviating pain, reducing disability, improving range of motion (ROM) and enhancing patient reported outcomes.

Methods: We conducted a systematic search across multiple databases, including PubMed, Cochrane Library, Web of Science, and Scopus from inception till April 1st, 2024. We included clinical studies evaluating the efficacy of HA, GCs, PRP, and BMA in GH OA. The outcomes included pain measured by the visual analogue scale (VAS), range of motion (ROM), disability measured by the Shoulder Pain and Disability Index (SPADI), and patient-reported outcomes assessed by the Western Ontario Osteoarthritis of the Shoulder (WOOS). We used Bayesian network meta-analysis (NMA) model to compare among the included interventions. We calculated the mean difference (MD), 95% credibility interval. The P score was used to rank the efficacy of the interventions. Forest and network plots for each outcome were generated using R version 4.4.0, Build 748 (RStudio, Inc.).

Results: This systematic review and Bayesian network meta-analysis incorporates data from 15 studies, encompassing a total of 1,968 patients diagnosed with GH OA. Pain relief measured by VAS served as the primary endpoint. Among the comparisons of HA, GCs, BMA, PRP, and placebo, GCs injections had the highest mean difference compared to placebo, although the difference was not statistically significant. GCs injections: Mean Difference (MD) = 12, 95% Credible Interval (CrI) = -15 to 40. As for ROM, HA is the highest (HA: MD = 8.4, 95% CrI = -11 to 28) but similar to the VAS results, neither HA nor GCs intraarticular injections show a statistically significant improvement in ROM compared to placebo. In SPADI, HA (HA: MD = -0.46, 95% CrI = -0.47 to -0.45.) shows a statistically significant improvement over GCs and PRP. Regarding WOOS, no treatment showed significant improvement. However, PRP (MD = 2.3, 95% CrI: [-3.9 to 4.0]) demonstrated a numerically higher mean difference compared to GCs and BMA.

Conclusion: Intra-articular HA injections significantly improve pain and reduce disability in GH OA. However, none of the treatments demonstrated significant improvements in ROM or patient-reported outcomes. High-quality randomized controlled trials are needed to confirm these findings and inform clinical practice.

P856

CAN'T SLEEP, WON'T SLEEP: A SYSTEMATIC REVIEW AND META-ANALYSIS OF INSOMNIA PREVALENCE IN 70,105 RHEUMATOID ARTHRITIS PATIENTS

M. A. Abdelsalam[1], M. A. Khairy[2], M. R. Awad[1], A. Al-Nabawy[2], M. Taha[3], M. A. Ali[2]

[1]Rheumatology and Rehabilitation Dept., Faculty of Medicine, Misr Univ. for Science and Technology, Giza, Egypt, [2]Faculty of medicine, Al-Azhar University for Boys, Cairo, Egypt, [3]Faculty of Medicine, Ain Shams University, Cairo, Egypt

Objective: Insomnia is a significant challenge for rheumatoid arthritis (RA) patients. Chronic pain conditions often exacerbate sleep disturbances, creating a vicious cycle where pain and sleep deprivation perpetuate each other with pain not only interrupting sleep but also causing poor sleep quality contributing to increased pain sensitivity. Insomnia exacerbates the pain and fatigue associated with RA, further diminishing physical function and psychological well-being. Despite this, the prevalence and impact of insomnia in RA patients remain under-recognized and under-treated. The aim of this work is to identify the frequency of insomnia in RA patients, highlighting the necessity for more research, increased awareness, and targeted therapeutic interventions.

Methods: We systematically searched PubMed, Web of Science, and Scopus databases from inception till January 20, 2024. Adhering to PRISMA guidelines, we screened and assessed the methodological quality of eligible studies, including only those of high quality. Statistical analysis included meta-analysis utilizing both random and fixed effects models to estimate pooled insomnia prevalence, accounting for variations in the study populations, and potential publication bias in the analyses using Jamovi 2.3.21.0.

Results: The literature search yielded 1,117 articles, we included nine studies that reported prevalence of insomnia cases within RA patients, incidence of new cases, or both. We identified diverse designs: three studies were cross-sectional, three were case-control studies, and three were cohort studies. Twenty-two percent of RA patients experienced insomnia, significantly surpassing the general population prevalence of 5.6%. Sample size median and range 227 (68 to 65,754). Utilizing both random and fixed effects models in our analysis, the aggregated random effects analysis revealed an insomnia prevalence of 47% (95% CI: 0.305 to 0.635) across nine studies, encompassing 70,105 patients. The pooled fixed effects estimate for insomnia prevalence was 19.0% (95% CI: 0.190 to 0.201). The fail-safe N analyses are (2851 ($p< 0.001$) and 5415 ($p< 0.001$)) for random and fixed effects models, respectively, Suggesting that the observed effect sizes are robust and unlikely to be influenced by publication bias. Global distribution showed that Sweden had the lowest prevalence (13.9%) [95% CI:0.13, 0.15] in Fixed-effect model.

Conclusion: This is the first systematic review and meta-analysis of insomnia prevalence in RA patients, revealing that RA patients are four times more likely to experience insomnia than the general population, emphasizing the need for heightened awareness among RA patients and healthcare providers. These findings highlight crucial gaps in the current understanding of insomnia in RA, advocating for further research in this area

P857

SOCIODEMOGRAPHIC DETERMINANTS OF QUALITY OF LIFE IN PATIENTS WITH CHRONIC LOW BACK PAIN: A CROSS-SECTIONAL STUDY

M. A. Ayachi[1], L. R. Rouached[1], N. G. Gharbi[1], S. B. Bouden[1], A. B. T. Ben Tekaya[1], I. M. Mahmoud[1], R. T. Tekaya[1], O. S. Saidane[1], L. A. Abdelmoula[1]

[1]Charles Nicolle Hospital, Tunis, Tunisia

Aim: To evaluate the impact of sociodemographic characteristics on the quality of life in patients with chronic low back pain.

Methods: This study included patients consulting for chronic low back pain. Sociodemographic variables such as age, marital status, gender, parenthood, educational level, occupation (unemployed, manual work, office work), and absenteeism due to illness were analyzed. Quality of life was assessed using the SF-36 score, focusing on the physical component score (PCS) and mental component score (MCS).

Results: A total of 124 patients were included, predominantly male (sex ratio: 4.4), with a mean age of 53.3 ± 13 years (range: 15–80 years) and an average duration of low back pain of 6.69 ± 4.67 years (range: 1–20 years). Most patients were married (80%), while 16% were single and 4% widowed. Educational levels were distributed as follows: 17.7% were illiterate, 32.3% had primary education, 34.7% had secondary education, and 15.3% had university-level education. Professionally, 76% were employed, including 16% in administrative positions, while 24% were unemployed. Absenteeism was reported in 6.9% of patients. Significant associations were observed between age, marital status, and PCS ($p = 0.03$ and $p = 0.015$, respectively). No significant associations were found for gender, educational level, or employment. Regarding the MCS, none of the variables showed a significant association ($p > 0.05$).

Conclusion: This study underscores the significant influence of sociodemographic factors, particularly age and marital status, on the physical quality of life in patients with chronic low back pain. These findings highlight the importance of integrating sociodemographic considerations into the comprehensive management of chronic low back pain to improve patient outcomes.

P858

ASSOCIATION BETWEEN ANXIETY, DEPRESSION, AND QUALITY OF LIFE IN CHRONIC LOW BACK PAIN PATIENTS

M. A. Ayachi[1], L. R. Rouached[1], N. G. Gharbi[1], S. B. Bouden[1], A. B. T. Ben Tekaya[1], I. M. Mahmoud[1], R. T. Tekaya[1], O. S. Saidane[1], L. A. Abdelmoula[1]

[1]Charles Nicolle Hospital, Tunis, Tunisia

Aim :
To investigate the association between the psychological impact of chronic low back pain and quality of life.
Methods: A cross-sectional study was conducted on 124 patients consulting for chronic low back pain. The psychological impact was assessed using the Hospital Anxiety and Depression Scale (HAD), and quality of life was evaluated using the SF-36 score, focusing on its physical (PCS) and mental (MCS) components.
Results: The study included 124 patients, predominantly male (sex ratio: 4.4), with a mean age of 53.3 ± 13 years (range: 15–80 years) and a mean duration of low back pain of 6.69 ± 4.67 years (range: 1–20 years).
The mean anxiety score was 8.61 ± 4.72 (range: 1–20), and the mean depression score was 8.55 ± 4.73 (range: 1–20). For anxiety, a higher frequency of symptoms was observed in patients with impaired PCS (55% vs. 30%), but the difference was not statistically significant (p = 0.121). Also, symptoms of anxiety were predominant in patients with impaired MCS (60% vs. 19% ; p<0.001)
For depression, a certain level of symptoms was more frequent in the group with impaired PCS (55% vs. 35%, p=0.197). Impairment of the MCS was significantly associated with depression, with a higher proportion of certain symptoms (60% vs. 24% ; p=0.001).
Conclusion:
This study highlights a significant association between impairment of the mental component of the SF-36 (MCS) and the presence of depressive and axiety symptoms in patients with chronic low back pain. These findings suggest that mental quality of life plays a critical role in the psychological burden of chronic low back pain, underlining the need for an integrated biopsychosocial approach in patient care.

ASSESSMENT OF COMBINED PATENTED CRYSTALLINE GLUCOSAMINE SULFATE (PCGS) AND PLATELET-RICH PLASMA (PRP) INJECTIONS IN KNEE OSTEOARTHRITIS MANAGEMENT

M. A. Ayachi[1], L. R. Rouached[1], S. M. Mahjoub[1], S. B. Bouden[1], I. M. Mahmoud[1], A. B. T. Ben Tekaya[1], R. T. Tekaya[1], O. S. Saidane[1], L. A. Abdelmoula[1]

[1]Charles Nicolle Hospital, Tunis, Tunisia

Introduction: Patented crystalline glucosamine sulfate (pCGS) and platelet-rich plasma (PRP) are emerging alternatives to traditional painkillers and NSAIDs for the management of knee osteoarthritis (OA). While the individual effects of both treatments have been extensively studied, the potential benefits of their combined use remain uncertain.
Objective: This study aimed to evaluate the effects of combining patented crystalline glucosamine sulfate (pCGS) with platelet-rich plasma (PRP) on knee osteoarthritis (KOA).
Methods: This study included patients diagnosed with knee osteoarthritis (KOA), classified as stages I to III according to the Kellgren and Lawrence grading system. Patients were randomized into two groups: Group A, which received a combination of patented crystalline glucosamine sulfate (pCGS) and PRP injections, and Group B, which received PRP injections only. Assessments were conducted at baseline (T0), 1 month (M1), and 3 months (M3), evaluating the following parameters: pain (VAS), neuropathic pain (DN4), and functional impairment (Lequesne index and KOOS score).
Results: A total of 48 patients with knee osteoarthritis were included in the study, predominantly female (sex ratio 0.23), with a mean age of 63 years [46-90]. The mean duration of osteoarthritis was 6.57 years ± 5.77 [1-20]. Among the participants, 11 patients (22.9%) received treatment with patented crystalline glucosamine sulfate (pCGS).
At 1 month, no significant differences were found between the "treatment" and "no treatment" groups for the following variables: VAS pain, DN4, KOOS pain, ADL, sport, quality of life (QOL), and Lequesne index. However, a significant difference was observed in the KOOS symptoms domain (p = 0.019).
At 3 months, the DN4 score showed a significant difference, with higher scores in patients receiving anti-arthritic treatment compared to those without treatment (p = 0.006). No significant differences were observed between the groups for the other variables assessed.
Conclusion: The combination of patented crystalline glucosamine sulfate (pCGS) and PRP injections did not demonstrate a significant advantage over PRP injections alone in the management of knee osteoarthritis.

P860

LOW BONE MASS IS ASSOCIATED WITH CAROTID ATHEROSCLEROSIS AND ARTERIAL STIFFNESS IN POSTMENOPAUSAL WOMEN

I. A. Skripnikova[1], O. V. Kosmatova[1], M. A. Kolchina[1], O. Y. U. Isaykina[1], V. A. Vygodin[1]

[1]Federal State Budgetary Institution National Medical Research Center for Therapy and Preventive Medicine of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Objective: to study the presence and the dynamics of associations between carotid atherosclerosis, arterial stiffness and bone mineral density (BMD) over a 10-year period.
Materials and methods: In 2022–2023, we conducted a 10-year follow-up survey of 107 women (follow-up rate: 87%). We analyzed 93 women ≥50 years without a history of cardiovascular diseases at baseline. Examinations were performed twice at the baseline and 10 years later on the 2nd visit: evaluation of the pulse wave velocity (PWV), augmentation index (AI) were carried out by applanation tonometry; the intima-media thickness (IMT), the presence and number of atherosclerotic plaques (AP) in carotid arteries were measured by B-mode ultrasonography. The BMD at lumbar spine (LS), femoral neck (FN), total hip (TH) was measured using double energy x-ray absorptiometry.
Results: During the follow–up period the rate of elevated IMT (≥0.9 mm) increased by 50% ($p<0.001$), the presence and the total number of AP increased by 22.5% ($p<0.001$) and by 45% ($p<0.001$) respectively. The rate of elevated IA ≥25% increased by 14% ($p<0.01$), while the rate of elevated PWV (≥10 m/s) did not change statistically significantly ($p=0.23$). BMD at FN has decreased by 5.3%, at TH by 3.2% ($p<0.001$), at LS by 0.8% ($p=0.09$). Age-adjusted odds ratios of developing oseopenia/osteoporosis for variables (PWV, AI, IMT, AP) and other covariates at baseline (age ≥55 years, hypertension, statins, angiotensin converting enzyme inhibitors, beta blockers, thiazide diuretics, bisphosphonates, denosumab) have demonstrated a 4.35-fold increase AP (OR = 4.35; 95% CI 1.73-10.95, p = 0.005) and a 7.17-fold increase IA (OR = 7.17; 95% CI 2.63-19.58, p = 0.001). Association of osteopenia/osteoporosis detection with such predictors as elevated PWV≥10 m/s and IMT ≥0.9 mm values were not statistically significant.
Conclusion: A 10-year prospective study showed significant changes in both vascular stiffness, subclinical AS and bone mass in postmenopausal women and confirmed the temporal relationship of the association of IA and carotid atherosclerosis with low bone mass, which allows us to consider these variables as common early markers of osteoporosis and atherosclerosis for stratification of a high risk of combined development of these diseases.

P861

ADDRESSING THE UNMET CHALLENGE OF PAIN IN RARE BONE DISEASES

M. A. Legrand[1], R. Chapurlat[2], M. K. Javaid[1]

[1]University of Oxford, Oxford, United Kingdom, [2]University of Lyon, Lyon, France

Introduction: Pain is a common symptom in many rare bone disorders, often linked to depression and a substantial decline in quality of life. However, there is little information on the quality of the pain as this may provide insights into pain mechanisms.
Objectives : To describe the self-reported frequency and characteristics of pain in adults withFibrous Dysplasia of Bone/McCune-Albright Syndrome (FD/MAS), Osteogenesis Imperfecta (OI), and X-linked Hypophosphatemia (XLH).
Methods: A retrospective cross-sectional study was conducted using the online UK-based RUDY registry. Adults with FD/MAS, OI, and XLH who were registered in the RUDY registry and completed the painDETECT questionnaire (PD-Q) at baseline were included. Pain prevalence and pain phenotypes were assessed based on baseline PD-Q results. WPI-score calculated from PD-Q pain mapping. Descriptive statistical analyses were performed using R®.
Results: 281 adults completed the PD-Q at baseline : 94 patients with FD/MAS, 94 with OI, and 93 with XLH. Of these, 86% experienced pain currently, 47% described their strongest pain as severe (≥8/10) in the past four weeks and 18% had generalized pain,with no difference between the three conditions. Pain phenotype and evolution profiles were similar, while pain sites differed between the three conditions. 21% of patients reported uncategorized pain.
Conclusion: Despite differences in the mechanisms underlying these bone diseases, the prevalence and main characteristics of pain appear similar, suggesting that a significant portion of the pain may be determined by bone-independent factors. The high prevalence of generalized and uncategorized pain in these three rare bone diseases suggests the presence of nociplastic features, which require further investigation.

SILENT THREAT : DECODING FRAGILITY FRACTURES OF PELVIS. A CASE REPORT

M. A. Muhamed Fuad[1], M. S. Othman[2], M. H. Mohmad Hassim[2]

[1]Orthopaedic Department/ Faculty Medicine and Health Sciences/ University Putra Malaysia, Serdang, Malaysia, [2]Orthopaedic Department/ Hospital Sungai Buloh, Sungai Buloh, Malaysia

Introduction Fragility fractures of the pelvis, a formidable challenge in the realm of orthopedics, present a silent yet pervasive threat to the well-being of an aging population.

Material and Methods Here we presented a case report on the challenges commonly faces in diagnosis of fragility fracture of the pelvis. Our patient who was an 83-year-old woman, presented with pain over left hip. inability to sit and ambulate following a slip and fall. Initial assessment by junior doctors missed the diagnosis of fragility fracture pelvis as the plain radiographs showed only a minor fracture over the left superior pubic ramus [Figure 1]. Upon further evaluation, patient was unable to ambulate despite a period of observation and analgesic treatment. Thus, computed tomography of pelvis was obtained which complete fracture of the left iliac crest correspond to Rommens Classification Type IIb [Figure2].

Figure 1: Plain Radiograph Pelvis and Hip

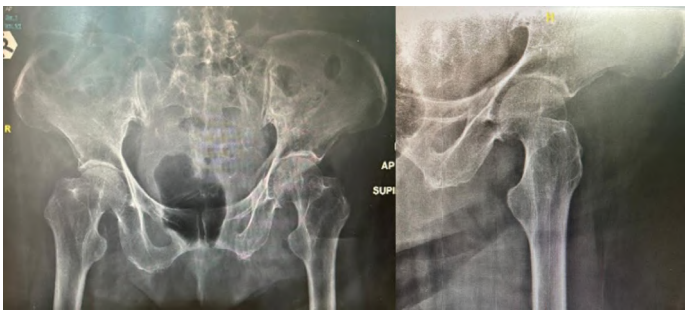

Figure 2: CT Pelvis with 3D Reconstruction show Rommens Type IIb Fracture of Iliac crest and superior pubic rami fracture

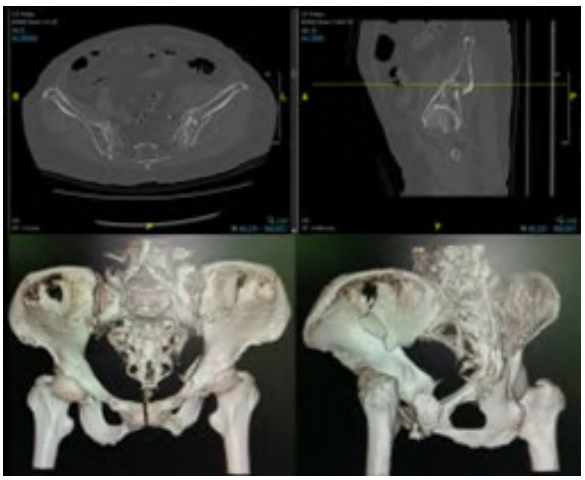

Results Patient underwent minimal invasive percutaneous screw fixation over the iliac crest and immediately next day patient able to sit and ambulate with wheelchairs. Visual Analog Score (VAS) reduce from 8 to 3 immediate post operatively. patient able to back to ambulation independent at 3 months post operative with no further dissociation of pelvic ring.

Conclusion Fragility fractures of pelvis are a silent threat to the well-being of the elderly population, easily missed and pose a significant challenge in diagnosis and management.

P863

PATELLAR CANNULATED SCREW FIXATION WITH SUTURE TAPE AUGMENTATION IN ELDERLY PATIENT: CASE SERIES

M. A. Muhamed Fuad[1]

[1]Orthopaedic Department/ Faculty Medicine and Health Sciences/ University Putra Malaysia, Serdang, Malaysia

Introduction

Patellar fractures are common injuries, accounting for approximately 1% of all skeletal fractures. Obtaining a stable anatomic reduction and maintaining it during the perioperative period is critical for restoring function, particularly in the elderly population with osteopenic bone [1]. Various fixation techniques have been described, including tension band wiring, cannulated screw fixation, and plate fixation.

Tension band wiring is a commonly used technique but poses challenges in comminuted fractures or osteopenic bone. The failure rate of tension band wiring has been well-documented in the literature. Plate fixation offers more rigid fixation but can be challenging due to the patella's subcutaneous location. Recently, cannulated screws with suture tape augmentation have been proposed as an alternative technique to improve fixation in osteoporotic bone [2].

Methods We present a case series of six elderly patients with patellar fractures treated with cannulated screw fixation and suture tape augmentation. The mean age of the patients was 68 years (range: 64–73). Only patients aged >60 years with transverse fractures were included. All patients underwent open reduction and internal fixation with cannulated screws and suture tape augmentation. They were evaluated for KSS scores at four months postoperatively and monitored for complications up to one year of follow-up.

Surgical Technique A standard midline longitudinal incision was made over the patella. The fracture site was exposed and anatomically reduced using a malleolar clamp. Two guidewires for 4.0 mm cannulated screws were introduced from the inferior part of the patella to the superior pole, ensuring both wires were parallel and centred.

The tip of each guidewire was placed at the second cortex, and the screw length was measured. The wires were further advanced into the quadriceps tendon. Half-threaded 4.0 mm stainless steel cannulated screws with washers were used for fixation in all cases [Figure 1].

Figure 1: Cannulated screw with washer insertion

The screw threads passed the fracture line to engage the second cortex. Fibre suture tape was passed through the cannulated holes using a wire passer and secured in a horizontal figure-of-eight pattern [Figure 2].

Figure 2: Fiber suture tape was tightened in a horizontal figure-of-eight manner

The retinaculum was repaired, and the wound was closed in layers. Postoperatively, patients were protected with a cylinder slab or knee brace for two weeks until the wound healed and were allowed weight-bearing as tolerated. Full range of motion exercises commenced two weeks postoperatively.

Results

All six fractures healed without complications such as infection, nonunion, or hardware failure [Table 1]. The average operation time was 40.5 minutes. Radiographic union occurred within 8–12 weeks (mean = 8.67 weeks). No patients required revision surgery or hardware removal at the one-year follow-up. None reported complaints related to prominent implants or pain during kneeling. Most patients achieved >100° knee flexion [Figure 3]. The KSS at four months ranged from 87 to 97 (mean = 91).

Patient	Age	Gender	Operation Time, min	Union Time, weeks	Complication at 1 year follow up	ROM knee at 4 months	KSS 4 months
A	64	male	40	8	nil	0-110	92
B	68	male	50	10	nil	5-100	87
C	70	female	36	8	nil	0-105	95
D	73	male	39	8	nil	0-110	96
E	65	female	38	8	nil	0-110	97
F	68	male	40	10	nil	0-105	91

Table 1: Patient Data on Operation Time, Union Time, Complication, ROM knee and KSS at 4 month.

Figure 3: ROM knee at 4 months of the procedure.

Discussion

Patellar fractures, which represent approximately 1% of all skeletal fractures, pose significant challenges, particularly in elderly patients [3]. The diminished bone quality in this population necessitates robust fixation techniques to ensure optimal healing and functional restoration. Our case series of six elderly patients treated with cannulated screw fixation augmented with suture tape highlights the potential of this technique in achieving favourable outcomes.

The modified tension band wiring (TBW) technique is a widely used approach but has several limitations, especially in cases of comminuted fractures or osteopenic bone. TBW can be technically challenging and is associated with complications such as loss of reduction, implant failure, and the need for subsequent hardware removal [4-6]. Plate fixation offers more rigid fixation but can be difficult due to the subcutaneous location of the patella and the risk of complications like skin irritation and infection.

Oyama et al. [7] conducted a retrospective multicenter study to identify predictors of postoperative complications associated with TBW in patellar fractures. Their analysis revealed that bending only one end of the Kirschner wires significantly increased the risk of implant migration. Additionally, a larger ratio between the patella size and the tension band and a wider distance between the K-wires were identified as risk factors for implant breakage. Notably, the study did not find significant risk factors for loss of reduction. These findings underscore the importance of meticulous surgical technique in TBW, emphasizing the proper bending of both K-wire ends and the precise placement of the tension band and K-wires to mitigate postoperative complications.

While conservative management may suffice for certain patellar fractures, surgical intervention is often warranted, particularly in displaced or comminuted fractures [8]. The choice of surgical technique depends on factors such as fracture pattern, bone quality, and surgeon preference. Traditional methods like TBW, while widely used, are associated with complications such as wire migration, breakage, and painful hardware, leading to reoperation

rates as high as 4.2% [6,7]. These limitations of TBW in osteoporotic bone underscore the need for alternative fixation strategies. The modified TBW technique, often employing cannulated screws, has gained popularity [2]. However, challenges remain in achieving and maintaining anatomical reduction, particularly in comminuted fractures. Plate fixation provides greater stability but presents technical difficulties due to the patella's subcutaneous location [1]. Our approach, which utilizes cannulated screws with suture tape augmentation, aims to enhance fixation strength while minimizing hardware-related complications.

As described by Monaco et al., the suture tape cerclage technique provides additional support and may reduce the risk of displacement, particularly in osteoporotic bone [9]. Additionally, the two-tension-band technique described by Xue et al. for revision surgery offers a valuable salvage option in cases of fixation failure [10].

Our results demonstrate uncomplicated healing and good functional outcomes in all six patients, suggesting the efficacy of cannulated screw fixation with suture tape augmentation. The absence of hardware-related complications and satisfactory KSS scores at four months are encouraging. However, larger studies with longer follow-ups are needed to validate these findings and compare this technique with other established methods. Further research should also explore the biomechanical properties of suture tape augmentation and its impact on fracture stability.

Conclusion

Cannulated screw fixation with suture tape augmentation is a promising technique for managing patellar fractures in elderly patients. This approach achieves stable fixation, promotes healing, and restores function while minimizing complications. Further research is warranted to validate these findings and determine the optimal role of this technique in clinical practice

INITIATION OF THERAPY FOR POSTMENOPAUSAL OSTEOPOROSIS WITH COMPENSATED HYPOTHYROIDISM

M. Ajdynan[1], A. Aksenova[2], V. Diomidova[3], N. Zhuravleva[3], E. Guryanova[4], M. Dimitrieva[3]

[1]YEREVAN STATE MEDICAL UNIVERSITY NAMED AFTER MKHITAR GERATSI, Erevan, Armenia, [2]Pirogov Russian National Research Medical University, Moskow, Russia, [3]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulianov Chuvash State University", Cheboksary, Russia, [4]The State Autonomus Institution of the Chuvash Republic Supplementary Vocational Education "Postgraduate Doctors' Training Istitute" of Health Care Ministry of the Chuvash Republic, Cheboksary, Russia

Objectives. To study the features of the primary diagnosis and therapy of postmenopausal osteoporosis (PMO) in women with compensated hypothyroidism.

Materials and methods. 46 women with thyroid pathology (thyroid gland) were examined (average age 65.2±4.1 years). A comprehensive clinical examination was performed (examination of thyroid function, ultrasound examination of thyroid, X-ray osteodensitometry (ODM), study of phosphorus-calcium metabolism).

Results. As a result of the studies, in 42.5% of cases, there was a multi–nodular goiter; single-nodular goiter - in 20%, autoimmune thyroiditis with compensated hypothyroidism – in 37.5%. Subclinical hyperthyroidism – 3 cases, amiodarone-induced hypothy-

roidism – 1 case. 35 patients were diagnosed with PMO.
Levothyroxine in doses from 25 to 112.5 micrograms was administered to 15 women (32.6%), with an average thyroid–stimulating hormone (TSH) level of 2.61±1.47 micrograms/ml. The average body mass index (BMI) is 25.12±3.51 kg/m2. The age of natural menopause was 45.8±5.1 years (n=31), and the age of surgical menopause was 43.0±1.41 years (n=4).
Fasting glucose – 5.22±0.35 mmol/L, HbA1c – 5.51±0.14%, total calcium – 2.45±0.071 mmol/L, ionized – 1.26±0.05 mmol/L. Vitamin D deficiency – 3 cases, deficiency – 5 cases.
ODM, average T-test values: axial skeleton – - 2.57±0.79 (median -2.69), left hip – -1.92±0.90 (median -2.0), neck – -1.95±0.97 (median -1.95), left forearm – -3.07±0.97 (median -3.1).
10-year fracture risk from 8.31 to 13.9% (average 11%). The hereditary history of fractures is not burdened.
The average age at the time of detection of PME was 61.7±5.2 years. Denosumab, calcium supplements 1000 mg per day, vitamin D were immediately prescribed, and recommendations on diet and physical activity were given.
Conclusions. PMO was detected at target TSH values against the background of levothyroxine compensation for hypothyroidism. This indicates the need for an active approach to the diagnosis of osteoporosis, regardless of TSH levels.

P865

ASSESSMENT OF SARCOPENIA IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE USING ULTRASOUND MUSCLE IMAGING

M. Ajdynan[1], A. Aksenova[2], V. Diomidova[3], N. Zhuravleva[3], E. Guryanova[4], A. Stepanova[3], T. Andreeva[4]

[1]YEREVAN STATE MEDICAL UNIVERSITY NAMED AFTER MKHITAR GERATSI, Erevan, Armenia, [2]Pirogov Russian National Research Medical University, Moskow, Russia, [3]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulianov Chuvash State University", Cheboksary, Russia, [4]The State Autonomus Institution of the Chuvash Republic Supplementary Vocational Education "Postgraduate Doctors' Training Istitute" of Health Care Ministry of the Chuvash Republic, Cheboksary, Russia

Objectives. To evaluate the muscle mass of patients with inflammatory bowel disease (IBD) through ultrasound (US) imaging.
Materials and Methods. A total of 72 patients with IBD and 12 in the control group (CG) were included in the study. The mean age of patients was 37.5 [27; 48] years, and in the CG, it was 37.75 [26.0; 49.5] years. In the IBD group, there were 39 females (54.1%) and 33 males (45.9%); in the CG, there were 5 females (46.1%) and 7 males (53.9%). The following parameters were assessed: body mass index (BMI), mid-arm circumference (MAC), mid-thigh circumference (MTC); grip strength (age- and sex-specific norms); ultrasound measurements of mid-arm thickness (US-MAT) and mid-thigh thickness (US-MTT); and skeletal muscle mass (SMM) via bioimpedance analysis.
Results. The majority of patients had a normal body mass (55%), while 10% had a deficiency; 22% were overweight, and 13% were obese. A reduction in MAC was observed among women with IBD in 11 (29%) cases and in 4 (11%) cases for men; however, no statistically significant differences were found when compared to the CG. The MTC measurements were lower in women (53.25 [48; 58.5] cm, p <0.05) and men with IBD (48.7 [46; 51.4] cm, p >0.05) compared to the CG (60.5 [55; 66] cm and 49 [45; 53] cm, respectively). Grip strength of the dominant hand was reduced in 11% of women and 12% of men with IBD, with no differences identified when compared to the CG.
The US-MAT measurements in women (21.06 [18.36; 23.76] mm) and men (24.79 [21.41; 28.17] mm) with IBD did not differ from the CG. However, the US-MTT in women with IBD (29.09 [24.52; 33.67] mm) was lower compared to the CG (37.63 [34.54; 40.73] mm, p <0.05), as was the case for men with IBD (31.86 [24.75; 38.97] mm vs 38.76 [36.67; 40.89] mm, p <0.05). US-MAT correlated with SMM (r=0.62; p <0.05) and muscle strength (r=0.50; p <0.05). US-MTT correlated with BMI (r=0.43; p <0.05), SMM (r=0.32; p <0.05), US-MAT (r=0.465; p <0.05), and muscle strength (r=0.24; p <0.05).
Conclusion. In patients with IBD, the MTC in women was lower than in the CG. The values of US-MTT in both women and men with IBD were lower than in the CG and correlated with BMI, SMM, and muscle strength.

VITAMIN D DEFICIENCY IN PATIENTS WITH RHEUMATIC DISEASES

M. Ajdynan[1], V. Diomidova[2], N. Zhuravleva[2], E. Guryanova[3], N. Ukhterova[2], Y. Markelova[2], S. Nurislamova[3]

[1]YEREVAN STATE MEDICAL UNIVERSITY NAMED AFTER MKHITAR GERATSI, Erevan, Armenia, [2]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulianov Chuvash State University", Cheboksary, Russia, [3]The State Autonomus Institution of the Chuvash Republic Supplementary Vocational Education "Postgraduate Doctors' Training Istitute" of Health Care Ministry of the Chuvash Republic, Cheboksary, Russia

Цели. Оценить распространенность гиповитаминозов и дефицита витамина D у больных ревматическими заболеваниями (РЗ).
Материалы и методы. В исследование включены 86 пациентов с РЗ и 27 лиц того же возраста без воспалительных РЗ. У пациентов с РЗ диагностированы системная склеродермия (ССД) – 51 человек, псориатический артрит (ПсА) – 15 человек и ревматоидный артрит (РА) – 20 пациентов. Забор крови производился в осенне-зимний период. Концентрацию витамина D (25(OH)D) в сыворотке крови определяли с помощью иммунохемилюминесцентного анализатора.
Результаты. Средняя концентрация 25 (OH)D составила 19,83±11,06 нг/мл у пациентов с ССД, 19,27±9,25 нг/мл у пациентов с ПсА, 16,87±7,35 нг/мл у пациентов с РА и 24,31±7,63 нг/мл в контрольной группе. Уровень 25 (OH)D был значительно ниже у пациентов с ССД и РА по сравнению с контрольной группой (p=0,033 и p<0,001 соответственно).

Не было обнаружено существенных различий в уровнях витамина D между пациентами с ПсА и контрольной группой. Среди всех обследованных лиц только 23% лиц без РЗ и 25% пациентов с ПсА имели нормальные уровни (≥30 нг/мл) 25(OH)D в сыворотке, что было значительно выше, чем проценты в группах РА и ССД (7% и 11% соответственно). Гиповитаминоз D (≥20–<30 нг/мл) был диагностирован у 19% пациентов с РА, 24% пациентов с ПсА, 33% пациентов с ССД и 42% в контрольной группе, в то время как дефицит витамина D (<20 нг/мл) наблюдался у 71%, 47%, 57% и 25% лиц соответственно. Не было обнаружено существенных различий в уровнях 25(OH)D в сыворотке между лицами моложе и старше 65 лет, а также по индексу массы тела (ИМТ). Среди лиц с РЗ, у которых по данным денситометрического исследования был выявлен остеопороз, у 83% был выявлен дефицит витамина D, что встречалось значительно чаще, чем у лиц с остеопенией или нормальной минеральной плотностью костной ткани (80% и 71% соответственно, p<0,04).

Заключение . Дефицит и недостаточность витамина D были обнаружены с высокой частотой как в группе RD, так и в контрольной группе. Дефицит 25(OH)D был значительно более распространен у пациентов с RA и SSc, а также у пациентов с остеопорозом, независимо от конкретного диагноза ревматического заболевания.

USE OF GENE-ENGINEERED THERAPY, BISPHOSPHONATES, CALCIUM, AND VITAMIN D3 IN THE TREATMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS

M. Ajdynan[1], V. Diomidova[2], N. Zhuravleva[2], E. Guryanova[3], N. Ukhterova[2], A. Stepanova[2], A. Mukhammadieva[3], E. Antonova[3]

[1]YEREVAN STATE MEDICAL UNIVERSITY NAMED AFTER MKHITAR GERATSI, Erevan, Armenia, [2]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulianov Chuvash State University", Cheboksary, Russia, [3]The State Autonomus Institution of the Chuvash Republic Supplementary Vocational Education "Postgraduate Doctors' Training Istitute" of Health Care Ministry of the Chuvash Republic, Cheboksary, Russia

Objective. To evaluate the efficacy of a combination of bisphosphonates with vitamin D3 on bone mineral density (BMD) in patients with rheumatoid arthritis (RA) at radiological stages II-III, receiving gene-engineered biological therapy (GEBT) via densitometry.

Materials and Methods. The study was conducted on 60 women (aged 46-49 years, 48 ±2.4) with confirmed RA diagnosis (according to ARA/EULAR 2010 classification criteria), presenting high activity levels (DAS 28: 5.5±3.00) and a disease duration of 13.4 ±3.5 years. The second radiological stage was noted in 35 subjects (58.2%), and the third stage in 25 (41.8%).

27 patients (45%) received GEBT: infliximab (20), adalimumab (3), tocilizumab (4). BMD assessments were conducted monthly using X-ray osteodensitometry.

Results. According to X-ray osteodensitometry, osteoporosis was present in 39 patients (64.1%), normal values in 12 (19%), and osteopenia in 10 (17.2%) prior to GEBT. The average BMD was measured at 0.691±0.05 g/cm².

To prevent secondary osteoporosis, bisphosphonates were prescribed: alendronate (59.2%), ibandronate (27.3%), and zoledronate (13.5%), along with calcium and vitamin D3 supplements. After one year, BMD increased to 0.704±0.008 g/cm² (p=0.002), with osteoporosis prevalence at 49.1%. BMD increased by 1.4%.

After two years, BMD was measured at 0.714±0.010 g/cm² (p=0.0001). Osteoporosis prevalence reached 47.3%, and osteopenia was present in 26.2% of cases.

Over the next three years, no signs of secondary fractures were observed, achieving a stable bone mineralization level (averaging 0.9%). RA activity also decreased (DAS 28: 3.1±0.8 points).

Conclusion. Gene-engineered therapy combined with agents that enhance bone metabolism (bisphosphonates, calcium, and vitamin D3) contributes to the remission of RA and prevents secondary fractures by stabilizing bone mass.

P868

GENDER-SPECIFIC ASSOCIATIONS OF MUSCLE STRENGTH AND FRAILTY IN OLDER ADULTS

M. Alghamdi[1], C. Cho[1], A. Swartz[1], S. Strath[1]

[1]Dept. of Kinesiology, Zilber College of Public Health, Univ. of Wisconsin - Milwaukee, Milwaukee, United States

Objective: Frailty, linked to sarcopenia and musculoskeletal decline, increases vulnerability to falls, fractures, and loss of independence. Frailty is more common in females, yet gender-specific lower limb muscular strength related determinants of frailty remain understudied. This study examined the relationship between specific lower-body muscle strength and frailty status while evaluating gender-based differences.

Methods: Eighty-two older adults (mean age: 70.3±10.2 years; 59.8% female) were classified as non-frail (SPPB > 10) or pre-frail/frail (SPPB ≤ 10). Maximal isometric strength was assessed for right-sided hip abductors (HA), hip lateral rotators (HLR), knee extensors (KE), ankle dorsiflexors (ADF), and ankle plantar flexors (APF). Logistic regression models evaluated frailty odds based on muscle strength, adjusted for age and gender. Gender interactions were also tested.

Results: Ankle plantar flexor strength showed a significant interaction with gender (p=0.026). Among females, each 1 kg increase in APF strength reduced frailty odds by 9.4% (OR=0.906, 95% CI:0.844–0.972, p=0.006), while this effect was not significant in males (p=0.610). Hip abductor strength demonstrated a significant effect across both genders (p=0.033). Each 1 kg increase in HA strength reduced frailty odds by 9.1% (OR=0.909, 95% CI:0.833–0.992). For other muscle groups, neither the main effects nor the interactions with gender reached significance. Hip lateral rotator strength (main effect: p=0.814; interaction: p=0.767), ADF strength (main effect: p=0.484; interaction:

p=0.179), and KE strength (main effect: p=0.054; interaction: p=0.841) did not exhibit meaningful impacts on frailty odds.
Conclusion: These findings reveal gender-specific predictors of frailty, with APF strength playing a key role in females and HA strength reducing frailty risk across genders. This suggests that muscle-specific training programs could be designed to address frailty risk effectively. Targeted strengthening of APF in females and HA across all individuals could form effective clinical interventions. Maintaining and strengthening the identified muscle groups may contribute to preventing frailty from developing. Such targeted interventions can enhance musculoskeletal health and support independence in older adults.

P869

SUCCESSFULNESS OF TELEMEDICINE IN THE MANAGEMENT OF GERIATRIC PATIENTS AT HIGH RISK OF FRAGILITY FRACTURES

M. B. Baroni[1], I. G. Macchione[1], V. Gemo[1], C. Properzi[1], F. Perini[1], A. R. Bianco[1], M. C. Ercolani[2], M. Mencacci[3], P. Manzi[4], A. Pasqualucci[5], G. De Filippis[5], P. Mecocci[1], C. Ruggiero[1], A. Cocomazzi[1], F. Mancinetti[1], D. Xenos[1]

[1]Orthogeriatric Service, Geriatric Unit, Department of Medicine and Surgery, Institute of Gerontology and Geriatrics, University of Perugia, S. Maria Della Misericordia Hospital, Perugia, Italy., Perugia, Italy, [2]IT Systems and Transition to Digital Administration, S. Maria Della Misericordia Hospital, Perugia, Italy., Perugia, Italy, [3]Technological Infrastructure Development, IT Department, Municipality of Florence, Firenze, Italy., Perugia, Italy, [4]Medical Direction, S. Maria Hospital, Terni, Italy., Terni, Italy, [5]Medical Direction, S.Maria Misericordia Hospital, Perugia, Italy., Perugia, Italy

Objectives: Telemedicine may improve the monitoring of patients with chronic diseases. Secondary prevention of fragility fractures is an urgent matter to be addressed by means of available technology, although supported by little evidence so far. We investigated the feasibility, efficacy, and satisfaction of managing older adults at high risk of fragility fractures during the COVID-19 lockdown.
Material & Methods: From January to July 2021, a prospective observational study for safety and adherence purposes was conducted among older patients (n=407) with ongoing treatments for secondary prevention of fragility fractures. The study procedures observe national and regional resolutions related to telemedicine service (TS), including equipment, staff behaviours, and patient reports.
Results: A majority (86.48% [n = 352]) of the eligible patients participated in remote visits, mainly women (88.2%), 81.4 ± 8.8 years of age, 49.6% independent in 5 out of 6 BADL, despite high comorbidity (4.9 ± 1.5), and polypharmacy (4.9 ± 3.1). Almost all were on second-line antifracture treatments (95.58%) due to previous major (84.03%) and minor (42.5%) fragility fractures.
About 58% reported good and very good reliability of the internet network, allowing easy access to the TS platform, and 54% declared the degree of satisfaction with TS as good and very good. Regarding the clinicians, about 75% of them acknowledged the efficacy of TS and expressed willingness to recommend the use of TS to colleagues. Ultimately, 68% of specialists defined the time dedicated to patients' remote visits as acceptable.
Conclusion: TS may be a chance to increase the availability of appropriate healthcare services to satisfy patients' needs and optimize healthcare resource allocation.

P870

CALCIUM INTAKE AND BONE MINERAL DENSITY (BMD): IS THERE A CORRELATION BETWEEN THEM IN A SPONDYLOARTHRITIS CONTEXT?

R. Dhahri[1], M. Ben Bahri[1], I. Fenniche[1], L. Ben Ammar[1], H. Ben Ayed[1], M. Aloui[1], K. Amri[1], I. Gharsalla[1]

[1]Tuniis military hospital, Tunis, Tunisia

Objective: To assess the relationship between calcium deficiency, as measured by the test "how to know if you lack Calcium" carried out by GRIO, and bone mineral density in patients with spondyloarthritis.
Methods: This was a cross-sectional study involving patients followed for spondyloarthritis (SpA), according to the 2009 ASAS criteria. The study was conducted over a 3-month period (Novembre 2024 to January 2025). Socio-demographic and clinical data were collected.
Daily calcium intake was assessed using the test "how to know if you lack Calcium" which evaluates mainly the calcium provided by dairy products (6 categories) Milk ,cheese sandwich or cheese soufflé, cheese, yogurt, white cheese, Flan or rice pudding or cream dessert. The calcium deficiency is defined by a score less than 10 points. Bone mineral density (BMD) was measured using dual-energy X-ray absorptiometry (DEXA) at the lumbar and femoral sites. Data analysis was performed using SPSS software. Results were considered statistically significant if the p-value was less than 0.05.
Results: Thirty patients were included in the study. The male-to-female ratio was 14 (28 men and 2 women). The mean age was 40,07 years (range: 23–62 years). The mean age at disease onset was 34.25 years (range: 18–62 years). The average disease duration was 6.1 years. The SpA phenotypes were distributed as follows: axial SpA (n=16), axial and peripheral SpA (n=10), arthritis associated with inflammatory bowel disease (n=3), and SAPHO syndrome (n=1). The mean lumbar spine T-score was -1,5724 SD, and the mean femoral T-score was -1,2496 SD. Bone mineral density was 1.417 ± 00,185 g/cm² at the lumbar spine and 0.916 ± 0.137 g/cm² at the femur. Ten patients had normal BMD, while 20 patients presented reduced BMD (osteopenia in 7 patients and osteoporosis in 13 patients). 23 patients out of 30 had calcium deficiency. There was no statistically significant correlation in bone mineral density between the two groups of patients (p=0,407).
Conclusion: The absence of correlation suggests that other factors, such as physical activity, hormonal levels, or calcium absorption issues, may have a greater impact on bone mass than calcium intake alone. It could also indicate that calcium, on its own, is not sufficient to significantly influence bone density without the presence of these additional factors.

P871

PERCEPTION OF RHEUMATIC PATIENTS REGARDING THE USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE (CAM)

R. Dhahri[1], M. Ben Bahri[1], I. Fenniche[1], L. Ben Ammar[1], H. Ben Ayed[2], M. Slouma[1], N. Gueddiche[3], I. Gharsalla[1], K. Amri[4]

[1]rheumatology department, Tunis military hospital, Tunis, Tunisia, [2]Faculty of Medicine of Tunis, Tunis, Tunisia, [3]internal medicine department, Tunis military hospita, Tunis, Tunisia, [4]orthopedics department, Tunis military hospital, Tunis, Tunisia

Introduction: Rheumatic patients appear to be high users of complementary and alternative medicine (CAM).
The **aim** of our study was to understand their perceptions regarding the use of CAM to better adapt care and integrate these practices in a safe manner.

Patients and Methods: This is a cross-sectional descriptive study involving patients with inflammatory rheumatic diseases , including rheumatoid arthritis (RA), spondyloarthritis (SPA), and degenerative diseases. A questionnaire was developed to collect sociodemographic, clinical, and paraclinical data from each patient.

Results: Forty-one patients were included in the study, 26 men and 15 women, with an average age of 47 years [21-77]. The diagnoses were SPA in 43.9%, degenerative disease in 39%, and RA in 17.1% of cases. Twenty-eight patients had already used CAM to treat their symptoms. The primary motivations for using CAM were the perception of it being a natural and safer option, as well as a complement to conventional treatment. Dissatisfaction with conventional care was reported in 10.3% of cases. Most patients did not disclose their use of CAM to healthcare professionals. Reasons for non-disclosure included not being asked by the doctor and fear of receiving a negative response. The most commonly used modalities were therapeutic massage (65.5%) and cupping therapy (58.6%). Acupuncture (10.3%) and herbal medicines (6.9%) ranked second. However, some practices, such as meditation, chiropractic care, energy healing, and homeopathy, were never used. Twenty-five patients had discussed complementary and alternative therapies with their doctor. In 80% of cases, healthcare professionals showed a positive attitude towards certain CAM modalities, particularly therapeutic massage. Regarding efficacy, 4 patients reported that CAM had a very beneficial effect, while 16 felt its impact was moderate. However, 4 patients rated its effectiveness as low, and 5 reported no effect. According to patients, the main disadvantages of CAM, in order of frequency, were: lack of scientific evidence on efficacy (27.8%), unknown side effects (27.8%), risk of interaction with conventional medications (11.1%), and high costs (8.3%). However, half of the patients noted no disadvantages to its use. The majority of patients (38) believed that healthcare professionals should provide more information on the effectiveness and safety of CAM. Opinions were divided on whether CAM could replace conventional treatments: 3 patients thought this was possible, 22 disagreed, and 15 favored a combined approach of CAM and traditional treatments.

Conclusion: Our study illustrates the positive perception of patients regarding complementary and alternative medicine (CAM), particularly cupping therapy. Healthcare professionals should expand their knowledge of CAM to better understand its potential benefits and integrate these approaches into a comprehensive management plan for patients.

P872

JOINT DISORDERS IN PATIENTS WITH ACROMEGALY: PHYSICIAN AWARENESS AND ACCESS TO HEALTHCARE SERVICES

M. Berlovich[1], M. Perepelova[1], K. Vazagova[1], L. Dzeranova[1], E. Pigarova[1], I. Belovalova[1], I. Dedov[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective: We present a study aimed at analyzing the prevalence of joint pain complaints among patients with acromegaly, as well as the awareness of various specialists regarding the necessity of actively identifying musculoskeletal complaints. The study also examines the potential for routing patients to specialized professionals, such as orthopedic surgeons and maxillofacial surgeons, and the implementation of rehabilitation programs. Arthropathy associated with acromegaly is recognized as a common and significant complication that contributes to morbidity and functional impairments in patients with acromegaly. Given the advancements in the treatment of acromegaly, which allow the majority of patients to achieve remission, the diagnosis and rehabilitation of associated complications have become of paramount importance.
Material and Methods: National survey of physicians of various specialties using online questionnaire.
Results: According to the conducted study involving 171 specialists, the majority of participants are endocrinologists (81.9%), other specialties included dentists (7.6%), pediatric endocrinologists (4.7%), maxillofacial surgeons (11.75%), and physicians of other specialties (4.1%). Among the respondents, 67.8% noted that patients with acromegaly experience damage to the musculoskeletal system, with the spine being the most commonly affected (39.7%) followed by the temporomandibular joint (TMJ) (32.1%). It is noteworthy that patients themselves report complaints of pain in the knees and hips (63.1%), in the spine (46.1%), as well as pain in the ankles, shoulders, and elbows (16.3% each). Specialists conduct differential diagnoses with rheumatological diseases through laboratory tests in 57.8% of cases. Experts note that 33.9% of patients report active complaints of pain in the TMJ. At the same time, 34.5% of physicians do not specifically inquire about the presence of pain or limitations in movement in the TMJ for patients with acromegaly. Only 11.1% of doctors have the opportunity to refer patients with musculoskeletal disorders to rehabilitation specialists.
Conclusion: The results we obtained show that the issue of mus-

culoskeletal system damage in patients with acromegaly (diagnosis, treatment, and rehabilitation) remains highly relevant and show the need for further development of the studies which will become the basis for improving patient routing and expanding diagnostic capabilities and subsequent rehabilitation.

P873

MAXILLOFACIAL MANIFESTATIONS OF PITUITARY ADENOMAS

M. Berlovich[1], L. Ebanoidze[1], M. Perepelova[1], E. Pigarova[1], L. Dzeranova[1], E. Przhiyalkovskaya[1], E. Melikov[2], A. Khasanov[2], A. Drobyshev[2]

[1]Endocrinology Research Centre, Moscow, Russia, [2]FSBEI HE "Rosunimed" of MOH of Russia, Moscow, Russia

Objective: We present a research study aimed at evaluating the prevalence of functional disorders associated with acromegalic maxillofacial changes and their impact on key health parameters. Acromegaly is a rare disorder caused by the hypersecretion of growth hormone, leading to characteristic craniofacial region (CFR) changes. These changes include mandibular overgrowth, maxillary expansion, increased interdental gaps, and subsequent bite abnormalities. Beyond their aesthetic implications, these maxillofacial alterations can have significant functional and health-related consequences.

Materials and Methods: A single-center, controlled, questionnaire-based study was conducted involving 30 patients diagnosed with acromegaly (median age: 47 years [39; 54], 43.3% male) and 18 patients with hormone-inactive pituitary adenomas (median age: 47 years [38; 57], 22.2% male). All participants were evaluated at the Department of Neuroendocrinology of Endocrinology Research Centre.

Results: Significant differences were observed between patient groups in the following areas: visual changes related to CFR (1 [0;2] vs 0 [0;0], p=0.004), speech and diction changes (0 [0;1] vs 0 [0;0], p=0.02), and feelings of depression associated with CFR (0 [0;1] vs 0 [0;0], p=0.04) in the acromegaly and non-acromegaly groups, respectively. In the acromegaly group, patients reported a significant correlations (p<0.05) between speech and diction impairments and drug therapy (r = 0.37), as well as health status over the past year (r = 0.46 and r = 0.44), quality of life during the last year with achieved IGF-1 levels (r = 0.51 and r = 0.49), disease duration, and duration of decompensated state. These parameters did not correlate with age, number of surgical interventions, or achieved IGF-1 levels.

Conclusions: Acromegaly is associated with a high prevalence of functional disorders and cardiovascular complications, significantly impacting patients' health and quality of life. Early diagnosis, normalization of IGF-1 levels, and targeted interventions to address craniofacial changes are essential to improving the quality of life for individuals with acromegaly.

P874

A SUB-COHORT CROSS-SECTIONAL ANALYSIS OF PATIENTS WITH OSTEOPOROSIS AND ANOREXIA NERVOSA AND THEIR RISK OF FRAGILITY FRACTURE

H. Raja[1], H. Amin[1], M. Bukhari[1]

[1]University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom

Objective Anorexia nervosa is defined by a persistently low body weight resulting from restricted energy intake, an intense fear of gaining weight or persistent behaviour that prevents weight gain, and a significantly disturbed self-perception of body weight or shape (*International Classification of Diseases, 11th Revision)*. Data on bone heath in cohorts with anorexia nervosa is sparse. This sub-cohort analyses reviewed patients between June 2004 and Nov 2019 aiming to determine whether low body fat and all FRAX risk factors are associated with increased fracture risk in a cohort of patients with Anorexia Nervosa.

Materials and Methods A retrospective study of patients for this sub-cohort was taken from a master data set of patients with Osteoporosis and all those with a formal diagnosis of Anorexia Nervosa were included in this data set. In total 467 patients were included in the analyses. Those with and without a fragility fracture had their risk factors as determined by FRAX compared. Body fat percentage was also examined as a stand-alone variable considering the patient population. Statistical analyses was performed using R programming language, with t-test or Kruskal-Wallis for continuous variables and Fisher's exact test for categorical variables. For categorical variables data is presented as mean (SD). Statistical significance was classified as a p-value <0.05.

Results The cohort included 179 patients with fractures and 287 patients with no fracture. Risk factors with a statistically significant difference between the groups were: Low femoral neck BMD, low fat percentage (33.3% (11.2) vs 30.1 (10.5)), previous fracture (10.6% vs 0.35%), family history (39.7% vs 25.4%), previous steroid therapy (11.7% vs 3.48%) and alcohol use (19% vs 8.71%). Smoking, history of rheumatoid arthritis and secondary osteoporosis did not achieve statistical significance. The risk factors with strongest association with fracture in the anorexia cohort were previous fracture, total fat percentage and previous steroid therapy.

Conclusion Not all FRAX risk factors were associated with fractures in this cohort of patients. Low body fat percentage was associated with an increased risk of fractures in a population of patients with Anorexia Nervosa and should be considered in screening for risk of fracture in this cohort.

X-LINKED HYPOPHOSPHATEMIC RICKETS IN ADULTS: INSIGHTS FROM A SINGLE-CENTER CASE SERIES

M. Buttazzoni[1], M. N. Aliquó Maciel[1], B. M. Perez[1], L. C. Plantalech[1], A. M. Galich[1], R. Guelman[1], M. Diehl[1]

[1]Hospital Italiano Buenos Aires, Buenos aires, Argentina

X-linked hypophosphatemic rickets (XLH) is a rare hereditary disorder caused by inactivating mutations in the PHEX gene, leading to FGF23-mediated renal phosphate loss. This study aims to describe the characteristics and therapeutic approaches in a historical cohort of adult XLH patients.

Methods: Retrospective observational analysis. Medical records of patients with osteomalacia assisted in our center between 2005 and 2022, including 22 adult patients diagnosed with XLH.

Results: The cohort comprised 82% females, with a median age of 45 years (range: 25–78). Median height was 1.49 m (IQR:1.42–1.55), BMI 25.2 kg/m² (IQR: 22.9–27.8). Median age at diagnosis was 2 years (IQR: 2–5), with 4 cases diagnosed in adulthood. Sixteen patients (73%) reported a family history of XLH. Manifestations included lower limb deformities(73%), bone pain(23%) and osteoarthritis(41%). Skeletal deformities were genu varum/valgum(73%), craniosynostosis(18%) and scoliosis(18%). Eight patients sustained 17 fractures, including femoral (41%) and pseudofractures (14%). Dental pathology affected 59%, nephrocalcinosis 14% and hearing loss 18% patients. Bone mineral density was normal in 80% of 16 evaluated cases.

Treatment included phosphate salts and calcitriol in 12 patients (55%) and only calcitriol in 6 (27%). Two patients transitioned to burosumab due to intolerance to phosphate salts, achieving improvement. Table 1 shows treatment improves TmP-GFR. Corrective orthopedic surgeries were performed in 73% of patients.

Conclusion: Our findings underscore the disease burden in adult XLH patients. Early diagnosis and multidisciplinary management are crucial to mitigate complications and enhance patient outcomes. Future efforts should focus on establishing a XLH registry to facilitate better disease monitoring and care standardization.

Table: Laboratory finding in patients with and without treatment

	Ref. range	Unit	No treatment	Treatment	p*
N.			14	18	
Serum Phosphate	2.5-4.5	mg/dl	2 (1.7-2.3)	2.2 (2-2.5)	0.29
TRP	>85	%	71 (64-75)	77 (66-82)	0.39
TmP-GFR	2.6–3.8	mg/dl	1.5 (1.2-1.6)	1.8 (1.3-2.1)	0.02
ALP	30-100	IU/l	96 (74-123)	109 (90-109)	0.44
PTH	15-65	pg/ml	90 (66-127)	80 (73-100)	0.69

Note: median (first quartile-third quartile) * Wilcoxon sign rank test paired comparisons in 12 cases

P876

REFERENCE RANGES AND ASSOCIATED FACTOR FOR TRABECULAR BONE SCORE IN VIETNAM: VIETNAM OSTEOPOROSIS STUDY

M. C. Doan[1], L. T. Ho-Pham[2], T. V. Nguyen[3]

[1]Pham Ngoc Thach University of Medicine, Hồ Chí Minh, Vietnam, [2]Saigon Precision Medicine Research Center, Hồ Chi Minh, Vietnam, [3]University of Technology Sydney, Sydney, Australia

Background: As bone mineral density (BMD) measured by DXA can only assess changes in bone mass, while trabecular bone score (TBS) is a surrogate indicator of bone microarchitecture and can predict the risk of fractures independently of BMD. The normative values of trabecular bone score in the Vietnamese population is unknown.

Objective: To estimate the reference ranges and associated factor for TBS among community-dwelling individuals in Vietnam.

Method: This cross-sectional study is part of the Vietnam Osteoporosis Study. The study involved 2683 women and 1454 men aged 20 years and older, who were randomly sampled from various districts within Ho Chi Minh City, Vietnam. BMD at the femoral neck, lumbar spine was measured by DXA (Hologic QDR4500). Lumbar spine TBS was obtained by the iNsight software, version 2.1 (Medimaps, Merignac, France). Anthropometric and clinical data were collected using a structured questionnaire. Multivariable regression analysis was used to determine the association between potential factors and TBS.

Results: The mean TBS for the young adult group (ages 20 to 39 years) was determined to be 1.46 ± 0.08 (overall), 1.47 ± 0.07 for men and 1.46 ± 0.08 in women. In men, these cutpoints were equal to a TBS less than 1.295 for a determination of degraded microarchitecture, and between 1.295 and 1.400 for a determination of partially degraded microarchitecture. In women, these cutpoints were 1.260 and 1.380, respectively. The best-fit models for TBS included age, height and BMD.

Conclusion: This research provides reference values for assessing the risk of fractures in the elderly in Vietnam, helping to more accurately evaluate the risk of fractures for the community.

P877

RELATIONSHIP BETWEEN T-SCORE AND PRESENCE OF VERTEBRAL FRACTURES IN HOSPITALIZED PATIENTS WITH HIP FRAGILITY FRACTURE

M. C. Ospino Guerra[1], A. Medina Orjuela[1], A. Casallas Vega[1]

[1]Fundación Universitaria de Ciencias de la Salud - FUCS. Hospital de San José., Bogotá, Colombia

Objectives: To describe the relationship between the T-score and the presence of vertebral fractures in patients with hip fragility fracture treated by the Fracture Liaison Service (FLS) of the San José Hospital in Bogotá, Colombia.

Materials and methods: Descriptive cross-sectional study. 50 patients hospitalized for hip fracture were included. They underwent dorsal-lumbar spine radiography as screening for vertebral fractures and bone densitometry using radiofrequency echographic multi-spectrometry (REMS) technology. The correlation between T-score values in the lumbar spine (LS), femoral neck (FN) and total hip (TH) was described using Spearman's rho coefficient.
Results: Eighty percent of the participants were female. The mean age was 78.8 +/- 8.69 years. Diabetes, chronic kidney disease, and vertebral fracture documented by radiography were diagnosed in 20.4%, 18.4%, and 20.4% of the patients, respectively. In patients with vertebral fracture vs. those without, the T-score was comparatively lower in FN (-3.2 vs. -2.8), TH (-2.8 vs. -2.5), and LS (-3.4 vs. -3.1). The correlation between LS T-score and FN T-score was 0.7 ($p< 0.001$), and the correlation between TH T-score and FN T-score was 0.94 ($p< 0.001$).
Conclusions: Vertebral fracture in patients hospitalized for hip fracture appears to correlate with lower T-score values at the 3 anatomical reference sites compared to patients in whom vertebral fracture was not documented. This may influence the choice of treatment and preventive measures to minimize the risk of refracture.

P878

CONCORDANCE BETWEEN MULTI RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY (REMS) AND DUAL X-RAY ABSORPTION FOR THE DIAGNOSIS OF OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN: A REAL-WORLD STUDY

A. Medina Orjuela[1], M. C. Ospino Guerra[1], A. Casallas Vega[1]

[1]Fundación Universitaria de Ciencias de la Salud - FUCS. Hospital de San José., Bogotá, Colombia

Objectives: To evaluate the concordance between bone densitometry (BMD) by radiofrequency echographic multi spectrometry (REMS) and dual energy X-ray absorptiometry (DXA) for the diagnosis of osteoporosis in postmenopausal women treated in the endocrinology clinic of an hospital in Bogotá, Colombia.
Methods: Descriptive cross-sectional study. Fifty women with an indication for BMD who underwent the examination by DXA and REMS methods were included. Diagnostic concordance was assessed by the percentage of patients classified within the same category by both methods (normal, osteopenia and osteoporosis) and their corresponding concordance correlation coefficient.
Results: The mean age was 67 +/- 12.4 years. Analysis revealed that based on DXA, 56% of patients were diagnosed with osteoporosis, 38% with osteopenia, and 6% had normal BMD. When these results were compared with REMS, it was found that 92.9% of patients classified with osteoporosis by DXA were identified in the same way by REMS. However, only 36.8% of patients diagnosed with osteopenia by DXA were classified in the same category by REMS and of 19 patients with osteopenia by DXA, 11 had osteoporosis by REMS. The agreement between the methods, measured by the concordance correlation coefficient (CCC), was 0.53 (95% CI 0.32–0.68; $p<0.01$) in the lumbar spine and 0.38 (95% CI 0.13–0.58; $p<0.01$) in the femoral neck. A larger sample is required to optimize the correlation results
Conclusions: These findings suggest that REMS showed a high concordance with DXA in the identification of osteoporosis, especially in the lumbar spine, allowing therapeutic decisions to be made given the possibility of obtaining results at the patient's bedside without exposure to ionizing radiation. It is important to consider the variability in the concordance according to the anatomical region evaluated and the factors that may affect it.[1] This is the first study in Colombia to determine the diagnostic concordance between both techniques, so further studies are recommended to expand these results.

OSTEOPOROSIS DUE TO INACTIVITY IN A YOUNG MALE PATIENT WITH RUPTURED AORTIC ARCH ANEURYSM – POST-SURGICAL INTERVENTION

M. Cevei[1], D. Stoicanescu[2], F. Andronie Cioara[1], A. Gherle[1], M. S. Deac[1], R. Mihut[1]

[1]UNIVERSITY OF ORADEA, FACULTY OF MEDICINE AND PHARMACY, ORADEA, Romania, [2]University of Medicine and Pharmacy "Victor Babes", Timisoara, Timisoara, Romania

The patient is a 50-year-old male with a medical history of right-sided hemiparesis following an ischemic stroke in the left middle cerebral artery (MCA) territory, secondary to cerebral infarction caused by thrombosis of the cerebral artery (October 22, 2020). The patient also has a ruptured aortic arch aneurysm with a giant hematoma, which displaces the trachea. He underwent surgical intervention with a Dacron 28 prosthesis replacement (December 9, 2020). Additional diagnoses include grade III hypertension and osteoporosis resulting from inactivity (April 2022). The patient is currently hospitalized for motor deficits affecting the right hemicorporeal side, difficulties with activities of daily living (ADLs), and motor aphasia.

Functional Assessment:

- **FIM (Functional Independence Measure) Score**: 50 out of 126 points (39.68%).
- **Barthel Index**: 30 out of 100 points – indicating severe dependency.
- **FAC (Functional Ambulation Classification)**: Level 1 – Ambulatory, requiring physical assistance (level 2).
- **Fall Risk**: 18 points on the Johns Hopkins Fall Risk Assessment Scale.

DXA (Dual-energy X-ray Absorptiometry) Results

DXA Data	Measurement Location	BMD (g/cm²)	Z-Score	10-Year Osteoporotic Fracture Risk	10-Year Hip Fracture Risk
2022	Right Hip	0,685	-2,4	4,74%	2,72%
	Left Hip	0,794	-1,8		
	Lumbar Spine	0,836	-1,5		
2024	Right Hip	0,631	-2,7	4,83%	2,7%
	Left Hip	0,786	-1,8		
	Lumbar Spine	0,727	-2,2		

Results There is a noticeable decline in BMD over the course of the disease. The motor deficit of the right hemibody corresponds with a more pronounced decrease in BMD at the right hip.
Conclusion Monitoring BMD progression in neurological patients is crucial for the prevention of osteoporotic fractures.

P880

MULTIPLE SCLEROSIS AND OSTEOPOROSIS: IMPLICATIONS FOR PATIENT CARE

D. Stoicanescu[1], A. Gherle[2], S. Deac[2], M. Cevei[2]

[1]University of Medicine & Pharmacy "Victor Babes" Timisoara, Timisoara, Romania, [2]University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania

Several studies have reported that individuals with multiple sclerosis have lower bone mineral density and higher rates of osteoporosis compared to healthy people. We describe a 55-year-old female patient known with secondary progressive multiple sclerosis for 18 years, with relapses after 8, 9 and 10 years from onset manifested by decreased muscle strength in the lower limbs. She was admitted to the clinic with tetraparetic motor deficit, orthostatic and gait deficit, deficit in performing transfers, moderate deficit in performing ADLs, cervical and lumbar pain, sphincter dysfunctions of retentive type, being diagnosed with tetraparesis with predominance of spastic paraparesis, chronic vertebrogenic lumbosacralgia with radiculalgia. She also had severe osteoporosis, with DXA total hip T-score -3.8 and lumbar spine T-score -2.0. Clinical examination revealed impossible walking and standing, ambulation possible in a wheelchair propelled by another person, transfers from supine to sitting at the edge of the bed with 100% help from another person, marked bilateral hypotonia and hypotrophy of the anterior and posterior calf muscles. Maintenance of the posture while sitting was difficult with lateral deviations, she did not actively mobilize lower limbs, had absent motor control and Ashworth spasticity score was 3. Deep tendon reflexes were abolished in both lower limbs, coordination was impossible to assess. She actively mobilized upper limbs; motor control was present but presented upper limbs coordination disorder, more pronounced on the right. Ashworth spasticity score was 2. FIM and Barthel scores were 85/126 and 60/100, respectively. Modified fatigue impact scale revealed 40 points out of 84; Penn Spasm Frequency Score was 1/4 and ADL score 6/10. Complex medical rehabilitation focused on personalized physiotherapy, breathing exercises, global analytical mobilizations, occupational therapy, Frenkel program from sitting position, robotic therapy, Vibramoov proprioceptive modulation therapy, laser, Vojta therapy and medication led to a slowly favorable evolution, with improvement of symptoms and functionality. These findings highlight the importance of muscle and bone health assessment as part of the management of multiple sclerosis patients.

BONE HEALTH IN PATIENTS WITH NON-METASTATIC PROSTATE CANCER ON ANDROGEN RECEPTORS INHIBITORS: A SYSTEMATIC REVIEW

M. Chakhtoura[1], C. Rhayem[1], G. El Hajj Fuleihan[1]

[1]American University of Beirut - Lebanon, Beirut, Lebanon

Background
Androgen deprivation therapy is commonly used in patients with prostate cancer, in combination with primary therapy, and has been associated with a deleterious impact on bone health. Although androgen receptors inhibitors (ARI) do not reduce androgen levels, recent data on second generation ARI suggests that these agents increase the risk of falls and fractures in patients with prostate cancer.
Objective
Our aim is to review the impact of ARI on bone turnover markers, bone mineral density and fractures in men with non-metastatic prostate cancer.
Material and methods
This is a systematic review of the literature. We included observational and interventional studies on patients with non-metastatic prostate cancer, receiving ARI, including apalutamide, darolutamide, enzalutamide or abiraterone, alone or in combination with another androgen deprivation therapy. Eligible studies reported on one or more skeletal parameters, including bone turnover markers, bone mineral density and fracture. We searched Medline and Embase from database inception until January 2025. We used MeSh terms and keywords relevant to prostate cancer, ARI and bone markers, density and fracture. We screened titles and abstracts and full text articles in duplicate and independently, and after a calibration exercise. We abstracted data on the population, intervention and outcomes of interest. We evaluated the risk of bias using the New Castle Ottawa quality assessment scale for observational studies and the Cochrane risk of bias assessment tool 2019 for interventional studies.
Results
Our search strategy yielded 839 citations. (We are in the process of finalizing the results that will be available by April 2025)
Conclusion
Given the significant role of ARI in the prognosis of patients with non-metastatic prostate cancer, it becomes crucial to investigate their potential deleterious effect on bone health. Our findings are expected to impact the approach to patients with non-metastatic prostate cancer on ARI, to preserve their bone health, as it is the

case with other modalities of androgen deprivation therapy.

P882

DESTRESSING MINDS. STRENGTHENING MUSCLES. YOGA AND ITS EFFECT ON MUSCLE STRENGTH IN HEALTHY INDIVIDUALS. A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

P. Bajaj[1], L. Nagendra[2], M. Samuel[3], M. Chandran[4]

[1]1.National University Health System and Ministry of Health Holdings, Singapore, Singapore, Singapore, [2]2.JSS Medical College, JSS Academy of Higher education and Research, Mysore, India, Mysore, India, [3]3.Systematic Review Unit, NUS Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, [4]Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore General Hospital. DUKE NUS Medical School, Singapore, Singapore

Background Muscle strength is crucially associated with BMD and falls risk. Yoga, an ancient practice that in general combines poses (asanas) and breathing exercises (pranayama), involves seated, standing, as well as supine postures that target most major muscle groups. Though its effects on balance, BMD and falls risk have been evaluated recently(1), studies exploring yoga's effects on muscle strength have not been systematically reviewed before. We evaluated randomized controlled trials (RCTs) comparing yoga's effects on hand grip strength (HGS) and lower limb strength (LLS) against no intervention controls (NIC) and active interventions (AC) such as Pilates, core stabilization exercises, and Taichi in healthy individuals.

Methods We systematically searched scientific databases following a predefined protocol. Heterogenous data were qualitatively summarized. We conducted a meta-analysis of studies comparing yoga to NIC and AC, using standardized mean differences (SMDs) to pool outcomes.

Results Twenty-five RCTs involving 1817 participants aged 6–90 years were analyzed. Yoga styles included Hatha, Ashtanga, Iyengar, Bikram etc. Yoga significantly improved HGS compared to NIC [SMD 0.50 (95% CI: 0.04–0.97); P=0.03; I²=77%]. A single study that compared yoga to AC reported positive HGS effects, with no between-group differences. Yoga also significantly enhanced LLS compared to NIC [SMD 1.51 (95% CI: 0.86–2.15); P<0.00001; I²=84%] and AC [SMD 0.44 (95% CI: 0.14–0.74); P=0.004; I²=8%]. Intervention lengths, and assessment methods showed significant heterogeneity.

Conclusion Yoga significantly enhances HGS and LLS in healthy individuals compared to controls, with modest improvement in LLS and comparable benefits in HGS to AC. Future research should standardize protocols to better explore optimal yoga practices for muscle strengthening and their mechanisms.

CLINICAL ADOPTION OF AI-DRIVEN OPPORTUNISTIC BONE HEALTH SCREENING IN CANADA

C. Syme[1], A. Jayarajah[2], A. Oikonomou[2], M. Cicero[1], A. Bilbily[1]

[1]16 Bit Inc., Toronto, Canada, [2]Sunnybrook Health Sciences Centre, University of Toronto, Toronto, Canada

Objective: To report on measures of clinical adoption of a regulatory-approved medical device that analyzes x-rays of the chest, lumbar spine, thoracic spine, pelvis, knee or hand/wrist, acquired for any indication, and alerts the radiologist at the time of x-ray reporting if the patient is likely to have low BMD (DXA T-Score < -1 at the femoral neck or lumbar spine).

Materials and Methods: For nine imaging organisations, we quantified x-ray accessions screened and those identified as at-risk for low BMD. At two organisations, we quantified the rate of radiologists including the finding in their x-ray reports, and whether reporting the finding led to a subsequent DXA. True positive rate of low BMD and elevated fracture risk were calculated when available.

Results: The device has prospectively screened 250,000 unique patients in Canada during routine clinical care. At each of the 9 imaging organizations, the sex- and age-group-specific rates of *device-flagged* low BMD were consistent with published rates of low BMD (by DXA) in the general population. At one academic centre, the mean rate of radiologists including the finding in their x-ray reports was 80%; at a community-based centre, the mean rate was 52% and ranged from 0-89%. Half of DXAs ordered in response to a reported finding were a patient's first-ever. 54% of patients who returned for DXA had elevated fracture risk. In men ≥65 years, first-ever DXAs triggered by the device (vs. not) identified significantly more patients with osteoporosis and elevated fracture risk. Of 51 family physicians who completed a survey, 78%

believe that the opportunistic screen is beneficial for patient care. Of 389 patients who completed a survey, 36% of flagged patients discussed bone health with their physician within six months of their x-ray, and 10-25% were newly diagnosed with osteoporosis.
Conclusion: Adoption of an opportunistic screen identifies patients who would benefit from clinical fracture risk assessments. In Canada, the device is facilitating appropriate follow-up care of patients at-risk of osteoporotic fractures. By including the results in their x-ray reports, radiologists can help address the care gap in osteoporosis, by providing a "smart nudge" to referring physicians to conduct the often-overlooked clinical fracture risk assessment.
Disclosures: MC, AB and CS report a relationship with 16 Bit Inc that includes employment and/or equity or stocks.

ASSESSMENT OF 10-YEAR RISK OF FRACTURE WITH BMD ADJUSTMENT (FRAXPLUS) IN MENOPAUSAL WOMEN WITH BILATERAL ADRENAL NON-FUNCTIONING TUMORS: A PILOT STUDY

M. Costachescu[1], A.-I. Trandafir[1], O.-C. Sima[1], A.-M. Gheorghe[1], G. Voicu[2], A. Ghemigian[3], E. Petrova[3], A. Dumitrascu[2], C. Nistor[3]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania, [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background: Accidentally detected bilateral adrenal tumors might display a mild autonomous cortisol secretion with a potential higher fracture risk, especially, in menopausal women. No specific algorithm is yet to integrate the osteoporosis profile in these patients.
Objective. This was a pilot study aimed to assess the 10-year fracture risk via traditional FRAX tool and FRAXplus with bone mineral density (BMD) adjustment. (https://www.fraxplus.org/)
Methods: Menopausal women diagnosed with non-functioning bilateral adrenal tumors (AT) underwent central DXA scan (GE Lunar Prodigy). Exclusion criteria: prior diagnosis of osteoporosis and previous exposure to anti-osteoporotic drugs. FRAX and FRAXplus provided 10-year major osteoporotic fracture risk (MOF) and hip fracture (HF), respectively, MOF1, and HF1.
Results: The studied population (N=26) included group AT (N=13) and 13 age-matched non-AT controls (group C) with a mean age of 53.46±6.41, respectively, 57.00±2.48 years, and years since menopause of 7.23±6.21, respectively, 10.08±3.55 ($p<0.5$). Lumbar BMD was similar between AT and C group, as well as femoral neck and total hip BMD. MOF had a median of 2.35 with interquartile interval (IQR) between 1.40 and 3.60% in group AT versus 2.70(2.30, 3.02)% in group C, and HF was 0.30(0.10, 0.90)% versus 0.20(0.14, 0.42)% ($p<0.5$ for each). MOF1 was 2.05(1.40, 2.60)% versus 2.25(2.20, 2.95)%, and HF1 of 0.25(0.10, 0.70% versus 0.25(0.10, 0.30)% ($p<0.5$ for each). MOF1 in group AT was statistically significant higher than in group C ($p=0.014$).
Conclusion. FRAXplus might prove a good discriminator in menopausal women with apparently non-secreting bilateral adrenal tumors in order to pinpoint the osteoporotic fracture risk.

P885

10-YEAR RISK OF FRACTURE ASSESSMENT WITH BMD ADJUSTMENT (FRAX PLUS) IN TERIPARATIDE CANDIDATES: A PILOT STUDY AMID 24-MONTH PROTOCOL FOR SEVERE MENOPAUSAL OSTEOPOROSIS

M. Costachescu[1], O.-C. Sima[1], E. Petrova[2], A. Ghemigian[2], A.-I. Trandafir[1], A.-M. Gheorghe[1], A. Dumitrascu[3], G. Voicu[3], C. Nistor[2]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [3]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Background: Severe osteoporosis poses supplementary risks of further fractures and fracture risk is essentially needed to capture the essence of this complicated picture
Objective: We aimed to assess the 10-year fracture risk of major osteoporotic fractures (MOF) and hip fracture (HF) via using traditional FRAX tool and FRAX plus that provided MOF and HF by using lumbar bone mineral density (BMD) in teriparatide (TPT) candidates.
Methods: Menopausal women with severe primary osteoporosis underwent 24-month TPT protocol (20 µg/day, subcutaneous) under annual DXA (Dual-Energy X-Ray Absorptiometry) control.
Results: 32 TPT candidates with mean age of 66.69±8.47years and year since menopause of 21.53±10.17 were evaluated at TPT initiation and after 24 months. Lumbar, femoral neck, and total hip BMD, as well as T-score were statistically significant higher after 2 years of TPT ($p<0.05$). MOF at baseline was 9.85±3.54%, respectively, HF was 3.67±2.40, similar at the end of protocol, of 9.70±3.73% and 3.58±2.36%, respectively ($p>0.5$ for each). MOF adjusted for lumbar BMD at baseline (6.66±2.29%) was similar after 2 years (6.56±2.28%) as well as HF adjusted for lumbar BMD (2.36±1.56% versus 2.30±1.52%, $p<0.5$). Comparing MOF via FRAX versus FRAXplus, respectively, HF, both were statistically significant lower according to FRAXplus at baseline and after 2 years ($p<0.001$ for each).
Conclusion: Using lumbar BMD for MOF and HF, the 10-year risk was lower than using traditional FRAX in high-risk patients with complicated osteoporosis. BMD improvement under medication was not captured by any of the 10-year risk assessment.

PRIMARY HYPERPARATHYROIDISM DUE TO MULTIGLANDULAR DISEASE AND ADRENAL TUMORS-RELATED MILD AUTONOMOUS CORTISOL SECRETION: IMPACT ON OSTEOPOROTIC FRACTURE RISK AND TAILORED DECISION THERAPY

A.-M. Gheorghe[1], M. Costachescu[2], O.-C. Sima[3], G. Voicu[4], A. Goldstein[4], E. Petrova[5]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [3]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Nuclear Medicine, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Background/Objective: The wide spectrum of primary hyperparathyroidism (PHPT) includes, among others, multi-glandular parathyroid disease. When associated with different endocrine tumors such as pituitary adenomas and adrenal tumours (AT), genetic profile should be taken into consideration. We aim to introduce a female with severe osteoporosis in the setting of PHPT associated with MACS (mild autonomous cortisol secretion)-positive AT. **Method:** This was a case report. **Results:** A 75-year-old female with osteoporosis diagnosed at 59 (menopause at 43) was treated with bisphosphonates for 16 years (alendronate-9 years, 1-year-drug holiday, alendronate-1 year risedronate-5 years). After first 9 years of alendronate, DXA showed lowest T-score at femoral neck: BMD=0.614g/cm^2,T=-2.1,Z=-0.4 and she had multiple vertebral fractures. She was confirmed with PHPT at 49[total serum calcium were between 10.4-11.7mg/dL(normal:8.4-10.2) and PTH between 65-77.4 pg/mL(normal:15-65)] associated with bilateral AT, non-secreting pituitary adenoma, type 2 diabetes, hypertension and psoriasis. After 16 years of bisphosphonates, BMD improved in association with conserving a partially degraded TBS (of 1.284). In the meantime, neck ultrasound showed upper bilateral parathyroid tumours of maximum 1.7 cm, but they were not confirmed at CT scan or MIBI Tc99m scintigraphy, and the patient postponed surgery. CT also confirmed bilateral ATs of maximum 2.7cm that involved a MACS confirmation [plasma cortisol after 1 mg dexamethasone overnight of 5.14µg/dL (normal<1.8)]. Due to long-standing presence of both types of endocrine tumours and declined surgery, she continued with risedronate.**Conclusion**: This case highlights multifactorial pathogeny of osteoporosis in patients with endocrine tumours.

IDENTIFICATION OF AN INTRATHYROIDAL PARATHYROID ADENOMA-RELATED PRIMARY HYPERPARATHYROIDISM AFTER 4-YEAR HISTORY OF SEVERE OSTEOPOROSIS

A.-M. Gheorghe[1], O.-C. Sima[2], M. Costachescu[3], A. Dumitrascu[4], E. Petrova[5]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Background/Objective: Both osteoporosis and primary hyperparathyroidism (PHPT) are conditions that predominantly affect postmenopausal women. In patients with PHPT, osteoporosis is one of the surgical indications both due to disease burden and considering the positive impact of parathyroidectomy on bone health. The improvement of bone status has been observed even in patients with osteopenia. We aim to introduce such a case.
Method: This was a case report.
Results: A 65-year-old female with metabolic syndrome and a 4-year history of severe osteoporosis (complicated with a low-trauma tibia fracture) was treated with oral bisphosphonates

until PHPT-related symptomatic hypercalcemia was identified. On admission, PHPT was confirmed: total calcium=13.2mg/dL (normal:8.4-10.2), PTH=489.3pg/mL (normal:15-65) associated with vitamin D deficiency based on 25-hydroxyvitaminD of 17.2ng/mL (normal>30). Increased resorption and formation according to the bone turnover markers was found: CrossLaps=1.03ng/mL (0.33-0.782) - resorption, respectively, formation - osteocalcin=101.4ng/mL (normal:15-46), P1NP=87.09ng/mL (normal:20.25-58.59), and alkaline phosphatase=154 U/L (normal:38-105). DXA showed: lumbar BMD=0.953g/cm^2, T-score=-1.9, Z-score=-0.4, total hip BMD=0.656g/cm^2, T-score=-2.8, Z-score=-1.8, femoral neck BMD=0.701g/cm^2, T-score=-2.4, Z-score=-0.9. She was switched to zoledronate 5mg/year to control hypercalcemia and act against bone loss. Cervical ultrasound showed a parathyroid tumour of 2.8 cm with SPECT/CT confirmation. The patient then underwent parathyroidectomy. (Intra-thyroid parathyroid adenoma with chief and oxyphil cells was confirmed). Post-operative panel was normal (total serum calcium=9.9 mg/dL). Further annual injection was continued in addition to 2000U/day cholecalciferol. **Conclusion**: Underlying overlapping endocrine causes of severe osteoporosis such as PHPT might be identified long-term after the anti-osteoporotic drug initiation.

FORESTALLING SEVERE OSTEOPOROSIS IN A MALE CONFIRMED WITH PRIMARY HYPERPARATHYROIDISM ASSOCIATED WITH AND HYPERTHYROIDISM

A.-M. Gheorghe[1], E. Petrova[2], O.-C. Sima[3], M. Costachescu[4]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania

Background/Objective: Hip fracture is associated with higher mortality in men despite a lower incidence compared to women. Osteoporotic fractures in men may be associated like primary hyperparathyroidism (PHPT) and hyperthyroidism. We aim to introduce such a case. **Method**: case presentation. **Results:** A 60-year-old male with a recent history of symptomatic hypercalcemia due to PHPT [total calcium=15.04mg/dL (normal:8.6-10.3), PTH=627pg/mL (normal:12-88)] treated with ibandronate 3 mg intravenously has mitral valvuloplasty, and aortic regurgitation. He was also confirmed with hyperthyroidism and treated with daily methimazole for 3 years. In the meantime, he suffered a fragility fracture at the right hip. Currently, hypercalcemia is controlled (total calcium=9.8mg/dL) with increased bone resorption [CrossLaps=0.54ng/mL (normal:0.101-0.504)], but normal bone formation markers [osteocalcin=43.52ng/mL (normal:14-46), P1NP=51.92ng/mL (normal:20.25-76.31), alkaline phosphatase=102U/L (normal:38-129)] amid mild vitamin D deficiency [25-hydroxyvitaminD=13.4ng/mL(normal>30)]. DXA confirmed osteoporosis: lumbar BMD=0.938g/cm^2, T-score=-2.3, Z-score=-2.5, total hip BMD=0.750g/cm^2,T-score=-2.6, Z-score=-2.3, femoral neck BMD=0.776g/cm^2, T-score=-2.3, Z-score=-1.7, third distal radius BMD=0.420g/cm^2,T-score=-2,Z-score=1.6SD, and partially degraded microarchitecture(TBS=1.303).Thyroid function normalized under treatment. Cervical ultrasound revealed a right inferior parathyroid tumour of 30x22x22 mm. The patient underwent synchronous right inferior parathyroidectomy and thyroidectomy with low-normal post-surgery calcemic values[total calcium=8.7mg/dL], Further annual zoledronate 5 mg was continued. **Conclusion**: Osteoporotic fractures may occur even in the early stages of PHPT. Long-standing undertreated hyperthyroidism adds to the fracture risk even in males. Therefore, PHPT diagnosis and treatment should not be overlooked in men with hip fractures, as the disease may progress to other fractures and life-threatening hypercalcemia, hence, increasing disease burden, and impaired quality of life.

BILATERAL ADRENAL TUMORS, PRIMARY HYPERPARATHYROIDISM, AND RHEUMATOID ARTHRITIS: BONE STATUS AMID PATIENT'S OPTION OF SURGERY

A.-I. Trandafir[1], O.-C. Sima[2], M. Costachescu[3], E. Petrova[4]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Mild autonomous cortisol secretion (MACS), primary hyperparathyroidism (PHPT), rheumatoid arthritis (RA), and type 2 diabetes (DM2) are fracture risk factors. We aim to introduce such a case.
Methods: case report.
Results: This is a 64-year-old patient with a 3-year history of bilateral nonfunctional adrenal adenomas (NFAI), RA, DM2, osteopenia, and multinodular goiter-related hypothyroidism since the age of 56 (controlled under levothyroxine), and hypertension. Since the age of 61, persistent mild hypercalcemia with high PTH was found[PTH=99.41pg/mL(normal:17.3-74.1)]; a upper right parathyroid tumour was detected by ultrasound. Bone turnover markers were normal[(formation) osteocalcin=16.42ng/mL(normal:15-46), alkaline phosphatase=79.5U/L(normal:35-104), P1NP=47.97ng/mL(normal:20.25-76.31), and (resorption) =CrossLaps=0.4ng/mL(normal:0.33 0.782)]. Currently, DXA showed stationary scores, the lowest T-score at lumbar spine [BMD=0.908g/cm^2,T-score=-2.1,Z-score=-1.4]. MACS was not confirmed [ACTH=13.79pg/mL(normal:7.2-63.3) plus second-day morning plasma after dexamethasone 1mg suppression test of 1.15µg/dL(normal<1.8)]. Computed tomography showed stationary bilateral nodular adrenocortical disease (largest diameter of 2.1 cm). The surgery for the parathyroid was postponed by the patient (indicated due to calcium levels). Zoledronate 5 mg/year was administered in addition to daily 2000U cholecalciferol.
Conclusion: In patients with NFAI, especially bilateral, a follow-up is mandatory due to potential bone and cardio-metabolic implications. Lack of surgery in PHPT might add to the overall picture. However, in this case, osteopenia was correlated with multiple factors like PHPT, rheumatoid arthritis, DM2, but the patient' decision was not to undergo surgery. Despite osteopenia at DXA, the anti-osteoporotic pharmacologic intervention should be considered due to the complex multidisciplinary panel of co-morbidities that might affect the skeleton health.

BONE HEALTH ASSESSMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS COMPLICATED BY AUTOIMMUNE HEPATIC CIRRHOSIS: OSTEOPENIA, DECREASED TBS, HYPOCALCEMIA AND VITAMIN D DEFICIENCY

O. P. Ionescu[1], B.-A. Sandulescu[2], O.-C. Sima[3], M. Costachescu[4], C. Nistor[4], M.-L. Ciobica[2]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy & Department of Internal Medicine I and Rheumatology, "Dr. Carol Davila" Central Military University Emergency Hospital, Bucharest, Romania, [2]Department of Internal Medicine I and Rheumatology, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Internal Medicine and Gastroenterology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [3]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: Osteoporosis is a common finding in patients with collagen disorders, particularly, those with systemic lupus erythematosus (SLE). The etiology is multifactorial, including glucocorticoids and other immunosuppressive drugs.
Objective: We aim to introduce such case.
Methods: case report.
Results: A 61-year-old woman known with a 3-year history of SLE, autoimmune cirrhosis and antiphospholipid syndrome, with long term glucocorticoid therapy (prednisone 10 mg/day) was admitted for itchy and erythematous rashes on her right calf, gingival bleeding, and fatigue. Clinical examination showed eczema on her right leg in addition to active cirrhosis. Blood tests revealed leukopenia of 3.02k/µL (Normal:4.10-10.9), thrombocytopenia of 49k/µL (Normal:140-440), low complement fractions: C3=33.3mg/dL (Normal:90-180) and C4=1.8mg/dL (Normal:10-40) associated with hypocalcemia 8.65mg/dL (Normal:8.80-10.6), hypovitaminosis D=15.5ng/mL (Normal:20-160), and hypomagnesemia=1.74mg/dL (Normal:1.90-2.5). Moreover, polyclonal hypergammaglobulinemia was confirmed: high IgA=1041mg/dL (Normal:70-400) and IgG=2631mg/dL (Normal:700-1600); positive autoimmune profile in terms of antinuclear antibodies R=9.5 (Normal:negative), anti-Ro(SS-A)=65.3U/mL (Normal<15), anti-La(SS-B)=30U/mL (Normal<15), and anti-Smith antibod-

ies>200U/mL (Normal<15). SLE-Disease-Activity-Index score of 4 points was better than initial score of 14. Thyroid evaluation was normal in terms of function. Abdominal ultrasound confirmed a cirrhotic liver, with no ascites. Central Dual-Energy X-Ray Absorptiometry (DXA) showed osteopenia: femoral neck BMD of 0.799 g/cm^2, T-score -1.5, Z-score 0.4, total BMD hip of 0.850 g/cm^2, T-score -1.3, Z-score -0.4, lumbar BMD of 0.913 g/cm^2, T-score -2.3, Z-score -1.2 and decreased trabecular bone score (TBS) of 1.101. A reduction in glucocorticoid dose (prednisone 5 mg/day) was recommended in addition to calcium and vitamin D supplementation and specific diet recommendations for the liver condition.

Conclusion: This case emphasizes multiple elements of bone health impairment in rheumatologic patients diagnosed with autoimmune conditions complicated with autoimmune liver ailments in addition to the glucocorticoid-induced bone loss. It is crucial to early detect and treat osteoporosis in lupus patients, especially those on long-term glucocorticoid therapy, in order to reduce the fracture risk and conserve the quality of life.

BONE FRAGILITY AMID THE DIAGNOSIS OF GRAVES' DISEASE, BREAST CANCER WITH EARLY HYPOGONADISM, AND BILATERAL SPORADIC NODULAR ADRENOCORTICAL DISEASE

A.-I. Trandafir[1], O.-C. Sima[2], M. Costachescu[3], A. M. Ghemigian[4], C. Nistor[5], E. Petrova[4]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background/Objective: Increased thyroid hormone levels may adversely affect the bone metabolism and mass, additionally to the menopause- or age-related effects and incidental endocrine tumours. We aim to introduce such a case. **Method:** case report. **Results:** A 56-year-old female has a 4-year history of TRAb-positive Graves' disease continuously treated with thiamazole. At age of 42, she was confirmed with mammary cancer (treated with surgery plus adjuvant radiotherapy, chemotherapy associated with surgical menopause and 5-year exposure to tamoxifen). She associates hypertension, bilateral sporadic nodular adrenocortical disease (largest tumour diameter of 2.2 cm) since the age of 43. Osteoporosis was confirmed 4 years ago at DXA [lumbar BMD=0.821g/cm^2, T-score=-3, Z-score=-2.3, femoral neck BMD=0.780g/cm^2, T-score=-1.9, Z-score=-0.9]. Zoledronate 5 mg per year was initiated (in addition to 2000 UI/day cholecalciferol) followed by i.v. ibandronate every 3 months. Currently, thyroid function normalized under low-dose of thiamazole. DXA improved [lumbar BMD=0.968g/cm^2, T-score=-1.8, Z-score=-1, femoral neck BMD=0.853g/cm^2, T-score=-1.1, Z-score=0.2] with suppressed bone turnover markers [osteocalcin=9.71ng/mL (normal:15-46), alkaline phosphatase=72U/L (normal:38-105), P1NP=19.35ng/mL (normal:20.25-76.31), and CrossLaps=0.18ng/mL (normal:0.3-0.782)]. Unsuppressed 2nd day-plasma-cortisol post-dexamethasone (1 mg) test confirmed non-functional adrenal profile [of 1.26µg/dL (normal<1.8)]. She continued with 3 mg ibandronate every 3 months in addition to 2000 UI/day cholecalciferol and 5mg/day thiamazol. **Conclusion**: Long-term history of hyperthyroidism, treatment for breast cancer, including surgically-induced primary hypogonadism, and adrenocortical disease represents a multi-factorial contribution to low BMD.

BONE HEALTH IMPROVEMENT FOLLOWING PARATHYROIDECTOMY IN A PATIENT WITH SYMPTOMATIC PRIMARY HYPERPARATHYROIDISM FOLLOWED BY ITS DETERIORATION AMID DEVELOPMENT OF END-STAGE KIDNEY DISEASE

A.-M. Gheorghe[1], O.-C. Sima[2], M. Costachescu[3], E. Petrova[4]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Endocrinology, Carol Davila University of Medicine and Pharmacy & Department of Endocrinology, C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Background: Primary hyperparathyroidism (PHPT) causes bone loss both directly and indirectly through comorbidities such as chronic kidney disease (CKD). Parathyroidectomy promotes bone mass gain. However, CKD may reduce this effect, as it is associated with a reduction in bone quality and quantity. While low turnover characterizes the early stages, more advanced stages are associated with high turnover.

Objective: We aim to analyse bone status in a patient with PHPT and CKD.
Method: This is a case report.
Results: A 63-year-old male with a history of total thyroidectomy for goitre was diagnosed with PHPT and had undergone surgery for urolithiasis. At diagnosis: total serum calcium=13.2mg/dL (normal:8.4-10.2), ionized calcium=5.7mg/dL (normal:3.9-4.9), phosphorus=2.5mg/dL (normal:2.7-4.5), PTH=288.2pg/mL (normal:15-65), 25-hydroxyvitamin D=19.1ng/mL (normal>30), and eGFR=55mL/min/1.73m^2. Bone turnover markers (BTM) showed increased resorption: CrossLaps=0.68ng/mL (normal:0.1-0.5), and normal formation: alkaline phosphatase=68U/L (normal:38-129), osteocalcin=45.8ng/mL (normal:14-46). DXA revealed osteoporosis: lowest score at third distal radius BMD=0.581 g/cm^2, T-score=-2.8, Z-score=-2.3. He continued with twice yearly denosumab and underwent right parathyroidectomy. One year post-surgery, calcium and PTH were still normal; BTM showed reduced formation with stationary DXA and low TBS of 1.281. Two years post-parathyroidectomy, end-stage kidney disease stage was confirmed. Additionally, he was offered alfacalcidol 0.5mg/day. One more year later, high-normal calcaemic level and normal PTH were associated with stationary DXA results.
Conclusion: While parathyroidectomy improves bone status in PHPT, the development of CKD (as a potential consequence of prior hypercalcemia) aggravates it. Denosumab might represent a valuable option against osteoporosis in this particular instance.

BEYOND BACK PAIN: MILD AUTONOMOUS CORTISOL SECRETION COMPLICATED WITH VERTEBRAL FRACTURES

A.-I. Trandafir[1], O.-C. Sima[2], C. Nistor[3], A. Dumitrascu[4], M. Costachescu[5], E. Petrova[6]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [4]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [6]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: The panel of osteoporotic fracture risks mild include the confirmation of mild autonomous cortisol secretion (MACS) in adrenal tumours (AT) or long-standing untreated thyrotoxicosis. We aim to introduce a subject with chronic back pain who was confirmed with MACS-AT. **Methods**: case report. **Results:** This is a 72-year-old female (menopause since the age of 46) was admitted for thyrotoxicosis [TSH=0.0045µUI/mL (normal:0.35-4.94) with positive TRAb=2.93UI/L (normal<1.75)], presenting palpitations, non-specific bone and muscle pain. She had chronic back pain which intensified a few months ago, leading to her admission to neurosurgery for L1 vertebroplasty. Other than mildly increased alkaline phosphatase=287 (normal:35-104)UI/L, and P1NP=77.02ng/mL (normal:20.25-76.31), the mineral metabolism assays were normal. DXArevealed osteoporosis: lumbar L3-L4 BMD=0.019g/cm^2, T-score=-9.5, Z-score=-7.8, total hip BMD=0.612g/cm^2, T-score=-3.2, Z-score=-1.8, femoral neck BMD=0.518g/cm^2, T-score=-3.9, Z-score=-2.2 and low TBS=1.191. Liver cholestasis was also confirmed: elevated total bilirubin=1.53 (normal:0.2-1.2), gamma-glutamyl transferase=483U/L (normal:9-64). After normalization of the thyroid function under thiamazol, a CT scan showed two left ATs with maximum diameter of 1.31 cm, respectively, and 3.04 cm. Baseline morning ACTH=7.92pg/mL(normal:3-66) and unsuppressed 2nd day plasma cortisol after 1 mg dexamethasone test=3.3µg/dL (normal<1.8) revealed MACS-AT. Zolendronate 5 mg/year was administered and vitamin D supplementation and mandatory endocrine follow-up was required.
Conclusion: In menopausal individuals with severe osteoporosis, overlapping ailments such as MACS-AT are prone to enhance the fracture risk. Under these specific circumstances, whether the adrenalectomy should be a mandatory step (especially, if complicated vertebral fractures are found) is still an open issue.

CONUNDRUM OF BISPHOSPHONATES DRUG HOLIDAY DECISION AMID MENOPAUSAL OSTEOPOROSIS AND BILATERAL ADRENAL TUMORS PRESENTING MILD AUTONOMOUS CORTISOL SECRETION

A.-I. Trandafir[1], O.-C. Sima[2], C. Nistor[3], A. Dumitrascu[4], M. Costachescu[5], G. Voicu[6], E. Petrova[7]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [4]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [6]Department of Nuclear Medicine, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [7]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Background/Objective: A tailored decision regarding the pharmacological intervention to address the reducing of the osteoporotic fracture risk in bilateral adrenal tumors (BAT) complicated with mild autonomous cortisol secretion (MACS) is mandatory since the clear effects of full-blown Cushing syndrome are not present. We aim to introduce the conundrum of such case. **Method**: case report. **Results:** A 71-year-old female has a 9-year history of BATs (largest diameter of 2.2 cm). 16 years prior she was diagnosed with menopausal osteoporosis and then treated for 6 years with alendronate until the lowest T-score at DXA improved from – 2.5 to -0.9 in lumbar spine. She remained in drug holiday for a decade. Currently, she associates metabolic elements such as hypertension, dyslipidemia, obesity (body mass index=31.08kg/m²), and prediabetes[A1 glycated hemoglobin=6.08%(normal:4.8-5.9)]. The mineral metabolism assessments were normal, including hormones [25-hydroxyvitaminD=28.3ng/mL(normal>30),PTH=52.77pg/mL(normal:15-65)] and bone turnover markers [osteocalcin=26.87ng/mL(normal:15-46), CrossLaps=0.53ng/mL(normal:0.33 0.782)]. MACS confirmation remained unchanged [baseline ACTH=11.23pg/mL(normal:3-66) and unsuppressed 2nd day-plasma-cortisol after 1 mg dexamethasone testing=1.96µg/dL(normal<1.8)]. No prevalent of incidental fractures (at screening thoracic-lumbar spine X-Ray) were found. A mild BMD reduction was found: lumbar BMD=1.069g/cm²,T-score=-0.9,Z-score=0.6; femoral neck BMD=0.828g/cm²,T-score=-1.3,Z-score=0.3, and partially degraded microarchitecture (TBS=1.341). A decision of re-starting medication against osteoporosis was done and intravenous ibandronate (3 mg every 3 months) was initiated in addition to vitamin D 2000 UI/day. **Conclusion**: The impact of MACS on bone health and metabolic conditions may be considerable; yet the strategies referring to the decision of bisphosphonates drug holiday under these specific circumstances are still debatable.

BONE STATUS IN A MALE PATIENT WITH CLEAR CELL RENAL CANCER-RELATED HYPERCALCEMIA OF MALIGNANCY AND END-STAGE KIDNEY DISEASE

A.-M. Gheorghe[1], O.-C. Sima[2], M. Costachescu[3], E. Petrova[4]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Endocrinology, Carol Davila University of Medicine and Pharmacy & Department of Endocrinology, C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Background: Hypercalcemia of malignancy (HCM) is a common complication of various malignancies, including renal carcinoma (RC), and may be caused by parathyroid hormone-related protein (PTH-rp), bone metastases or ectopic calcitriol production. **Objective**: We aim to introduce such a case in a male patient with RC-related HCM. **Method**: This was a case report. **Results:** A 66-year-old male had a history of HCM in the setting of clear cell RC. At diagnosis, he had normal renal function, hypercalcemia [serum total calcium=16.9mg/dL (normal:8.8-10.2), ionized calcium=7.47mg/dL (normal:3.82-4.82)] and hypophosphatemia [phosphorus=2.4 mg/dL (normal:2.5-4.5)], hypervitaminosis D [1,25-dihydroxyvitamin D=96pg/mL (normal:19.9-79.3), 25-hydroxyvitaminD=17.6ng/mL (normal:30-55.5)], and suppressed PTH<1.2pg/mL (normal:15-65), and increased bone turnover markers (BTM) [CrossLaps=1.48ng/mL (normal<0.704), osteocalcin=47.6ng/mL (normal:14-46), alkaline phosphatase=145 U/L (normal:40-129)]. After fluid therapy and denosumab s.c., hypercalcemia improved to 13 mg/dL. The patient underwent left total nephrectomy and adrenalectomy. Postoperatively, cal-

cium decreased to 10.4mg/dL with normal PTH-rp<0.5 pmol/L (normal<1.3) and PTH=26.58 pg/mL. BTM were normal: Cross-Laps=0.15 ng/mL (normal: 0.104-0.504), osteocalcin=24.83ng/mL (normal:14-46), alkaline phosphatase=76U/L (normal:38-129). DXA revealed osteoporosis: lowest T-score of -3 at femoral neck BMD (g/sqcm) of 0.684, Z-score of -1.6. Bone scintigraphy excluded metastases. 2 years following surgery, total calcium level remained high-normal, while 3 years later; he had end-stage kidney disease G3a and supressed BTM with stationary DXA and reduced TBS results and normal adrenal function. Treatment with 0.25 mg of alfacalcidol was continued.

Conclusion: Renal cell carcinoma may impair bone quantity and quality both by HCM and chronic kidney disease.

VERTEBRAL FRACTURE IN A PATIENT WITH BREAST CANCER, EARLY MENOPAUSE, AND ADRENAL TUMOR

A.-I. Trandafir[1], O.-C. Sima[2], C. Nistor[3], D. Terzea[4], M. Costachescu[5], E. Petrova[6]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [4]Department of Pathology and Immunohistochemistry, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [6]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Early menopause might overlap with the presence of an adrenal tumour and breast cancer as multiple contributors to bone loss and increased osteoporotic fracture risk. We aim to introduce such case. **Method:** case report. **Results**: This is a 64-year-old female admitted for the evaluation of a left adrenal tumor of 1.48 cm that was discovered 2 years prior amid a computed tomography scan control following surgery for breast cancer (additionally, she received neoadjuvant chemotherapy, radiation therapy, and tamoxifen). She had surgical menopause since the age of 42 for a benign condition. She was also detected at that point with a L1 vertebral fracture whereas DXA showed: lumbar BMD=1.032g/cm^2, T-score= -1.1, Z-score= -0.8, femoral neck BMD=0.650g/cm^2, T-score= -2.8, Z-score= -2.2. Hence, she was offered ibandronate 3 mg/3 months until present time. She associates hypertension, dyslipidemia, obesity, non-secreting pituitary micro-adenomas, and goiter and normal thyroid function. Currently, after no incidental fracture, BMD improved: lumbar BMD=1.039g/cm^2,T-score= -1.1, Z-score= -0.4, femoral neck BMD=0.684g/cm^2, T-score= -2.5, Z-score= -1.8. The confirmation of a non-secreting adrenal profile was re-done [baseline ACTH of 24.9 pg/mL (normal:3-66); plasma morning cortisol of 18 µg/dL (normal:4.82-19.5), respectively, post-1 mg dexamethasone test of 1.1 µg/dL (normal:<1.8)]. She continued zoledronate 5 mg/year and vitamin D supplementation. **Conclusion**: The concurrent diagnosis of a vertebral fracture with an adrenal tumour, metabolic issues, and multimodal management for mammary cancer makes more difficult the overall strategy, but prompt intervention against osteoporosis reduces the overall burden.

MULTIPLE CONTRIBUTORS TO SEVERE OSTEOPOROSIS IN A FEMALE DIAGNOSED WITH BILATERAL ADRENAL TUMORS, SYSTEMIC LUPUS ERYTHEMATOSUS AND SCLERODERMA

A.-I. Trandafir[1], M. Costachescu[2], E. Petrova[3], O.-C. Sima[4]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [3]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Systemic lupus erythematosus, scleroderma and menopausal status are important contributors to the bone loss. We aim to present such patient. **Method**: case report. **Results**: This is a 63-year-old woman admitted for reassessment of bone status in the setting of a right humerus fracture despite treatment with a bisphosphonate. Her medical history includes menopause at 48 and osteoporosis since the age of 61, bilateral nonfunctional adrenal adenomas (right-1.3cm and left-1.1cm) since 9 years ago, systemic lupus erythematosus, scleroderma, and breast adenomas. The first DXA (Dual-Energy X-Ray Absorptiometry) evaluation was done 3 years ago, showing osteopenia [L1-4 BMD (bone mineral density)=1.057g/cm2, T-score=0.1SD, Z-score=1.5SD; femoral neck BMD=0.633g/cm^2, T-score=-2SD, Z-score=-0.7SD]. She startedrisedronate (35mg/week) until present time. Currently, the biochemistry and hormonal panel of calcium-phosphorus metabolism was normal [including total serum calcium, serum phosphorus, 25-hyroxyvitamin D, and parathormone], as well as bone turnover markers [of formation: osteocalcin=16.86ng/mL(normal:15-46), alkaline phosphatase=73.4UI/L(normal:35-104), and P1NP=63.61ng/mL(normal:20.25-76.31), and of resorption: CrossLaps=0.35ng/mL(normal:0.33-0.782)]. DXA-BMD decreased [L1-L4 BMD=1.010g/cm^2, T-score=-1SD, Z-score=-0.2SD; femoral neck BMD=0.690g/cm^2, T-score=-2.5SD, Z-score=-1.6SD] with trabecular bone score of 1.225 cofirming partially degraded microarchitecture. Bilateral adrenal adenomas were stationary at imaging scans, also, showing an adequate suppression after 1-mg-dexamethasone [second-day-plasma cortisol=0.93µg/dL(normal<1.8)], and normal baseline [ACTH=10.71pg/mL(normal:3-66)]. Zoledronate 5mg/year was offered (plus cholecalciferol supplementation). **Conclusion:** Adrenal adenomas, especially bilateral and in menopause, potentially impact the bone mass. However, in this case, as mentioned, other negative contributors to the overall fracture risk were identified.

DIAGNOSTIC AND THERAPEUTIC CHALLENGES IN BRAF V600E POSITIVE POORLY DIFFERENTIATED THYROID CARCINOMA WITH SUSPECTED OSSEOUS METASTASES: A CASE REPORT

A. Dumitrache[1], O.-C. Sima[2], M. Costachescu[3], C. Nistor[4]

[1]Faculty of Medicine, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [3]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy & Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [4]Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: Poorly differentiated thyroid carcinoma (PDTC) is an aggressive malignancy associated with significant challenges in diagnosis and management, including cases with suspected bone metastases.
Objective: We aim to introduce such a case with PDTC and equivocal findings regarding osseous metastases, underscoring the complexities of imaging and therapeutic decision-making.
Results: A 57-year-old male presented rapidly enlarging goitre and bilateral latero-cervical lymph nodes involvement and normal thyroid function. Computed tomography revealed significant tracheal deviation. Total thyroidectomy with latero-cervical lymphadenectomy was performed. Pathological exam confirmed PDTC. Sanger DNA sequencing identified the *BRAF V600E* pathogenic variant. Postoperatively, thyroglobulin exceeded detectable limits (>500 ng/mL;normal:3.5–77), consistent with extensive residual/metastatic disease. Serum calcium dynamics showed decreasing postoperatively calcium levels (total serum calcium of 6.7 mg/dL) amid transient hypoparathyroidism. Whole-body iodine-131 scintigraphy highlighted intense radiotracer uptake in thyroid remnants, diffuse pulmonary and osseous metastases, including a lesion at the left parietal skull and costal determinations. However, the osseous lesions were not confirmed on 99mTc-HDP bone scintigraphy. Similarly, SPECT/CT revealed no definitive pathological uptake in bone, and findings were attributed to degenerative changes. Based on sustained iodine uptake, the decision was made to continue radioiodine therapy (initial dose of 100 mCi) postponing zoledronate.
Conclusion: Despite imaging discrepancies, the decision to con-

tinue intensive radioiodine therapy might help bone involvement at this point of evolution. Targeted therapy addressing positive *BRAF V600E* profile remains a further potential option. The extensive pulmonary dissemination, alongside unconfirmed osseous metastases, highlights the need for a multidisciplinary approach. This case underscores the challenges in diagnosing and managing osseous metastases in PDTC that requires a tailored approach.

IS THERE A DXA REFLECTION OF A MILD AUTONOMOUS CORTISOL SECRETION IN AN ADRENAL TUMOUR?

A.-I. Trandafir[1], E. Petrova[2], M. Costachescu[3], A. Dumitrascu[4], O.-C. Sima[5]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: One-third of apparently non-secreting adrenal tumors reveal mild autonomous cortisol secretion (MACS) which can negatively impact cardio-metabolic, and bone health, particularly in menopause. We aim to introduce such report. **Method**: case presentation. **Results:** This is a 66-year-old female (physiological menopause since the age of 52) admitted for the evaluation of bilateral adrenal masses (largest diameter on the right of 2.43cm, respectively, of 4.65cm on the left) that were incidentally discovered via ultrasound (performed for non-specific gastrointestinal complaints). On admission, impaired glucose tolerance (glycated hemoglobin A1c of 6.02%) was confirmed. Suppressed baseline ACTH [3.77pg/mL (normal:7.2-63.3)] and non-suppression of morning plasma cortisol following dexamethasone test [3.74mg/dL (normal<1.8)] pinpointed MACS. Computed tomography highlighted the same tumour diameters. Normal parathormone [54.93pg/mL (normal:15-65)] and total serum calcium[9.68mg/dL(normal:8.4-10.2)] associated a low 25-hydroxyvitamin D [11.6ng/mL (normal>30)]. Bone turnover markers were normal [osteocalcin=18.23ng/mL (normal:15-46), CrossLaps=0.45ng/mL (normal:0.33-0.782)]. Dual-Energy X-Ray Absorptiometry showed osteopenia [lumbar bone mineral density(BMD)=1.021g/cm^2,T-score=-1.4SD, Z-score=-0.9SD; femoral neck BMD=0.784g/cm^2, T-score=-1.6SD, Z-score=-1SD]. Bone microarchitecture was normal (TBS=1.358). Vitamin D supplementation was offered. In the absence of adrenal venous sampling (which was available), the decision to performing an adrenalectomy on the adrenal tumor (having +2cm larger diameter than the opposite, and overall >4cm) was done. **Conclusion**: Despite the absence of overt Cushing syndrome, MACS requires a careful evaluation of the cardio-metabolic-bone negative effects, including with respect to a potential post-adrenalectomy improvement. In particular, adrenal venous sampling is necessary for individuals with ACTH-independent MACS-positive bilateral adrenal tumors, especially in cases with similar sizes.

ASSESSMENT OF BONE DENSITY AND QUALITY IN A MALE PATIENT WITH FAMILIAL ISOLATED PRIMARY HYPERPARATHYROIDISM

A.-M. Gheorghe[1], O.-C. Sima[2], M. Costachescu[3], A. M. Ghemigian[4], E. Petrova[4]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Background/objective: Primary hyperparathyroidism (PHPT) induces bone loss especially at cortical sites and impairs trabecular bone score (TBS) as bone microarchitecture measurement.

Factors commonly associated with PHPT such as metabolic syndrome, especially diabetes mellitus, may further impact the microarchitecture. We aim to introduce the bone health assessment in a case of familial isolated symptomatic PHPT. **Method**: This is a case report. **Results**: A 45-year-old male who complained of fatigability, constipation, and generalized bone pain and arthralgia was then confirmed with PHPT. The patient was overweight and had all the components of metabolic syndrome. His father also had suffered from PHPT (familial PHPT). On admission, PHPT was confirmed in terms of calcium=12.6mg/dL(normal:8.4-10.2), ionized calcium=5.73mg/dL(normal:3.9-4.9), phosphorus=1.6mg/dL(2.3-4.7) and PTH=352.3pg/mL(15-65). Bone turnover markers(BTM) were high in terms of resorption CrossLaps=2.16ng/mL(normal:0.158-0.442), and formation: osteocalcin=154.5ng/mL(normal:14-42), P1NP=261.9ng/mL(normal:20.25-58.59). DXA revealed osteopenia: lumbar BMD=1.097g/cm^2, T-score=-1.1, Z-score=-1.4, femoral neck BMD=0.973g/cm^2, T-score=-0.7, Z-score=-0.6, total hip BMD=0.946g/cm^2, T-score=-1.1, Z-score=-1, non-dominant third distal radius BMD=0.406g/cm^2, T-score=-2.3, Z-score=-2.3 and normal TBS of 1.390 with no prevalent fractures. In order to control hypercalcemia and to address the bone loss, intravenous zoledronate (4mg) was offered. Ultrasound showed a right parathyroid adenoma of 3.1 cm which was confirmed at SESTAMIBI-Tc99m scan. He underwent selective single parathyroidectomy and experienced post-operatory hypocalcaemia (total serum calcium=7.6mg/dL). Further serial check-up is mandatory. **Conclusion**: Despite markedly increased BTM and low BMD in the setting of PHPT-related symptomatic hypercalcemia, and further fracture risk factors such as metabolic syndrome components, this patient had no alteration of bone microarchitecture.

PITFALLS OF PARATHYROID TUMOUR LOCALIZATION AMID MULTIPLE ENDOCRINE TUMOURS SYNDROME

A.-M. Gheorghe[1], O.-C. Sima[2], M. Costachescu[3], A. Dumitrascu[4], E. Petrova[5]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Background/Objective:Multi-glandular parathyroid disease, pituitary and adrenal tumours are part of multiple endocrine neoplasia.Primary hyperparathyroidism(PHPT) affects the bone status, like some others co-tumours. We aim to introduce a male with PHPT-related multiple endocrine tumours.**Method:**This is a case report.**Results:**A 57-year-old patient with PHPT, and non-functioning pituitary adenoma(4.4x3.5mm) had metabolic syndrome.The patient was first diagnosed with PHPT at 47 [serum total calcium=11.3mg/dL (normal:8.4-10.2),PTH=115pg/mL(normal:11-67)] and had negative localization at MIBI-Tc99m parathyroid scintigraphy. Over the years, total calcium remained between 10.7-11.4mg/dL and PTH between 44.69-62.8pg/mL.At 56, DXA remained normal: lumbar BMD=1.198g/cm^2,T-score=-0.2,Z-score=-0.3, femoral neck BMD=1.127g/cm^2,T-score=0.4,Z-score=1.3, non-dominant third distal radius BMD=0.932g/cm^2,T-score=1.6,Z-score=2.6. 10-year risk assessment of major osteoporotic fracture was of 1.5% and 0.1% for hip fracture. Bone turnover markers showed reduced formation[osteocalcin=12.17ng/mL(normal:14-46)] and normal resorption [CrossLaps=0.27ng/mL(normal:0.104-0.504)].Currently, calcitonin was mildly elevated[20.9pg/mL(normal:1-11.8)] with normal thyroid ultrasound and the patients remained under thyroid surveillance. PHPT-related assays (a maximum total calcium of 10.8mg/dL) were stationary and computed tomography(CT) finally identified upper bilateral parathyroid tumours. Parathyroidectomy was postponed by the patient. Additionally, adrenal CT showed a tumour(10x1.08mm) with suppression at dexamethasone test[basal ACTH=18.14pg/mL(normal:3-66), plasma morning cortisol=7.39mg/dL(normal:6.2-19.4)]. Genetic testing was declined by the patient.**Conclusion**:A patient with long-standing hypercalcemia due to multi-glandular disease, with intermittently normal PTH levels over the years and poor tumour localization amid imaging investigations, associated with non-functioning pituitary and adrenal tumours might pose some challenges to the bone health. The impact normohormonal PHPT on bone mass is an open issue. Of note, calcium-based stimulation testing for mildly increased calcitonin might not be feasible in PHPT.

DISEASE MODIFYING OA DRUG (DMOAD) EFFECT OF A NUTRACEUTICAL COMBINATION CONTAINING N-ACETYL-GLUCOSAMINE (100 MG) IN EROSIVE HAND OSTEOARTHRITIS. OUR PRELIMINARY RESULTS

M. D'Arienzo[1], C. Marrese[1], P. Sergiacomi[1], L. Cesari[2], G. Miceli[3], D. Fiore[1]

[1]ASL Roma 1, Roma, Italy, [2]ASL Roma 2, Roma, Italy, [3]Orthopedic Outpatient Center, Roma, Italy

Erosive Hand Osteoarthritis (EHOA) is a relatively frequent form of Hand Osteoarthritis, more common in over-fifty female patients. Classically EHOA affects the interphalangeal (IP) and Distal Interphalangeal (DIP) joints of the hands. It is characterized by an acute onset of pain and swelling, with functional impaired condition. Additional features include osteolytic lesions in subchondral bone with typical erosions of joints, producing the "gull-wing sign".

N-Acetyl-D-Glucosamine (GlcNAc) seems to be able to affect osteoclast differentiation and to reduce the expression of IL-1 beta, a Proinflammatory cytokine.

Material and Methods

Aim of our 60-month observation was to evaluate the benefits of a daily dose of a nutraceutical support containing 100 mg of N-Acetyl-D- Glucosamine (GlcNAc), beyond Glucosamine (500 mg), and Boswellia Serrata BOSCAR® (PCT/IB2024/051169) (100 mg), in 80 female outpatients, fulfilling ACR criteria, mean age 69.4 yrs and mean disease duration 8.2 yrs.

At baseline (T0) patients had a significant exceeding of 5.0 in VAS pain and radiographic central erosion in ≥ 1 joints. Hand function was assessed by Dreiser Functional Index.

Results

All patients performed 3 three-months cycles per year. They were evaluated after each treatment year.

At T1, almost 70% of patients had a satisfactory reduction on a VAS Scale and Dreiser's scores showed an improvement.

At the last control (T5), more than 80% of patients reported a significant control of pain, reduction of swelling and a better joint function.

Conclusion

In our patients, GlcNAc reduced progression of erosive osteoarthritis and symptoms. It could be considered as a Disease-modifying OA drug (DMOAD).

ASSOCIATION OF OSTEOGENESIS IMPERFECT AND COOLEY'S ANEMIA, AN UNPRECEDENTED SITUATION!

M. D. Malik[1], L. Lynda[2]

[1]department of medicine ,university mouloud mammeri, Tizi ouzou, Tizi Ouzou, Algeria, [2]Department of medicine, University mouloud Mammari, Tizi ouzou, Algeria

Introduction:

Osteogenesis imperfecta (OI), or brittle bone disease, is characterized by bone fragility and osteopenia. It associates skeletal and extra-skeletal signs.

Cooley's anemia is homozygous form of beta-thalassemia.

We report a situation where these two pathologies coexist.

Observation:

31-year-old female patient from a non-consanguineous marriage, with a family history of heterozygous beta-thalassemia and osteogenesis imperfecta. She has a homozygous B- thalassemia with iron chelation and transfusions complicated by hemochromatosis with primary amenorrhea, hypoparathyroidism and hepatomegaly, treated in rheumatology for OI type IV according to Sillence and Glorieux classification by intravenous bisphosphonates since the age of 18 years, stopped because of secondary hypocalcemia to the hypoparathyroidism.

Physical examination reveals failure to thrive, gray skin, pectus carinatum, scoliosis, lower limbs curvature, yellow opalescent teeth and enlarged abdomen.

Biology:

Normocytic normochromic anemia

Hypocalcemia, hypoparathyroidism, hypovitaminosis D, normal alkaline phosphatase and normal phosphatemia.

Radiology:

Diffuse demineralization, the pelvis in the heart of playing card, fish vertebrae, Looser fracture on the femoral shaft, hair-on-end appearance of the skull, a gridded appearance of the epiphyses.

Bone densitometry:

Z-score: -2.5 at the neck and spine

The patient received a treatment for hypocalcemia and hypovita-

minosis D, then in addition intravenous biphosphonate with tight control.

Discussion:

OI is a rare genetic disorder with autosomal dominant or recessive transmission, caused by mutations in chromosomes 7 or 17 encoding the chains of type I collagen fibers, with polymorphic clinical expression, which is not particularly associated with other diseases.

Cooley's anemia is also a genetic disease due to β globin gene mutation on the chromosome 11, it is autosomal recessive transmission. Like OI, it is not known to have any associations with other diseases.

CLINICAL MANIFESTATIONS OF HYPOTHYROIDISM IN FEMALE PATIENTS WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY OF 58 CASES

M. Dhifallah[1], S. Rahmouni[1], M. Mrad[2], E. Bouallègue[2], M. Abbes[1], K. Zouaoui[1], S. Rekik[1], A. Bahlous[2], S. Boussaid[1], H. Sahli[1]

[1]Rhumatology department, La Rabta Hospital, Tunis, Tunisia, [2]Biochemistry Department, Pasteur Institute of Tunis, Tunis, Tunisia

Introduction

Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease primarily affecting the joints, though it can also involve various organ systems. Among its associated comorbidities, thyroid disorders, particularly hypothyroidism, are frequently reported.

Objectives

- Describe the various clinical manifestations of hypothyroidism in the course of rheumatoid arthritis (RA).
- Outline the biological and immunological profile of thyroid involvement in RA.

Patients and Methods

This cross-sectional study included female patients with RA, meeting the ACR-EULAR 2010 criteria. Thyroid function tests (thyroid-stimulating hormone (TSH) and free thyroxine (FT4)) and assays for antithyroid antibodies (ATAs) (anti-thyroglobulin antibody (ATG), anti-thyroperoxidase antibody (ATPO), and anti-TSH receptor antibody (ARTSH)) were conducted.

Results

Fifty-eight RA patients were included in our study, of whom 17% (n=10) had hypothyroidism. The mean age of these patients was 54.3 ± 13.72 years [30.1–68.16].

The clinical manifestations of hypothyroidism observed, in order of frequency, were: physical fatigue (n=7), hair loss (n=6), mental fatigue (n=3), drowsiness (n=3), dry skin (n=4), hair thinning (n=3), constipation (n=2), weight gain (n=1), and cold intolerance (n=1). No patients exhibited bradycardia, cramps, or myxedema.

The average values for FT4, TSH, ATPO, ATG, and ARTSH were 24.95 ± 26.6 pmol/L, 3.14 ± 2.41 mIU/L, 37.21 ± 66.53 IU/mL, 69.37 ± 127.4 IU/mL, and 0.94 ± 0.32 IU/L, respectively.

Antithyroid antibodies were positive in 3 patients: one patient had both ATPO and ATG positivity, another had positive ARTSH, and the third had positive ATPO.

Conclusion

Our study reveals a prevalence of hypothyroidism in RA patients estimated at 17%, consistent with data in the literature. The most frequently observed symptoms were fatigue and hair loss. Thyroid monitoring is recommended, especially in cases with suggestive symptoms.

P905

GENDER DISPARITIES IN QUALITY OF LIFE IN RHEUMATOID ARTHRITIS

M. Dhifallah[1], S. Boussaid[1], S. Rahmouni[1], M. Abbes[1], K. Zouaoui[1], S. Rekik[1], H. Sahli[1]

[1]Rhumatology department, La Rabta Hospital, Tunis, Tunisia

Background/Aims: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatism in adults. Through chronic inflammation and joint deformities, RA leads to functional, socio-economic, and psychological consequences that can negatively impact the quality of life (QoL) of patients. **Objective**: To investigate whether there is a difference in the impact on QoL between male and female RA patients. **Methods:** We conducted a cross-sectional study including 60 patients diagnosed with RA according to the 2010 ACR-EULAR criteria. RA activity was assessed using the Disease Activity Score (DAS28). QoL was measured using the Short Form 36 (SF-36) score, a questionnaire with 36 items exploring eight dimensions: physical functioning (PF), role limitations due to physical health (RP), role limitations due to emotional problems (RE), vitality, emotional well-being, social functioning (SF), bodily pain, and general health perceptions. A score ranging from 0 to 100 was calculated, with a lower score indicating poorer QoL. **Results:** We included 60 RA patients: 40 women (F) with a mean age of 52.12±9.32 years and 20 men (M) with a mean age of 48.45±12.79 years. The age difference was not statistically significant (p=0.263). The average disease duration was longer in women (M: 7.55±6.43 vs F: 11.41±8.33 years, p=0.05). The DAS28 score was higher in men (M: 3.88±0.8 vs F: 3.46±0.89, p=0.314). Women had a significantly lower overall SF-36 score (M: 55.85±11.38 vs F: 44.63±9.27, p < 0.001). Men scored higher in physical functioning (M: 56.18±11.09 vs F: 46.65±10.79, p=0.003), role limitations due to physical health (M: 50.93±12.16 vs F: 44.71±9.39, p=0.002), vitality (M: 52.64±12.34 vs F: 42.86±9.95, p=0.002), role limitations due to emotional problems (M: 54.43±9.1 vs F: 44.63±9.66, p < 0.001), and social functioning (M: 54.34±8.61 vs F: 44.68±9.47, p < 0.001). No significant differences were noted between the two groups in emotional well-being (p=0.393), bodily pain (p=0.450), or general health perception (p=0.074). **Conclusion:** Our study highlighted a more pronounced decline in QoL among female RA patients, consistent with previous findings in the literature. These patients require more comprehensive and attentive management of the disease to ensure better QoL and, consequently, a more effective therapeutic response.

P906

RHEUMATOID CEREBRAL VASCULITIS : A SCARCE YET SERIOUS COMPLICATION

M. Dhifallah[1], S. Rekik[1], I. Jabrouni[1], M. Abbes[1], S. Rahmouni[1], K. Zouaoui[1], S. Boussaid[1], H. Sahli[1]

[1]Rhumatology department, La Rabta Hospital, Tunis, Tunisia

Background/Aims: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease that primarily affects the joints but can also involve various extra-articular organs, including the cardiovascular, pulmonary, and nervous systems. One of the rare but serious neurological complications of RA is rheumatoid cerebral vasculitis (CV), which occurs in a subset of patients, typically those with long-standing erosive seropositive disease. Rheumatoid CV is a potentially life-threatening condition characterized by inflammation and damage to the small and medium-sized vessels of the central nervous system, leading to a wide range of neurological symptoms.
Methods: Herein, we present a rare case of a cerebral vasculitis (CV) in patient with long standing RA managed using cyclophosphamide and steroids.
Results: Our patient is a 59-year-old female patient with a 20-year-history of erosive seropositive rheumatoid arthritis treated with methotrexate at a dose of 10 mg per week and a daily corticosteroid therapy of 5 mg prednisone. She complained of sudden onset severe headaches accompanied by persistent bilateral visual blurring for 15 days. Neurological examination did not reveal any meningeal signs. Temporal artery pulses were present. Fundoscopy showed no papillary edema. Joint examination revealed arthritis in both knees and synovitis of the bilateral 2nd and 3rd metacarpophalangeal joints. Biological work-up revealed elevated C-reactive protein (CRP) level of 57mg/L and erythrocyte sedimentation rate (ESR) levels of 135 mm/hour. Immunological assessment was positive for rheumatoid factor, anti-CCP antibodies, and antinuclear antibodies. Anti-DNA and anti-neutrophil cytoplasmic antibodies were negative. Serologies for human immunodeficiency virus, hepatitis B, and hepatitis C were negative. Magnetic resonance imaging showed dot-like areas of high-signal in a periventricular subcortical distribution on both sides consistent with vasculitis lesions. Based on these findings, the diagnosis of rheumatoid cerebral vasculitis was made. The patient was Pulse therapy with methylprednisolone (1g/d for 3 days) and cyclophosphamide (1 g) once a month. For her RA, methotrexate treatment was increased to 15 mg per week. We noted at 6-month follow-up disappearance of headaches, normalization of CRP to 2 mg/L and ESR to 39 mm/hour, and regression of supratentorial lesions on follow-up MRI.
Conclusion: CV tends to occur more often in patients with long-standing seropositive RA , as was the situation with our patient. The clinical manifestations of CV are diverse. Our patient experienced acute headache and blurred vision. Nevertheless, other symptoms can include hemiplegia, partial epilepsy, cranial nerve involvement, visual field loss, altered consciousness, confusion, and cognitive impairment or dementia.

P907

PRO-INFLAMMATORY CYTOKINES IN PSORIATIC ARTHRITIS AND THEIR IMPLICATION IN DISEASE ACTIVITY

M. Dhifallah[1], M. Slouma[1], L. Kharrat[1], A. Tezeghdenti[2], I. Gharsallah[1]

[1]Rheumatology department, Military Hospital of Tunis, Tunis, Tunisia, [2]Immunology department, Military Hospital of Tunis, Tunis, Tunisia

Background/Aims: Psoriatic arthritis (PsA) is a chronic immune-related inflammation that affects joints, enthesis, skin and nails. Its pathology is complex and implicates several cytokines. We aimed to determine the pro-inflammatory cytokines serum levels in psoriatic arthritis and their relationship to the disease activity.
Methods: We conducted a cross-sectional study that compared patients diagnosed with psoriatic arthritis (G1) according to the Assessment of SpondyloArthritis International Society (ASAS) and/Or ClASsification criteria for Psoriatic ARthritis (CASPAR) with a Control group (G0). Sociodemographic parameters were collected. Disease activity was assessed by using the Ankylosing Spondylitis Disease Activity Score (ASDAS) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). We measured serum levels of the following cytokines: interleukin17 (IL17), interleukin22 (IL22), interleukin1 (IL1), interleukin6 (IL6), interleukin23 (IL23), and Tumor Necrosis factor (TNFα).
Results: Each group included 31 patients. G1 had 21 men and 10 women and G2 had 24 men and 7 women. There was no significant age difference between the groups (G1= 47.29±15.55 vs 43.193±9.31 years, p=0,124). BASDAI and ASDAS mean scores were 3,72±1,96 and 2,91±1,41, respectively. The level of IL6 and TNF-α was higher in patients from G1 in comparison with G2 (serum concentration mean values of IL-6 were: G1=14,91 vs G2=1,96 pg/ml and TNF-α G1=20,45 vs G2=7,31 pg/ml. however, the results were not statistically significant (p> 0.05). The following interleukins were significantly higher in patients with PsA: IL1 (G1=5,75 vs G2=4,00 pg/ml, p=0.028), IL17 (G1=116,74 vs G2=1,08 pg/ml, p<0.000), IL22 (G1=47,12vs G2=10,63 pg/ml, p=0.001) and IL23 (G1=27,27 vs G2=1,59 pg/ml, p<0.000). We noted that BASDAI score was correlated to TNF-α serum level (r=0.543, p=0.016). ASDAS score was correlated with IL1 (r=0.448, p=0.048), IL6 (r=0.469, p=0.037), IL17 (r=0.451, p=0.046), and IL22 (r=0.464, p=0.039) serum levels.
Conclusion: In this study, we found that IL-1, IL-17, IL-22, and IL-23 levels were significantly higher in patients with psoriatic arthritis compared to controls. Additionally, disease activity scores (BASDAI and ASDAS) were correlated with the serum levels of TNF-α, IL-1, IL-6, IL-17, and IL-22. These results suggest that pro-inflammatory cytokines play a critical role in PsA and could serve as potential targets for disease management.

P908

NEUROPATHIC ARTHROPATHY OF THE KNEE AS A SEQUELA OF UNDIAGNOSED TERTIARY SYPHILIS

M. Dhifallah[1], S. Rekik[1], I. Jabrouni[1], M. Abbes[1], K. Zouaoui[1], S. Rahmouni[1], S. Boussaid[1], H. Sahli[1]

[1]Rhumatology department, La Rabta Hospital, Tunis, Tunisia

Background/Aims: Tabetic arthropathy is a neurogenic destructive condition secondary to infection by the treponema. It affects 4 to 10% of tabetics.
Methods: We report a new case of knee involvement in tertiary syphilis.
Results: A 53-year-old patient, with no medical history, was admitted for exploration of right knee pain with swelling evolving for 7 months, without history of trauma or fever. There was a history of untreated superficial and painless genital ulceration that appeared 20 years ago and multiple unprotected sexual intercourses. On examination, the right knee was swollen, painless, and without local inflammatory signs. Neurological examination revealed a peripheral neurogenic syndrome in both lower limbs (absent Achilles reflex on the right and decreased on the left) without posterior cord syndrome or pyramidal syndrome. Laboratory tests revealed lymphopenia at 1300 cells/mm3 and a mild biological inflammatory syndrome. Standard right knee radiograph showed internal femoro-tibial narrowing with osteolysis of the internal femoral condyle and medial edge of the internal tibial plateau, associated with multiple bone formations and intra-articular fragments. Knee computed tomography concluded a hypertrophic form of neurogenic osteoarthropathy. As part of the etiological investigation, craniospinal magnetic resonance imaging was normal. Syphilitic serology was positive with TPHA at 1/1280 and VDRL ++. Lumbar puncture revealed hyperproteinorrhea at 0.7g/L associated with a TPHA levels >1/64 and VDRL ++. Thus, the diagnosis was tabetic arthropathy of the right knee associated with neurosyphilis. The patient was treated with Penicillin G at a dose of 6 million units x 4/day intravenously for 15 days.
Conclusion: Tabes dorsalis, a late tertiary neurosyphilis manifestation, arises in 2%-9% of untreated cases. Tabetic arthropathy develops in 6%-10%, sometimes appearing three decades post-primary syphilis. Diagnosis often relies on radiological evidence alongside positive serological/spinal fluid tests.

P909

DIAGNOSTIC YIELD OF DISCO-VERTEBRAL BIOPSY IN INFECTIOUS SPONDYLODISCITIS

M. Dhifallah[1], M. Slouma[1], R. Battikh[2], I. Gharsallah[1]

[1]Rheumatology department, Military Hospital of Tunis, Tunis, Tunisia, [2]Infectiology department, Military Hospital of Tunis, Tunis, Tunisia

Background/Aims: Infectious spondylodiscitis (ISD) is a rare condition with an increasing incidence due to extended life expectancy, an increase in the susceptible population, and improvement in investigations. We aimed in this study to assess the contribution of disco-vertebral biopsy (DVB) in the etiologic diagnosis of ISD.
Methods: We conducted a retrospective descriptive study involving 80 patients diagnosed with infectious spondylodiscitis, all seen in a Rheumatology department over 7 years [2016-2023]. Epidemiological, clinical, biological, and anatomopathological data were collected.
Results: Our study included 80 patients with a mean age of 57.29 years ± 15.36 and a gender ratio (M/F) of 1. Comorbidities were present in 30 patients (37.5%) as follows: diabetes (n=30), hypertension (n=19), hemodialysis (n=7), cancer (n=6), and dyslipidemia (n=5). The average duration of symptom evolution was 2.75 months. Ninety-two percent of patients experienced spinal pain, 46% weight loss, 43% fever, 39% general weakness, and 37.5% anorexia. Raised inflammatory marker was seen in 76% of cases, with mean values of C-reactive protein and erythrocyte sedimentation rate at 77.35 ± 81.8 mg/l and 62.9 ± 33.9 mm, respectively. Disco-vertebral biopsy was performed in 22 cases. For other cases, the identification of the pathogen agent was made based on blood cultures (n=15), soft tissue (n=25) biopsy, and positive Wright serology (n=10). No germ was incriminated in 15 cases. Disco-vertebral biopsy was contributory in 68% of cases (n=15), revealing: giant-cell granuloma with caseous necrosis (41%,n=9), granulomatous reaction (9%,n=2), and non-specific inflammatory infiltrate (50%,n=11). DVBD allowed the identification of common pathogens in 3 patients (Staphylococcus, Streptococcus, Enterococcus) and the extraction of Brucella DNA through Polymerase Chain Reaction (PCR) in one patient.
Conclusion: Our study showed that DVB was necessary in only 72,5 % of cases when other investigations were non-conclusive. Despite its invasive nature, DVB contributed significantly to identifying the causative micro-organism of infectious spondylodiscitis and aids in guiding effective therapeutic management.

P910

TELEWORKING VS. ON-SITE WORK: INSIGHTS INTO THE PREVALENCE AND SEVERITY OF MUSCULOSKELETAL DISORDERS

S. Bouden[1], M. Dhifallah[1], L. Rouached[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Rheumatology department, Charles Nicolle Hospital, Tunis, Tunisia

Background
Musculoskeletal disorders (MSDs) are a prevalent occupational health issue, further intensified during the COVID-19 pandemic due to the rapid shift to teleworking [1]. This change in work environments has raised concerns about its impact on employee health.
Objectives
This study aimed to evaluate the prevalence of MSDs among employees during teleworking and on-site work and to compare the intensity of these disorders between the two work settings.
Methods
Data collection was performed using an online questionnaire distributed via Google Forms. Participants included employees who

had experience in both on-site work and teleworking. Key variables included demographic characteristics, work duration, frequency and length of breaks, and device usage. The validated French version of the Nordic Musculoskeletal Questionnaire (NMQ) was employed to assess the presence and impact of MSDs [2].

Results

A total of 145 employees participated in the study. The sex ratio was 1.01 (73 males/72 females), with an average age of 33 ± 8 years. Participants had been working at their company for an average of 7 ± 6.5 years. The mean duration of telework experience was 16±14 months.

Regarding work schedule, employees reported an average of 7±1 hours of daily work in both settings, with 72% working 5 days per week on-site and 65% working 5 days per week during teleworking. The average daily break time was 73±39 minutes on-site and 79±10 minutes during telework. Most participants used a laptop for work (88% on-site; 90% during telework).

During on-site work, 75% of participants (n=108) reported MSDs. The most affected regions were the lower back (64%, pain level 5±3), upper back (63%, pain level 4±3), and neck (60%, pain level 5±3). While during teleworking, 90% of participants (n=130) reported MSDs. The most affected regions were the lower back (78%, pain level 5±3), upper back (68%, pain level 4±3), and neck (69%, pain level 4±3).

The prevalence of MSDs was statistically higher during teleworking than during on-site work (p=0.04), particularly regarding the lower back (p=0.03), hips (p=0.001) and ankles (p=0.04).

Conclusions

The prevalence and intensity of MSDs were significantly higher during teleworking compared to on-site work. These findings highlight the need for targeted interventions, including ergonomic adaptations and education on healthy work practices, to mitigate the risk of MSDs in teleworking environments.

P911

IMPACT OF TELEWORKING ON THE PREVALENCE AND RISK FACTORS OF MUSCULOSKELETAL DISORDERS

M. Dhifallah[1], S. Bouden[1], L. Rouached[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Rheumatology department, Charles Nicolle Hospital, Tunis, Tunisia

Background

The incidence of musculoskeletal disorders (MSDs) in the workplace has significantly increased in recent years, particularly with the widespread adoption of teleworking. This shift, accelerated by events such as the COVID-19 pandemic, has raised concerns about the ergonomic and health implications of remote work environments [1,2].

Objectives

This study aimed to evaluate the prevalence of MSDs among employees during teleworking, identify associated risk factors, and assess the impact of work conditions on these disorders.

Methods

Data collection was performed using an online questionnaire distributed via Google Forms. Participants included employees who had experience in both on-site work and teleworking. Key variables included demographic characteristics, work duration, frequency and length of breaks, and perceived stress levels. The validated French version of the Nordic Musculoskeletal Questionnaire (NMQ) was employed to assess the presence and impact of MSDs.

Results

A total of 145 employees participated in the study. The sex ratio was 1.01 (73 males/72 females), with an average age of 33±8 years. Participants had been working at their company for an average of 7±6.5 years, with a mean telework duration of 16±14 months. During teleworking, employees reported an average of 7±1 hours of daily work, with 65% working 5 days per week. The average daily break time was 79±10 minutes. 90% of teleworkers used a laptop, with 70% for 6 hours or more per day. The average perceived stress level among teleworkers was 5±2.

MSDs were reported by 90% of teleworkers (n=130). The most affected regions were the lower back (78%, pain level 5±3), upper back (68%, pain level 4±3), and neck (69%, pain level 4±3). The prevalence of MSDs during teleworking was influenced by the total duration of teleworking (p=0.01), the number of breaks (p=0.01), the break duration per day (p=0.03), the time spent on a laptop (p=0.01) and the perceived stress levels (p=0.001).

Conclusions

The findings demonstrate a high prevalence of MSDs during teleworking, with significant associations with work habits, stress, and ergonomic factors. These results underscore the need for targeted interventions, including ergonomic adjustments, structured breaks, and stress management strategies, to mitigate the risks of MSDs in teleworking environments.

DIABETIC BONE PARADOX AND PREVALENT VERTEBRAL FRACTURES: A CROSS-SECTIONAL STUDY OF 504 HIP-FRACTURE WOMEN

M. Di Monaco[1], C. Castiglioni[1], F. Bardesono[1], M. A. Minetto[2], C. Busso[2], G. Massazza[2]

[1]Osteoporosis Research Center, Division of Physical and Rehabilitation Medicine, Presidio Sanitario San Camillo, Torino, Italy, [2]Division of Physical and Rehabilitation Medicine, Department of Surgical Sciences, University of Turin, Torino, Italy

OBJECTIVE. Hip fractures occur at higher BMD in the women with type 2 diabetes mellitus (T2DM) than in controls, consistently with the diabetic bone paradox, i.e., high risk of fracture despite high bone mineral density (BMD). However, no studies have addressed BMD in women with T2DM who have prevalent vertebral fractures at the time of their first hip fracture. We aimed to test the hypothesis that BMD levels could be higher in the hip-fracture women with versus without T2DM in the absence but not in the presence of prevalent vertebral fractures.
MATERIAL AND METHODS. We investigated 504 hip-fracture women with and without prevalent vertebral fractures. At a median of 19 days after the hip fracture we assessed femoral BMD by dual-energy x-ray absorptiometry and prevalent vertebral fractures by x-ray examination.
RESULTS. The 185 women without vertebral fractures had BMD higher in the presence (N=29) than in the absence (N=156) of T2DM (mean T-score difference was 0.67, 95% CI from 0.31 to 1.03, P<0.001). After adjustment for 8 potential confounders, the odds ratio to have densitometric osteoporosis for a woman without T2DM was 3.21 (95% CI from 1.10 to 9.33, P=0.032). On the contrary, in the 319 women with vertebral fractures T2DM was not associated with BMD.
CONCLUSIONS. At the time of an original hip fracture, we found a BMD gap between women with and without T2DM in the absence but not in the presence of prevalent vertebral fractures. Adjustments of fracture risk calculation in T2DM have been authoritatively suggested, because high BMD levels may falsely lead to risk underestimation. Our data suggests that no adjustments may be needed for the risk estimation in patients with prevalent vertebral fractures. Further data from longitudinal studies are needed to define the role of both prevalent vertebral fractures and BMD in fracture risk of patients with T2DM.

P913

FALLS EFFICACY BUT NOT FEAR OF FALLING AFFECTS THE FUNCTIONAL RECOVERY AFTER HIP FRACTURE: A SHORT-TERM PROSPECTIVE SYUDY

M. Di Monaco[1], C. Castiglioni[1], F. Bardesono[1], E. De Toma[2], C. Busso[3], G. Massazza[3], M. A. Minetto[3]

[1]Osteoporosis Research Center, Division of Physical and Rehabilitation Medicine, Presidio Sanitario San Camillo, Torino, Italy, [2]Service of Occupational Therapy, Division of Physical and Rehabilitation Medicine, Presidio Sanitario San Camillo, Torino, Italy, [3]Division of Physical and Rehabilitation Medicine, Department of Surgical Sciences, University of Turin, Torino, Italy

OBJECTIVE. To assess the role of falls efficacy (one's perceived ability to undertake activities without falling) and its independence from fear of falling assessed by a single question in affecting the functional recovery after a fall-related hip fracture.
MATERIAL AND METHODS. We focused on inpatients admitted to our rehabilitation ward after a fall-related fracture of the hip. Falls efficacy in various activities of daily living was assessed at rehabilitation admission by using the Falls Efficacy Scale International (FES-I, full version with 16 items), whereas fear of falling (FoF) was investigated by a 4-level single question ("Are you afraid of falling?"). At the end of the subacute rehabilitation course, we measured functional independence by using the Barthel index. Successful rehabilitation was defined with a Barthel index score ≥ 85. The patients with cognitive impairment on the Short Portable Mental Status Questionnaire were excluded from the study.
RESULTS. The study sample included 186 consecutive inpatients. At bivariate analysis, a significant inverse correlation was found between FES-I scores assessed on admission to rehabilitation and Barthel index scores evaluated at rehabilitation discharge: r=-0.248; P=0.001. The significant association between FES-I and Barthel index scores persisted after adjustment for 9 variables: age, sex, hip-fracture type, 25-hydroxyvitamin D, prevalent neurologic impairment, concomitant upper limb fractures, pressure ulcers, pre-fracture Barthel index, and FoF (P<0.001). For the patients with a low FES-I score (< 50th percentile) the adjusted odds ratio for achieving successful rehabilitation was 4.24 (95% CI from 1.75 to 10.25, P=0.001) versus the patients with FES-I scores ≥ 50th percentile.
CONCLUSIONS. Falls efficacy investigated by FES-I, but not fear of falling, significantly affects the functional recovery following a fall-related fracture of the hip and should be routinely assessed in the subacute setting.

P914

UNVEILING A RARE GENETIC ANOMALY: NEW MUTATION IN ACRO-DENTO-OSTEO DYSPLASIA LINKED TO HAJDU-CHENEY SYNDROME

C. Marques-Gomes[1], M. Diz-Lopes[1], L. Costa[1], M. Bernardes[1]

[1]Rheumatology Department, ULS São João, Porto, Portugal

Introduction:
Hajdu-Cheney syndrome (acro-dento-osteo-dysplasia syndrome), is a rare genetic disorder whose prevalence is less than one person in one million.

Presentation:
A 20-years-old man presented with a 2-years history of bone fractures, both high and low impact (metacarpals and distal phalanges of hands), and of maxillary bone resorption after tooth extraction. Anamnesis was negative for inflammatory rheumatic disease. Past medical history included hear surgery due to hearing loss and chronic snoring with diagnosis of sleep apnea at the age of 11 (from ages 11 to 13, the patient used a device to widen the palate). There was no relevant family history. He had coarse voice, retrognathia, downslated palpebral fissures, long philtrum, full cheek, hypertelorism and digital pseudoclubbing, without peripheral arthritis. Blood and urine tests were normal. Radiological examination showed band osteolysis in the 2nd distal phalanges of both hands, acroosteolysis of all distal phalanges in the hands and feet, erosions in the first metatarsophalangeal joint and osteosynthesis material in 2ndand 5th metacarpals (Fig. 1). DXA detected low vertebral bone mineral density (*Z-Score*: -2,85 SD). A congenital osteolysis syndrome was suspected. The genetic study detected a mutation not previously described in the NOTCH2 gene [variant c.6596dup, P.(Ser22001lefs*4)] which it would be expected to have a deleterious impact. Considering all the findings, the diagnosis of Hajdu-Cheney syndrome was made. Treatment with zoledronic acid (5 mg intravenous, annually) was started. Currently, he has received two infusions of zoledronic acid and we did not observed new bone fractures.

Fig. 1 – Hands (A) and feet (B) radiographic images showing band osteolysis in the 2nd distal phalanges of both hands, acroosteolysis of all distal phalanges in the hands and feet, erosions in the first metatarsophalangeal joint and osteosynthesis material in 2nd and 5th metacarpals.

Discussion:
HCS is characterized by generalized osteoporosis and focal bone loss (acro-osteolysis and dental). It is associated with cranial, facial, musculoskeletal and, sometimes, cardiovascular alterations. According to *ORPHANET*, less then 100 cases are registered. Clinical presentation varies from early infancy to late adulthood, worsening over time because of its age-dependent evolution. Bone fragility is an important issue in management comorbidities. Anti-resorptive treatment (bisphosphonates) may offer a beneficial option to treat osteoporosis and prevent new bone fractures. As this disease is particularly rare, the accumulation of clinical reports is extremely important. We report the second case of HCS in Portugal with a new mutation which has not been previously identified.

LONG-TERM FRACTURE INCIDENCE AND PREDICTORS IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS: DATA FROM REUMA.PT

M. Diz-Lopes[1], B. Fernandes[2], C. Marques Gomes[1], T. Martins Rocha[1], M. Correia Natal[1], B. Esteves[1], I. Almeida[3], M. Sebastião[4], M. Bernardes[1], L. Costa[1]

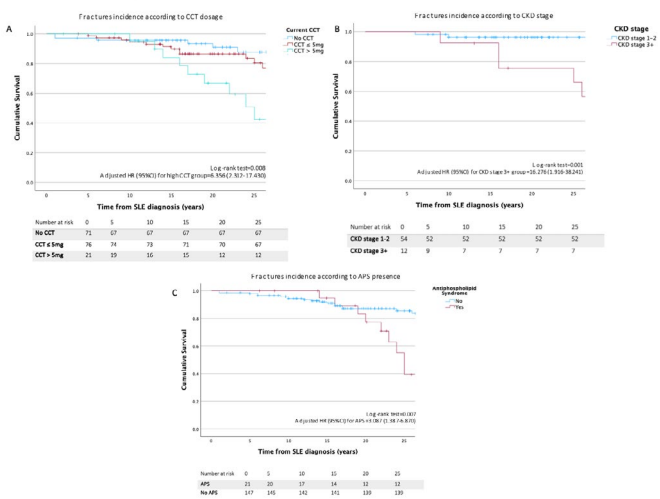
[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal, [2]Nephrology Department, Unidade Local de Saúde de São João, Porto, Portugal, [3]Rheumatology Unit, Unidade Local de Saúde de Viseu Dão-Lafões, Viseu, Portugal, [4]Rheumatology Department, Hospital do Divino Espírito Santo, Ponta Delgada, Ponta Delgada, Portugal

Objectives:
Patients with systemic lupus erythematous (SLE) have an increased bone fragility and fracture risk. We aimed to study the prevalence and risk factors for fractures in a portuguese population with SLE.

Methods:
Retrospective single-center study including patients with SLE diagnosis according to the 2019 EULAR/ACR classification criteria extracted from Reuma.pt/SLE (portuguese national registry). Patients were excluded if they were lost to follow-up for reasons other than death. Vertebral radiographies and clinical registries were reviewed for fractures.

Results:
A total of 170 patients with SLE were included, mostly female (n=156, 75%). Mean age at diagnosis was 32.1±13.5 years old, median follow-up time was 22 (15.4-30.2) years, and the mean current age was 54.1 ±12.6 years old. Current corticosteroid (CCT) dosage was 2.5 (0-5.0) mg prednisolone equivalent, 84 (49.4%) patients were currently taking classic disease modifying rheumatic drugs (DMARDs) and 24 (14.1%) biologic DMARDs. A total of 71 patients (34.1%) were no longer under CCT. Thirty-three (15.9%) fractures occurred during follow-up, 23 (11.1%) patients had densitometric osteoporosis and 30 (17.6%) were under anti-osteoporotic treatment.
Patients who sustained fractures were older (p=<0.001), had more frequent hypertension (p=0.003), diabetes (p=0.011) and antiphospholipid syndrome (APS, p=0.017). Most women with fractures were post-menopausal (n=26, 81.3%). The current CCT dosage was higher in patients with fractures (p=<0.001). The occurrence of major cardiovascular events (p=0.048) and death (p=0.008) were also more prevalent in the fractures group. Amongst patients with renal involvement, a chronic kidney disease (CKD) stage ≥ 3 was associated with fractures (p<0.001).
In the survival analysis, patients under a CCT dosage > 5mg, lupus nephritis with CKD stage ≥3 and patients with associated antiphospholipid syndrome had a significantly higher incidence of fractures during follow-up (Figure 1). When adjusting for current age, lupus nephritis CKD stage ≥ 3 (HR 16.276 CI 95% 1.916-38.241, p=0.011), higher corticosteroids dosage (HR 6.356 CI 95% 2.312-17.430, p=<0.001), the presence of densitometric osteoporosis (HR 2.406 CI 95% 1.042-5.553, p=0.040) and APS (HR 3.087 CI 95% 1.387-6.870, p=0.006) independently predicted the occurrence of fractures during follow-up.

Figure 1 - Fracture survival analysis according to (A) CCT dosage, (B) CKD stage, (C) APS presence



Footnote: CCT – corticosteroids; SLE – systemic lupus erythematous; HR – hazard ration; CKD – chronic kidney disease; APS – antiphaspholid syndrome

Discussion:
SLE lupus nephritis patients with worse renal function, with concurrent antiphospholipid syndrome and under prednisolone >5mg/daily appear to be particularly at high-risk for fractures and may warrant an earlier and more vigilant fracture prevention strategy.

P916

FRACTURE INCIDENCE AND RISK FACTORS IN PERITONEAL DIALYSIS PATIENTS

M. Diz-Lopes[1], B. Fernandes[2], T. Martins Rocha[1], L. Costa[1], A. Oliveira[2], A. Beco[2], R. Neto[2], J. Frazao[2]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal, [2]Nephrology Department, Unidade Local de Saúde de São João, Porto, Portugal

Objectives:
Predicting fracture risk in chronic kidney disease (CKD) patients is still a challenge in clinical practice. Particularly in peritoneal dialysis (PD), there is scarce evidence about fracture incidence and risk. The aim of this study was to evaluate the incidence of fractures in a cohort of PD patients and its association with risk factors.

Materials and Methods:
This was an observational, retrospective, single-center study of a cohort that received PD for a period ≥ 12 months. Patients were excluded if they received hemodialysis and/or had renal transplantation before the period of PD. Data from yearly blood tests and clinical evident fractures were collected. FRAX was calculated with the *web-based* FRAX tool including CKD as secondary osteoporosis. Radiographies of the thoracic and/or lumbar spine were evaluated for vertebral fractures.

Results:
A total of 184 patients were included with a median PD vintage of 43 (26-66.8) months. Mean age at the beginning of PD was 52.7 (14.3) years and 51.1% (n=94) were males. Twenty-two (12%) fractures were identified (incidence rate of 33/1000 patient-year). Patients with fractures during follow-up were older (p<0.001), had longer PD vintage (p=0.021), had a lower body mass index (BMI) (p=0.009), and more incidence of previous fractures (p=0.007). Additionally, they had lower (but normal) phosphorus levels (p<0.001) and lower parathyroid hormone (PTH) levels (p=0.019), with more patients in the group with PTH levels ≤ 150pg/mL (p=0.038). The vascular calcification score (VCS, Adragao) was higher in patients with fractures (p=0.007). During follow-up, patients with fractures had a higher death rate (p=0.022). FRAX was significantly higher in the group with fractures, with 4 (26.7%) of the patients with a high fracture risk (p=0.040). Area under the curve for major fracture risk was 0.755 (95% CI 0.651-0.858).
When adjusting for the existence of previous fractures (the factor with most impact in the outcome), older age, time on PD, lower BMI, lower PTH, and higher FRAX score independently predicted the occurrence of fractures (table 1). VCS also increased the odds of sustaining a fracture, but this did not achieve significance.

Table 1 - Regression models for outcome variable (Fractures, n=22)

	Univariate logistic regression				Multivariate logistic regression			
Parameters	OR	OR lower 95% CI	OR upper 95% CI	p-value	OR	OR lower 95% CI	OR upper 95% CI	p-value
Age	1.047	1.012	1.084	0.009*	1.038	1.002	1.076	0.038*
PD vintage (months)	1.013	1.001	1.026	0.034*	1.016	1.004	1.029	0.011*
BMI	0.928	0.876	0.980	0.008*	0.925	0.874	0.979	0.007*
Previous fracture	7.598	2.095	27.551	0.002*	--	--	--	--
PTH	0.996	0.993	0.999	0.010*	0.997	0.994	1.000	0.036*
PTH (≤150 vs >300pg/mL)	5.862	1.255	27.368	0.024*	5.075	1.017	25.327	0.048*
Phosphorus	0.451	0.254	0.804	0.007*	0.501	0.279	0.909	0.023*

VCS (≥3)	2.512	0.993	6.358	0.052*	2.148	0.814	5.671	0.123
FRAX without BMD for major fracture	1.001	1.000	1.002	0.019*	0.019	1.001	1.003	0.012*
FRAX without BMD for hip fracture	1.001	1.000	1.002	0.006*	1.002	1.001	1.003	0.004*

Footnote: *statistically significant, p<0.05; **adjusted for previous fracture
PD: peritoneal dialysis; PTH: parathyroid hormone; VCS: vascular calcification score; FRAX: Fracture risk assessment; BMD: bone mineral density; OR: odds ratio; CI: confidence interval

Discussion:
In this young and equally sex-distributed cohort of PD patients, fracture incidence was high, and its risk increased with age, PD vintage and PTH levels ≤150pg/mL. FRAX had a good performance in predicting fractures.

P917

SARCOPENIA PREDICTS POORER MOBILITY AFTER HOSPITALIZATION WITH A FRAGILITY HIP FRACTURE

M. Diz-Lopes[1], G. Terroso[1], C. Marques Gomes[1], C. Vaz[1], E. Costa-Maia[1], F. Silva[1], T. Martins Rocha[1], L. Costa[1]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal

Objectives
Sarcopenia and osteoporosis are associated with aging and represent a major health burden, leading to poor functional outcomes and death. We aimed to study the prevalence of sarcopenia after a fragility hip fracture and its association with mobility (elderly mobility scale – EMI), quality of life (Health Assessment Questionnaire – HAQ and EQ5D) and death.

Material and Methods
Cross-sectional single-center study including patients ≥ 50 years old with a fragility hip fracture registered in the portuguese national registry of rheumatic patients (reuma.pt), integrated in the Fracture Liasion Service, with an evaluation of hand-grip strength, anthropometry (calf circumference – CC or mid-upper arm circumference - MUAM), EMI, HAQ and EQ5D in up to 6 months after the fracture. Sarcopenia was diagnosed when low grip strength and low muscle quantity were present.

Results
172 patients were included, mostly female (n= 139, 80.8%) and with a current age of 70 (2.83) years old. All patients were hospitalized after the fracture and 72.7% of the surgeries occurred in the first 48h. After discharge, 42 (24.4%) patients were referred to nursing homes. Half of the patients (n=88) performed physical rehabilitation after discharge and 2 patients died. Low muscle strength was present in 77 (44.8%) patients. According to anthropometry, 96 (55.8%) patients had low muscle quantity. A diagnosis of sarcopenia was made in 60 (34.9%) patients.
Sarcopenia was associated with older age (p=0.036), lower body mass index (p=0.001), lower EMI score, with more patients included in the worst mobility category (43.3% vs 24.1%, p=0.015) and higher disability according to HAQ (p=0.017, table 1). There was no association with death.
In the multiple linear regression, sarcopenia was an independent predictor of poorer mobility. Having sarcopenia represented a score of less -2.640 points in EMI (-4.604; -0.675, p=0.009), regardless of current age, being discharged to a nursing home or having performed physical rehabilitation post hip fracture.

Table 1 - Comparative analysis of the patients with and without sarcopenia

Variables	Sarcopenia (low muscle strength and quantity**)		
	Sarcopenia N=60	No sarcopenia N=112	p-value
Age (years), mean (SD)	81 (74.5-85)	78 (73.5-83.5)	0.036*
Female, n (%)	48 (80)	91 (81.3)	0.843
Current smoker, n (%)	1 (1.7)	4 (3.6)	0.738
Alcohol consumption, n (%)	7 (12.1)	14 (12.5)	0.434
BMI, kg/m2, median (IQR)	21.3 (19.4-25.6)	27.1 (23.6-29.3)	<0.001*

Elderly mobility scale category, n (%)			0.015*
Good	21 (35)	63 (56.3)	
Intermedium	13 (21.7)	22 (19.6)	
Bad	26 (43.3)	27 (24.1)	
HAQ, median (IQR)	2.063 (1.563-2.531)	1.750 (0.968-2.250)	0.017*
EQ5D, median (IQR)	0.288 (0.125-0.406)	0.325 (0.288-0.657)	0.070
Previous fracture, n (%)	27 (45)	65 (59.6)	0.068
Time of the surgery after current fracture, n (%)			0.902
First 48h	42 (85.7)	83 (86.5)	
After 48h	7 (14.3)	13 (13.5)	
Physical rehabilitation after current fracture, n (%)	30 (56.6)	58 (58)	0.868
After discharge, n (%)			0.298
Home	36 (67.9)	36 (67.9)	
Nursing home	17 (32.1)	17 (40.5)	
DXA results (after fracture), n (%)			
BMD femur neck	0.729 (0.562-0.756)	0.669 (0.612-0.767)	0.389
T-Score femur neck	-2.2 (-3.550;-1.900)	-2.6 (-3.150;-1.800)	0.635
Visual acuity problems, n (%)	28 (46.7)	51 (45.5)	0.887
Audition problems, n (%)	31 (51.7)	41 (36.6)	0.055
Physical exercise, current, n (%)	29 (25.9)	9 (15)	0.101
Death, (%)	1 (1.7)	1 (0.9)	0.577

Footnote:
** low muscle strength defined as grip strength <27kg men; <16kg women; low muscle quantity defined as calf circumference <31cm and/or mid-upper arm circumference ≤28.6 cm men and ≤27.5 women). Diagnosis of sarcopenia according to EWGSOP2 definition.
*Statistically significant, p<0.05

Conclusions
The diagnosis of sarcopenia after a fragility hip fracture was associated with poorer mobility in the 6 months after the hospitalization and thus could be useful for predicting prognosis in this population.

P918

FRACTURE RISK EVALUATION IN BREAST CANCER WOMEN UNDER HORMONOTHERAPY IN A SPECIALIZED RHEUMATOLOGY-ONCOLOGY CONSULTATION

M. Diz-Lopes[1], M. Correia Natal[1], T. Martins Rocha[1], G. Terroso[1], L. Costa[1]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal

Objectives: Breast cancer (BC) and hormonotherapy (HT) represent a risk factor for bone loss and fractures. A vigilant strategy for these women is necessary to provide a structured primary prevention of fractures. We aimed to describe bone health status and interventions in a specialized consultation.
Material and Methods: Retrospective study including consecutive women with breast cancer under HT referred to a specific Rheumatology-Oncology consultation in the last 2 years. Clinical, radiographic, and dual x-ray absorptiometry (DXA) data was collected.

Results:
A total of 100 women were evaluated. Of these, 61 had high fracture risk according to European Society for Medical Oncology (ESMO) clinical practice guidelines. Mean age was 60 (10.2) years old and 96.7% women were post-menopausal, with 21.3% presenting early menopause. Before referral, 9 (14.8%) patients had clinical fractures and 4 (6.6%) had asymptomatic vertebral fractures. Most patients (n=39, 62.9%) were under aromatase inhibitors (AI) therapy, 5 (8.2%) with tamoxifen + goserreline and 13 (21.3%) transitioned from tamoxifen to AI. The median duration of HT before referral was 4 (1-5.5) years and, additionally, 83.6% of the patients had chemotherapy and 77% radiotherapy.
DXA before starting HT was obtained in 65.6% of the patients and, during HT, 86.9% women had a DXA performed. When comparing the DXA results (before and during HT treatment), there was a significant loss of femoral neck bone mineral density (BMD) (p=0.001) and lumbar BMD (p=0.001), with a median of 3 (2-5.5) years between DXAs (table 1).
Of the 61 patients with indication for fracture prevention treatment, only 12 (19.4%) were under anti-osteoporotic treatment before referral, and treatment was started in a total of 44 women (72.1%), mainly with zoledronate 4mg (49.2%) and denosumab 60mg (19.7%), both every 6 months.

Table 1 – Comparison of dual x-ray absorptiometry (DXA) scan results before and during hormonotherapy using Wilcoxon signed-rank test (median time between DXA scan 3 (2-5.5) years)

Dual x-ray absorptiometry (DXA) scan	Before starting HT	During HT	p-value
FN T-Score	-1.3 (-2;-0.7)	-1.8 (-2.3;-1.3)	0.001*
FN BMD	0.815 (0.727-0.884)	0.776 (0.700-0.836)	0.015*
Lumbar T-Score	-2.1 (-2.6;-1.4)	-2.4 (-2.8;-2.1)	0.001*
Lumbar BMD	0.931 (0.868-1.01)	0.892 (0.837-0.917)	0.001*

Footnote: HT – hormonotherapy; FN – femoral neck; BMD – bone mineral density
*p<0.05 considered statistically significant

Conclusion:
In our center, a structured evaluation of women with BC under HT identified most as having an indication for treatment and allowed treatment to be started. Future studies evaluating the follow-up of these women is needed to reflect the treatment effect.
Acknowledgments: *these authors contributed equally to this work

BONE MINERAL DENSITY AND BODY COMPOSITION IN PATIENTS WITH VARIOUS CAUSES OF CHILDHOOD GROWTH HORMONE DEFICIENCY (COGHD) AFTER COMPLETION OF GROWTH

M. Doknic[1], M. Stojanovic[1], T. Milenkovic[2], S. Todorovic[2], V. Zdravkovic[3], M. Jesic[3], M. Curcic[4], S. Pekic Djurdjevic[1], D. Miljic[1], M. Nikolic Djurovic[1], I. Cekic[1], I. Jevtic[1], Z. Jemuovic[1], I. Soldatovic[5]

[1]Neuroendocrine Department, Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Belgrade, Serbia, [2]Mother and Child Health Care Institute of Serbia "Dr Vukan Cupic", Belgrade, Serbia, [3]University Children's Clinic, Belgrade, Serbia, [4]Medical Faculty, University of Belgrade, Belgrade, Serbia, [5]Institute of Medical Statistics and Informatics, Belgrade, Serbia

Introduction: Patients with COGHD represent a heterogeneous group in many respect, preferably due to different causes of this hormone deficiency. Studies are inconsistent in relation to bone mineral density (BMD) and body composition (BC) of these subjects.
Aim: To investigate the influence of the etiology of COGHD on bone mineral density and body composition of patients after completion of growth in transition period.
Patients and Methods: In a monocentric, observational, retrospective cross-sectional study, we investigated 298 COGHD patients (16-25 years old, mean age 19.1±2.5 years, 193 males) at first evaluation after transfer from pediatrics to the adult department. Sixty subjects experienced childhood-onset endocranial tumor (TUM, 20.1%). Other patients had congenital (CON, 57.8%) or idiopathic COGHD (IDI 21.2%). Cross-sectional analyisis of BC and BMD were performed in these patients.
Results: The three observed etiological groups did not differ according to body weight, body height, BMI and waist/hip ratio (p>0.05**).** TUM patients had significantly lower BMD (g/cm^2) and Z-sc at spine (P < 0.05) compared to CON and IDI subjects after the transfer to adult department. IDI patients showed **higher muscle mass (45.9±**9.4kg) compared to the CONG (40.4**±**8.1 **kg) and TUM (44±**8.0kg) groups, but not significantly (P <0.05). IDI demonstrated lower fat mass (14.4±6.8kg) compared to TUM (32.4±6.2%; 17.3±6.8kg) and CON (26.9±7.2 **%; 20.4±**9.2 **kg) groups (**P < 0.05).
Conclusion: The etiology of COGHD has been shown to be an important factor in bone mass and body composition after the end of growth in the transitional period. We have shown that patients with tumor-induced GHD have an unfavorable BC, with a susceptibility to lower BMD, and therefore a risk of bone fracture.

P920

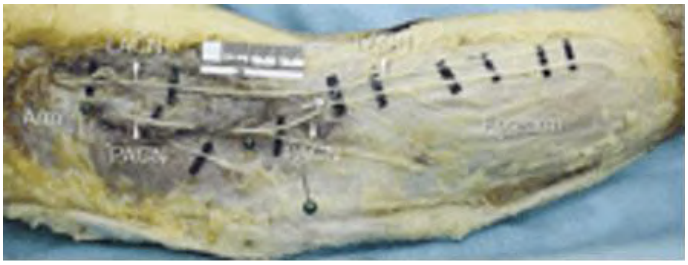
POSTERIOR ANTEBRACHIAL CUTANEOUS NERVE (PACN) INFILTRATION FOR THE TREATMENT OF LATERAL EPICONDYLITIS A PROSPECTIVE OBSERVATIONAL STUDY

M. E. Garcia Retegui[1], E. Lodoso Ochoa[1], P. Plou Garcia[1], N. De la Puente Vitini[1], B. Mugabure Bujedo[1], R. Agudo Bozal[1], I. Diez Hernandez[1], C. Yarnoz Ruiz[1], A. Osorio Lopez[1], M. Castaño Coedo[1]

[1]Hospital Donostia, San Sebastián , Spain

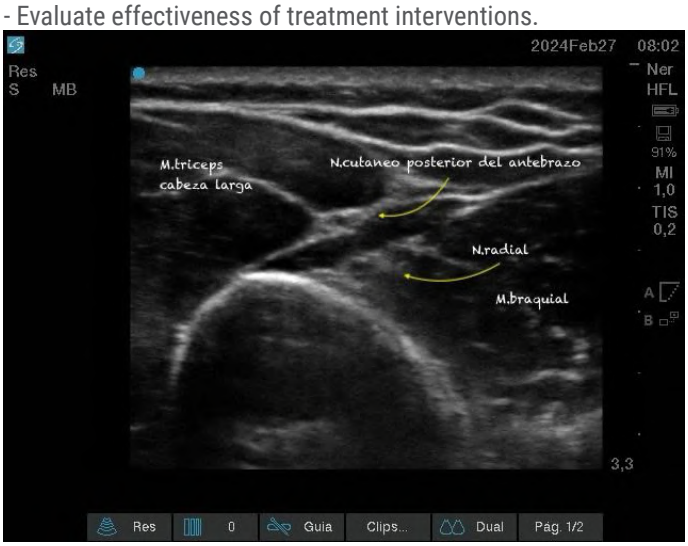
Introduction
Lateral epicondylitis (LE) is the most common cause of lateral elbow pain (incidence of 4-7 per 1000 person-years). It is common in athletes and manual workers. It often results in functional impotence, and its diagnosis is mainly clinical. The posterior antebrachial cutaneous nerve (PACN) is a sensory branch of the radial nerve that innervates the lateral epicondyle and the dorsal area of the forearm. It originates from the radial nerve distal to the spiroid fossa of the humerus and proximal to the lateral intermuscular septum. It

courses posterolaterally until it penetrates into the subcutaneous tissue to innervate the lateral epicondyle.



Objectives

Based on existing literature, we performed ultrasound-guided infiltration of the PACN in patients with clinical and physical examination compatible with LE:
- To assess the reliability of ultrasound as an imaging method to identify the nerve and guide the therapeutic intervention.
- Evaluate effectiveness of treatment interventions.



Material and Methods

We recruited 14 patients diagnosed of Lateral Epycondylitis, with VAS>4 (average-VAS: 6.9) and functional limitation.

1st visit:

- Ultrasound-guided infiltration of the PACN using bupivacaine 15 mgs and betamethasone 6mg. Effectiveness by physical examination and VAS scale at 30 min.

4th folowing up:

- VAS<4: We repeated the infiltration if reported persistent functional limitation and mild to moderate pain.
- VAS>4: We associated RFP 42º, 6min, prior to infiltration, in patients who reported persistent functional limitation and moderate to severe pain.

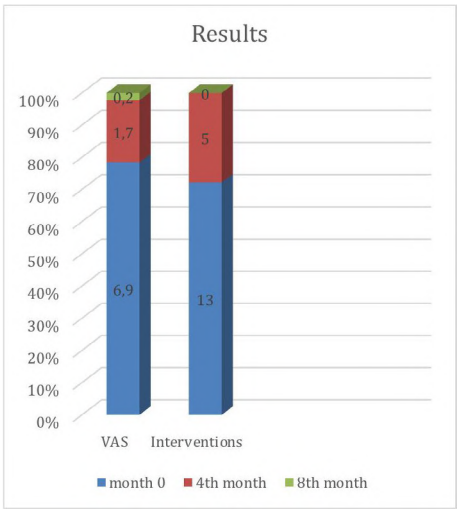
We completed the **8-month follow-up.**

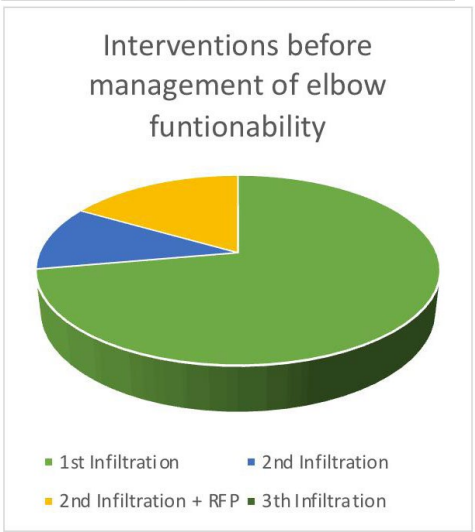
Results

Ultrasound localisation of the PACN was possible and reliable in all cases (P 5/5).

PACN blockade was effective after 30 minutes in 100% of cases (VAS 0).

Eight patients did not require further interventions, two required new infiltration at 4º months, and three patients needed RFP plus nerve infiltration.





** One patient was excluded (post-infiltration anxiety crisis).

Conclusions:

High-resolution ultrasound is useful to identify small nerves and guide perineural procedures effectively. Therapeutic procedures targeting the PACN could establish an effective line of treatment for pain secondary to LE. Further studies will be necessary to obtain more evidence in the treatment of pain secondary to LE.

UNCOMMON PRESENTATION OF MONOSTOTIC FEMORAL PAGET'S DISEASE

M. E. Santos[1], S. D. Rodrigues[1], A. C. Moniz[1], D. Melim[2], T. Saldanha[3], M. Costa[1], J. C. Branco[1], A. Sepriano[1]

[1]1Rheumatology Department, Unidade Local de Saúde de Lisboa Ocidental - Hospital de Egas Moniz, Lisbon, Portugal, [2]3Rheumatology Department, Centro Hospitalar do Funchal, Serviço de Saúde da Região Autónoma da Madeira, Funchal, Portugal, [3]4Radiology Department, Unidade Local de Saúde de Lisboa Ocidental – Hospital Egas Moniz, Lisboa, Portugal

Introduction: Paget's disease of bone (PDB) is a chronic skeletal disorder characterized by disorganized bone remodeling, leading to structural abnormalities and increased fragility. Diagnosis combines clinical, analytical, and radiographic findings. Monostotic PDB is rare (10–20%), and femoral involvement typically occurs proximally. Distal femoral involvement is atypical, often mimicking malignancy or infection. (1) Progression to sarcoma is a rare complication (<1%).

Case Description: A 70-year-old male hospitalized for subependymoma excision at neurosurgery department reported recent-onset left knee pain, leading to a rheumatology evaluation. Examination revealed firm swelling over the medial aspect of the left knee without effusion or mobility limitations, which the patient described as longstanding, without previous pain or other associated symptoms. Knee radiographs (X-Rays) showed enlargement and altered bone architecture and density of the medial femoral condyle (Figure 1A). Differential diagnosis included malignancy, osteomyelitis, and PDB. Initial laboratory results were unremarkable, including normal alkaline phosphatase (ALP). Further bone turnover markers (BTM) evaluation showed elevated levels of N-terminal telopeptide of type I collagen, C-terminal telopeptide of type I collagen and Procollagen type I N-terminal propeptide. Bone scintigraphy (BS) revealed unspecific increased osteoblastic activity in the left femur, not differentiating between PDB, infection or malignancy (Figure 1C). To program a surgical bone biopsy to a definite diagnosis, a magnetic resonance imaging (MRI) of the knee was performed, showing an intact cortical bone without suspicious lesions (Figure 1B), reducing the likelihood of malignancy or infection. A multidisciplinary team decided against risky invasive biopsy and empirically administered 5 mg intravenous zoledronic acid. The patient's pain resolved within one month. Follow-up at six months showed resolution of osteoblastic activity (Figure 2B) and improved bone architecture (Figure 2A), confirming atypical monostotic PDB.

Conclusion: This case highlights a rare and atypical presentation of long-term asymptomatic monostatic femoral PDB. The integration of various imaging modalities and biochemical markers, beyond AlP, was essential for its diagnose.

Figure 1: A- initial knee radiograph with enlargement and bone architecture alteration at left medial femoral condyle; **B** – initial knee MRI (axial T1 post-gadolinium) showing signal transformation into areas of intermediate signal with relatively regular cortical thickening and evident contrast enhancement in areas where the cortical bone is destroyed; **C** – initial entire body bone scintigraphy with moderate to intense radiotracer uptake in the distal two-thirds of the diaphysis and the distal epiphysis of the left femur.

Figure 2: A - 6-month after treatment knee radiographs with improvement of bone architecture, previously deteriorated; **B** - 6-month after treatment entire body bone scintigraphy with absence of significantly increased osteoblastic activity in the left femur.

P922

THE ASSOCIATION BETWEEN FRAILTY AND MORTALITY, AND ASSOCIATED FACTORS, BIRJAND LONGITUDINAL ADULT STUDY

P. Ebrahimi[1], M. Payab[1], F. Sharifi[1], M. Tammadon[1], A. Khezrpour[1], M. Ebrahimpur[1]

[1]Tehran university of medical Sciences, Tehran, Iran

Introduction: Frailty syndrome is a physiologic process characterized by declined capacities in multiple organs. It makes patients more prone to worse health outcomes. Frailty is commonly observed in older adults and is associated with decreased strength, endurance, and functional capabilities. This condition is associated with a higher risk of falls, hospitalization, disability, and mortality. Increased age, female gender, lower physical activity, and malnutrition are claimed to be associated with risks of frailty syndrome. However, there is no common consensus regarding these factors.

Methods: This study included 1364 patients who were interviewed and examined. Their related data regarding various factors, diseases, sociodemographic characteristics, and social and lifestyle habits were documented. Finally, their association with frailty and phenotype was assessed, and correlation and relative incidence risk were calculated using univariate and multivariate logistic regressions.

Results: *This study showed that* females were slightly frailer (55.73%) compared to males (44.27%). However, this difference was insignificant. Age and frailty were significantly associated ($p = 0.000$). Frailty was most common in individuals with ideal body weight (45.04%) and least common among the overweight group (28.24%). A weakly significant association between BMI categories and frailty was observed ($p = 0.040$). Higher rates of frailty were seen in illiterate individuals (64.89%) compared to those with higher education (e.g., 0.76% frail among academics). A strong association was noted between education level and frailty ($p < 0.001$). The risk of frailty was significantly higher in widowed women compared to married women ($p = 0.003$). The mortality rate was higher in the frail group (13.74%) than in the non-frail group (3.97%). A strong association between frailty and death was observed ($p = 0.000$). Logistic Regression Analysis also showed that frailty was a predictor of death. Frail individuals had significantly higher odds of mortality, with an odds ratio (OR) ranging from 2.08 to 3.85 across different models, and adding variables (e.g., sex, age, BMI, waist circumference, multimorbidity, education) incrementally showed that age was consistently a strong predictor of death (OR ~1.08–1.09).

Conclusion: Frailty is closely tied to age, education, marital status, and BMI categories. This study showed that frailty is a strong independent predictor of mortality, even after adjusting for other factors. Additionally, education level and multimorbidity significantly influence the risk of death.

P923

ASSESSMENT OF THE QUALITY OF LIFE OF GERONTOLOGICAL PATIENTS AFTER MYOCARDIAL INFARCTION

M. Elgendi[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]Global care Hospital, Giza, Egypt, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

The quality of life of elderly patients depends on many factors: on the state of health, measures of social support, the ability to optimally interact with people around.

Objective. To evaluate the quality of life of gerontological patients after a myocardial infarction according to the WHO questionnaire according to the quality of life of the population of the population of the SF-100.

Methods. The study was conducted in the department of medical rehabilitation of the city hospital from 10.02.2024 to 10.10.2024. An examination of 80 patients over 75 years old was conducted. A survey was carried out using the WHO questionnaire according to the quality of life of the SF-100. Patients signed a voluntary informed consent to participate in the study.

Results. The average age of patients was 75.9±4.9 years, in men - 74.4±5.1 years, in women 78.6 ±4.7 years. The average period after the acute myocardial infarction was 4.7±1.3 months. When assessing energy in everyday life, only 7% of respondents are fully satisfied with this indicator, 92% on the contrary experience energy (23% rarely mark the breakdown, 42% quite often, 20% very often and 7% note a significant energy deficiency). In the question "How much do you enjoy life?" Only 12% of patients gave a positive answer, while 88% of respondents do not fully enjoy life. When assessing the cognitive capabilities of 92% of patients, memory disorders are noted (14% of patients note the minimum discomfort in this regard, 45% bothers this moderately, 26% are significantly not satisfied with their memory, 7% are not fully satisfied).

The quality of sleep is not satisfied with 87% of people. When evaluating anxiety and depression, 85% of patients note the presence of poor mood, despair and depression (6% of patients note these symptoms “very often”, 11% of “often” surveyed, 42% of patients

With moderate frequency, 27% "rare"). 91% of patients feel lonely. Among issues on assessing satisfaction and their appearance, 93% of people are not satisfied.

Conclusion. The results of the study of the quality of life show a decrease in the quality of life in elderly patients. An important stage in the structure of individual programs for the restoration treatment of patients of the gerontological profile is psychological rehabilitation.

P924

ASPECTS OF THE QUALITY OF LIFE OF GERIATRIC PATIENTS

M. Elgendi[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]Global care Hospital, Giza, Egypt, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. Assessment of the quality of life of gerontological patients using the SF100 questionnaire.
Methods. The work was carried out on the basis of the city hospital from 10.01.2024 to 10.07.2024. In the examination, 70 patients over 75 years were included. A survey was carried out using the WHO questionnaire according to the quality of life of the population of the population of the SF100. All patients signed a voluntary informed consent.
Results. The average age of patients was 79.25±3.8 years, in men - 78.1±4.4 years, in women 80.4±3.2 years. 32.8% (n=23) had disability, of which the third group was 47.8% (n=11), the second group - 47.8% (n=11), the first group - 3.35% (n =1).
When assessing the physical capabilities of 95% of respondents, varying degrees of severity of movement restrictions are noted (16% minimum restrictions, 38% moderate restrictions, 32% pronounced restrictions, 9% of patients cannot move at all); 91% of patients noted the presence of restrictions in the performance of everyday tasks (22% experience minimal restrictions, 52% moderate restrictions, 17% pronounced restrictions).
To the question "How do you evaluate your ability to work?" 9% of patients noted that 14% have extremely weak performance, 45% moderate performance, 21% are good and only 11% of patients note sufficient performance.
When evaluating the pain syndrome, it was revealed that 11% of patients had no pain; In 85% - the presence of pain, while patients note rare episodes of pain (25%), frequent pain (34%), very frequent pains (33%); Chronic pain syndrome (5%).
To the question of the need for drug therapy: 75% noted the need for medication (33% of patients notes a relatively weak dependence, 24% - moderate, 18% pronounced dependence).
Conclusion. Patients over the age of 70 have low quality of life. Heriah specialists need to pay attention to this fact when organizing treatment.

P925

RHEUMATOID ARTHRITIS: FOCUS ON ASSESSING THE STATE OF SKELETAL MUSCLES AND THE SEVERITY OF PAIN SYNDROME

M. Elgendi[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2], A. S. Komelyagina[3], I. R. Bufolova[2]

[1]Global care Hospital, Giza, Egypt, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia, [3]Noth-Western State Medical University named after I.I. Mechnikov, St. Petersburg, Russia

Background. Pain is a leading symptom in patients with rheumatoid arthritis. In patients with rheumatoid arthritis, a decrease in muscle force, a deterioration in the function of skeletal muscles are often observed.
Objective. Purpose: to study the relationship between muscle strength and the degree of severity of pain in patients with rheumatoid arthritis.
Methods. In the study include 90 women with rheumatoid arthritis, confirmed according to the criteria of ASR/EULAR (2010). A survey of patients, an assessment of the pain syndrome of the bone-muscular system on the visual analogue scale (your Scale for Pain Assessment), the determination of the muscle strength of the lower and upper extremities using the “stand from the chair” and the cystic dynamometry of the underinative hand, respectively, were carried out. The functional state of the muscles was estimated by the speed of walking by 5 meters and the test “Stand and go”. To identify associations between the level of pain and muscle status, a single -factor logistic regression analysis was used.
Results. In the examined patients of the age of the age, it was 55.2 [52.0; 62.0] year, duration by rheumatoid arthritis - 10.0 [7.0; 13.0] years, pain on your 50 [44; 56] mm. The median of the muscle force of the under -means was 11 [7; 15] kg, and the lower extremities - 17.2 [12.6; 21.8] seconds. The reduced strength of the muscles of the upper extremities was found in 67.3% of people, and the lower extremities in 56.2% of the examined. Low muscle strength at least one of the tests was noted in 75.2% of patients. The median speed and the time of execution of the “Stand and go” test amounted to 0.9 [0.8; 1.1] m/s and 11 [9; 12] C, respectively. The functional state of the muscles was reduced in 56.7% of patients. In the course of regression analysis, it was revealed that the pain according to your > 50 mm was associated with low muscle strength and physical performance of the muscles of the lower extremities (OR 2.38 95% DI 1.23–4.65 and OR 2.70 95% DI 1.30–6.27, respectively, p<0.01).
Conclusions. The strength of the skeletal muscles was reduced in 75.2% of the examined persons, and reduced physical performance in 56.7% of patients with rheumatoid arthritis. The presence of pain in your more than 50 mm was associated with an increase in the risk of lowering muscle strength by the lower extremities by almost 2.3 times, and violations of the functional state of the skeletal muscles by 2.8 times.

P926

ASSOCIATION OF ABCG2 GENE POLYMORPHISM 421C>A (Q141K, RS2231142) WITH COLCHICINE EFFICACY

M. Eliseev[1], M. Chikina[2], O. Zhelyabina[1], Y. Kuzmina[1], E. Panina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, Moscow, Russia, [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation., Moscow, Russia

Objective: To evaluate the efficacy of colchicine in patients with different missense genetic variants of the ABCG2 gene (Q141K; rs2231142) in gout patients.

Materials and Methods: The study included 59 gout patients aged over 18 years with serum uric acid levels >360 μmol/L who were not receiving urate-lowering or anti-inflammatory therapy. All patients were treated with colchicine at 0.5–1 mg/day and febuxostat at 80–120 mg/day. Genotyping of the ABCG2 gene polymorphism 421C>A (rs2231142) was performed. Colchicine efficacy was assessed in patients with different genotypes (CC, CA, AA) of the ABCG2 gene.

Results: Among 59 patients, 38 (64%) had the CC genotype, 18 (31%) had the CA genotype, and 3 (5%) had the AA genotype. The impact of different ABCG2 genotypes (rs2231142) on the frequency of arthritis flares and their intensity was assessed in patients with CC (n = 38) and CA/AA (n = 21) genotypes (Table 1). The analysis revealed no significant influence of genotype on the frequency or intensity of arthritis flares (p > 0.05 in all cases).

Table 1 — The Impact of Different Genotypes of the ABCG2 Gene (rs2231142) on the Frequency and Intensity of Arthritis Flares in Patients with CC (n = 38) and CA/AA (n = 21) Genotypes

Parameter	Genotype CC (n = 38)	Genotype CA/AA (n =21)	p
Total number of flares during the observation period, Me [25th; 75th percentile]	0 [0; 1]	1 [0; 1]	0,5
Number of flares during months 0 to 3 of observation, Me [25th; 75th percentile]	0 [0; 1]	0 [0; 1]	0,6
Number of flares during months 3 to 6 of observation, Me [25th; 75th percentile]	0 [0; 0]	0 [0; 0]	0,9
Pain intensity on the Visual Analog Scale (VAS) during months 0 to 3, mm (M ± SD)	53,8±17	51,8±24,6	0,8
Pain intensity on the Visual Analog Scale (VAS) during months 3 to 6, mm (M ± SD)	54±16,3	64,6±13,3	0,2
Pain intensity on the Visual Analog Scale (VAS) over the entire observation period, mm (M ± SD)	56,8±17,2	57,3±22,9	0,9

Conclusion: The presence of different genotypes of the ABCG2 gene (Q141K; rs2231142) does not influence colchicine efficacy regarding the frequency or intensity of arthritis flares.

P927

COMPARISON OF EFFICACY AND SAFETY OF DIFFERENT COLCHICINE DOSES IN PATIENTS WITH GOUT

M. Eliseev[1], M. Chikina[2], O. Zhelyabina[1], Y. Kuzmina[1], E. Panina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, Moscow, Russia, [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation., Moscow, Russia

To compare the efficacy and safety of long-term administration of different doses of colchicine (0.5 mg/day vs 1.0 mg/day) for the prevention of arthritis flares during the initial months of xanthine oxidase inhibitor therapy.

Materials and Methods:

The study included 96 patients diagnosed with gout (ACR/EULAR 2015 criteria). Patients were randomized into three groups using fixed randomization:

Group 1: Colchicine 0.5 mg/day and febuxostat 80 mg/day.

Group 2: Colchicine 1.0 mg/day and febuxostat 80 mg/day.

Group 3: Febuxostat 80 mg/day (without colchicine).

The observation period lasted six months. The following outcomes were compared: frequency of arthritis flares, intensity of pain (assessed using the Visual Analog Scale, VAS) during flares, and incidence of adverse events (AEs).

Results: The relative risk (RR) of arthritis flares in patients receiving colchicine 0.5 mg/day compared to those not receiving anti-inflammatory therapy was 0.61 (95% CI 0.39–0.95, p=0.02). For colchicine 1.0 mg/day, the RR was 0.44 (95% CI 0.25–0.76, p=0.001). No significant differences in odds ratios (OR) were observed between the groups receiving colchicine 0.5 mg/day and 1.0 mg/day (OR 1.40, 95% CI 0.73–2.67, p=0.3).

The frequency of arthritis flares was comparable between the colchicine 0.5 mg/day and 1.0 mg/day groups (p=0.6), as was the number of patients who did not experience flares (18 [56%] vs. 22 [69%], p=0.3). In the group not receiving colchicine, only 9 patients (28%) did not develop arthritis flares (p=0.02 compared to 0.5 mg/day group; p=0.001 compared to 1.0 mg/day group).

Patients receiving colchicine 1.0 mg/day (but not 0.5 mg/day) reported significantly lower pain intensity on the VAS during arthritis flares compared to the group without therapy (p=0.04). The incidence of adverse events was comparable across all groups.

Conclusion: Long-term use of low-dose colchicine is fully justified, with 0.5 mg/day being equally effective as 1.0 mg/day in preventing arthritis flares. Moreover, the risk of adverse events is minimal for both colchicine doses (0.5 mg/day and 1.0 mg/day) in patients with gout.

P928

ASSOCIATION OF SERUM URIC ACID LEVELS WITH BONE MINERAL DENSITY IN PATIENTS WITH GOUT

M. Eliseev[1], O. Zhelyabina[1], Y. Kuzmina[1], M. Chikina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

The interplay between gout, serum uric acid (sUA) levels, and bone health, particularly bone mineral density (BMD), remains insufficiently studied.

Objective To evaluate the association between sUA levels and BMD in patients with confirmed gout.

Materials and Methods The study included 73 patients who underwent dual-energy X-ray absorptiometry (DXA) of the lumbar spine and proximal femur. Among them, 14 individuals (19.1%) were younger than 40 years, for whom the Z-score was determined, and 59 individuals (80.9%) were older than 40 years, for whom the T-score was calculated. Data on various biochemical parameters were collected, including serum vitamin D levels, with a median value of 21.7 ng/mL [17.8; 26.6].

Results Of the participants, 91.7% were male, with a mean age of 49.1 ± 10.3 years. The mean sUA level was 493.5 ± 80.6 μmol/L. No significant correlations were found between sUA levels and BMD in the femoral neck or proximal femur (r=0.008; p=0.94 and r=0.02; p=0.86, respectively). A moderate correlation was identified between sUA levels and the T-score in the lumbar spine (r=0.36; p=0.036), and a weak positive correlation between sUA levels and BMD in the lumbar spine (r=0.207; p=0.078). No correlations were observed between serum calcium levels or age and BMD.

Conclusions No association was found between sUA levels and the Z-score in any of the analyzed regions. However, a moderate association with the T-score in the lumbar spine was identified.

P929

ORTHO-GERIATRIC SERVICE ACROSS EUROPEAN COUNTRIES

M. Eltayeeb[1], K. Tan[1], M. Jurate[2], M. Vassallo[3], M. Kotsani[4], T. Masud[5]

[1]Nottingham University Hospitals, Nottingham, United Kingdom, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania, [3]Karen Grech Hospital and Mater Dei Hospital, Malta, Malta, [4]Hellenic Society for the Study and Reseach of Aging, Athens, Greece, [5]Healthcare of Older People Department, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Introduction:
Ortho-geriatrics is a recognised geriatric services/subspecialty in Europe with different models of care. However, there is significant variation in the development of this service across the continent, with some countries offering a well-developed service and others having little or no service. This survey collected data from European countries on the type and frequency of orthogeriatric services provided, as part of a broader survey examining the different geriatric medicine services provided.

Methods:
We asked board members of the European Union of Medical Specialities-Geriatric Medicine Section to fill in a cross-sectional survey about the existence and frequency of orthogeriatric services (as part of a broader survey) in their countries. The questionnaire categorised service availability from institutions into four levels– No(none), Yes-Minority(<25%), Yes-Some(25%-75%) or Yes-Majority(>75%).

Results:
We received responses from 39 countries, which we categorized into four geographical regions: Nordic(NORD;n=5), Central-Western Europe(CWE;n=9), Eastern Europe(EE;n=17), Southern Europe(SE;n=8). We found a significant variation in the availability of services between countries. More services were provided in the NORD (73%) and CWE (77%) regions. In contrast, orthogeriatric services were lacking in EE (only 14%) and SE (42%). Overall, 26 (66%) countries reported having some orthogeriatric services, although only 9 countries (23%) had this service in the majority (>75%) of hospitals.

Discussion:
This is the first comprehensive survey of provision of orthogeriatric services across Europe and shows wide discrepancy between the 4 regions of Europe. The data gathered will be valuable for discussions with policy makers in developing orthogeriatric services in their countries.

ARTIFICIAL INTELLIGENCE-BASED RADIOMICS ON OPPORTUNISTIC COMPUTED TOMOGRAPHY FOR PREDICTING VERTEBRAL FRACTURES IN WOMEN WITH BREAST CANCER UNDER HORMONE-DEPRIVATION THERAPIES

M. F. Birtolo[1], A. Piasentier[1], R. Levi[2], F. Carrone[3], G. Savini[2], M. Battaglia[2], L. M. S. Gentile[1], S. Bodini[1], R. Colle[1], A. Fanti[1], A. G. A. Lania[1], L. S. Politi[2], G. Mazziotti[1]

[1]Endocrinology, Diabetology and Medical Andrology Unit, IRCCS Humanitas Research Hospital, Milan, Italy, [2]Neuroradiology, IRCCS Humanitas Research Hospital, Milan, Italy, [3]Humanitas MaterDomini, Endocrinology Service, Varese, Italy

Introduction: women under estrogen-deprivation therapies (HDTs) for breast cancer are at high fracture risk, but currently available fracture prediction tools are imprecise. Emerging evidence suggests that radiomics may contribute to fracture risk assessment in general population, but its application in this context is unknown.

Objective: To identify radiomic features (RFs) on opportunistic computed tomography (CT) associated with vertebral fractures (VFs) in women under HDTs, and to develop a radiomics-based model predictive of VFs. Methods: Radiomics analyses were performed on CT scans of 109 women (median age 61.1 years, range 27-85) exposed to HDTs (median 27.1 months). Lumbar vertebrae were automatically segmented (convolutional neural network) for RFs extraction. Each feature was tested for its ability to predict VFs. Patients were randomly divided into training and test co-

horts for the development and validation of the predictive model. **Results:** Morphometric VFs were diagnosed in 23 women (21.1%), in association with older age (P=0.013), lower total hip T-score (P=0.041) and higher FRAX score for major fractures (P=0.045). The machine-learning model based on 20 RFs showed a high ability to predict VFs (ROC 0.832), outperforming that of T-score and FRAX score, even when lower thresholds than conventional ones were used (ROC 0.77 and 0.45, respectively). The RF "information measure of correlation" was the most relevant feature in the model, suggesting that a reduction in texture cross-correlation is positively associated with the development of VFs (p<0.001). **Conclusions:** The radiomics-based machine learning model showed high potential in identifying women at high fracture risk during HDTs.

P931

GENERAL POPULATION AWARENESS ABOUT OSTEOPOROSIS AND 10-YEAR FRACTURE RISK

M. Fominykh[1], A. Popov[1], S. Emelyanova[1], A. Panova[1]

[1]Ural State Medical University, Yekaterinburg, Russia

The aim of the study was to assess the level of awareness about osteoporosis (OP) among men and women who applied for a preventive check—up, to identify key risk factors and determine the 10—year risk of fractures.

Methods: A cross-sectional anonymous survey enrolled 80 respondents (56 women and 24 men), aged 26 to 71, who applied for a routine general practitioner check-up during November 2024. Each respondent filled out the "One—Minute Osteoporosis Risk Test" questionnaire developed by the International Osteoporosis Foundation (IOF), a screening tool designed to pre-assess risk factors for osteoporosis. To assess the risk of fractures, the FRAX® tool was used to assess 10—year risk of fractures in respondents over the age of 50. All patients had not been examined before and had not received treatment for osteoporosis.

Results and discussion. The average age of the respondents was 47.7±11.0. Mean BMI was 26.0±6.1 kg/cm^2. The sampling was stratified by age. The Group 1 consisted of 48 persons aged from 26 to 49 (mean 40.4±6.1) average body mass index 24.4±5.3. Group 2 included 32 respondents aged 50 and over (mean 58.6±7.0), average body mass index was 28.5±6.5.9.

General level of awareness about OP was significantly higher in the younger group than in Group 2: 41.2% vs 34.4% respectively. This may indicate a higher level of awareness among young people about the risks of osteoporosis, possibly due to greater attention to health issues, especially in the context of disease prevention. The greatest difficulties among the respondents were caused by issues related to the first symptoms of the disease, family history, frequency of occurrence among different gender groups, as well as issues of treatment and prevention. In our study, 37.7% of women and 29.7% of men among the younger age group answered positively to questions on the family history of OP. In the older age group, the awareness about family history of OP and fractures was significantly lower: 21.9%. Every third respondent was able to give answers about possible early symptoms of osteoporosis (for example, pain) that may occur before the fractures diagnosis. It is noteworthy that the majority of respondents (58.8%) could not answer the question about prevention measures and treatment of OP. Vitamin D3 deficiency prophylaxis was reported as 37.5% in Group 1 versus 21.9% in Group 2. Also, there were 49.7% respondents with sufficient physical activity in Group 1 versus 31.2% persons in Group 2.

The data obtained confirm that the level of physical activity decreases with age, which, in turn, may contribute to the risk of OP. A survey of respondents on such harmful habits as smoking and alcohol consumption showed that among all the respondents, the proportion of smokers was 57.5%, mostly men, which confirms the importance of preventive measures to reduce smoking, especially among men. Also, 10.0% of women reported alcohol consumption within the acceptable range against 28.8% males.

FRAX® assessment in Group 2 revealed 9 persons of moderate risk of fractures and 5 subjects of high 10-year risk of fractures. 6 women had a history of low energy traumatic fractures, men had no history of fractures. All 6 women who had a low-traumatic fracture, had a history of smoking for many years, 3 of the them had a history of parental hip fracture, another one had been taking glucocorticoids for years.

Conclusions. The overall level of awareness about the problem of osteoporosis among the respondents was 37.9%. The greatest difficulties were noted when answering questions about the first symptoms of the disease, the prevalence of osteoporosis among different gender groups, as well as methods of OP treatment and prevention. Thus, it is necessary to enforce efforts to increase the level of general population awareness about OP preventive measures. FRAX® scale should be implicated into preventive health check-ups in 50 and over aged persons to identify individuals with a high 10—year risk of fractures for further prevention of low-energy fractures.

P932

10 YEARS FOLLOW UP FOR TREATMENT OF OSTEOARTHRITIS OF THE FIRST CARPOMETACARPAL JOINT WITH EXCISION OF THE TRAPEZIUM

M. Foteva[1], M. Samardziski[1], A. Andonovski[1], T. Teodorova[1]

[1]University Clinic for Orthopedic Surgery, University St. Cyrill and Methodius, Skopje, Republic of North Macedonia

Osteoarthritis of the first carpometacarpal joint is a common condition mostly affecting middle-aged women. The advanced stages and the severe form often require surgery. Numerous surgical procedures are used, but there is still no consensus on the best procedure for any given patient. Excision of the trapezium was introduced in 1949 by Gervis and has been commonly used. There are many reports favoring this procedure, and there are reports that indicate slow postoperative rehabilitation, decreased thumb length , unstable thumb , diminished grip and pinch strength. We have been using this procedure for 20 years now.

Objective: We report our postoperative results at 10 year fol-

low-up on 15 hands.
Material and methods: 15 hands (12 F, 3 M), average age at operation 57 years (47-61). All patients were right handed. 10 operations were done on the right thumb and 5 on the left. All patients were reviewed by the authors. At 10- year follow-up, all patients underwent physical and radiographic examination and were graded into excellent, good, fair and poor groups.
Results: There was dramatic relief of pain following the procedure in all patients and this has remained for the entire follow-up period. 7 patients had excellent results (46,6%), 5 good result (33,3%), and 3 (20%) a fair result, with no patient having a poor result. On the operated side the mean pinch strength was 84% of the non-operated side and the mean grip strength was 79%.
We conclude that simple excision of the trapezium is a satisfactory procedure for the majority of these patients. Early mobilization of the thumb maintains the adequate web space and thumb abduction, which in turn seems to maintain the grip and pinch strength with some diminishment. Postoperative rehabilitation may be long, but our results show that this procedure gives durable results and there is high level of patient satisfaction.
Key words: osteoarthritis of the thumb, trapezium, trapeziectomy, surgery for osteoarthritis.

P933

SERUM PROTEOMICS UNVEILS NOVEL PATHWAYS OF ALTERED BONE METABOLISM IN METABOLIC SYNDROME AND TYPE 2 DIABETES

M. Gerbaix[1], D. Couteix[2], F. Dutheil[2], S. Ferrari[1]

[1]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [2]Université Clermont Auvergne, CHU Clermont-Ferrand, University Hospital of Clermont-Ferrand, Clermont Ferrand, France

OBJECTIVES
Type 2 Diabetes Mellitus (T2D) is associated with low bone turnover and bone fragility despite normal-high BMD. T2D frequently coexists with Metabolic Syndrome (MetS), characterized by central obesity, dyslipidemia, hypertension, and impaired fasting glucose. We previously reported that MetS and T2D progressively decrease bone turnover while increasing BMD, though underlying mechanisms remain unclear. This study aimed to explore regulatory pathways of altered bone metabolism in MetS and T2D using a proteomic approach.
METHODS
Serum proteomic profiles were assessed by Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS) in age-matched men and women with MetS (59±5 yrs; n=26), MetS-T2D (60±5 yrs; n=26), and healthy controls (Ctr; 60±5 yrs; n=26). Data were analyzed with Spectronaut (Biognosys) and R-based bioinformatics tools.
RESULTS
Of 541 analyzed proteins, 56 were dysregulated between MetS and Ctr, 75 between MetS-T2D and Ctr, and 26 between MetS-T2D and MetS. Among them, PEDF (Pigment epithelium derived factor) was significantly upregulated in MetS and MetS-T2D vs Ctr (+6%; +23%; p<0.05) and correlated positively with HbA1c (r=0.3; p<0.01), lumbar spine BMD (r=0.2; p<0.05), hip BMD (r=0.4; p<0.01), and negatively with CTX (r=-0.4; p<0.01). IGFBP2 (Insulin like growth factor binding protein 2) was downregulated in MetS and MetS-T2D (-42%; -54%; p<0.0001) and correlated negatively with HbA1c (r=-0.4; p<0.001) and hip BMD (r=-0.3; p<0.01), but positively with OCN, P1NP, and CTX (r=0.3; p<0.05). Gene ontology enrichment analysis highlighted pathways related to lipid transport, cholesterol metabolism, inflammation, and extra cellular matrix (ECM) degradation, with several proteins correlated to bone parameters. Among them, LBP (Lipopolysaccharide binding protein) was upregulated in MetS and MetS-T2D vs Ctr (+30%; +41%; p<0.05) and correlated positively with HbA1c (r=0.3; p<0.05) and negatively with P1NP (r=-0.3; p<0.05). CRP (C reactive protein) was upregulated in MetS and MetS-T2D vs Ctr (+137%; +194%; p<0.05) and negatively correlated with P1NP and CTX (r=-0.22; p<0.05). Moreover, MMP-9 (Matrix metalloproteinase 9), a key ECM-degrading enzyme, was upregulated in MetS and MetS-T2D vs Ctr (+78%; +56%; p<0.05) and negatively correlated with OCN, P1NP, and CTX (r=-0.3; p<0.05).
CONCLUSION
Overall, this proteomic analysis delineates new potential mechanisms of low bone turnover and/or higher BMD in MetS and T2D. They include both systemic and bone-derived proteins related to osteoblastic functions (PEDF, IGFBP2), lipids transport (LBP), as well as inflammation (CRP) and ECM degradation (MMP-9), thereby potentially contributing to diabetic bone fragility.

P934

INTEGRATION OF REHABILITATION AND THERAPY IN PATIENTS WITH OSTEOPOROTIC FRACTURES: A CASE REPORT

M. Gocevska[1], B. Mitrevska[1], C. Gjerakaroska Savevska[1], B. Kalchovska[1], M. Manoleva[1], D. Gecevska[1], V. Koevska[1]

[1]University Clinic For Physical Medicine And Rehabilitation, Skopje, Republic of North Macedonia

Introduction: Osteoporosis is a major public health concern due to its association with increased risk of fractures, reduced mobility, and higher mortality rates. Rehabilitation plays a crucial role in improving outcomes in patients with osteoporotic fractures, complementing pharmacological therapy to restore function and quality of life.
Objective: This case report aims to demonstrate the effectiveness of an individualized rehabilitation program integrated with pharmacological treatment in a patient with an osteoporotic fracture.
Case Description: We present the case of a 72-year-old female patient with a history of osteoporosis and a low-energy distal radius fracture. Initial management included fracture stabilization and initiation of anti-osteoporotic medication (bisphosphonates and calcium/vitamin D supplementation). A personalized rehabilitation program was developed, focusing on progressive strength training, balance exercises, and functional mobility. Rehabilitation sessions were conducted daily over a 3-week period under multi-

disciplinary supervision.
Results: The patient showed significant improvement in grip strength (+35%), range of motion in the wrist (measured with a goniometer: flexion improved by 20°, extension by 25°, and pronation/supination by 15° each), and pain reduction (VAS score decreased from 6 to 2). Functional independence was restored, as evidenced by resumption of daily activities without assistance. The combined approach highlighted the synergy between pharmacological and rehabilitation strategies.
Conclusion: This case underscores the importance of a multidisciplinary approach in managing osteoporotic fractures. Tailored rehabilitation, combined with medical therapy, optimizes functional recovery and enhances the overall quality of life in patients with osteoporosis.

P935

SCIENTOMETRIC INSIGHTS INTO THE RELATIONSHIP BETWEEN AIR POLLUTANTS AND BONE HEALTH

M. Golabchi[1], M. Dehghanpour Abyaneh[2], O. Tabatabaei-Malazy[3]

[1]Department of Energy (DENERG), Politechnico Di Torino, 10129 Torino, Torino, Italy, [2]Department of Mechanical and Aerospace Engineering (DIMEAS), Politechnico Di Torino, 10129 Torino, Torino, Italy, [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Previous studies have shown a link between air pollutants and bone health in the general population. This study aims to conduct a scientometric analysis of the scientific literature on the association between air pollutants and bone health in the elderly population.
Material and Methods: We carried out a bibliometric study with a comprehensive search of the Scopus database up to 16 Jan 2025. After excluding unrelated papers, we extracted bibliometric metrics such as publication trends, productive countries and institutions, active researchers, key journals, and popular research topics, from the remaining papers using Scopus's "analyze results", and "citation reports" tools, along with VOSviewer 1.6.20.
Results: Out of 1749 records, 47 studies were relevant to this topic. A trend of increasing publications was observed, with the highest number in 2024 (n=8, 17.02%). The majority of the papers were original articles (n=39, 82.98%). The top three productive countries were China (n=16, 34.04%), the US (n=7, 14.89%), and the UK (n=4, 8.51%). Most of the papers published in “Osteoporosis International” (n=5, 10.64%), "Journal of Clinical Endocrinology and Metabolism" (n=3, 6.38%), and “International Journal of Environmental Research and Public Health” (n=2, 4.25%). The total citation number of these 47 articles was 1767. The most cited paper (676 citations) was a review article titled “Environmental factors that influence the cutaneous production of vitamin D ", published in “American Journal of Clinical Nutrition ". The top three affiliations producing these documents were all based in China: “Ministry of Education of the People's Republic of China”, (n=6, 12.76%), “Tibet University” (n=3, 6.38%), and “Kunming Medical University” (n=3, 6.38%). The leading subject areas were medicine (n=38, 80.85%), and environmental science (n=12, 25.53%). The top authors were “Guo, B.” and “Zhao, X”, each with three publications, all from China. Out of the 113 keywords, the most frequent were "air pollution", "osteoporosis", "bone mineral density" and "particulate matter".
Conclusions: This study highlights the growing body of research on the link between air pollution and bone health, with China as the leading contributor and *“Osteoporosis International”* as a key journal for influential publications. However, further research in this area is essential.

P936

VITAMIN D AND K STATUS IN POSTMENOPAUSAL WOMEN WITH NORMAL AND LOW BONE MINERAL DENSITY

M. Herrmann[1], S. Zelzer[1], A. Meinitzer[1], D. Enko[1], K. Makris[2], S. Tournis[3], I. Trifonidi[3], E. Chronopulos[3], L. Spanou[4], N. Alonso[1], M. Keppel[1]

[1]Medical University of Graz / Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria, [2]KAT General Hospital / Clinical Biochemistry Department, Athens, Greece, [3]University of Athens / Laboratory for Research of the Musculoskeletal System "Th. Garofalidis", Athens, Greece, [4]Athens Red Cross Hospital / Endocrinology Department, Athens, Greece

Objectives: Deficiencies of vitamin D and K are believed to promote bone loss, osteoporosis and osteoporotic fractures, but existing evidence is controversial. Functional vitamin D deficiency is characterized by a low vitamin D metabolite profile, accelerated bone metabolism and increased mortality. Vitamin K, a cofactor of γ-glutamylcarboxylase, modulates bone metabolism through post-translational conversion of glutamate residues in osteocalcin (OCN) and matrix-Gla-protein (MGA). At present, data regarding the relationship between multiple metabolites of both vitamins and BMD are scarce. Therefore, this study aimed to measure several metabolites of both vitamins by liquid chromatography tandem mass spectrometry (LC-MS/MS) in a cohort of postmenopausal women with low and normal bone mineral density (BMD).
Methods: Vitamin metabolites (25-hydroxyvitamin D (25[OH] D), 24,25-dihydroxyvitamin D (24,25$(OH)_2$D), phylloquinone (K1), menaquinone-4 (MK-4) and MK-7) were measured in 131 serum samples by LC-MS/MS. The vitamin D metabolite ratio (VMR) was calculated. Parathyroid hormone (PTH), type I procollagen-N-terminal-peptide (PINP) and C-terminal telopeptides of type I collagen (CTX-I) were measured by immunoassay. Dual X-ray absorptiometry was performed to identify participants with normal (T-score>-1) and low (T-score<-1) BMD.
Results: Mean age was 58.2±8.5 years. BMD was normal in 68 and low in 63 women. Median (interquartile range) for 25(OH)D and total vitamin K concentrations were 53.5 (39.6-65.9) nmol/L and 1.33 (0.99-2.39) nmol/L. All vitamin metabolites were comparable in individuals with normal and low BMD. Furthermore, BMD and trabecular bone score were comparable in participants

with adequate and inadequate vitamin status (at least one criterion was met: 25(OH)D <50 nmol/L, $24,25(OH)_2D$ <3 nmol/L, VMR <4 %, total vitamin K <0.91 nmol/L). PTH, but not PINP or CTX-I, was inversely correlated with 25(OH)D, $24,25(OH)_2D$ and VMR. Synergistic effects between vitamin D and K were not observed.
Conclusions: Vitamin D and K status is not related to BMD and trabecular bone quality in postmenopausal women. Inverse associations were only seen between vitamin D metabolites and PTH.

P938

FAMILIAL ALKAPTONURIA: DIAGNOSTIC CHALLENGES AND VARIABILITY IN LATE-ONSET MANIFESTATIONS—A CASE SERIES OF THREE SIBLINGS

M. I. Maza[1], B. B. Bengana[1], B. A. Boukabous[1], C. F. Cheriat[1], G. H. Guerboukha[1], O. I. Ouafi[1], L. S. Lefkir[1]

[1]University of medical sciences of Algiers/ Rheumatology department / Hospital of Beni Messous, Algiers, Algeria

Introduction Alkaptonuria, a rare autosomal recessive metabolic disorder caused by a deficiency of homogentisic acid oxidase, results in the systemic deposition of homogentisic acid. We describe three members of a consanguineous family affected by this hereditary condition, showcasing the diverse clinical presentations and delayed diagnoses typical of the disease.
Case Reports
Case 1: A 66-year-old woman presented with progressive lower back stiffness, restricted hip and shoulder movement, and a limp. Examination revealed bluish discoloration of the ear cartilage, sclera, and nails. Imaging identified lumbar disc calcifications, extensive spinal osteophytes, severe bilateral hip osteoarthritis, and advanced shoulder arthropathy. The clinical and radiological findings confirmed the diagnosis. The patient's history revealed a sister with similar mobility issues, prompting her evaluation.
Case 2: A 62-year-old woman, the elder sister, had bilateral hip pain with limited movement and scleral hyperpigmentation. Observation of urine darkening under light exposure confirmed alkaptonuria. Radiographs showed severe hip arthropathy requiring total hip replacement. The family history revealed a brother with childhood episodes of darkened urine, leading to his investigation.
Case 3: The 50-year-old brother was asymptomatic but was found to have characteristic lumbar spine calcifications on imaging. Despite the absence of rheumatologic symptoms, the radiological findings established the diagnosis of alkaptonuria.
Discussion
This familial cluster highlights variability in the clinical spectrum of alkaptonuria. While the sisters developed disabling ochronotic arthropathy, the brother remained asymptomatic into middle age. Ochronosis often manifests with musculoskeletal symptoms later in life, complicating early diagnosis. Initial signs, such as urine discoloration, are frequently overlooked. Characteristic pigmentation provides a critical diagnostic clue, but advanced structural damage can occur insidiously, as seen in this series. Despite the availability of supportive care, no curative treatment exists.
Conclusion
This case series emphasizes the unpredictable nature of alkaptonuria within familial contexts, demonstrating significant variations in clinical presentation and progression. Early recognition through clinical signs, radiological features, and genetic testing is essential for timely intervention. Enhanced awareness of this rare disorder is crucial to prevent delayed diagnoses and mitigate the impact of advanced ochronotic arthropathy.

P939

COMPARISON OF RADIOLOGY AUGMENTED VS ASYNCHRONOUS OF ARTIFICIAL INTELLIGENCE (AI) ENABLED VERTEBRAL FRACTURE (VF) REPORTING

J. Threlkeld[1], J. Connor[2], C. Chisholm[1], Y. Kimmel[3], M. K. Javaid[4]

[1]Bradford Teaching Hospitals NHS Foundation Trust, Radiology, Bradford, United Kingdom, [2]Bradford Teaching Hospitals NHS Foundation Trust, Fracture Liaison Service, Bradford, United Kingdom, [3]Nanox-AI, Petah Tikva, Israel, [4]University of Oxford, NDORMS, Oxford, United Kingdom

Objectives:
To compare the performance of using synchronous AI-augmented general radiology reporting with asynchronous dedicated MSK expert review of CT scans flagged by AI.
Material and Methods:
Using the Nanox-AI HealthVCF AI model, CT scans that included the thoracic or lumbar spine were re-analysed at a high specificity setting to identify those with potential moderate or severe vertebral fractures. If the AI flagged a potential vertebral fracture, the CT images were annotated for the reporting radiologist to confirm, and the patient be referred to the Fracture Liaison Service (FLS). In addition, all AI-flagged CT scans were sent to a separate server for asynchronous reading by a musculoskeletal (MSK) radiologist. We used Fisher's exact test to compare the number of vertebral fractures referred to the FLS from the two pathways.
Results
Between December 2023 and November 2024, 10,679 scans were analysed, with 1,311 flagged by the AI as potential vertebral fractures. An MSK radiologist confirmed 946 (72.2%) as vertebral fractures. Non-MSK radiologists reported 62% of scans. Overall, 20.9% of scans with at least one confirmed vertebral fracture were not reported and referred. Trainees had the lowest missing rate, with the highest missing rate being for outsourced and locums radiologists ($p<0.001$) (Figure). The commonest non-MSK speciality was gastroenterology (24% of all scans), with a missing rate of 18.2%. The highest non-MSK missing rates were from Chest/Nuclear Medicine (29.6%), head&neck (26.7%) and Breast (26.3%).
Conclusion
Even with AI-informed prompting, a fifth of scans with confirmed VF were not reported. This supports asynchronous reading of the AI-flagged scans and should inform local implementation.

IMPACT OF AI-ENABLED VERTEBRAL FRACTURE (VF) IDENTIFICATION ON FRACTURE LIAISON SERVICE (FLS) KEY PERFORMANCE INDICATORS (KPIS) AND TREATMENT RECOMMENDATIONS VARIES BY FLS

F. A. A. Clemeno[1], D. Chappell[2], J. Connor[3], J. Threlkeld[4], C. Chisholm[4], K. E. S. Poole[2], J. Boylan[5], J. Turton[5], M. Stone[5], C. Toogood[6], T. Santos[6], M. Sampson[7], M. Baxter[8], E. Curtis[9], R. Eckert[10], O. Sahota[11], Y. Kimmel[12], R. Pinedo-Villanueva[1], M. K. Javaid[1]

[1]University of Oxford, NDORMS, Oxford, United Kingdom, [2]NIHR Cambridge Biomedical Research Centre, Department of Medicine, Cambridge, United Kingdom, [3]Bradford Teaching Hospitals NHS Foundation Trust, Fracture Liaison Service, Bradford, United Kingdom, [4]Bradford Teaching Hospitals NHS Foundation Trust, Radiology, Bradford, United Kingdom, [5]University Hospital Llandough, Bone Research Unit, Cardiff, United Kingdom, [6]University Hospital Southampton NHS Foundation Trust, Fracture Liaison Service, Southampton, United Kingdom, [7]University Hospital Southampton NHS Foundation Trust, Radiology, Southampton, United Kingdom, [8]University Hospital Southampton NHS Foundation Trust, Medicine for Older People, Southampton, United Kingdom, [9]University of Southampton, MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom, [10]Oxford University Hospitals NHS Foundation Trust, Fracture Liaison Service, Oxford, United Kingdom, [11]Nottingham University Hospitals NHS Trust, Department of Medicine for Older People, Nottingham, United Kingdom, [12]Nanox-AI, Petah Tikva, Israel

Objectives:

To compare the KPIs of FLSs before and after the introduction of AI-enabled VF identification across FLSs in England and Wales.

Materials and Methods:

The Nanox-AI HealthVCF AI model was implemented in 3 FLSs to identify potential vertebral fractures from existing CT scans with additional funding for FLS administrators and nurses. The KPIs for identification, assessment, treatment recommendation and follow-up were compared before (Jan to Nov 2023) and after (Jan to Nov 2024) AI implementation using the FLS-Database of England and Wales. Each AI-FLS was supported to deliver patient-co-produced Quality Improvement (QI). Up to 4 control FLSs for each AI-FLS were identified, matching on spine fracture identification KPI in 2023 to account for secular changes. Differences in proportions were compared using two-proportion z-tests.

Results

While overall VF identification doubled from 25.1% (2023) to 55.4% (2024), p<0.001, there were marked differences between AI-sites (Figure). Non-AI Control sites demonstrated a smaller increment in VF identification from 28.6 to 31.3% (p=0.007) which was inconsistent across sites. The change in KPI for VF patients varied by AI-FLS. Time to assessment significantly worsened in Hosp B and C but remained stable in Hosp A. DXA within 12 weeks worsened in Hosp B (85.7% to 66.7%) and Hosp C (92.3% to 80.6%) with little change in Hosp A (96.8 to 94.9%). The proportion of patients who were recommended treatment remained unchanged except for Hosp C, where it worsened from 85.2 to 71.4% (p=0.01).
For non-vertebral fracture (NVF) patients in AI-FLSs, time to assessment worsened in Hosp A & C (p<0.03) but improved in Hosp B. DXA within 12 weeks did not significantly change except for Hosp C where it improved (91.9% to 96.6%, p=0.02). The treatment recommendation rate for NVF significantly improved in Hosp B and C (p<0.003) and was unchanged in Hosp A.

Conclusion

As expected, AI implementation significantly improved VF identification but had differential effects on the KPI for VF and NVF between the AI-FLSs despite a focus on QI. These findings highlight the importance of enhancing QI when implementing AI-enabled VF identification in the FLS setting.

DELIVERING ROMOSOZUMAB FOR HIGH FRACTURE RISK PATIENTS IN THE FRACTURE LIAISON SERVICE (FLS) SETTING: SERVICE MODIFICATIONS AND EARLY RESULTS

C. I. Maushart[1], R. Eckert[2], S. Connacher[2], M. K. Javaid[1]

[1]University of Oxford, Nuffield Department of Orthopaedics-Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom, [2]Oxford University Hospital, Metabolic Bone Unit, Oxford, United Kingdom

Objective The UK guidelines recommend first line romosozumab (Romo) for postmenopausal people with a recent hip, vertebral, humerus or wrist fracture and a BMD T-score ≤-3.5 or T-score ≤-2.5 with a vertebral fracture within 24 months, a history of ≥2 osteoporotic vertebral fractures, or a very high FRAX-based fracture risk. These patients are routinely seen by FLS where anabolic treatment usually requires referral to the specialist bone clinic.

Methods A patient co-developed, multidisciplinary team (MDT) identified changes to the FLS pathway to enable access to Romo: Fractures below the knee were excluded, and spine fracture detection enhanced by standardising referral from positive VFA and AI analyses of existing CT scans. All patients without a history of cardiovascular disease were automatically referred for DXA and completed a questionnaire including QRISK3. If eligible by DXA, patients were sent lab tests (including HbA1c, non-fasting lipids) and the Royal Osteoporosis Society Romo leaflet before their FLS Nurse telemed assessment. Eligible cases were reviewed in weekly MDT meetings with the clinical lead. Treatment was initiated using homecare providers.

Results From 01/2024 to 09/2024, the FLS identified a total of 1705 postmenopausal women with newly diagnosed fractures, including major osteoporotic fractures of the hip (n=361), humerus (n=193), spine (n=376), or wrist (n=232). After clinical assessment, Romo was started in 61 patients (3.6%). Almost half of these patients had a vertebral fracture (n=30) and nearly a third a wrist fracture (n=19, Figure 1). The median time from first fracture to treatment recommendation was 147 (IQR 104-194) days and from fracture to Romo initiation was 170 (IQR 119-209) days.

Conclusion
Integrating Romo into the FLS setting required a pathway redesign for patient identification, assessment, treatment recommendation and monitoring. Further work is required to assess clinical and patient experience and satisfaction.

ORAL HYGIENE IN SPONDYLOARTHRITIS: UNVEILING KNOWLEDGE GAPS AND OPPORTUNITIES FOR PREVENTION

Z. S. Zanned[1], M. K. Maatallah[1], B. N. D. Ben Nessib[1], K. L. Kharrat[1], M. F. Majdoub[1], F. H. Ferjani[1], K. D. Kaffel[1], H. W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Mannouba, Tunisia

Introduction: Periodontal disease has been linked to various chronic systemic diseases, including chronic inflammatory rheumatic diseases. Some studies hypothesize that in genetically predisposed individuals, periodontal pathogens may trigger a response responsible for the development of spondyloarthritis (SpA). These findings have heightened interest in the oral hygiene habits of patients with SpA.
Objectives: To evaluate the knowledge and habits of patients with SpA regarding oral hygiene.
Methods: A prospective descriptive study was conducted, including patients diagnosed with SpA according to the ASAS 2009 criteria. Demographic data, SpA-related information, and treatment details were collected. Oral hygiene practices were assessed using a questionnaire.
Results: Thirty-six patients with SpA were included. The mean age was 42.6±12.5 years, with a male predominance (70%). The mean disease duration was 12.4±3.5 years. Seventeen patients (47.2%) were active smokers, and 5 (16.6%) consumed alcohol.

The mean BASDAI was 4.5±2.3, and the mean BASFI was 4.6±2.2. Regarding oral complaints, dental pain was reported by 30.5% (11 patients), gingival bleeding during brushing by 22.2% (8 patients), and tooth mobility by 2.7% (1 patient). For daily oral hygiene, 83.3% of patients brushed their teeth regularly. Among them, 58.3% (21 patients) brushed once per day, and 8.3% (3 patients) brushed twice daily. Most patients brushed for two minutes in 50% (18 patients) of cases, while 38.8% (14 patients) did not pay attention to brushing duration. The use of dental floss and mouthwash was observed in only 8.3% (3 patients) and 16.6% (6 patients), respectively.
Regarding toothbrush replacement, 38.8% (14 patients) replaced their toothbrush every 2 months, while 25% (9 patients) did so every 3 months or more. The last dental visit occurred within 3 months for 27.7% (10 patients), between 3 and 6 months for 41.6% (15 patients), and over 1 year ago for one-third of patients (11 patients).
Statistical analysis revealed that poor oral hygiene practices were significantly associated with active smoking (p=0.02) and higher BASDAI scores (p=0.03). Patients with gingival bleeding during brushing had significantly longer disease duration (p=0.04). Additionally, irregular dental visits were associated with higher pain scores on the VAS scale (p=0.01).
Conclusion:
The level of knowledge regarding oral hygiene among patients with spondyloarthritis appears to be insufficient. These findings highlight the importance of prevention and awareness programs focused on oral hygiene. Strengthened collaboration between rheumatologists and oral healthcare professionals could help mitigate the potential impact of periodontal factors and improve the overall management of these patients.

P943

LONG-TERM OUTCOMES OF DENOSUMAB THERAPY IN SACRAL ANEURYSMAL BONE CYST: A 7 YEAR FOLLOW-UP CASE REPORT

M. K. P. Kardum Pejić[1], N. G. T. Gojo Tomić[1], J. P. Pejić[1], D. P. Perović[1]

[1]Dubrava University Hospital, ZAGREB, Croatia

Background: Aneurysmal bone cysts (ABCs) are rare, benign, but locally aggressive bone lesions that can present significant therapeutic challenges, particularly in anatomically complex regions such as the sacrum. While surgical resection and radiotherapy remain standard treatment options, alternative approaches are warranted in cases where these interventions pose high risks. Denosumab, a monoclonal antibody targeting RANKL, is approved for the treatment of giant cell tumors of bone (GCTBs) and has shown potential benefits in ABCs due to their similar pathophysiology, characterized by osteoclast-mediated bone resorption.

Case report: An 18-year-old female diagnosed with a sacral ABC was initiated on denosumab therapy in April 2016 due to the high surgical risk associated with the lesion's location. Treatment followed the standard GCTB protocol, with an initial loading dose of 120 mg subcutaneously weekly for 4 weeks, followed by monthly injections for a total duration of 12 months. The patient experienced complete pain resolution early in the treatment course. Follow-up MRI scans at 6 and 11 months demonstrated significant new bone formation and lesion stabilization. At the 7-year follow-up, the patient remains asymptomatic, with stable imaging findings and no recurrence. No adverse effects, including hypocalcemia or osteonecrosis, have been observed, and the patient continues regular vitamin D supplementation as part of ongoing bone health management.

Conclusion: This case highlights the long-term efficacy and safety of denosumab in the management of sacral ABCs. The treatment provided sustained symptomatic relief and radiological stability without complications. Denosumab represents a promising therapeutic alternative in cases where surgery is not feasible, with appropriate metabolic monitoring and bone health support.

Keywords: aneurysmal bone cyst, denosumab, sacral lesion, bone health, long-term follow-up, RANKL inhibition.

P944

LONG-TERM BISPHOSPHONATE THERAPY AND MEDICATION-RELATED OSTEONECROSIS OF THE JAW (MRONJ): A CASE REPORT

M. K. P. Kardum Pejić[1], M. T. Tarle[1], J. P. Pejić[1]

[1]University Hospital Dubrava, ZAGREB, Croatia

Introduction: Bisphosphonates are widely used in the treatment of osteoporosis due to their effectiveness in reducing fracture risk. However, long-term use has been associated with rare but serious complications, including medication-related osteonecrosis of the jaw (MRONJ). This case highlights the importance of regular monitoring and careful evaluation of prolonged bisphosphonate therapy, especially in cases where treatment duration extends beyond recommended guidelines.
Case Report: A 1943-born female patient with a 27-year history of bisphosphonate therapy for osteoporosis, which was inadvertently continued beyond the recommended duration, presented with swelling and pain in the right submandibular region. Initial imaging revealed a suspected abscess, and the patient underwent incision and drainage, followed by antibiotic therapy. Despite initial improvement, subsequent imaging confirmed the presence of MRONJ, although no significant radiological signs were observed at the onset of symptoms.
Further imaging showed minor sclerosis in the mandibular region, prompting discontinuation of bisphosphonates. Antibiotic therapy was administered, and hyperbaric oxygen therapy was recommended. An endocrinological reassessment led to the discontinuation of bisphosphonates, along with the introduction of vitamin D supplementation and dietary recommendations for calcium-rich foods to support osteoporosis management.
Conclusion: This case underscores the need for cautious long-term prescribing of bisphosphonates and the importance of early recognition and multidisciplinary management of potential

complications such as MRONJ. Regular follow-ups and reassessments are crucial to optimizing osteoporosis treatment while minimizing adverse effects.

P945

FAMILIAL HYPERCALCIURIC HYPERCALCAEMIA (FHH) AND OSTEOPOROSIS IN A PATIENT TREATED WITH CINACALCET AND ZOLEDRONIC ACID

M. Kavanagh[1], D. Fitzpatrick[2], G. Steen[1], N. Maher[1], N. Fallon[1], C. O'Carroll[1], R. Lannon[1], K. Mccarroll[1]

[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland, [2]Mater Miscericordiae University Hospital, Dublin, Ireland

Introduction: Familial hypocalciuric hypercalcaemia (FHH) is a rare autosomal dominant condition. The majority of cases results from a mutation in the Calcium Sensing Receptor (CSAR). This shifts the set point higher for serum calcium giving rise to mild hypercalcaemia and a high or non-suppressed serum parathyroid hormone (PTH). While FHH is not associated with bone loss it may co-exist with osteoporosis, cause symptomatic hypercalcaemia and be mistaken for primary hyperparathyroidism. We report the case of a female with FHH, symptomatic hypercalcaemia and osteoporosis that was treated with cinacalcet and zoledronic acid.

Case: A 54-year-old lady with osteoporosis (lowest T-score -2.5), intolerant of oral bisphosphonates, was referred to our clinic. Medical history included FHH (CSAR mutation positive) diagnosed at age 36 presenting with mild hypercalcaemia (serum calcium 2.85 mmol/l) and a non-suppressed serum PTH (45 pg/ml). There was no immediate family history so primary hyperparathyroidism was initially suspected. However, 24-hour urinary calcium was low (1.5 mmol) and genetic testing confirmed FHH. She also had a childhood diagnosis of cyclic neutropenia (ELA gene positive) with recurrent sepsis, until treated with G-CSF. G-CSF was the only potential risk factor for osteoporosis apart from being menopausal. Given her intolerance of oral bisphosphonates, she was started on zoledronic acid. At clinic, she complained of dehydration and polyuria for over one year and had persistent hypercalcaemia (2.84mmol/l). Four weeks after starting cinacalcet her serum calcium decreased to 2.60 mmol/l, remained lower at 3 months (2.56 mmol/l) and was associated with improved symptoms

Discussion: FHH is rare and may co-exist with osteoporosis though can be mistaken for primary hyperparathyroidism. Importantly, even without a family history the diagnosis should be considered, as 5-10% may result from de novo mutations. Symptomatic hypercalcaemia is rare in FHH but can respond to cinacalcet, though case reports are limited, and long-term data is lacking. G-CSF appears to be associated with bone loss though more studies are needed to further explore this.

P946

HIGHER SERUM URATE ASSOCIATED WITH INCREASED RISK OF HIP FRACTURE INDEPENDENT OF BONE MINERAL DENSITY

M. Kavanagh[1], G. Steen[1], N. Maher[1], N. Fallon[1], C. O'Carroll[1], R. Lannon[1], K. Mccarroll[1]

[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland

Objective: Serum urate is associated with higher bone mineral density (BMD) but the relationship with fracture is more complex and conflicting. Some studies have identified an increased risk of hip fracture with increasing serum urate and in patients with gout. We aimed to explore the relationship between serum urate and hip fracture in patients attending our bone health clinic.

Material and methods: We identified patients attending our bone health clinic with a history of hip fracture who had serum urate levels measured. The relationship between urate and hip fracture was explored in multinomial regression adjusting for age, sex, renal function (eGFR), body mass index, serum 25(OH)D, parathyroid hormone, and total hip BMD.

Results: There were 1600 patients of whom 70% were female, mean age 70.0 years. Compared to those in the lowest quartile of urate, those in both the highest and third highest quartile had an increased risk of hip fracture (p=0.001). This remained significant after adjusting for hip BMD with a respective increased risk in the highest quartile (OR 2.17, CI 1.36 – 3.47, p=0.001) and third highest quartile (OR 1.68, CI 1.08 – 2.62, p=0.020).

Conclusion: Serum urate positively predicted hip fracture independent of BMD. This suggests that any increased fracture risk may be mediated by negative effects on bone quality. Limitations were that we were not able to account for thiazide diuretics and confounding factor such as diabetes or a diagnosis of gout. Further studies are required to elucidate on the complex relationship between serum urate and bone health.

P947

EXTERNAL VALIDATION OF A DEEP-LEARNING BASED OSTEOPOROSIS SCREENING METHOD USING CHEST FRONTAL RADIOGRAPH - A SINGLE CENTER, RETROSPECTIVE STUDY

J. Song[1], M. Kim[1], S. Park[1], H. Bae[1]

[1]Promedius Inc., Seoul, South Korea

Objective: This study aims to externally validate the performance of a deep-learning model for screening osteoporosis using frontal chest radiographs.

Materials and Methods: We retrospectively included individuals (age ≥ 50yrs) who visited Yangji Hospital in Seoul, South Korea, from June 2023 to June 2024, and underwent both a chest posteroanterior radiograph (CXR) and a DXA scan on the same date. For AI analysis, we used commercially available AI software (CXR:OSTEO, Promedius Inc.), which analyses CXR to produce a confidence score (0–1). Based on this score, the individuals are clas-

sified as either high or low risk for osteoporosis. We assessed the model's performance by using the bone mineral density (BMD) category from DXA T-scores as the reference standard. Subgroup analysis was conducted based on age or sex. Also, the model's AUC was compared with that of calcaneal quantitative ultrasound (QUS).

Results: Among the 500 subjects (76.4% female; mean age, 63.3 years), 100 individuals had osteoporosis, while 400 did not. The model demonstrated an AUC of 0.866 (95% CI: 0.827–0.905). Using the pre-defined threshold 0.5 for binary classification, the sensitivity, specificity, PPV, and NPV were 77.0%, 80.3%, 49.4%, and 93.3%, respectively. In the sex-based subgroup analysis, the model achieved AUCs of 0.87 and 0.80 for female and male subjects, respectively. The AUC ranged from 0.82 to 0.91 among different age groups. Compared with QUS, the model's AUC of 0.866 was higher than the previously reported QUS AUCs (0.66–0.766).

Conclusion(s): The deep-learning model demonstrated robust performance in identifying individuals with osteoporosis from CXRs during external validation. This highlights its potential as a screening tool for osteoporosis, utilizing CXRs, the most widely used imaging modality worldwide.

P948

ADVANCING OPPORTUNISTIC SCREENING OF STRATIFIED BONE MINERAL DENSITY DISORDERS USING DEEP LEARNING ON CHEST X-RAY

M. Kim[1], M. Kim[1], S. Park[1], H. J. Bae[1]

[1]Promedius Inc., Seoul, South Korea

Objective:
Bone mineral density (BMD) disorders, including osteoporosis and its osteopenia subtypes (mild, moderate, advanced), are highly prevalent conditions that significantly increase the risk of fractures if left undiagnosed or untreated. While Dual-Energy X-ray Absorptiometry (DXA) remains the gold standard for BMD assessment, its high cost and limited accessibility hinder its use in opportunistic screening. This study aims to develop a deep learning model leveraging chest X-rays (CXRs) to classify BMD into normal BMD or osteoporosis categories and further stratify osteopenia into specific subtypes. By enabling precise and early detection, this approach seeks to enhance bone health management through cost-effective and scalable solutions.
Materials and Methods:
We retrospectively collected 69,201 CXR images and corresponding DXA scans from a single tertiary care hospital in South Korea. BMD was categorized using DXA T-scores into normal BMD (≥ -1.0), mild osteopenia (-1.0 to -1.49), moderate osteopenia (-1.5 to -1.99), advanced osteopenia (-2.0 to -2.49), and osteoporosis (≤ -2.5). The dataset was split into 80% for training the deep learning model and 20% for internal validation. For external validation, an additional 3,338 chest X-ray images were acquired from an external institution to evaluate the model's generalizability. We developed a cascaded deep learning architecture that first classifies each chest X-ray as normal BMD, osteopenia, or osteoporosis, and then further stratifies osteopenia cases into mild, moderate, and advanced subtypes. Model performance was assessed using the area under the receiver operating characteristic curve (AUC) to ensure accurate classification and stratification of BMD disorders.
Results:
For internal validation, the model achieved AUC scores of 0.934, 0.947, 0.738, 0.804, and 0.867 for normal BMD, osteoporosis, and osteopenia subtypes (mild, moderate, advanced), respectively. Similarly, during external validation, the model demonstrated consistent performance, achieving AUC scores of 0.868 for normal BMD, 0.899 for osteoporosis, and 0.652, 0.754, and 0.819 for osteopenia subtypes.
Conclusion:
The deep learning model effectively classifies BMD into normal BMD, osteoporosis, and stratifies osteopenia into mild, moderate, and advanced subtypes using CXRs. This detailed stratification enables targeted interventions and early prevention of osteoporosis progression, improving patient outcomes and optimizing healthcare resources through scalable and efficient bone health monitoring.

P949

THE IMPACT OF SARCOPENIA RISK ON FUNCTIONAL AND NUTRITIONAL STATUS IN OLDER ADULTS UNDERGOING JOINT REPLACEMENT SURGERY FOR OSTEOARTHRITIS

M. Koca[1], B. Çubukcu[1], F. N. Barlık[1], H. B. Çevik[2], S. Cihan[2], O. B. Keçelioğlu[2], E. Duman[2], G. Şengül Ayçiçek[1]

[1]Department of Geriatrics, Etlik City Hospital, Ankara, Turkiye, [2]Department of Orthopedic Surgery, Etlik City Hospital, Ankara, Turkiye

Objective
Osteoarthritis (OA) and sarcopenia are two common musculoskeletal disorders frequently observed in older adults. Understanding and addressing the interplay between OA and sarcopenia is crucial in managing musculoskeletal health in older adults.
Material and Methods
Patients 65 years and older with OA who were hospitalized for joint replacement surgery in orthopedic surgery ward underwent comprehensive geriatric assessment (CGA). Patients were grouped into two according to their sarcopenia risk status that was determined with SARC-F score and groups were compared in terms of individual CGA components.
Results
A total of 82 patients were consecutively included in the analysis. Of the study sample, mean age was 72.90 and 68.29 % was women. Two groups were similar regarding their mean age and

sex distribution. Whereas patients with a SARC-F score of 4 or more and thus at high risk of sarcopenia were observed to be more dependent in both basic and instrumental activities of daily living (ADL) according to their Katz ADL and Lawton-Brody IADL scores, respectively. Moreover, high-sarcopenia risk group carried a higher malnutrition risk with lower Mini Nutritional Assessment short form scores and more prone to frailty having higher frailty scores with Clinical Frailty Scale.

	High Sarcopenia Risk SARC-F≥4 n=45	SARC-F<4 n=37	*P*
Age	73.51 (SD:4.67)	72.16 (SD:4.53)	0.19
Sex (female)	34 (75.55%)	22 (59.45%)	0.11
Katz ADL	5 (IQR:1)	6 (IQR:1)	**0.003**
Lawton-Brody IADL	7 (IQR:2)	8 (IQR:0)	**<0.001**
CFS	5 (IQR:1)	4 (IQR:1)	**<0.001**
GDS	3 (IQR:5.5)	1(IQR:3)	**0.011**
MNA-sf	10.5 (IQR:1.25)	12.0 (IQR:1)	**0.001**
Vitamin B12	245 (IQR:175.5)	290 (IQR:154.5)	0.27
Ferritin	97.0 (IQR:81)	86.5 (IQR:72.25)	0.31
25-OH Vitamin D	13.5 (IQR:12.25)	17 (IQR:15.5)	0.09

Conclusion

Patients with OA who are at high risk for sarcopenia demonstrated greater dependency in daily living activities, higher malnutrition risk, and increased frailty levels. These findings underscore the importance of integrating sarcopenia screening and targeted interventions into the management and rehabilitation of older adults with osteoarthritis to improve functional outcomes and overall health.

TRABECULAR BONE SCORE AND BACK PAIN IN WOMEN WITH RHEUMATOID ARTHRITIS

M. Kozyreva[1], N. Demin[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to assess the bone microarchitecture using the trabecular bone score (TBS) and its association with back pain in women with rheumatoid arthritis (RA)

Material and methods: 128 women with a confirmed RA were divided into two groups: I - 100 people (mean age 58.8±11.9 years) with back pain according to VAS ≥40 mm, II - 28 persons (mean age 57.8±10.6 years) with back pain according to VAS <40 mm. All patients underwent questionnaires, dual-energy X-ray absorptiometry (DXA) of the lumbar spine (Lunar Prodigy Advance, USA). The bone microarchitecture was assessed depending on the TBS level: degraded - TBS ≤ 1.23, partially degraded – TBS 1.23 - <1.31, normal microarchitecture - TBS ≥ 1.31. Lateral vertebra assessment (LVA) was performed. The study was approved by the local ethics committee.

Results: Low TBS was detected in 29%, partially degraded microarchitecture in 20% and normal microarchitecture in 51% of the examined patients. In group I, the median TBS was 1.31 [1.21; 1.40], and in group II - 1.32 [1.22; 1.43], p>0.05. Low TBS was observed in 28% of patients in group I and in 32% in group II (p>0.05). In group I, vertebral fractures (VF) were diagnosed in 14 (14%) individuals, and in group II – in 1 (3.6%) patient (p>0.05). Among patients with VF, the mean level of back pain was 69.1 [49.5; 77.5] mm, and in women without fractures - 30.5 [20.0; 50.0] mm, p<0.05. Low TBS was significantly more common in patients with VF, and normal bone microarchitecture - in patients without VF (p<0.05).

Conclusion: Degraded bone microarchitecture was found in 29% of patients with RA. No association was observed between the TBS and the severity of back pain. Significant differences in back pain were found in patients with VF compared to those without them. Low TBS was significantly more common in patients with VF than in patients without them.

P951

ASSOCIATION OF TRABECULAR BONE SCORE WITH CLINICAL AND LABORATORY PARAMETERS IN WOMEN WITH RHEUMATOID ARTHRITIS

M. Kozyreva[1], N. Demin[1], O. Nikitinskaya[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to establish the frequency of damaged bone microarchitecture according to trabecular bone score (TBS) and to evaluate the relationship with biochemical parameters in women with rheumatoid arthritis (RA).

Material and methods: 193 women with a confirmed RA (mean age 60.7±9.9 years) were included. Questionnaires, laboratory examination (determination of erythrocyte sedimentation rate (ESR), glucose, total cholesterol, uric acid, creatinine, total protein, parathyroid hormone (PTH), albumin, alkaline phosphatase (ALP), calcium and phosphorus levels); dual-energy X-ray absorptiometry (DXA) of the lumbar spine were performed. TBS calculation of was done using TBS Insight software, version 3.0. The study was approved by the local ethics committee.

Results: According to TBS data, microarchitecture was normal in 87 (45.1%) women, partially degraded in 48 (21.9%), and degraded in 58 (30%) individuals. Negative associations were found between TBS and age (r=-0.36, p<0.0001), duration of postmenopausal period (r=-0.17, p<0.05), PTH level (r=-0.29, p<0.05), ALP level(r=-0.21, p<0.05), as well as a positive association with phosphorus level (r=0.27, p<0.05). No associations with other biochemical parameters were found. Univariate linear regression analysis confirmed the relationship between TBS and age (β = -0.36, p < 0.0001), duration of postmenopausal period (β = -0.17, p < 0.05), PTH (β = -0.30, p < 0.05), ALP (β = -0.21, p < 0.05) and phosphorus (β = 0.27, p < 0.05) levels in women with RA.

Conclusion. Bone microarchitecture as measured by TBS was inversely associated with age, duration of postmenopausal period, PTH and ALP levels, and directly associated with phosphorus levels.

P952

PREVALENCE OF CLINICAL MANIFESTATIONS AMONG HYPOPHOSPHATASIA SUBJECTS IN CENTRAL AND EASTERN EUROPEAN COUNTRIES

M. Kužma[1], J. Payer[1], R. Petrovič[2], M. Szegedi[3], I. Dzivite-Krišane[4], M. Žerjav Tanšek[5], J. Haschka[6], H. Resch[7], R. Kocijan[6]

[1]5th department of Internal medicine, Comenius University Faculty of medicine, University Hospital, Bratislava, Slovakia, [2]Institute of Medical Biology, Genetics, and Clinical Genetics, Comenius University Faculty of Medicine, University Hospital, Bratislava, Slovakia, [3]Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary, [4]Children's University Hospital, Riga, Latvia, [5]Department of Pediatric Endocrinology, Diabetes, and Metabolic Diseases at the Division of Pediatrics, University Medical Centre, Ljublana, Slovenia, [6]Ludwig Boltzmann Institute of Osteology at Hanusch Hospital of OEGK and AUVA Trauma Center Vienna-Meidling, Vienna, Austria, [7]St. Vincent Hospital Vienna, II Medical Department, Vienna, Austria

Introduction: Hypophosphatasia (HPP) is a rare, life-threatening, progressive, systemic, congenital metabolic disorder caused by a "loss-of-function" mutation in the *ALPL* gene, which encodes tissue-nonspecific alkaline phosphatase (TN-ALP). HPP is a multi-organ disease, with its hallmark feature being impaired bone mineralization.
Aim: The objective of this study was to evaluate the prevalence of HPP in the Central and Eastern European (CEE) region and to assess the frequency of its clinical manifestations, including skeletal, joint, neurological, and renal symptoms.
Patients and Methods: A cross-sectional study was conducted on 49 patients with genetically confirmed HPP. Detailed clinical information was available for 34 patients from five CEE countries.
Results: The analyzed cohort consisted of 14 males and 20 females, with a mean age of 51 years. Among these, 10 patients presented with the pediatric form of HPP, while 18 were diagnosed with adult-onset HPP. A total of 33 patients (92%) exhibited TN-ALP levels below the reference range. Only one patient received treatment with asfotase alfa. Chronic pain was reported by 25 patients (69%), while tooth loss, fractures, and bone deformities were observed in 9, 15, and 6 patients, respectively. One patient had a bone mineral density (BMD) in the osteoporotic range, and three patients had a trabecular bone score (TBS) ≤1.23. Other clinical manifestations included calcifying periarthritis (7 patients), seizures (3), nephrocalcinosis (3), hypercalcemia (3), kidney stones (2), ectopic calcifications (1), and pseudogout (1). Notably, 24 patients (71%) reported the regular use of at least four analgesics.
Conclusion: This study, based on one of the largest reported cohorts of HPP patients highlights that chronic pain is the most prevalent symptom, often necessitating the use of multiple analgesics. Bone-related complications, such as fractures and deformities, and joint-related conditions, particularly calcifying periarthritis, are also frequent. These findings emphasize the need for greater awareness of HPP, along with dedicated research efforts to enhance patient care and improve access to effective treatments.

P953

GLOBAL BURDEN AND MANAGEMENT OF HYPOPHOSPHATAEMIC OSTEOMALACIA: AN IOF SURVEY

M. L. Brandi[1], P. Halbout[2], D. D. Pierroz[2], N. Harvey[3]

[1]FirmoLab, FIRMO Foundation, Florence, Italy, [2]International Osteoporosis Foundation, Nyon, Switzerland, [3]University of Southampton, Southampton, United Kingdom

Objectives: This study aimed to explore the burden and management of hypophosphataemic osteomalacia (HO).

Materials and Methods: A survey was developed consisting of seven general questions about respondents and their experiences of treating patients with HO, and a second section inviting non-identifying information on up to five patients with HO. The survey was disseminated to the International Osteoporosis Foundation (IOF) network.
Results: Forty clinicians from 24 countries participated, with most based in academic medical centres. Respondents reported managing over 1,000 patients with HO, primarily diagnosed with X-linked hypophosphataemia (XLH; 35%), tumour-induced osteomalacia (TIO; 24%) and fibrous dysplasia/McCune–Albright syndrome (FD/MAS; 16%). Management patterns varied by diagnosis, with XLH and TIO primarily managed by endocrinologists, while FD/MAS was more often managed by rheumatologists. Respondents provided additional information on 19 patients with XLH, 28 with TIO and 9 cases of other types of HO. Common symptoms across XLH and TIO included bone pain (XLH: 67%, TIO: 88%), muscle pain (XLH: 61%, TIO: 76%) and muscle weakness (XLH: 61%, TIO: 88%). Many patients with XLH had discontinued phosphate and vitamin D therapies, with a subset starting burosumab. In contrast, phosphate and vitamin D therapies were commonly used for patients with TIO, and many were being considered for tumour resection, with limited use of burosumab. Pain medication use, including opiates, was relatively high across all patients.
Conclusions: Awareness of XLH and TIO was particularly high among respondents, indicating strong global interest from bone specialists. Patients with XLH and TIO continue to experience troublesome musculoskeletal symptoms. To enhance patient outcomes, it's essential to educate healthcare professionals worldwide on XLH and TIO, along with management approaches.

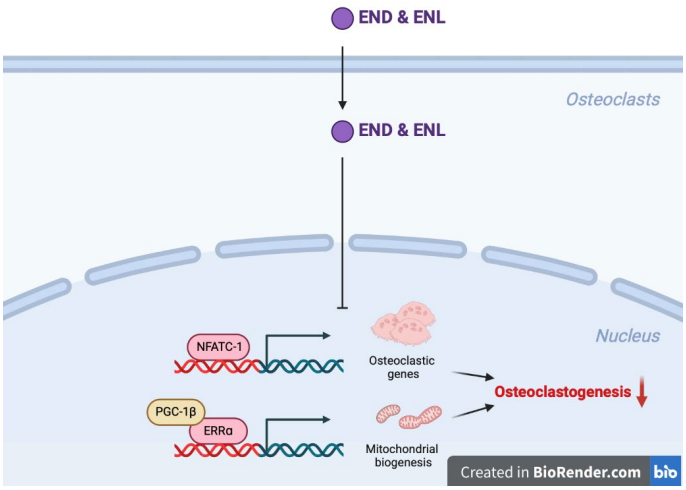
ENTERODIOL AND ENTEROLACTONE INHIBIT RANKL-INDUCED OSTEOCLASTOGENESIS BY REGULATING PGC-1B/ERR□ MEDIATED MITOCHONDRIAL BIOGENESIS

M. L. Hsu[1], P. C. Chen[1], C. H. Hou[2]

[1]National Taiwan Normal University, Taipei city, Taiwan, [2]National Taiwan University Hospital, Taipei city, Taiwan



Objective(s)

Osteoporosis (OP) is the most common bone disease in the elderly and postmenopausal women. OP occurs when the rate of bone resorption exceeds the rate of bone formation, leading to decreased bone density and increased risk of fractures. Osteoclasts are specialized cells responsible for bone resorption, a highly energy-demanding process. Receptor activator of nuclear factor-κB ligand (RANKL)-induced osteoclastogenesis results in increases in mitochondria size and number, several factors related to mitochondrial biogenesis and functions, such as peroxisome proliferator activated receptor-gamma coactivator-1β (PGC-1β) and estrogen-related receptor α (ERRα) have been shown to play a fundamental role in mitochondrial biogenesis and osteoclast differentiation. Thus, focusing on osteoclast metabolic shifts could be a key for the treatment of osteolytic diseases including OP.

Enterodiol (END) and enterolactone (ENL) are plant-based polyphenolic compounds digested in the colon by bacteria. Both END and ENL have been reported have antioxidant and estrogen-like physiological regulatory functions. However, previous studies have not clearly elucidated the mechanisms by which END and ENL protect bone, particularly their roles in regulating osteoclast differentiation and function, which require further investigation.

Material and Methods

Tartrate-resistant acid phosphatase (TRAP) staining, F-actin ring staining and bone resorption assay were performed to evaluate the inhibitory effects of END and ENL on RANKL-induced osteoclastogenesis in macrophage cell line RAW 264.7 and mouse bone marrow-derived mononuclear cells (BMMs). RNA-seq was employed to identify the differential genes by END and ENL. The molecular mechanism of END and ENL were investigated by quantitative reverse transcription polymerase chain reaction (RT-qPCR), and western blot.

Results

100 μM END and ENL significantly inhibit osteoclast differentiation, F-actin ring formation and bone resorption from both RAW 264.7 cells and BMMs. Treatment with 100 μM END and ENL reduced the expression levels of differentiation markers Integrin-β3, MMP-9, Cathepsin K, NFATc-1 and c-FOS. 100 μM END and ENL suppress PGC-1β/ERRα-dependent mitochondrial biogenesis in osteoclastogenesis.

Conclusion

In summary, our findings demonstrated that END and ENL may influence osteoclast differentiation and function by regulating mitochondrial energy metabolism, offer new therapeutic reagents for preventing OP.

P955

RADIATION-INDUCED ACCELERATED AGING IN BREAST CANCER SURVIVORS: A PROSPECTIVE COHORT STUDY PROTOCOL

M. Locquet[1], V. Remouchamps[2], J. Douxfils[3], C. Beaudart[1]

[1]Public Health Aging Research & Epidemiology (PHARE) Group Research Unit in Clinical Pharmacology and Toxicology (URPC) NAmur Research Institute for LIfe Sciences (NARILIS) Department of Biomedical Sciences- Faculty of Medicine, University of Namur, Namur, Belgium, [2]Radiotherapy Oncology Department, CHU-UCL-Namur, Namur, Belgium, [3]Unit in Clinical Pharmacology and Toxicology (URPC), Department of Pharmacy, NAmur Research Institute for LIfe Sciences (NARILIS), University of Namur, Namur, Belgium

Objective: Radiotherapy (RT) in breast cancer (BC) survivors is suggested to accelerate aging by close interrelationships between cancer, anti-cancer RT, and induced aging mechanisms. This study aims to develop a large prospective cohort to compare the incidence of accelerated aging outcomes between BC survivors treated with RT and cancer-free controls.

Materials and Methods: The cohort will include BC women survivors treated with RT and age-matched cancer-free women controls. BC survivors will be recruited from Belgian oncology clinics, while controls will be identified through referrals, advertisements, and negative mammogram screenings. Data collection involves (i) baseline and follow-up evaluations (1, 3, and 5 years) including but not limited to comprehensive geriatric assessments to diagnose sarcopenia, frailty, osteoporosis and physical function using validated tools (Dual X-ray absorptiometry, strength dynamometer, Short Physical Performance Battery test, FRAX tool) (ii) cancer and treatment data (BC survivors) including detailed records of BC subtype, stage, radiotherapy protocol (e.g., dose, fractionation, irradiated field, total dose to critical structures, site-specific dose reconstruction) (iii) data linkage with the Belgian Cancer Registry and StatBel (Belgian statistics office) for long-term follow-up of aging clinical manifestations and survival outcomes. The study will be conducted at CHU-UCL-Namur (Namur, Belgium), Cliniques Universitaires Saint-Luc (Brussels, Belgium), and poten-

tially extended to other Belgian centers (CHU-Liège, Jules Bordet Institute). It hypothesizes that BC survivors treated with RT will present earlier and higher incidence of aging-related outcomes, including sarcopenia, osteoporosis, and frailty, compared to cancer-free controls and the general population. Advanced statistical methods will be applied, such as Fine-Gray competing risk models and linear mixed models for internal group comparisons (BC survivors vs. cancer-free controls) and standardized incidence ratio/excess relative risks for external comparisons with Belgian reference registries (BC survivors vs. Belgian reference population).
Results: Not applicable
Conclusion: This study protocol hypothesizes that RT for BC may trigger accelerated aging in survivors. Early identification of this aging process could enable personalized RT protocols, preventive aging interventions during BC survivors' supportive care, and the development of novel therapeutic targets addressing aging-related endpoints.

P956

ROMOSOZUMAB IN SWEDEN – A REGISTRY STUDY ON OSTEOPOROSIS PATIENTS

M. Lorentzon[1], T. Borgen[2], B. L. Langdahl[3], E. Bajtner[4], T. Kaarill[4], H. Skröder[5], J. Liseth Hansen[5], C. Andersson[4], A. Moayyeri[6]

[1]Sahlgrenska Osteoporosis Centre, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [2]Department of Rheumatology, Drammen Hospital, Vestre Viken Hospital Trust, Drammen, Norway, [3]Department of Endocrinology, Aarhus University Hospital, Aarhus, Denmark, [4]UCB, Copenhagen, Denmark, [5]Quantify Research, Stockholm, Sweden, [6]UCB, Brussels, Belgium

Objectives: Romosozumab (Romo) was approved for treatment of severe osteoporosis (OP) for postmenopausal women at high risk of fracture in the European Union in December 2019; since July 2020, it has been reimbursed in Sweden for postmenopausal women with OP and vertebral or hip fracture within the last year. This is the first study to characterise Romotreated patients in Sweden.
Material and Methods: We conducted a retrospective cohort study utilising data from patient and prescription registries in Sweden. Included patients were females aged ≥50 receiving OP medication from July 2020 to August 2024. The study included three patient cohorts that: i) were treated with Romo (cohort 1); ii) had OP-related fractures within the last two years but were treated with other OP medications (cohort 2), and iii) had no OP-related fractures within two years prior to initiating other OP treatments (cohort 3). Index date was defined as the first dispensation of Romo or other OP treatment after the date that Romo was reimbursed in Sweden. The baseline period was the five years prior to index. Baseline patient characteristics were compared between cohorts using chisquared (categorical) or Wilcoxon signed-rank tests (continuous).
Results: Overall, 132,945 patients were included; patient characteristics are shown in the **Table**. Patients treated with Romo (cohort 1) were generally younger and had lower prevalence of comorbidities and glucocorticoid use than cohorts 2 and 3. Of 1,114 patients treated with Romo, 76.9% did not receive any prior community or outpatient pharmacydispensed OP treatment, compared with 65.1% and 48.0% in cohorts 2 and 3, respectively. In the past year, cohort 1 had lower hip fracture incidence compared with cohort 2 (9.0% vs. 22.8%, p<0.001), and modestly greater spine (27.8% vs. 17.7%, p<0.001) and nonhip nonspine (50.5% vs. 39.1%, p<0.001) fracture incidence.
Conclusions: This study offers insight into the patterns of Romo use in clinical practice in Sweden. The available data suggest that over three-quarters of patients who received Romo had not received prior OP treatment, suggesting that first use of osteoanabolic agents in the treatment sequence of OP is largely being followed.

Use of glucocorticoids, n (%)	351 (31.5)	5,225 (18.8)	39,404 (37.9)
Osteoporosis diagnosis,[l] n (%)	991 (89.0)	8,858 (31.9)	14,389 (13.8)

[a] It is unlikely that patients are treated with non-romosozumab without meeting reimbursement criteria; poor use of ICD codes during vertebral fracture assessment likely accounts for the discrepancy observed between non-romosozumab treatment and recorded rates of vertebral and hip fractures. [b]Despite the reimbursement criteria for romosozumab specifying fractures sustained in the past year, a 2-year cut-off was used to define cohort 2 as treatment lasting times may surpass a year. Select additional non-hip non-spine fractures were included in the definition of OP-related fracture, based on clinical practice in Sweden. [c]Includes alendronate and risedronate. [d]Treatment history can include more than one treatment for each patient; OP treatment naïve includes patients who had never received prior community- nor outpatient pharmacy-dispensed OP treatments. [e]Includes: myocardial infarction, congestive heart failure, peripheral vascular disease, cerebrovascular disease. [f]Includes: diabetes without chronic complication, diabetes with chronic complication. [g]Includes: pulmonary heart diseases, chronic lower respiratory diseases, lung diseases due to external agents, other interstitial pulmonary diseases with fibrosis, and respiratory conditions due to inhalation of chemicals. [h]Includes: rheumatoid arthritis and related conditions, systemic lupus erythematosus, systemic sclerosis, dermatomyositis and polymyositis, overlap syndromes, polymyalgia rheumatica, and other systemic involvement of connective tissue. [i]Includes antipsychotics (lithium excluded), anxiolytics, hypnotics and sedatives, antidepressants, vasodilators used in cardiac diseases, antihypertensives, diuretics, beta blocking agents, calcium channel blockers, renin-angiotensin system inhibitors, alpha-adrenoreceptor antagonists, dopaminergic agents, opioids. [j]Fracture history can include more than one fracture across the three categories. [k]Previous glucocorticoid use defined as a minimum cumulative dose equivalent to ≥450 mg prednisolone within a three-month time window within the baseline period. [l]Includes: osteoporosis with current pathological fracture, osteoporosis without pathological fracture. OP= osteoporosis; SD= standard deviation.

P957

AN EXPLORATION OF CULTURE DEPENDENT MODIFIABLE RISK FACTORS FOR LOW BACK PAIN IN ADDIS ABABA, ETHIOPIA: - DEVELOPING AN INTEGRATED PREVENTATIVE MODEL

M. M. Belay[1], T. M. Mgutshin[2]

[1]Addis Ababa University, Addis Ababa, Ethiopia, [2]Unisa, Pretoria, South Africa

Background: The magnitude of LBP has increased in recent years. It has remained neglected with profound negative impact on the society. The risk factors continue to increase throughout communities as a result of limited preventive methods. Aim: The aim of this study was to offer in-depth exploration of cultural and social factors in vulnerability to LBP in order to develop a culturally sensitive integrated preventative model in Addis Ababa, Ethiopia.
Methods: A sequential explanatory mixed methods research design was employed to investigate the complex phenomenon of the study. Quantitative and qualitative data was collected through a combination of data collection tools that included interviewer-administered questionnaires and semi-structured interviews from both the back patients and healthcare providers in each of the selected public hospitals. Participants with back pain and healthcare providers working in the public hospitals were identified and sampled through a simple random sampling and purposive sampling technique, respectively. Findings: In the first phase, 170 participants took part in the study. Back pain is a multifactorial disorder, where the contributions of bio-medical and cultural factors for its occurrence are noteworthy. Chi square analysis showed a statistical association between seventeen variables of interest related to the participant group of individuals affected by LBP. In the second phase, back patients perceived that they were predisposed to LBP due to lack of knowledge and awareness on available prevention methods. Additionally, healthcare providers were blamed for their limited involvement in awareness-building about the severity and impacts of LBP. The low awareness rates were associated with increased risk of the development of LBP among the productive group of the community members. Conclusions: Prevention of LBP should not be seen as only involving bio-medical factors bust also other influences that include cultural and social factors. The emergent model has the benefit of integrating bio-medical, cultural and social modifiable factors for the prevention of LBP. Key concepts: LBP, culture, modifiable risk factors, non-modifiable risk factors, socio-demographic factors, psychosocial factors, work-related factors, socio-cultural factors.

P958

DEVELOPMENT OF A COST-EFFECTIVE OSTEOPOROSIS RISK SCORING SYSTEM FOR EARLY DETECTION IN LOW-RESOURCE SETTINGS: A COMMUNITY-BASED APPROACH

M. M. Muzzammil[1]

[1]Sindh government services hospital karachi, Karachi, Pakistan

Purpose:
Osteoporosis poses a significant public health burden, particularly in developing countries where advanced screening tools like dual-energy X-ray absorptiometry (DXA) are scarce. This study aimed to develop and validate a simple, community-based osteoporosis risk scoring system that can be used in low-resource settings to identify high-risk individuals for early intervention.
Methods:
A cross-sectional study was conducted in Karachi, Pakistan, involving 750 participants aged 40 years and above who attended a public hospital for routine health check-ups. A structured questionnaire, based on key osteoporosis risk factors, was developed and administered to collect demographic, clinical, and lifestyle data. Radiographic assessments, including vertebral X-rays to detect compression fractures and osteopenia, were performed on a subset of participants. Points were assigned for various risk factors, including age, gender, BMI, smoking status, alcohol consumption, history of falls, and X-ray findings. Participants were stratified into four risk categories (low, moderate, high, and very high) based on their total score. Statistical analysis, including multivariate logistic regression and receiver operating characteristic (ROC) curves, was used to assess the score's predictive accuracy.
Results:
The scoring system successfully categorized participants into low (38%), moderate (32%), high (20%), and very high (10%) risk groups. The model demonstrated strong predictive validity, with an area under the ROC curve (AUC) of 0.82. Sensitivity was 83%, and specificity was 75%, with a positive predictive value of 47% and a negative predictive value of 95%.
Conclusion:
This osteoporosis risk scoring tool offers a simple, cost-effective method for early identification of high-risk individuals in low-resource settings. It can significantly improve screening rates, allowing for timely interventions to prevent osteoporotic fractures in underserved populations.

P959

UNDIAGNOSED VERTEBRAL FRAGILITY FRACTURES IN PATIENTS WITH DISTAL RADIUS FRAGILITY FRACTURES: AN OPPORTUNITY FOR PREVENTION OF MORBIMORTALITY IN OSTEOPOROTIC PATIENTS IN DEVELOPING COUNTRIES

M. M. Muzzammil[1]

[1]Sindh government services hospital karachi, Karachi, Pakistan

Purpose: This study's main goal was to look into the frequency, location, kind, and severity of asymptomatic vertebral fragility fractures (VFF) in people who had fractures of the fragility of the distal radius. Although VFF is frequently misdiagnosed, it is linked to higher mortality, morbidity, and hip fracture risk. The study also attempted to investigate the relationship between VFF and certain demographic and lifestyle factors, as well as FRAX data, in this patient population.

Methods: Between Jan 2021 and Jan 2022, individuals with low-energy distal radial fractures who presented to the emergency room of tertiary care hospital of karachi Pakistan were the subject of a cross-sectional study and were 45 years of age or older except those who fitted the exclusion criteria (n=208). The thoracic and/or lumbar spine was imaged using radiology, and information on demographics, way of life, and FRAX (Fracture Risk Assessment Tool) was gathered. Using the Genant semiquantitative approach, an impartial and blinded orthopaedist identified VF in the images and determined their severity. SPSS version 20 was used to analyse the data.

Results: 211 (41.21%) of them were found to have radiographic VFF and Only 12 (2.34%) of the 512 patients who were tested were getting osteoporotic therapy. The thoracic spine (32.7%), followed by the lumbar spine (43.12%), was the area most frequently afflicted. In 24.17% of the patients, multiple fractures of the thoracolumbar spine were found. The wedge form (54.5%), followed by biconcave (30.81%) and crush (14.7%), was the most prevalent VFF type. The majority of detected VFF were rated as having a 25–40% height loss (64.9%) then severe (>40%) fractures (35.1%), according to the Genant grading method. Notably, there were no variations in smoking, drinking, BMI, or FRAX score between patients with and without VFF that were statistically significant.

Conclusion: Based on our study's findings, it's clear that osteoporotic vertebral fragility fractures occur in almost half of individuals with distal radius fractures. The lumbar spine is notably the most affected region, predominantly with wedge fractures. Given the high prevalence of asymptomatic vertebral fragility fractures (VFF), proactive measures are necessary to mitigate associated risks. Prioritizing comprehensive fall risk assessments for these patients and interventions to enhance bone mineral density and strength are crucial. Early identification of asymptomatic VFF enables timely intervention, optimizing patient care and minimizing the risk of complications in this vulnerable population

P960

CLINICAL CORRELATES OF NUTRITIONAL STATUS AND PONSETI TECHNIQUE SUCCESS IN CLUBFOOT PATIENTS

M. M. Muzzammil[1]

[1]Sindh government services hospital karachi, Karachi, Pakistan

Objective: Malnutrition is a critical health issue, particularly prevalent in developing countries, and is a major risk factor for diseases and mortality in children. Clubfoot or congenital talipes equinovarus (CTEV) is a common form of congenital orthopedic abnormality, and the Ponseti method has become the gold standard for its treatment over the last two decades. The primary objective of this study was to determine the prevalence of malnutrition in clubfoot patients and its impact on the outcome of the Ponseti technique in patients presenting to the Orthopedic Clinic of a tertiary care hospital in Karachi, Pakistan. Additionally, we aimed to assess the correlation between clinical tests, such as CBC, serum albumin levels, serum electrolytes, and nutritional status.

Methods: We conducted a cross-sectional study from January to December 2022, including a total of 153 clubfoot patients. The WHO classification of weight-for-age index was used to assess the nutritional status of patients, and clinical tests were also conducted to evaluate the correlation between malnutrition and the outcome of the Ponseti technique. Statistical analysis was performed with a P value ≤ .05 deemed significant.

Results: Of the 153 patients, 121 (74.5%) were in good nutritional status, while 32 (25.5%) were malnourished. The average number of casts required per patient and the proportion of patients requiring 6 or more casts were higher in the malnourished group (45.5% vs. 21.42%). The number of Achilles tenotomy procedures performed in the malnourished group was also higher (76.4% vs. 51.8%). Clinical tests showed a direct correlation between nutritional status and outcomes of the Ponseti technique.

Conclusion: Our study reveals a significant correlation between patients' nutritional status and the outcome of the Ponseti technique. Malnutrition can lead to an increased number of casts required for treatment and a higher likelihood of relapse and failure of treatment. The study also highlights the importance of clinical tests in evaluating the nutritional status of patients and its correlation with the outcomes of the Ponseti technique.

P961

REVOLUTIONIZING OSTEOPOROTIC DISTAL RADIUS FRACTURE CARE IN ASIA: TERIPARATIDE'S SWIFT ACCELERATION OF HEALING IN A PIONEERING DOUBLE-BLINDED TRIAL

M. M. Muzzammil[1]

[1]Sindh government services hospital karachi, Karachi, Pakistan

Objective:
As the Asian population experiences rapid aging, osteoporosis emerges as a prominent and costly health concern. Distal radius fractures, among the most prevalent fractures, are associated with an elevated risk of subsequent fractures. The swift attainment of union is crucial for the early resumption of daily activities and the mitigation of complications. Although teriparatide has demonstrated efficacy in accelerating fracture healing, there is a dearth of literature on its application in osteoporotic distal radius fractures among the Asian population. This study aims to evaluate the potential of teriparatide in expediting fracture healing.

Method:
A double-blinded randomized controlled trial, conducted from January 2015 to June 2019, included patients with extra-articular osteoporotic distal radius fractures managed conservatively with casting. The primary objective was to compare the impact of 8 weeks of once-daily subcutaneous teriparatide (20 micrograms) versus a placebo on the time to radiographic healing. Radiographic healing was defined by cortical bridging in three of four cortices, with secondary objectives including the time to healing of four cortices, assessment of anatomic deformity, and functional evaluations. Patients underwent screening on the day of the fracture, followed by randomization, an 8-week treatment period, an 8-week follow-up, and a safety extension for an additional 36 weeks.

Results:
Out of 214 screened patients, 202 women were enrolled, with 12 discontinuing before or during treatment. The remaining 202 women were randomly assigned to once-daily placebo (n 107) or 20 mg teriparatide (n 107). The median time to healing was significantly shorter in the teriparatide group (95% CI 2.5 to 0.7 weeks, p .005), with no significant between-treatment differences in secondary objectives. Both groups exhibited significant improvements in pain scores, functional tests, and grip strength compared to baseline.

Conclusion:
This study demonstrates that teriparatide (20 micrograms) accelerates the time to healing in conservatively managed distal radius osteoporotic fractures. Additionally, there were significant improvements in pain scores, functional tests, and grip strength after the 8-week treatment period. This suggests the potential for teriparatide to enhance fracture repair in this population.

P962

TERIPARATIDE INTERVENTION IN STEROID-INDUCED OSTEOPOROSIS: UNVEILING THE PREVALENCE, CHARACTERISTICS, AND THERAPEUTIC IMPACT ON VERTEBRAL FRACTURES

M. M. Muzzammil[1]

[1]Sindh government services hospital karachi, Karachi, Pakistan

This study explores the prevalence and management of vertebral fractures (VF) resulting from steroid-induced osteoporosis, with a specific focus on the role of teriparatide. Under the headings of Objective, Methodology, Results, and Conclusion, we investigate the impact of long-term glucocorticoid therapy on VF, characterize their occurrence, severity, and location, and assess the efficacy of teriparatide in managing these fractures.

Objective:
To determine the prevalence of asymptomatic vertebral fractures, characterize their location, type, and severity, and evaluate the role of teriparatide in managing fractures in patients on long-term glucocorticoid therapy.

Methodology:
This cross-sectional study involved screening 415 patients on prolonged steroid therapy for eligibility. Data collection included demographic, lifestyle, and FRAX information, along with radiological imaging of the thoracic and lumbar spine. An independent orthopedist, blinded to patient details, reviewed images for VF and utilized the Genant semiquantitative method for severity quantification. Additionally, the study explored the relationship between prior fractures and the risk of new fractures.

Results:
Among the screened patients (mean age 45.3 ± 25.12 years), 65.30% exhibited radiological VF. The thoracic spine (52.02%) was the most affected location, with wedge fractures being the most prevalent type. Teriparatide significantly reduced new VF compared to the placebo group. The study also observed prior fracture healing, as evidenced by reduced pain scores and improved quality of life in the teriparatide group.

Conclusion:
This study underscores a high prevalence of VF in patients on long-term glucocorticoid therapy, emphasizing an increased risk of new VF and non-VF. Teriparatide emerges as a promising treatment option, demonstrating greater increases in bone mineral density and significantly fewer new vertebral fractures. The findings suggest teriparatide's potential effectiveness in managing vertebral fractures secondary to steroid-induced osteoporosis, particularly in developing countries.

P963

A COMPARISON OF POSTOPERATIVE OUTCOMES BETWEEN INTERNAL BRACE AUGMENTED HAMSTRING TENDON AUTOGRAFT ACL RECONSTRUCTION AND NON-AUGMENTED HAMSTRING TENDON AUTOGRAFT

M. M. Valbuena[1], R. A. Jurilla[1]

[1]Philippine Orthopedic Center, Quezon City, Philippines

Anterior cruciate ligament (ACL) is the most injured knee ligament. The gold standard for management of acute ruptures of ACL is surgical treatment with ACL reconstruction (ACLR) using tendon or ligament autograft. *Background*. Internal brace augmented ACL reconstruction is a technique that marries a previously published technique with the potential advantages of suture tape augmentation to increase the biomechanical strength of the reconstruction at the time of surgery and potentially reinforcing the graft thereafter**.** *Methods*. Patients were randomly assigned into an experimental group or a control group. A total 67 patients were included in the study 36 patient underwent ACLR with hamstring tendon autograft and 31 patients underwent ACLR with internal bracing. Self-reported outcomes were measured using IKDC, Tegner- Lysholm and KOOS at 1 month, 4 months, 8 months and 1 year post-operatively. Joint laxity was assessed post-operatively at 4 months, 8 months and 1 year *Results.* IKDC scores revealed significant differences ($p < .001$) between the two surgical techniques at all time points. Tegner-Lysholm scores by the one-year mark showed continued improvement on both groups. The control group mean score was 95.7 (median 97), whereas the intervention group exhibited enhancement with a mean score of 98.5 (median 100). The intervention group recorded a mean KOOS score of 67.8 (median 69), indicating comparatively better early functional recovery and knee-related quality of life than the control group's mean score of 53.9 (median 52). The consistent negativity of the pivot shift test results in both groups suggests that most patients maintained a stable knee joint post-surgery, regardless of whether they received the intervention or not. *Conclusion*. The study concludes that hamstring autograft with internal bracing offers superior self-reported outcomes and knee stability compared to autograft alone, emphasizing the need for optimized surgical techniques to enhance patient outcomes and improve postoperative quality of life.

TARGETED THERAPY AND ONCOLOGICAL RISK: EVALUATION OF RHEUMATOLOGISTS' KNOWLEDGE AND ATTITUDES

R. Rahmouni[1], M. Mahjoub[1], Z. Zouaoui[1], R. Rekik[1], B. Bousaid[1], S. Sehli[1], [2]

[1]Rheumatology department Of Rabta Hospital, Tunisia, Tunis, Tunisia, [2], ,

Introduction: While the use of targeted therapies (TT) in rheumatology offers promising prospects, it also raises complex questions, particularly in patients with a personal history of neoplasia. The aim of our study was to describe rheumatologists' attitudes and knowledge regarding the prescription of TT in patients with CIRD who have a history of neoplasia or presenting with an active neoplasia.

Patients and methods:

A 19-item questionnaire was administered to rheumatology residents.

Results:

Eighteen participants were included. The sex ratio was 0,29 and the mean age was 28 years [25-32]. The average duration of practice in rheumatology was 2 years.

Before prescribing TT, 50% systematically inquired about a family history of neoplasia and 66,7% systematically investigated personal history of precancerous lesions.

Regarding the screening methods used were as follows: Patient interview and clinical examination (100%), mammography (17,6%), Pap smear (17,6%), (0%), PSA testing (58,8%), and Hemoccult test (17,6%).

Before prescribing TT, physicians considered the following; the type of cancer (92,9%), date of diagnosis (64,3%), oncological treatments received (21,4%), duration of remission (100%), and the risk of recurrence (78,6%).

Regarding the timing of prescription of TT in patients with a history neoplasia in remission, 38,9% adhered to a 5-year waiting period and 61,1% believed that timing depended on the type of cancer and/ the TT.

In case of solid neoplasia history, the preferred therapies were: anti-CD20 (56,7%), anti-TNF alpha (27,8%), anti-IL6 (22,2%), Abatacept (11,1%), anti-IL17 (16,7%), anti-IL23 (11,1%), anti-IL23/12 (11,1%), and JAKI (11,1%). While in case of lymphoma history, they were as follows: anti-CD20 (64,7%) JAKI (29,4%), anti-TNF alpha (17,6%) and anti-IL17 (5,9%) and).

Once initiated, 82,4% recommended monitoring for recurrence of neoplasia and/or the development of a new neoplasia.

In case of active neoplasia in a patient with active rheumatic disease, 16,7% considered maintaining the patient on corticosteroids alone, 83,3% opted for a combination of corticosteroids and CsDMARDs, and X considered switching to TT.

Conclusion: Greater awareness is required to effectively manage patients with a history of neoplasia.

P965

ASSESSING THE DUAL IMPACT OF TERIPARATIDE AND ZOLEDRONIC ACID ON OSTEOPOROSIS AND SARCOPENIA IN POSTMENOPAUSAL WOMEN IN BANGLADESH

M. Majumder[1], A. Mahadi[1], H. Shihab[1], N. Sakib[2]

[1]Central medical college, Cumilla, Bangladesh, Cumilla, Bangladesh, [2]Partner in Health and Development, Coxsbazar, Bangladesh, Coxsbazar, Bangladesh

Background:
Osteoporosis and sarcopenia are significant musculoskeletal challenges in postmenopausal women, characterized by bone mass loss and muscle weakness with substantial increase of fracture risks and reduction of quality of life. In most studies, sequential therapy with anabolics followed by antiresorptives was tested with promising results.This study aims to evaluate the efficacy of teriparatide followed by zoledronic acid in improving bone mineral density and functional outcomes in postmenopausal women with severe osteoporosis and osteoporosis with BMD >-3.5 in Bangladesh, exploring the potential dual impact on both bone and muscle health.
Objective:
The objective of this study was to determine whether this sequential therapy could effectively improve osteoporosis and sarcopenia, ultimately fracture riskreduction and sarcopenia improvement in postmenopausal women in a tertiary level hospital of Bangladesh.
Methods:
We conducted a prospective cohort study at Central Medical College, Cumilla, Bangladesh, from January 2020 to July 2023. The study included 400 menopausal women diagnosed with OP (T-score ≤ -2.5 with fragile fracture and T score < -3.5 without fracture) and sarcopenia (defined by low muscle mass, muscle strength, and physical performance). Participants received daily subcutaneous injections of teriparatide (20 mcg) for 18-24 months (Mean 21.3±2.4 months), followed by annual intravenous infusions of zoledronic acid (5 mg). Treatment continuation with zoledronic acid mean (SD) duration of treatment 14.7±3.6 months. BMD and T-scores at the lumbar spine and femur neck were measured at baseline and 42 months using DXA scans. Functional outcomes, including walking speed, Timed Up and Go (TUG) test, handgrip strength, and Relative Skeletal Muscle Index (RSMI), were assessed at the same intervals to evaluate both osteoporosis and sarcopenia progression.
Results :
Total of 430 menopausal women were screened, and 400 completed the study. The mean age of participants was 61.21 years. Significant improvements in BMD and T-scores at both the lumbar spine and femur neck were observed at all follow-up intervals. At desired follow up, lumbar spine BMD increased from 0.79 to 1.01 g/cm² (p = 0.001), and femur neck BMD increased from 0.63 to 0.77 g/cm² (p = 0.001). Corresponding T-scores improved from -3.31 to -2.53 (p = 0.001) and from -3.03 to -2.45 (p = 0.001) for the lumbar spine and femur neck, respectively.
Functional outcomes showed significant enhancements. Walking speed increased from 0.65 to 0.86 m/s, while TUG time decreased from 13.90 to 10.34 seconds. Handgrip strength showed marked improvements, with right handgrip strength increasing from 17.71 to 29.49 kg and left handgrip strength from 15.77 to 25.48 kg. The Relative Skeletal Muscle Index (RSMI) improved from 5.51 to 6.57 kg/m². Sarcopenia status changed notably over the 42-month period. Initially, 62.5% were Non-Sarcopenic, which fluctuated: decreasing to 52.75% at 12 months, increasing to 67.75% at 24 months, and further to 77.75% at 42 months. Conversely, Sarcopenic individuals, starting at 37.5%, rose to 47.25% at 12 months before declining to 32.25% at 24 months and 22.25% at 42 months, indicating a significant improvement in sarcopenia status over time.
Conclusions: Sequential treatment with teriparatide followed by zoledronic acid significantly improves bone mineral density and functional outcomes in postmenopausal women with severe osteoporosis and improved various parameters of sarcopenia.
Keywords: Osteoporosis, Bone Mineral Density, Teriparatide, Zoledronic Acid, Postmenopausal Women, Sarcopenia.
Acknowledgement: We acknowledge the help of radiology department and biochemistry department for their help in conducting the study.

VALIDATION OF MODIFIED ELISA WITH ANTIGEN IMMOBILIZED ON MAGNETIC POLYACRYLAMIDE BEADS FOR MEASUREMENT OF ANTI-DSDNA ANTIBODIES

M. Mamus[1], A. Trofimenko[1], E. Mozgovaya[1], S. Bedina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Background: ELISA is currently one of the most widely used methods of laboratory diagnostics. One of the most promising improvements of ELISA is the use of an antigen immobilized not on the surface of a plate well, but on a mobile carrier containing a ferromagnet. One of the options for such a carrier is magnetically controlled polyacrylamide beads (MPB) obtained by emulsion polymerization.
Objective: to compare the characteristics of ELISA of antibodies to double-stranded DNA (anti-dsDNA) using MPB and standard indirect ELISA for the same analyte.
Materials and methods: ELISA of IgG class antibodies to dsDNA was used as a reference method, using kits manufactured by Orgentec Diagnostika (Germany). MPB was synthesized by emulsion polymerization; ELISA using MPB was described in detail in our previous works (Gontar I.P., 2006). A pool of sera from patients with systemic lupus erythematosus was used as a positive control; the presence of anti-dsDNA was confirmed by Western blotting. To construct a calibration curve, 8 replicates were prepared for each concentration. Nonparametric ROC analysis was performed by comparing 68 separate measurements of sera from patients with systemic lupus erythematosus (n=21) and a negative control replicate (PBS).

Results: LOD of anti-dsDNA using the reference method was 0.9 IU/ml, using MPB – 0.5 IU/ml. LOQ for the reference method was 2.2 IU/ml, using MPB – 1.8 IU/ml. The dividing point of positive and negative results, calculated by the ROC analysis, was 19.7 IU/ml for the reference method, and 18.4 IU/ml for MPB. On the linear sections of the calibration curves, the normalized difference between the arithmetic mean of the replicate series and the corresponding value of the regression equation was on average 3.4% for the reference method and 2.2% for MPB. The coefficient of variation on the linear sections of the calibration curves was on average 3.1% for the reference method and 2.5% for MPB. The dispersion of the residuals was on average 3.9 IU/ml for the reference method and 1.8 IU/ml for the measurement using MPG (p=0.001, Fisher's test).
Conclusions: the measurement of anti-dsDNA using MPB has advantages in terms of analytical sensitivity, accuracy, and convergence of results. This enables the wide application of this modification of ELISA in practice.

P967

APPLICATION OF DNASE I-SPECIFIC AUTOANTIBODIES FOR SLE DIAGNOSIS. QUANTIFICATION OF PERFORMANCE CHARACTERISTICS

M. Mamus[1], A. Trofimenko[1], E. Mozgovaya[1], S. Bedina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Background: Establishment a diagnosis of systemic lupus erythematosus (SLE) is currently often a very difficult task. The main reason for this is the insufficient diagnostic significance of individual signs of SLE found by means of physical examination, routine laboratory and instrumental tests. The use of various systems of diagnostic criteria allows increasing the accuracy of disease diagnosis only for cases with a detailed polysyndromic clinical picture. Given these circumstances, when verifying the diagnosis of SLE, the requirements for the diagnostic accuracy of tests significantly exceed the capabilities of the methods currently used, which necessitates the search for new laboratory markers of SLE.
Objective: Evaluation of the diagnostic accuracy of determining serum antibodies to DNase I in comparison with antibodies to dsDNA in differentiating SLE from other autoimmune rheumatic diseases.
Materials and Methods: Serum samples were obtained from 54 patients with verified SLE, 52 control patients suffering from the most common autoimmune rheumatic diseases (rheumatoid arthritis, systemic sclerosis, systemic vasculitis, dermatomyositis, Sjogren's disease) and 44 healthy volunteers. The concentration of antibodies to DNase I and dsDNA was measured by ELISA. The diagnostic accuracy of antibodies to DNase I and comparison of the two tests were performed using ROC analysis.
Results: Antibodies to DNase I were detected in 35 patients with SLE and in 8 patients in the control group, while no significant differences in the average antibody concentration were found. The optimal dividing point between these groups was the border of positive and negative results. For this point, the sensitivity was 64.81%; specificity - 84.62%; the likelihood ratio of a positive result was 4.21; the likelihood ratio of a negative result was 0.42. The area under the ROC curve for the concentration of antibodies to DNase I was 0.774, being not significantly different from the same indicator for antibodies to dsDNA.
Conclusions: When differentiating SLE from the most common autoimmune rheumatic diseases, the diagnostic accuracy of the test for serum antibodies to DNase I is very high and is not inferior to the generally accepted standard - the determination of antibodies to dsDNA.

P968

HIGH-THROUGHPUT SEQUENCING OF BONE METABOLISM GENES AND THEIR ASSOCIATION WITH OSTEOPOROSIS RISK

M. Marozik[1], A. Rudenka[2], V. Samokhovec[3], K. Kobets[1], E. Rudenka[2]

[1]Institute of Genetics and Cytology of the National Academy of Sciences of Belarus, Minsk, Belarus, [2]Belarusian State Medical University, Minsk, Belarus, [3]1st Minsk City Clinical Hospital, Minsk, Belarus

Objective: The study aims to investigate the association of genetic variants in bone metabolism-related genes with the risk of osteoporosis using high-throughput sequencing technology. By identifying key genetic contributors, the research seeks to enhance early diagnostic strategies and personalize preventive measures for individuals at high risk.
Material and Methods: The study cohort consisted of 456 individuals (recruited at 1st Minsk City Hospital, Belarus), including 251 with osteoporosis and 205 age- and sex-matched controls. DNA was extracted from peripheral blood, followed by targeted sequencing of 68 genes implicated in bone metabolism using the Illumina platform, generating an average coverage depth of 100×. Functional annotations of significant variants were obtained using ANNOVAR and *in silico* tools such as SIFT and PolyPhen-2.
Results: A total of 1,238 single nucleotide variants (SNVs) and small insertions/deletions were identified across the targeted genes. Statistical analysis revealed significant associations between osteoporosis risk and several genetic variants. In the *COL1A1* gene, the rs1800012 T allele was associated with a 1.8-fold increased risk (p = 0.002). The *VDR* rs731236 variant correlated with reduced BMD (p = 0.005). The rs9533156 G allele in the *RANKL* gene was linked to elevated susceptibility (p = 0.01), while the *OPG* rs2073617 T allele exhibited a protective effect (p = 0.004). Additionally, the rs4754 A allele in the *SPP1* gene was associated with decreased BMD (p = 0.003), the rs2234693 C allele in the *ESR1* gene was linked to increased osteoporosis risk (p = 0.007), and the rs59983488 T allele in the *RUNX2* gene was associated with impaired bone formation (p = 0.002). Pathway enrichment analysis highlighted disruptions in Wnt/β-catenin signaling and osteoclast differentiation as key contributors to osteoporosis pathogenesis. Variants with predicted deleterious effects exhibited strong functional relevance in regulatory regions of the

affected genes.
Conclusion: This study underscores the critical role of genetic variants in bone metabolism-related genes in modulating osteoporosis risk. These findings provide a foundation for the development of genetic screening tools and targeted interventions aimed at reducing osteoporosis-related morbidity and mortality.

P969

SERUM LEVELS OF FERRITIN, INTERLEUKINS 6 AND 17A IN RHEUMATOID ARTHRITIS

M. Masko[1]

[1]Vitebsk state medical university, Vitebsk, Belarus

Objective. Rheumatoid arthritis (RA) is characterized by significant clinical polymorphism. To optimize the treatment of RA, it is necessary to develop a personalized approach based on the determination of the value of various biomarkers in the clinical course of RA. The aim of this work was to determine the levels of proinflammatory cytokines and ferritin in RA and to establish their effect on the clinical course of RA.
Material and Methods. The object of the study was 62 patients with RA and 33 healthy volunteers. Serum levels of interleukin 6 (IL-6), interleukin 17A (IL-17A), and ferritin were determined by ELISA.
Results. We found an increase ($p<0.05$) in the levels of cytokines IL-6 (4,98 pg, 95%CI:2,59-12,33) and IL-17A (0,00 pg, 95%CI:0,00-3,77), as well as ferritin (150,75 ng, 95%CI:76,50-207,56) in RA compared with the control group (0,11 pg, 95%CI:0,00-0,70; 0,00 pg, 95%CI:0,00-0,00; 41,16 ng, 95%CI:17,38-160,65, respectively. Subsequently, all patients were divided into three groups depending on the level of ferritin established in the study.
Differences in CRP levels were found between the study groups, it was the lowest in the low ferritin group compared to the other two groups ($p<0.05$). The levels of IL-17A and IL-6 did not differ between the groups ($p>0.05$).
Correlation analysis revealed that the level of IL-6 positively correlated with the level of CRP ($r=0.264$, $p<0.05$). The IL-17A level showed a significant association with systemic manifestations ($r=0.260$, $p<0.05$) and RF levels ($r=0.409$, $p<0.05$). Ferritin levels were correlated with CRP levels ($r=0.353$, $p<0.05$) and RF levels ($r=0.313$, $p<0.05$).
Conclusions. Serum ferritin is a promising and affordable biomarker in RA and can be used for personalized assessment of the condition of a patient with RA, differential diagnosis of anemia, and risk assessment of macrophage activation syndrome. The pathogenetic pathways of ferritin regulation in RA require further study.

P970

TIME OF ANTERIOR CRUCIATE LIGAMENT INJURY PROFESSIONAL AND RECREATIONAL ATHLETES

M. Milankov[1], V. Krstic[2], R. Matijevic[3]

[1]Polyclinic Milankov Med, Novi Sad, Serbia, [2]Polyclinic Sport Medica, Novi Sad, Serbia, [3]University Clinical Center of Vojvodina, Novi Sad, Serbia

Introduction: The anterior cruciate ligament (ACL) is the primary stabilizer and the most frequently injured ligament of the knee joint. ACL injuries typically occur during sports activities. Given their high incidence and the fact that they predominantly affect young, active individuals involved in sports and work, ACL injuries represent a significant epidemiological issue.
Objective: The aim of this study is to determine during which part of training, season, month, day of the week, and time of day ACL injuries most commonly occur among professional and recreational athletes.
Materials and Methods: The study included 1,152 patients treated at the Clinic for Orthopedic Surgery and Traumatology of the Clinical Center in Novi Sad between 2012 and 2017. Of the 1,152 participants, 671 were recreational athletes, while 481 were professional athletes.
Results:A significantly higher number of participants sustained ACL injuries in the middle of training ($p<0.001$). Recreational athletes most frequently sustained injuries in the middle of the season, whereas professional athletes were most commonly injured at the beginning of the season. Statistically, more injuries occurred in the middle of the season ($p<0.001$). Among recreational athletes, May recorded the highest number of injuries, while October was the critical month for professional athletes. Sunday was the day with the most injuries for recreational athletes, while Saturday was the critical day for professional athletes. There was a statistically significant difference in favor of injuries occurring on Saturdays ($p<0.001$). Both groups of athletes were most often injured in the afternoon.
Conclusion: The highest number of ACL injuries occurred in the middle of training, during the middle of the season, in October, on Saturdays, and in the afternoon. Injury prevention protocols could represent the next significant step in managing ACL injuries. Understanding when ACL injuries most frequently occur could yield long-term results and reduce the incidence of ACL injuries.

UNDERSTANDING PAIN: HOW DO PATIENTS AND PHYSICIANS APPROACH IT?

M. Minea[1], L. Vlădăreanu[2], D. Oprea[3], C. Oprea[3], L.-E. Stanciu[3], M.-G. Iliescu[2]

[1]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania. Ovidius University Faculty of Medicine Doctoral School, Constanta, Romania, Techirghiol, Romania, [2]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania. Ovidius University Faculty of Medicine Doctoral School, Constanța, Romania. Department of Medical Rehabilitation, Faculty of Medicine, Ovidius University of Constanța, Romania, Techirghiol, Romania, [3]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania. Department of Medical Rehabilitation, Faculty of Medicine, Ovidius University of Constanța, Romania, Techirghiol, Romania

Objectives: We aimed to evaluate the characteristics of pain (that significantly impact the quality of life) and its changes after rehabilitation treatment.
Materials and Methods: A descriptive study of 354 patients admitted to our hospital over five months used specific questionnaires to gather demographic and medical data, pain attributes, onset, history and previous medication. The pain intensity was assessed on a visual analogue scale (VAS) before and after ten days of complex rehabilitation treatment (2,3). The p-value was calculated for statistical significance, and the correlation between variables was evaluated using the Pearson coefficient (-r).
Results: The group, aged between 30 and 83 years, included 245 women and 109 men who addressed rehabilitation treatment for different pathologies. 203 accused vertebral pain, followed by knee (60) and hip (37). 129 patients had high pain intensity (VAS > 7), 179 medium level (4-6), and 46 noted low intensity (< 4). Before the admission, 283 used medications for pain control, the majority (232) nonsteroid-anti-inflammatory drugs, followed if needed by corticosteroids, combined or alternated with painkillers. 82 patients took these pills, advised by friends, neighbours, media, or a pharmacist. Pain relief was achieved in 315 cases at discharge, with 31 remaining stationary. The average delta VAS for the group with acute pain was 3.38, for subacute, 2.15 and in the case of chronic pain, 1.91. A weak correlation was found between the VAS value at admission and delta VAS (r=0.37).
Conclusions: Most of the patients reported improvement after the rehabilitation therapy, considering that one-third had high-intensity pain on admission. The sooner that treatment was initiated, the more effectively it reduced pain. More than a quarter of the patients who took medication before admission didn't consult a specialist.

Department of Medical Rehabilitation, Faculty of Medicine, Ovidius University of Constanța, Romania, Techirghiol, Romania, [3]Emergency Clinical County Hospital "Sfântul Apostol Andrei" Constanța. 3rd Department - Clinical Medical Disciplines, Faculty of Medicine, Ovidius University of Constanța, Constanța, Romania

Musculoskeletal ultrasound (MSUS), a technique used to assess joints and surrounding structures, could discover and initially describe subcutaneous nodules. To establish the relevance of this method, we aimed to present two cases of patients referred for ultrasonographic evaluation of these types of structures located in the thoracic area. A machine with a linear probe (10-14 MHz) was used, with the scanner settings adjusted and Doppler mode applied. The patients were clinically evaluated, and their medical history, current medication, and biological data were noted. Case report 1: The first patient, male, 56 years old, without traumatic or oncologic history nor biological changes, presented an immobile, firm subcutaneous nodule accompanied by pain located on the right sternoclavicular joint, which occurred 18 months ago and progressively increased in size. MSUS described a hypoechogenic, inhomogeneous, imprecisely delimited nodular structure of 2/2/2cm. The discontinuous and irregular bone cortex below presented Doppler signal. MRI identified a tumour involving the first rib and sternum. Plasmacytoma was diagnosed by biopsy, and the patient is now following radiotherapy with a positive response. Case report 2: The second male, aged 30, with an important inflammatory syndrome, presented a superficial nodule in the proximity of the right second sternocostal joint, which appeared 6 months ago, alongside local episodic pain, temporarily resolved after nonsteroidal anti-inflammatory drugs. MSUS identified a nodule of 3/3/0.4cm, relatively well-defined, hypoechogenic, slightly inhomogeneous, with Doppler signal, irregularity of the bone cortex of the second rib and enlarged superficial axillary lymph nodes with cortical Doppler signal. The CT scan showed osteochondritis in the second right rib and axillary adenopathies. The diagnosis of lymphoma was given on the biopsy of the structure and lymph nodule, and the chemotherapy was applied with good evolution.
Conclusions. Ultrasound is preferred as an initial investigation in assessing subcutaneous structures and is well tolerated by patients, although it does not give a final diagnosis. The report should include a detailed description of all ultrasound features, the suspected pathology, and recommendations for further investigations.

P973

THE ASSOCIATION OF HYPOGLYCEMIA AND FALLING RISK IN POPULATION WITH DIABETES: INSIGHTS FROM A NATIONAL SURVEY

M. Mirzad[1], A. Golestani[1], N. Rezaei[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Background: Diabetes mellitus leads to various complications such as diabetic peripheral neuropathy and bone remodeling issues, both of each increase fall risk. Moreover, the management of diabetes often involves the risk of hypoglycemia, which can further compromise stability and increase falling. We aimed to evaluate the association of diabetes, its control and hypoglycemia occurrence with falling in Iran.

Methods: We used the nationally representative sample of STEPwise approach to non-communicable diseases (NCD) risk factor surveillance (STEPS) 2021 cross sectional study in Iran. Diabetes was defined as fasting blood sugar levels ≥126 mg/dL or current use of any antihyperglycemic medications. Diabetes control was determined based on hemoglobin levels <7%. Hypoglycemia was assessed through self-reports collected only from participants aware of their diabetes status. We asked about having hypoglycemia symptoms during the last two weeks. Falls were evaluated based on a question that asked if participants had experienced a falling accident leading to physical injury in the past year. Weighted prevalences were reported with corresponding 95% confidence intervals (95% CIs). Logistic regression analyses were performed to assess associations between diabetes status, control, hypoglycemia, and fall, with crude and age-sex adjusted odds ratios (ORs) and p-values reported. All statistical analyses were conducted using R version 4.4.1 with the survey package.

Results: The prevalence of falls among individuals with diabetes (n = 2437) was 3.32% (95% CI: 2.40-4.24), compared to 2.34% (2.01-2.67) in normoglycemic participants (n = 15641). For controlled diabetes (n = 748), the fall prevalence was 2.39% (1.16-3.62) versus 3.84% (2.59-5.08) in uncontrolled diabetes. Among participants aware of their diabetes, those with a hypoglycemia history (n = 416) had a prevalence of falling at 4.84% (2.56-7.13) compared to 2.74% (1.92-3.56) without hypoglycemia. After adjusting for age and sex, diabetes mellitus and controlled diabetes were not associated with increased odds of falling, while hypoglycemia showed significantly higher odds in the crude model (OR: 1.81 [1.92-3.56]), remaining elevated but not statistically significant after adjustment (adjusted OR: 1.79 [1.00-3.20]) (Table 1).

Conclusion: Although the fall is a rare condition and its prevalence is not statistically different between subgroups of diabetes, controlled diabetes, and hypoglycemia, the odds of falls are increased in people with diabetes who experience hypoglycemia. These findings underscore the importance of effectively monitoring hypoglycemia to prevent falls and their consequences in individuals with diabetes.

Table 1: Association between diabetes, controlled diabetes and history of hypoglycemia and fall.

Variable	Categories	Crude		Age-Sex adjusted	
		OR (95%CI)	P value	OR (95%CI)	P value
Diabetes	No	Ref			
	Yes	1.44(1.04-1.98)	0.02	1.11(0.8-1.55)	0.524
Controlled Diabetes	No	Ref			
	Yes	0.61(0.33-1.15)	0.127	0.6(0.32-1.12)	0.11
Hypoglycemia	No	Ref			
	Yes	1.81(1.92-3.56)	0.047	1.79(1-3.20)	0.051

P974

THE ASSOCIATION OF ESTROGEN RECEPTOR PVUII POLYMORPHISM WITH OSTEOPOROSIS IN BUSHEHR COHORT FROM IRAN

A. Kakavand Hamidi[1], A. Rezazade[2], N. Fahimfar[1], M. Mohammad Amoli[1]

[1]Tehran University of Medical Sciences, Tehran, Iran, [2]Islamic Azad University, Tehran, Iran

Objectives: Genetic studies suggest that the polymorphisms of the gene estrogen receptor (ER), important in calcium absorption and bone strength, are associated with osteoporosis in different populations. In this study, we aim to assess the association of *PvuII* polymorphism of ER with osteoporosis within an Iranian population.

Material and Methods: People who participated in this study were selected from the Bushehr cohort, the Iran population. From 283 individuals recruited 85 were diagnosed with osteoporosis and 198 were normal. Genotyping was done by polymorphism chain reaction (PCR) followed by restriction fragment length polymorphism (RFLP) and Statistical software for data science (Stata/SE 12.0) was used to assess the association between genotype and allele frequency with osteoporosis and *pvalue*<0.05 was considered as significance.

Results: The frequency of genotypes CC, TC, and TT were as follows in patients with osteoporosis and without respectively: *N*= 17/44; 46/97; 22/57. The frequency of ER *PvuII* T and C alleles among patients with osteoporosis and without were as follows: *N*=90/211; 80/185. When the association between genotype and allele frequency of patients with osteoporosis was assessed compared to normal individuals using chi-square cross-tabulation there was no significant association. Also, when the results were adjusted for age, sex, BMI status, menopause status, and quality of bone using both one-variable and multi-variable logistic regression (for genotype frequency [TT *vs.* CC]: OR: 0.66; 95%CI [0.2-1.9], *p*=0.44; for allele frequency [T *vs.* C]: OR: 1.17;95%CI [0.7-1.9], *p*=0.53) there was no significant association.

Conclusions: Contrary to a high prevalence of osteoporosis in Iran there was no study evaluating the association of ER *PvuII* polymorphism with osteoporosis. Evaluating this polymorphism

in the elderly population of the Bushehr cohort contributes to our understanding of the genetic basis of osteoporosis among the Iranian population. However, our non-significant result might come from our small study population. The genetic study of more patients with osteoporosis in populations like Iran can help us for a better understanding of the biological process underlying osteoporosis as well as the development of new therapies among others.

P975

AGGRESSIVE AND UNCOMMON SOFT TISSUE SARCOMA OF THE EXTREMITIES: THE MYXOFIBROSARCOMA

M. Montatore[1], G. Muscatella[2], F. Masino[2], A. Sciacqua[1], R. Gifuni[1], M. Balbino[1]

[1]Univeristy of Foggia, Foggia, Italy, [2]University of Foggia, Foggia, Italy

Objectives: To learn more about myxofibrosarcomas, which are a group of rare and heterogeneous tumors with various subtypes and prognosis. They are differentiated by their local infiltration activity and extremely high rate of local recurrence.
Material and Methods: Myxoid-like soft tissue lesions can be benign or malignant. They can present as cysts on radiologic examination and share histological characteristics. Myxoid liposarcoma, myxoid leiomyosarcoma, myxoid chondrosarcoma, ossifying fibromyxoid tumor, and myxofibrosarcoma are all malignant. Myxofibrosarcoma, a frequent kind of sarcoma in elderly persons, is a slow-growing, painless mass with larger tumors that may cause pain. Pathologists classify myxofibrosarcoma into three classes using a system developed by the French Federation of Sarcoma Group Cancer Centres (FNCLCC). This approach determines tumor grade using three microscopic features: differentiation, mitotic count, and necrosis.
Results: The imaging test includes US, CT, and MRI scans, which can establish its presence.
Surgery is the primary treatment for sarcoma; resection can be extensive, but recurrence is usual. Radiotherapy can be used as a neoadjuvant or adjuvant treatment to improve local control rates, whilst chemotherapy is utilized to reduce large tumors before surgery.
Conclusion: Soft tissue sarcomas are exceedingly rare malignancies; myxofibrosarcoma, a member of this diverse category, is a connective tissue-based cancer. It is one of the most frequent forms of sarcomas in older persons, with locally infiltrative activity and a very high rate of local recurrence. The diagnosis is difficult due to the various types of presentation, and all radiologists should be familiar with the radiological findings displayed in this case in order to raise the suspicion of this specific type of tumour, which was verified only by one excisional biopsy in its histology.

BONE TURNOVER SUPPRESSION RATE ACCORDING TO OFF-TREATMENT AND ANTI-RESORPTIVE INTERVENTIONS: A STRATIFICATION ANALYSIS

M. Muzzi[1], C. Costa[1], B. Camargos[2]

[1]Faculty of the Medical Sciences Minas Gerais / Faculdade de Ciencias Médicas de Minas Gerais, Belo Horizonte, Brazil, [2]Rede Mater Dei de Saúde, Belo Horizonte, Brazil

Objectives β-isomerized C-terminal telopeptide (β-CTX-I) is a bone turnover marker used for osteoporosis management. Biochemical assays, nomenclature, and clinical application standards have been published. Nevertheless, studies on reference intervals are still needed. Our objective is to evaluate β-CTX-I values according to its anti-resorptive (AR) effect on- and off-treatment in postmenopausal women.
Material and Methods The study employed a non-random, consecutive sampling approach. Eligible criteria were postmenopausal women assisted at a Fracture Liaison Service (FLS) in Brazil. Exclusion criteria were chemotherapy, rheumatological conditions, and chronical kidney disease. Expected β-CTX-I levels were defined according to different ARs. Higher potency AR denosumab (DMAB) is expected to suppress β-CTX-I levels below 0,100 ng/mL. β-CTX-I was expected above 0,350 ng/mL for off-treatment (Off-T) patients, that were used as controls. Between DMAB and Off-T, HRT levels were expected to be under 0,350 ng/mL and BIS levels under 0,250 ng/mL. The agreement between expected and observed β-CTX-I for each drug was evaluated. Samples were collected after 8-hour overnight fasting. Previous physical activity was avoided and Manual ELISA CrossLaps™ assays were performed at one single facility.
Results One-hundred postmenopausal women had β-CTX-I, calcium, PTH, and vitamin D measured. The results were grouped according to the treatment used. A total of 42 from 43 (97,6%) Off-T patients, 22 of 22 (100%) DMAB group, 5 of 7 (71,4%) HRT group, and 26 of 28 (92,8%) BIS group, showed β-CTX-I levels according to the expected cutoffs described above. Off-T and DMAB patients showed the best correlation of expected vs. observed β-CTX-I levels; while HRT showed the worst.
Conclusions β-CTX-I is a reliable tool to assess treatment response, notably for BIS and DMAB. Non-suppressed bone turnover can also be assessed in Off-T patients. Treatment response can be stratified for different ARs. β-CTX-I suppression thresholds may be individualized according to drug potency and help to evaluate adherence on a clinical setting. Further studies are needed to define accurate β-CTX-I cutoffs for different ARs.

P977

EXPLORING BONE HEALTH IN CYSTIC FIBROSIS: INSIGHTS FROM A PORTUGUESE COHORT

M. Natal[1], B. Esteves[1], A. Amorim[2], G. Terroso[1], L. Costa[1]

[1]Rheumatology Department, ULS São João, Porto, Portugal,
[2]Pneumology Departement, ULS São João, Porto, Portugal

OBJECTIVE: To evaluate the prevalence and progression of bone disease (BD) in Portuguese cystic fibrosis (CF) patients and its association with clinical and biochemical factors.

METHODS: A retrospective, observational study was conducted using medical records of adult CF patients followed at a tertiary hospital in Portugal. Data on sociodemographic characteristics, lung function tests, biochemical markers of bone health, and dual-energy X-ray absorptiometry (DEXA) scans were collected. DEXA results included Z-scores and bone mineral density (BMD) values from the first and most recent scans. Patients were classified based on the presence of BD (osteopenia or osteoporosis, defined by Z-scores from the lumbar spine, total femur, and femoral neck [FN]). Comparative analyses were performed between patients with and without BD, and longitudinal changes in Z-scores and BMD were assessed.

RESULTS: Of the 39 patients included in the study, 22 (56.4%) were women, all premenopausal, and the median age at the time of the most recent DEXA scan was 32.0 years (IQR 20.0). The median BMI was 20.95 kg/m² (IQR 4.12), with 8 patients (20.5%) having a BMI <18.5 kg/m². The mean 25(OH)vitamin D level was 27.72 ± 13.19 ng/mL, with 21 patients (53.8%) exhibiting vitamin D deficiency (levels <20 ng/mL). Thirty-four patients (87.2%) were on cholecalciferol supplementation.

Of the 25 patients (64.1%) with BD, 10 (25.6%) had osteoporosis, and 8 (20.5%) had a history of prior or current bisphosphonate therapy. Only one patient had a fragility fracture. Patients with BD showed significantly lower %forced vital capacity (p=0.016) and higher parathyroid hormone levels (p=0.019) compared to those without BD, with no other significant differences.

Among the 35 patients with previous DEXA scans, a paired-samples t-test revealed a statistically significant decrease in FN BMD between the first and most recent scans (mean decrease: 0.041 g/cm³; p=0.019).

CONCLUSION: Despite their young age, BD is highly prevalent among patients with CF and appears to be associated with reduced pulmonary function. Despite widespread cholecalciferol supplementation, vitamin D deficiency remains common. A significant decline in FN BMD over time underscores the importance of early detection and targeted interventions to address bone health in this population.

P978

DENOSUMAB THERAPY IN SYSTEMIC MASTOCYTOSIS-ASSOCIATED OSTEOPOROSIS: A CASE STUDY

M. Natal[1], B. Esteves[1], L. Costa[1], G. Terroso[1]

[1]Rheumatology Department, ULS São João, Porto, Portugal

CASE PRESENTATION:

A 64-year-old woman with a 27-year history of osteoporosis (OP) presented with multiple low-impact fractures, including vertebral, femoral, and rib fractures. Initially attributed to hyperparathyroidism (treated with parathyroidectomy resulting in normalization of her parathyroid hormone levels), her condition persisted despite alendronate therapy for over 20 years.

Due to a history of three anaphylactic episodes, two of which during anesthesia induction, she was referred to the Immunoallergology clinic. Initial studies documented a baseline serum tryptase of 380 µg/L (REF < 11.40 µg/L). Further investigations revealed normal complete blood count and biochemical studies, a bone marrow biopsy with histological and immunofluorescence findings consistent with systemic mastocytosis (SM), and a skin biopsy showing perivascular and interstitial mast cell infiltration. Thus, a diagnosis of SM was established.

As part of the SM work-up, bone densitometry was conducted, showing T-scores of -2.6 and -3.3 for the lumbar spine (LS) and femur, respectively. She was referred to the Rheumatology clinic, where it was concluded that her long-standing OP was secondary to SM. As such, she was started on biannual denosumab therapy, which she is currently maintaining. Follow-up DEXA scan showed significant improvement in LS bone mineral density (T-score -1.4 after 2 years of treatment).

DISCUSSION:

Although SM is a rare cause of secondary OP, it should always be considered in patients with unexplained osteoporosis, particularly in the presence of symptoms related to mast cell release. Tryptase measurement is the initial test, and the diagnosis can be definitively established with a bone marrow biopsy.

Skeletal involvement in SM is common. The interplay between the mediators secreted tends to favour bone resorption, either by promoting osteoclastic or inhibiting osteoblastic activity. As such, antiresorptive agents are the treatment of choice. Bisphosphonates are effective, however, given the increased evidence of the importance of the RANK/RANKL in the pathogenesis of the disease, denosumab therapy may be the preferred option, and in this case resulted in significant bone mineral density gain after two years of biannual injections.

P979

CELIAC DISEASE AND OSTEOPOROSIS: DEMOGRAPHIC AND CLINICAL INSIGHTS FROM A HOSPITAL-BASED STUDY

M. Natal[1], B. Esteves[1], G. Terroso[1], L. Costa[1]

[1]Rheumatology Department, ULS São João, Porto, Portugal

OBJECTIVE: To describe the characteristics of celiac patients who develop osteoporosis (OP) in a Portuguese hospital center.
METHODS: We conducted a retrospective descriptive study, including patients diagnosed with celiac disease (CD) who were subsequently diagnosed with OP and referred for a Rheumatology consultation at a tertiary hospital in Portugal. Data on sociodemographic characteristics, biochemical markers, and dual-energy X-ray absorptiometry (DEXA) scans (baseline and 3-year follow-up) were collected.
RESULTS: Seven patients were included, with a mean age of 54.1 ± 3.0 years at OP diagnosis. Most were postmenopausal women (5/7, 71.4%). The mean BMI was 21.2 ± 0.9, and two patients were smokers (28.6%). Comorbid autoimmune diseases included psoriasis and type 1 diabetes mellitus (1 patient each). Diarrhea was the most common presenting symptom (n=4), followed by weight loss (n=3), oral ulcers (n=2), and nausea/vomiting (n=1). Two patients were asymptomatic. One patient had a family history of low-energy hip fracture, and another had a personal history of a low-energy forearm fracture.
Baseline DEXA scans revealed the lowest T-scores and Z-scores predominantly at the lumbar spine (6/7, 85.7%), with mean values of -3.18 ± 0.34 and -2.08 ± 0.49, respectively. Laboratory data showed that 100% of patients had vitamin D deficiency, including two with severe deficiency (<10 ng/mL). Anemia was observed in one patient. The mean calcium and alkaline phosphatase levels were 4.73 ± 0.10 mEq/L and 92.7 ± 11.6 U/L, respectively.
Five patients (71.4%) adhered to a gluten-free diet, and all received calcium and/or vitamin D supplementation. Only one patient received pharmacological treatment for OP during the first three years. Follow-up DEXA scans showed an overall improvement in T-scores (+0.50 ± 0.25) and Z-scores (+0.53 ± 0.22).
CONCLUSION: Osteoporosis is a significant concern in celiac patients, warranting early screening with DEXA, regardless of clinical severity or nutritional deficiencies. Despite dietary adherence and supplementation, these patients remain at risk. Rheumatologists should consider CD in cases of severe osteoporosis, low BMI, and vitamin D deficiency. These findings emphasize the need for a multidisciplinary approach to optimize management and outcomes.

THE ASSOCIATION BETWEEN STATIN USE AND RISK OF FALL AND ITS OUTCOME AMONG OLDER ADULTS; BIRJAND LONGUITIDINAL AGING STUDY

P. Ebrahimi[1], M. Ebrahimpur[1], F. Sharifi[1], Z. Hoseini Tavasol[1], N. Azizi[1], M. Payab[1]

[1]Tehran university of medical Sciences, Tehran, Iran

Introduction: Falls are a significant public health concern, particularly among older adults, where they represent one of the leading causes of injury, disability, and mortality. Identifying risk factors for falls is critical to developing effective prevention strategies. Statins, widely prescribed for their cholesterol-lowering effects and cardiovascular benefits, have raised questions regarding their potential impact on fall risk. While statins are generally considered safe, they can cause side effects such as muscle weakness (myopathy) and fatigue, which may impair balance and increase susceptibility to falls. Conversely, statins might indirectly reduce fall risk through improved vascular health and reduce inflammation, which can benefit physical functioning.
Methods: This study included 1348 patients interviewed and examined in the Birjand Longuitidinal Aging Study (BLAS). Their related data were documented regarding various factors, diseases, sociodemographic characteristics, and social and lifestyle habits. Finally, their association with falls and the history of statin use were evaluated, and correlation and relative incidence risk were calculated using univariate and multivariate logistic regressions.
Results: The variables between fallers and non-fallers were compared using two-sample T-tests.
Higher BMI (MD: -2.35, $p < 0.001$), higher Waist Circumference (MD: -3.28, $P<0.01$), Maximum Handgrip Strength (MD:4.57, $p < 0.001$), and Maximum Gait Speed (MD:0.16, $P = 0.0025$) were significantly different between faller and non-fallers. Moreover, female gender and less physical activity were significantly related to falling risk. Statin use showed no statistically significant association with the risk of falls (4.89% among statin users, 6.15% among non-statin users, $P= 0.408$). Subgroup analyses reveal some differences by cholesterol category but no strong or consistent associations with statin use.
Conclusion: This study showed that statin use does not consistently or significantly affect falls across models. Moreover, the male sex was consistently protective against falls. The logistic regressions revealed that higher BMI and older age are associated with increased fall risk in several models, and more activity levels significantly reduce fall risk.

P982

EARLY DETECTION OF OSTEOPOROSIS USING ARTIFICIAL NEURAL NETWORKS: A COMPARATIVE ANALYSIS OF MACHINE LEARNING APPROACHES

M. Pehlivan[1], A. Polat[2], D. Cengiz[1], C. Kayabasi[1], A. Okyar Bas[1], C. Balci[1], B. B. Dogu[1], M. G. Halil[1], M. Cankurtaran[1], M. Esme[1]

[1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Geriatrics, Ankara, Turkiye, [2]Social Security Institution (SSI) of Turkiye, Ankara, Turkiye

Objective: To develop different machine learning models for early detection of osteoporosis and determine the most effective method in osteoporosis risk assessment by comparing their diagnostic performances.

Material and Methods: The study analyzed data from 5,831 individuals obtained from the National Health and Nutrition Examination Survey (NHANES) database between 2017-2019 (1). The dataset was first examined for missing data and outliers, and necessary preprocessing steps were applied. Data augmentation method was used to address dataset imbalance. Three different machine learning approaches were compared: logistic regression, random forest, and multilayer artificial neural networks. The multilayer artificial neural network was designed with an input layer, two hidden layers, and an output layer. The dataset was split into training (80%) and testing (20%) sets. Model performances were comparatively evaluated using accuracy, sensitivity, specificity, precision, F1-score, and area under the ROC curve (AUC).

Results: The multilayer neural network achieved the highest performance with 82% accuracy, 82% sensitivity, 31% precision, and 0.87 AUC score. The model successfully identified 82% of high-risk patients, enabling early-stage identification of osteoporosis cases. The random forest model achieved 86% accuracy, 59% sensitivity, 34% precision, and 0.84 AUC score, while the logistic regression model achieved 79% accuracy, 74% sensitivity, 27% precision, and 0.82 AUC score. When evaluated in terms of the F1-score, which is the most decisive among performance metrics, the multilayer artificial neural network reached the highest value at 45%.

Conclusion: The multilayer neural network demonstrated superior performance compared to other machine learning approaches in early detection of osteoporosis. High sensitivity rates indicate that using the model as an early diagnostic tool in clinical practice could both reduce healthcare costs and improve patient outcomes. This model, which can be particularly useful in evaluating risk factors, may contribute to early diagnosis of the disease. The findings emphasize the importance of integrating artificial intelligence tools in osteoporosis screening programs.

Table : Performance Comparison of Machine Learning Methods

Model	Precision	Sensitivity	Accuracy	F1-Score	AUC
Logistic Regression	0,27	0,74	0,79	0,39	0,82
Random Forest	0,34	0,59	0,86	0,43	0,84
Multilayer Artificial Neural Network	0,31	0,82	0,82	0,45	0,87

ASSOCIATION BETWEEN SERUM HEMOGLOBIN LEVEL AND BONE MINERAL DENSITY IN ADULTS: IRANIAN MULTI-CENTER OSTEOPOROSIS STUDY (IMOS)

M. A. Khadembashiri[1], S. Mohseni[2], A. Aghakhani[1], K. Khalagi[3], M. J. Mansourzadeh[1], M. Pejman Sani[2], M. Mohajeri-Tehrani[2], F. Farzadfar[4], N. Fahimfar[1], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran, [3]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran, [4]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective

Previous studies have investigated the relationship between hemoglobin (Hb) levels and bone mineral density (BMD) with controversial findings. This study aimed to evaluate this association using data from the 4th Iranian Multicenter Osteoporosis Study (IMOS), a population-based national survey, including a population sample aged 50 years and older.

Material and Methods

The present study was conducted as a cross-sectional data analysis derived from the fourth round of the IMOS. Demographic information, Hb levels, and BMD measurements were collected. BMD was measured with dual-energy X-ray absorptiometry (DXA). Low BMD was defined as a T-score less than -1 at each site including hip, femoral neck, or lumbar spine. Multiple linear regression analysis was used to assess the relationship between Hb levels and BMD.

Results

This study included 1,426 participants (54.2% female) with the mean age of 62.6 ± 8.0 years. The mean Hb levels among patients with or without osteoporosis were 12.9 ± 2.0 mg/dl and

13.1 ± 1.9 mg/dl, respectively (p-value= 0.08). It was demonstrated a positive relationship between Hb levels and BMD at hip (β=0.0079, 95% CI: 0.002- 0.0135, p-value=0.006) and femoral neck (β=0.0064, 95% CI: 0.0015- 0.0113, p-value=0.01) in men but not in women. However, there was no significant correlation between Hb levels and spine BMD in either gender.

Conclusion

The findings highlight the complexities of the association between Hb and BMD, which is modified by variables such as bone region, gender, and study population characteristics. Future studies should unravel these associations and investigate the underlying mechanisms.

SCIENTOMETRIC ANALYSIS OF ACROMEGALY PUBLICATIONS: AN OVERVIEW OF THE STATE OF RESEARCH

R. Atlasi[1], N. Rezaei[2], S. Mohseni[1], M. Pejman-Sani[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Department of Medical Library and Information Sciences. School of Paramedicine. Hamadan University of Medical Sciences. Hamadan. Iran, Hamedan, Iran

Objectives: Acromegaly is a rare hormonal abnormality caused by excessive growth hormone in the body that leads to excessive growth of bones and soft tissue. So, this research aims to provide an overview of the state of research in this field by analyzing the studies conducted during past years in the field of acromegaly.

Material and Methods: The search strategy was conducted in the Web of Science (WOS) database until August 14, 2024. All documents containing the word "Acromegaly" in the title or keywords were retrieved. The results were analyzed and illustrated using the bibliometrix R-package 4.1.1. and WOS software.

Results: 7444 documents were analyzed and the most published documents were articles (n=5033) and then by a difference, meeting abstract and review articles. The USA (n=1388), Italy (n=875), England (n=662), and France (n=471) have had the most scientific productions in the field of acromegaly, respectively. "University of London" (n=244) and "Assistance Publique Hopitaux Paris" (n=205) also were the most active organizations. "Annamaria Colao" (n=178) and "Andrea Giustina" (n=131) both from Italy and "Philippe Chanson" (n=130) from France are the most prolific authors. The "Journal of Clinical Endocrinology& Metabolism" (n=522), "Pituitary" (n=331) and "Clinical Endocrinology" (n= 317), have published the most articles in this field. Most of the articles were in English then in French and German Language. In addition, among these articles, 12 were Highly-Cited Papers (HCP) that "Shlomo Melmed" from the USA with 8 articles (79%) having the most HCP articles. "Oregon Health & Science University" in the USA has also published the most HCP articles(n=17) and "Journal of Clinical Endocrinology & Metabolism" (n=3) continues to publish the most articles including HCP in this field. The most of topics in these articles were "growth hormone", "growth factor-I", "quality-of-life" and "somatostatin analog therapy".

Conclusion: Many different studies have been conducted on acromegaly in the past years. Most of them were carried out in the USA and Italy countries, and the journal that published the most articles in this field, including HCP, was the "Journal of Clinical Endocrinology & Metabolism". More effective studies need to be done by researchers in this field.

BONY DEFORMITIES AND FRACTURES UNVEILING MCCUNE-ALBRIGHT SYNDROME: A CASE REPORT

M. Pontes Ferreira[1], C. Dantas Soares[1], A. Cunha[1], S. Almeida[1], D. Barros[1], J. Tavares-Costa[1], D. Santos-Faria[1]

[1]Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal

Introduction: McCune-Albright Syndrome (MAS) is a rare genetic disease characterized by polyostotic fibrous dysplasia, café-au-lait skin pigmentation and endocrinopathy. Additional features may include limb abnormalities, scoliosis, sensorineural hearing loss and precocious puberty[1].

Clinical case: A 42-year-old man with history of multiple fractures at a young age sustained a femoral shaft fracture in 2020 after a fall. In 2021 he suffered a fracture of the L1 vertebrae with no trauma. A CT scan revealed multiple expansive bony lesions with ground-glass appearance. X-rays showed abnormal bone growth and remodelling, affecting the iliac bone, femur, tibia, fibula and femoral head, along with limb deformities and scoliosis. Blood

tests showed hypercalcemia, hypophosphatasia, hypocalciuria, high levels of parathyroid hormone and alkaline phosphatase and low serum vitamin D. Procollagen Type 1 N-Terminal Propeptide and N-Telopeptide of Type I Collagen were marked elevated. He was diagnosed with non-toxic multinodular goitre. Genetic testing identified the c.601C>T, p.(Arg201Cys) mutation in the GNAS gene, confirming MAS.

Discussion: Polyostotic fibrous dysplasia is a common feature of MAS and results in abnormal bone growth and remodelling, predisposing pathological fractures, as seen in our patient. This case highlights the importance of scrutinize clinical history and combine imagological features and calcium-phosphate imbalance in order to recognizing MAS, with the genetic testing firming the diagnosis. MAS patients are prompt to fragility fractures, well recognized as cause of important health costs and impairing quality of life, thus, correct management is imperative.

WHEN BONE VANISHES: A RARE SYNDROME

M. Pontes Ferreira[1], A. Cunha[1], C. Dantas Soares[1], S. Almeida[1], D. Barros[1], D. Santos-Faria[1], J. Tavares-Costa[1], D. Roriz[2]

[1]Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal, [2]Radiology Department, Unidade Local de Saúde do Alto Minho, Viana do Castelo, Portugal

Introduction: Gorham-Stout Syndrome (GSS) is a rare disorder of unclear aetiology, characterized by progressive osteolysis[1].

Clinical case: A 54-year-old woman with morbid obesity, type 2 diabetes, no smoking, alcohol or toxophiliac habits and hip and knee osteoarthritis reported progressive hip pain and gait limitation since 2022. There were no signs of inflammatory arthropathy and no phospho-calcium metabolism imbalance except for vitamin D deficiency.

Plain radiographies showed bilateral reabsorption of the acetabular head (picture 1A), not present in previously. Computer tomography (CT) scan (picture 1B) presented severe acetabular dysplasia with deformity and resorption of the femoral heads, significant sclerosis with intra-articular thickening and inflammatory pannus. The magnetic resonance imaging (MRI) (picture 1C-D) demonstrated femoral heads' bone loss and bone marrow infarction in the proximal right femur, suggesting rapidly destructive osteoarthritis.

The radiological and clinical findings are consistent with GSS.

Discussion: GSS is a rare disorder, characterized by destruction of osseous matrix resulting in osteolysis[1], which can involve one or multiple bone sites. There are multiple clinical presentations depending on affected bone, and unspecific symptoms are common, delaying diagnosis[1]. The prognosis is variable, depending on the existence of other manifestations, such as pleural effusion or development of complications as spinal cord involvement[1]. Reporting these cases and imaging findings is central for enhancing understanding and recognition of this condition.

ERDHEIM-CHESTER DISEASE: A CASE STUDY HIGHLIGHTING DIAGNOSTIC COMPLEXITY

A. Cunha[1], M. Pontes Ferreira[1], S. Almeida[1], D. Barros[1], D. Santos Faria[1], J. Tavares-Costa[1], D. Peixoto[1]

[1]Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal

Introduction

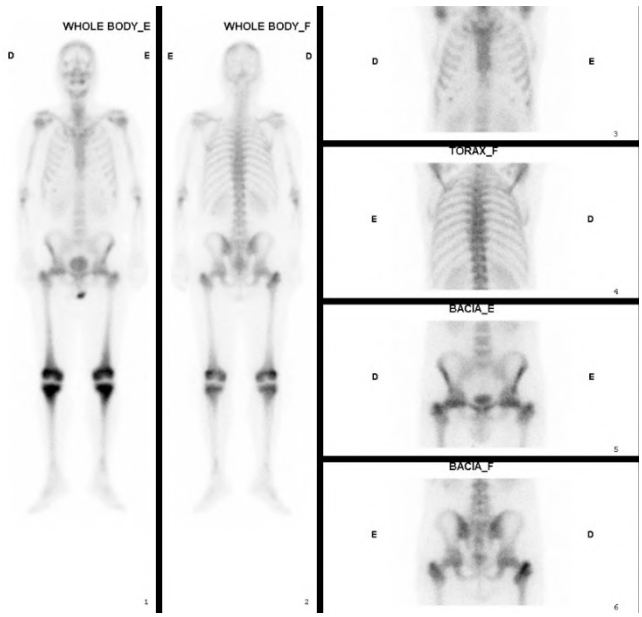
Erdheim-Chester disease (ECD) is a rare non-Langerhans histiocytosis, more frequent in elderly males. The clinical presentation is highly variable, making diagnosis challenging.

Case Report

We present the case of a 62-year-old male with prostate cancer and essential thrombocythemia (ET), the first diagnosed at 55 years old, currently receiving radiotherapy and hormone therapy, and the latter diagnosed at 56 years old, managed with hydroxyurea. In 2023, a PET scan revealed an asymptomatic right proximal femoral epiphyseal lesion that raised the suspicion of bone metastasis, evolution to myelofibrosis or possible chronic recurrent multifocal osteomyelitis. A subsequent biopsy showed fibrotic intertrabecular spaces without neoplastic involvement and no representation of hematogenous marrow. The patient also exhibited persistently elevated inflammatory markers. Due to these findings, he was referred to rheumatology in early 2024. A bone scintigraphy was ordered, revealing intense uptake in both femoral and tibial epiphyses and less intense uptake in the distal third of the tibial diaphysis and bilateral proximal femurs. Further imaging revealed an asymptomatic pericardial effusion. After a comprehensive evaluation by oncology, cardiology, haematology and rheumatology, given the combination of symmetric lower extremity bone lesions, chronic pericardial effusion of unknown aetiology and history of ET, ECD became a primary consideration. A posterior review of the biopsy indicated findings compatible with ECD, and genetic analysis confirmed a BRAFV600 mutation, establishing the diagnosis. Subsequent studies revealed bilateral orbital and perirenal involvement. He recently started vemurafenib.

Conclusion

This case highlights the diagnostic complexities of ECD, where a high index of suspicion was key. Biopsy is the primary diagnostic tool, but even if the pathological presentation is not sufficiently typical, ECD cannot be completely excluded, requiring comprehensive judgment alongside clinical and imaging findings. The BRAFV600 mutation was crucial in confirming the diagnosis and guiding treatment. Vemurafenib, a BRAF inhibitor, shows therapeutic potential, but its long-term efficacy and safety remain uncertain. Ongoing research is needed for better understanding and long-term management protocols.



P988

NUTRITIONAL OSTEOMALACIA CAUSED BY DIABETIC ENTEROPATHY: A CASE REPORT

M. R. Sebastião[1], M. Oliveira[1], U. Sushko[1], C. Furtado[1], L. M. Santos[1]

[1]Rheumatology Department - Hospital do Divino Espírito Santo de Ponta Delgada EPER, Ponta Delgada, Portugal

Osteomalacia (OM) is caused by inadequate mineralization of osteoid. Nutritional OM is the most common acquired form in adults, often due to low calcium and vitamin D intake.

Case Report: A 65-year-old man with type 1 diabetes and chronic diarrhoea due to diabetic enteropathy, was admitted for decompensated diabetes due to poor adherence. He presented insidious weight loss, diffuse bone pain in the pelvis and legs, muscle wasting and impaired gait in the past few months. Physical exam found sarcopenia, decreased lower limb proximal muscle strength and impaired gait. He had anemia, hypoalbuminemia, elevated alkaline phosphatase (ALP), severe hypovitaminosis D (3ng/mL) and low 24-hour urine calcium. Corrected calcium, phosphorus, magnesium, iPTH, C-reactive protein and urinary phosphorus were normal. Spinal CT showed multiple biconcave fractures of contiguous vertebrae in all segments - "codfish" vertebrae (fig.1A). Pelvic CT depicted multiple linear fractures in various stages of healing - Looser's zones (fig.1B-D). DXA showed low lumbar (-3,5) and femoral neck (-3.2) T-scores. Thoraco-abdominal-pelvic CT showed no malignant or mesenchymal tumours. Bone biopsy was not available. High dose calcifediol lead to clinical improvement and normal vitamin D and ALP within 4 weeks.

Conclusion: Diagnosing nutritional OM requires a high suspicion: symptoms are unspecific, asymptomatic hypovitaminosis D is common, and analytical findings may not occur simultaneously. Low BMD in DXA does not distinguish from osteoporosis, which often coexist. Calcifediol below 12ng/mL is known to impair mineralization and cause OM. Looser's zones and codfish vertebrae

are classic radiological features. Iliac bone biopsy is gold standard, but it is not widely available. Prompt treatment is crucial for prognosis.

CHRONIC LOW BACK PAIN: THE EXTENT OF THE SOCIAL AND CLINICAL BURDEN

Y. Makhlouf[1], M. Rachdi[1], S. Miladi[1], H. Boussaa[1], Y. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Fazaa[1], A. Laatar[1]

[1]Department of Rheumatology, Mongi Slim Hospital, Tunisia., Marsa, Tunisia

Introduction

Assessing disease perception in patients with non-specific chronic low back pain (CLBP) is recognized as essential due to its impact on the prognosis of this condition [1]. This study aimed to explore the relationship between disease perception and the socioclinical characteristics of women with CLBP.

Patients and methods

This was a cross-sectional study involving female patients with CLBP. Disease perception was assessed using the Brief Illness Perception Questionnaire (BIPQ): a 9-item questionnaire with a total score ranging from 0 to 80, where higher scores indicate a perception of the disease as more threatening. Pain severity and functional disability were evaluated using the Visual Analog Scale (VAS) and the the Oswestry Disability Index (ODI) respectively. The level of statistical significance was set at $p < 0.05$.

Results

Fifty-six women with non-specific CLBP were included in the study. The mean age was 52.4 years [23–56], with a disease duration of 8.7 years [1–24] and 4.7 annual exacerbations [2–8] on average. Overall, participants spent 3.5 hours per day [1–6] engaging in sustained physical activity. The mean VAS score for low back pain was 4/10 [1–7]. Functional disability, assessed using the ODI, was minimal in 26.7%, moderate in 60.7%, and severe in 12.5% of patients. Additionally, 67.8% of the patients used pharmacological treatments to manage their CLBP and 23 patients (41%) completed their physiotherapy sessions. The mean BIPQ score was 53.2 [21–80]. The mean scores for the first eight BIPQ items were as follows: "Consequences" 6.3 [2–10], "Timeline" 5.8 [2–8], "Personal Control" 4.8 [1–9], "Treatment Control" 7.5 [3–10], "Identity" 6.7 [1–6], "Concerns" 6 [2–7], "Coherence" 5.4 [1– 6], and "Emotional Response" 6.9 [2–7]. The primary perceived causes of low back pain (item 9) were household chores (50.2%), prolonged standing (48%), heavy lifting (45%), stress (31.6%), and exposure to cold (12.6%). Perceiving the disease as more threatening was significantly associated with a higher number of exacerbations ($p = 0.032$) and greater pain severity ($p = 0.048$). The belief that symptoms would persist longer (item 2) was significantly associated with greater functional disability ($p = 0.022$) and more severe pain ($p = 0.01$). Pessimistic perceptions regarding the effectiveness of prescribed treatment (item 4) were significantly associated with older age ($p = 0.05$), a higher number of hours of sustained physical activity ($p < 0.01$), and greater functional disability ($p = 0.038$). A more negative emotional impact (item 8) was significantly associated with a higher number of exacerbations ($p = 0.01$), more hours of sustained physical activity ($p = 0.04$) and more severe pain ($p = 0.05$).

Conclusion

Our study highlighted that negative disease perceptions, especially concerning prognosis, emotional impact, and treatment effectiveness were significantly associated with pain severity, functional disability, and other socioclinical factors."

METHOTREXATE OSTEOPATHY - A CASE REPORT A RARE COMPLICATION OF COMMON MEDICATION

M. Rakusa[1]

[1]UMC Ljubljana/Dept. of Endocrinology and Faculty of medicine, Univ. of Ljubljana, Ljubljana, Slovenia

Introduction

Stress fractures are cracks in the bones of the lower extremities caused by excessive strain or other factors that weaken the bone. Methotrexate can impair bone metabolism, leading to non-traumatic stress fractures, chronic pain, and subsequent immobility.

Methods

We present a case of a 66-year-old female with spontaneous, unhealed fractures of the lower limbs. She had a history of rheumatoid arthritis and leukopenia as part of Felty's syndrome. The patient was treated with methotrexate (20 mg weekly), folic acid, cholecalciferol (7,000 IU weekly), and occasionally filgrastim. She experienced progressively worsening pain in the right ankle, both feet and knees, without any evident injury. On the scale, pain was assessed as 8/10 and rendered the patient unable to walk. Magnetic resonance imaging (MRI) of the bones revealed stress frac-

tures of the left calcaneus, the distal epiphysis of the right tibia, the second metatarsal of the right foot, and the medial condyle of both knees. Bone mineral density was decreased to osteoporotic levels, with the lowest T-score of -3.0 SD. Laboratory findings were in normal range as follows: corrected calcium 2.36 mmol/L, phosphate 1.02 mmol/L, alkaline phosphatase (AF) 1.89 µkat/L, creatinine 57 µmol/L, 25-hydroxyvitamin D 73.2 nmol/L, iPTH 29 ng/L, CTX 0.476 µg/L, and PINP 59.7 µg/L.

Results

Based on the fractures in typical locations and the absence of other causes, methotrexate osteopathy was confirmed. In consultation with the rheumatologist, methotrexate was discontinued, and treatment with teriparatide (20 µg daily) was initiated. One month after starting teriparatide therapy, the patient reported reduced pain, assessed on a scale of 2/10. Laboratory results showed an increase in alkaline phosphatase to 3.10 µkat/L, consistent with increased bone formation. However, a follow-up MRI showed no signs of bone healing.

Conclusion

Methotrexate osteopathy is a rare treatment complication. It is characterised by non-traumatic stress fractures of the distal and proximal tibia, calcaneus, talus, and metatarsals in patients treated with methotrexate. Discontinuation of methotrexate is critical for bone healing. Due to the rarity of methotrexate osteopathy, the optimal treatment approach is not entirely clear. Case studies have demonstrated accelerated healing with the osteoanabolic drug teriparatide.

P991

NATIONWIDE INSIGHTS FROM 608 ORTHOPEDICIANS: EMPHASIZING PEAK BONE MASS, FRACTURE PREVENTION, AND EARLY SUPPLEMENTATION IN BONE HEALTH OPTIMIZATION

M. Reddy[1], S. N. Yadav[2], S. D. Viswanadha[3], M. N. Alam[4], B. S. K. Patro[5], T. Chaurasia[6], D. Shah[7], H. Singh[8], J. Panse[9], V. K. Anand[10]

[1]Enel Speciality Hospitals, Nellore, India, [2]Hari Bandhu Fracture Clinic, Varanasi, India, [3]Visakha Spinetics, Vizag, India, [4]Alam Ortho Hospital, Purnia, India, [5]Ganjam, Ganjam, Orissa, India, [6]GSVM Medical College, Kanpur, India, [7]Dilip Shah Clinic, Mumbai, India, [8]PGIMS, Rohtak, India, [9]Inlaks & Budhrani Hospital, Pune, India, [10]Anand Clinic, Delhi, India

Introduction

Optimal Peak Bone Mass (PBM) is critical for bone health, yet awareness and practices vary. The CARE-BONE survey aimed to assess orthopedic perspectives and identify gaps in PBM optimization across India.

Methods

608 orthopaedic were engaged in a nationwide, pan-India mapping exercise to comprehensively understand the importance of optimal peak bone mass in orthopedic practice. Conducted via a secure digital platform from the survey ensured data integrity and confidentiality. Participants rated 7 key therapy-related statements on a 5-point Likert scale. Statistical analysis, performed using GraphPad 10.4.1, defined strong consensus as a weighted score above 100.

Results

The mean experience was 16 ± 12 years (95% CI 15 to 17). The cumulative man-years of experience were 9447 years. The survey highlighted the critical importance of optimizing PBM in orthopedic practice. The highest weighted scores emphasized PBM's role in fracture prevention (120.0) and the long-term benefits of Vitamin D supplementation (118.5). There was broad consensus on the significance of early calcium and Vitamin B supplementation for fracture healing (117.2) and the importance of acquiring PBM in respondents under 30 years (117.1). While calcium supplementation in ages 25-30 (108.9) and preventive strategies for osteoporosis (112.9) showed slight variability, the overall findings highlight PBM as a cornerstone of bone health. Awareness levels among the younger generation revealed gaps, with 52.8% showing low awareness and only 5.92% demonstrating high awareness. The overall mean response scores were: Strongly agree: 61±39.4 (95% CI 51 to 71), Agree: 53±4.9 (95% CI 48 to 58), p<0.0001

Discussion

The CARE-BONE survey emphasizes the critical role of Peak Bone Mass in fracture prevention and bone health, with strong consensus on early calcium and Vitamin D supplementation, especially in individuals under 30. Variability in responses regarding supplementation in ages 25-30 highlights the need for standardized guidelines. Over half of younger orthopedicians showed low PBM awareness, that highlights the need for targeted educational initiatives. These findings reaffirm PBM as a cornerstone of orthopedic care, urging further research and policy interventions.

P992

BONE MINERAL DENSITY AND DISEASE DURATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: INSIGHTS FROM A SINGLE-CENTRE STUDY

M. Rexhepi[1], B. Rexhepi-Kelmendi[2], B. Krasniqi[3], S. H. Krasniqi[4]

[1]Rheumatology Clinic -University Clinical Centre of Kosova, Faculty of Medicine University of Prishtina, PRISHTINA, Albania, [2]Rheumatology Clinic -University Clinical Centre of Kosova, PRISHTINA, Albania, [3]Medical University of Tirana-Faculty of Medicine, PRISHTINA, Albania, [4]Institute of Clinical Pharmacology, Faculty of Medicine University of Prishtina, PRISHTINA, Albania

Objective:

Osteoporosis is a common comorbidity in patients with rheumatoid arthritis (RA), and its prevalence increases with age. RA, a chronic inflammatory autoimmune disease, accelerates bone loss through both inflammatory mechanisms and the prolonged use of therapy, which are commonly prescribed to manage disease activity. The risk of osteoporosis in RA patients is further compounded by the duration of the disease, with older individuals being particularly vulnerable. Age-related changes in bone metabolism, combined with the inflammatory processes of RA, result in a higher likelihood of reduced bone mineral density. The

study aims to define the correlation between osteoporosis and the duration of diseases related to the age of rheumatoid arthritis patients.
Material and Methods:
The sample for the work consisted of consecutive patients meeting RA criteria treated at the in-patient department of the Rheumatology Clinic. The sample size was 100 subjects, which, in addition to the general characteristics, also analyzes bone mineral density results at the beginning of hospitalization and, after six months, presented as a standardized T-score. The statistical analysis was done for parametric data, a T-test was performed, and the Pearson correlation was used to confirm the relationship between parameters.
Results:
The average age of the sample analyzed was 50.9±5.7 years, with an average RA disease long-lasting 7.8±3.4 years. During the correlation between the T-score and age of the study population and the duration of the disease from diagnosis, respectively, a low positive correlation was gained (r=0.2). There is an evident significant difference among T-score values at the time of admission (before) and after six months of treatments (p= 0.000446).
Conclusion:
Based on the diagnostic values T-score, osteoporosis was more evident in older patients with RA who had a longer duration of the disease. Proper evidence-based treatment is crucial for ameliorating disease and improving bone mineral density results. Detailed projects should be designed for the future with a larger sample size to study other possible factors that could affect bone density, such as glucocorticoids, lifestyle, and quality of life.
Key words: rheumatoid arthritis, osteoporosis, age

P993

DOMAINS OF SENILE ASTHENIA SYNDROME IN PATIENTS WITH CHRONIC HEART FAILURE

M. Rostom[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2], J. A. Strunkova[2]

[1]Beni-Suef Hospital, Beni-Suef, Egypt, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective: Systematize domains of senile asthenia syndrome in patients with chronic heart failure (CHF).
Methods: 120 patients over 75 years old are included, hospitalized in a hospital with CHF decompensation (tightness of shortness of breath, heartbeat, edema on the limbs).
To evaluate the SSA, a questionnaire "Age is not a hindrance" was used. The clinical domain (Charleson index, NYHA, a power scales), functional domain (Bartel Index), psychocognitive domain (Montreal Cognitive Assessment - MoCA, geriatric scale of depression), social domain (family status, housing conditions, education).
Results: Senile asthenia was observed in 58.3% (n=70) of hospitalized patients of senile age with asthenia syndrome, preiasthenia in 39.1% (n=47). Median (IQR) of age amounted to 79.85 [77.0-80.7] year, 70.8 % (n=85) women. Clinical domain: patients were characterized by high comorbits (Charleson index - 8.6±1.6 points) and high proportion of malnutricity 85.0% (n=102). In 85.8% (n=103) patients, III-IV functional class according to NYHA was observed. Functional domain: in 70.8% (n=85) patients, a complete/pronounced dependence on outside help was observed, which was more often observed with the accompanying syndrome of senile asthenia than in patients without senile asthenia – 65.9% against 29.7%, p <0.05, respectively. Psychocognitive domain: cognitive disorders were observed in 81.6% (n=98) patients (the average MoCA score – 15.5±3.7).
Heavier cognitive dysfunction was observed with senile asthenia syndrome than without senile asthenia - 13.3±4.2 versus 17.9±4.7, p<0.05, respectively. In 81.6% (n = 98) of patients, depression was noted. Social domain: 49% (n=78) patients live only 4.16% (n=5) - in the nursing home. 55.8% (n=67) patients are not married, 64.2% (n=77) have secondary education, 35.8% (n=43) - higher. When conducting logistics regression, the most significant predictors of senile asthenia (SSA) were: III–IV functional class according to NYHA (OR 5.4, 95% CI 1.4–21.7, p<0.05), expressed/complete dependence From outside help (OR 4.5-94 % CI 2.0-10.8, p<0.05), each MoCA score reduced the likelihood of senile asthenia of the senile asthenia syndrome by 10%.
Conclusion: The domain approach to patients with chronic heart failure is necessary for monitoring and optimizing pharmacotherapy and solving social issues.

P994

RISK FACTORS FOR REDUCING MINERAL BONE DENSITY IN PATIENTS WITH HODGKIN LYMPHOMA

M. Rostom[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2], J. A. Strunkova[2]

[1]Beni-Suef Hospital, Beni-Suef, Egypt, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Hodgkin's lymphoma is an oncgetological disease in which osteoporosis often occurs. The development of osteoporosis is due to the influence of antitumor and adjuvant therapy. Currently, most algorithms for the diagnosis of osteoporosis are applicable to patients of older age groups. Important are timely diagnosis and prevention of osteoporosis in young patients with Hodgkin lymphoma.
Objective. To study the risk factors for reducing the mineral density of bone tissue, to develop an algorithm for early diagnosis in patients with Hodgkin lymphoma.
Methods. The study included 45 people with a diagnosis of Hodgkin lymphoma, each of whom signed an informed consent to participate in the study. Each of the patients took place of radiation and chemotherapeutic therapy.
22 people were included in the control group. All groups of patients were comparable by gender, age and anthropometric data. Each participant answered questions from the questionnaire "Risk Fracture Factors". All patients have been carried out densitometry and designed by the Z-criterion. The measurement of the mineral density of bone tissue was carried out in the area of the hip neck, the proximal thigh and the lumbar spine. Given the results obtained, we developed a methodology for the prevention of

osteoporosis in patients with Hodgkin lymphoma after radiation and chemotherapy.
Results. In patients with Hodgkin lymphoma, a significant decrease in the mineral density of bone tissue was revealed, mainly in the lumbar spine. Based on the survey data, we established the risk factors of osteoporosis: a low level of physical activity, a history of the hip neck, the forearm fractures, other history fractures, smoking, low body weight index, age, low calcium consumption, a history of parents, gender fractures, gender , removal of the ovaries. Given the results obtained, we developed a methodology for the prevention of osteoporosis in patients with Hodgkin lymphoma after radiation and chemotherapy. The prevention technique included therapeutic exercises, diet, intake of calcium preparations, prescribing drugs that restore the structure of bone tissue (antiresorbetic and anabolic drugs).
Conclusion. The methodology for the prevention of osteoporosis in patients with Hodgkin lymphoma after radiation and chemotherapy allows you to reduce the frequency of fractures.

P995

ASSESSMENT OF SARCOPENIA, ASTHENIA AND LIVER ENCEPHALOPATHY IN PATIENTS WITH CIRRHOSIS BEFORE AND AFTER LIVER TRANSPLANTATION

M. Rostom[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2], N. V. Tolmacheva[2]

[1]Beni-Suef Hospital, Beni-Suef, Egypt, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Sarcopenia and liver encephalopathy - frequent complications of cirrhosis of the liver, are predictors of adverse prognosis in patients with cirrhosis. Liver transplantation is the main treatment for the terminal stage of liver disease.
Objective. Assess the presence and severity of sarcopenia, asthenia and liver encephalopathy in patients with cirrhosis of the liver before and after liver transplantation.
Methods. The study included 47 patients with liver transplantation included in the liver transplantation sheet and 20 patients after liver transplantation (7 months after the liver transplantation). The average age of patients before liver transplantation was 57.1±1.7 years, after the liver transplantation - 48.8±3.4 years. The patients were distributed as follows: before the liver transplantation of women - 32 (68%), men - 15 (32%); after the liver transplantation of men and women, 50%. The severity of the liver cirrhosis was estimated by Child-Pugh index: class A – 17 (36.2%) patients, class B – 8 (17%), class C – 22 (46.6%). The average score for the model of assessing the final stage of the Meld liver disease is 15.0. The muscle mass was evaluated by the measurement of the circumference of the shoulder, the muscle force- with dynamometry, to identify the degree of asthenia, Liver Frailty Index (LFI) was used, West-Haven criteria were used to determine the stage of liver encephalopathy, the number of numbers was used, the level of ammonium of capillary blood.
Results. In a group of patients with cirrhosis of the liver before the liver transplantation, the average value of the shoulder circumference was 26 [24; 29] cm, the average compression force of the hand is 20.4 [17.7; 23,1] kg. The average value of the LFI index was 4.11 [3.47; 4.75], which corresponds to the definition of "Pre-FRIIL". According to West-Haven criteria, 22 (46.8%) patients with cirrhosis of the liver had liver encephalopathy: the minimum-11 (23.4%), I stage - 5 (10.6%), II stage - 6 (12.4%), the average value of the number of the number of numbers was 75 [45; 105] sec, blood ammonium level was 99.5 [68; 131] μmol/l. In the group after transplantation, there was no statistically significant difference compared to the group to transplantation by the value of the circumference of the shoulder (25.6 [24; 27.3] cm, p>0.05), the average compression power (19.85 [19.85 [19.85 [16.01; 23.7 kg, p>0.05), the value of the LFI index (3.84 [3.47; 4,22], p>0.05), the time of execution of the number of numbers [30; 71] secμ, p>0.05). The level of ammonium after transplantation was significantly lower than in the group before transplantation (44.5 [34; 55] and 102.5 [71; 134] μmol/l (p<0.05).
Conclusion. 7 months after the liver transplantation in patients with cirrhosis of the liver, we did not establish changes in sarcopenia, asthenia and liver encephalopathy.

P996

LONG-TERM INTAKE OF GLUCOCORTICOIDS BY PATIENTS WITH RHEUMATOID ARTHRITIS: FOCUS FOR COMPLICATIONS

M. Rostom[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2], T. Z. Andreeva[2], A. S. Komelyagina[3]

[1]Beni-Suef Hospital, Beni-Suef, Egypt, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia, [3]Noth-Western State Medical University named after I.I. Mechnikov, St. Petersburg, Russia

Objective. The use of glucocorticoids in the treatment of patients with rheumatoid arthritis is widespread both in Russia and around the world. However, the duration and dose regime of glucocorticoids often go beyond clinical recommendations. Therefore, the study of the consequences of prolonged use of glucocorticoids in the treatment of rheumatoid arthritis becomes very relevant.
Methods. Of the 80 patients with the activity of the RA (ACR/EULAR of 2010), hospitalized in the rheumatological department of the city hospital in 2020–2023, 2 groups of patients were identified: the first – patients with rheumatoid arthritis who use systemic glucocorticoids for more than 6 months. (n=50): the duration of the intake of glucocorticoids 48 [27:79] month, the average dose of prednisolone at the time of inclusion in the study: 6.5±4.5 mg/day. The second group is patients with RA without the experience of taking glucocorticoids (n=30). To assess the profile of concomitant pathology, a cumulative index of diseases (CIRS) was used.
Results. The age of patients in the first group is 45.1±10.2 years (p<0.0001), in the second group 39.7±11.5 years (p <0.0001), the duration of the disease in the first group 16.1±8,4 years (p=0.0003); In the second group 7.5±5.7 years (p=0.0004).
In patients with rheumatoid arthritis of the first group III-IV, radiological stages were found in 34.8% of cases; in the second group – 16.2%; OR=1.5 [1.1; 2.1], p=0.02).

The frequency of the Difficult-to-Treat variant of rheumatoid arthritis (EULAR 2021) in the first group was 11.2%; in the second group – 5.3%, OR=2 [1; 2.7], p = 0.027). At the same time, the activity of rheumatoid arthritis in DAS28 at the time of inclusion in the study in groups was comparable (the first group: 5.2 [4.5; 5.9]; second group: 4.7 [4.3; 5.1]).
Therapy of rheumatoid arthritis in the first group was characterized by a large number of used basic anti-inflammatory drugs (first group: 2.7±1.2; second group: 2.4±0.7, p=0.0003), more frequent development of methotrexate-induced hepatitis (the first group is 14.5%; the second group is 12.1%; OR=1.55 [1; 2.5], p=0.039).
In the first group, the time interval between the debut of the rheumatoid arthritis and the initiation of biological therapy was larger – 10 [2; 18] years), in the second group – 7 [3; 11] years, p=0.0001) and directly correlated with the duration of glucocorticoid therapy (r=0.27) with a comparable qualitative structure of the used genetic and engineering biological drugs. In the first group, tuberculosis, hypertension, chronic kidney, cataract, osteoporosis (p<0.043) and its complications with a comparable frequency of cardiovascular diseases, diabetes, and gastrointestinal lesions were diagnosed. The first group revealed a higher Cumulative Illness Rating Scale (CIRS) index, and the CIRS severity index was lower than in the second group (p <0.05).
Conclusions. Long-term use of glucocorticoids lengthened the time to the prescription of genetically engineering biological drugs and was accompanied by an increase in multilomorbid load.

P997

HEALTH IMPACT ASSESSMENT OF THE SECONDARY FRACTURE PREVENTION PROGRAM AT THE HOSPITAL DE SAN JOSÉ DE BOGOTÁ

M. Rueda[1], A. Medina[2], N. Camargo

[1]Socidad de Cirugia Hospital San José de Bogotá, Bogotá, Colombia, [2]Sociedad de Cirugia Hospital San José de Bogotá, Bogotá, Colombia

Objectives: To describe clinic and sociodemographic characteristics, treatment, initiation and continuation of treatment, falls, disability and factors associated with refractures and mortality after 1 year of follow-up of patients admitted to the Secondary Fracture Prevention Program at the Hospital San José in Bogota Colombia since 2022 until October 2023.

Material and Methods: Retrospective cohort study carried out in hospitalized patients with fragility fractures admitted to the Fracture Liason Service (FLS) named Secondary Fracture Prevention Program at the Hospital San José in Bogota-Colombia between January 2022 and October 2023 who completed a one-year follow-up. Variables were analized at 3, 6 and 12 months after the fracture ocurred accoding to Key Performance Indicators (KPI) established by Capture the Fracture Program of the International Osteoporosis Foundation (IOF).

Results: 137 patients with one year follow-up were included (74,4% women) with a median of age of 78,5 years. Regarding the fracture site: 71%, 7%,10%, 9% and 3% were in hip, vertebra, ratio, humerus and other respectively. 94% of patients received indications to start pharmacological management prior to discharge of which, 32,8% started the treatment and only 24,8% were under treatment 12 months postfracture. In 20.4%, telephone follow-up was not carried out. Mortality rate was 17.5%.

Discussion: The FLS are intended to treat osteoporosis, prevent falls and thus avoid subsequent fractures and associated mortality. According to the KPIs to rate the performance of an FLS, it was found that a new fall was present in 5,8% and a new fracture in 7,2% of patients, disability was present in 45,2% during one-year of follow up. Mortality was associated with lower 25OHvitamin D levels 15,56 vs 25,46 (p=0.002). Refracture was associated with lower total hip T-Score -2.59 vs -1.86 (p= 0.046).

Conclusions:
There are multiple limitations in telephone follow-up of patients. Despite having indications to start treatment, there is difficulty in carrying out the administrative procedures required to start and continue therapy. This represents a wake-up call for the health system to reduce follow-up access barriers and reduce refractures and mortality.

HYPOPHOSPHATASIA, A CASE REPORT AND EXPERIENCE WITH THE START OF TREATMENT IN AN ADULT

M. Rueda[1], A. Medina[2], C. Coronado[2]

[1]Socidad de Cirugia Hospital San José de Bogotá, Bogotá, Colombia, [2]Sociedad de Cirugia Hospital San José de Bogotá, Bogotá, Colombia

Objective

To describe a case of hypophosphatasia (HPP), the diagnostic challenge, response
and the difficulties with the initiation of treatment with asfotase alfa.

Material and Methods

The data were collected from clinical history with the patient's authorization and a review of the literature was carried out with the key words: hypophosphatasia, adults, asfotase.

Results

39-year-old woman of short stature, product of consanguineous parents. Complete tooth loss since 10-years-old, multiple fractures in lower and upper limbs, severe mobility limitations confining her to a wheelchair, generalized pain and evidence of bone deformities in extremities. WOMAC-score showed: Pain 15, stiffness 4 and functionality 61. Laboratory tests showed slightly elevated serum calcium and phosphorus levels, normal PTH, 25OHvitamin D and phosphaturia. Nutritional deficiency or metabolic causes were ruled out. X-rays of long bones showed nonunion fractures, osteomalacia signs and rickets deformities in the extremities. Severely diminished alkaline phosphatase (ALP) was found (<10 IU/L) in three separate measurements. A diagnosis of HPP was made. Measurement of ALP substrates, genetic studies and counseling were requested to identify mutation of the ALPL gene (not essential for diagnosis) and treatment with asfotase alfa was started; with just one dose the bone pain has improved.

Discussion

HPP is an orphan disease, with autosomal dominant or recessive inheritance mechanism, secondary to pathogenic variants in the ALPL gene that lead to decreased non-tissue-specific ALP activity, allowing adequate bone mineralization. Asfotase alfa is a recombinant ALP approved in Colombia for hypophosphatasia in children. In adults, this indication is off label, however adults with HPP who received asfotase alfa for ≥ 6 months experienced improvements in mobility, physical function, and HRQoL.

Conclusions:

Low diagnostic suspicion and difficult recognition by medical personnel generate an under diagnosis of HPP. Its consequences on bone health have an impact on the patient's functionality and quality of life. Its treatment is expensive, with approval in Colombia only for pediatric cases, which makes it difficult to obtain, start and maintain.

P999

SEVERE IDIOPATHIC OSTEOPOROSIS IN A YOUNG PATIENT

M. S. Deac[1], M. Cevei[1], D. Stoicanescu[2], A. Gherle[1], R. Mihut[1]

[1]UNIVERSITY OF ORADEA, FACULTY OF MEDICINE AND PHARMACY, ORADEA, Romania, [2]University of Medicine and Pharmacy "Victor Babes", Timisoara, Timisoara, Romania

Osteoporosis is often associated with aging but the condition can also affect younger.

This case report describes 49-year-old patient, with a medical history of the following conditions: idiopathic osteoporosis (2016), Helicobacter pylori-positive gastritis (2005), perforated acute cholecystitis (2021), anxious-depressive disorder with a psychotic episode (2021), SARS-CoV-2 infection (2020), and mixed dyslipidemia, presents with the following clinical findings on physical examination: pronounced dorsal kyphosis and muscle contracture in the lumbar region.The family medical history is notable for Charcot-Marie-Tooth disease in the mother and sister.

Investigations conducted to exclude secondary causes of osteoporosis reveal normal renal function, euthyroidism, normal cortisol levels, normal serum testosterone, normal calcium and parathyroid hormone levels, and normal alkaline phosphatase. In light of these findings, the diagnosis of idiopathic osteoporosis is established.

The patient was initially treated with Alendronate sodium and Colecallciferol, which was discontinued due to gastric issues, and subsequently continued with Denosumab (1 injection every 6 months), along with Vitamin D3 (2000 IU daily), and Calcium citrate with Vitamine D3 (1 tablet daily for 2 weeks), for a total duration of 46 months.

In June 2024, a decision was made to discontinue Denosumab treatment and continue with Vitamin D supplementation alone.

Z-Score

Year	Lumbar spine	Right hip	Left hip
2016	-3,5	-2,6	-2,0
2017	-3,9	-2,5	-2,2
2020	-3,3	-2,4	-2,1
2021	-3,3	-2,0	-1,9
2022	-3,0	-2,0	-1,8
2023	-2,7	-1,8	-1,2
2024	-2,4	-1,9	-1,2

Bone densitometry confirms significantly decreased bone mineral density for the patient's age.The Lumbar spine TBS is 1.219 which suggests a degraded microarchitecture compared to reference population.
Conclusion The importance of investigating and treating osteoporosis in young men, even in the absence of an obvious etiology, is underscored.

P1000

YOUNG FEMALE PATIENT WITH INACTIVITY OSTEOPOROSIS AFTER SPINAL CORD INJURY(SCI)

R. Mihut[1], M. Cevei[1], F. Andronie Cioara[1], A. Gherle[1], M. S. Deac[1]

[1]UNIVERSITY OF ORADEA, FACULTY OF MEDICINE AND PHARMACY, ORADEA, Romania

The consequences of immobilisation-induced bone loss are significant, as they not only heighten the risk of fractures but also contribute to functional limitations, longer recovery times, and poorer overall health outcomes.
Objectives
This case report describes 27-year-old patient, with a medical history of the following conditions: T7 - T8 vertebro-medullar trauma (SCI) due to road traffic accident (12.09.2020) operated (17.09.2020 - T7 laminectomy - anterior decompression with bilateral metalic synthesis), minor cranio-cerebral trauma, inactivity-related Osteoporosis (2022),presents with the following: paraplegic-type motor deficit, sphincter disorders, ADL deficit.

Materials and methods
The John Hopkins Health System Corporation scale shows a high risk of falling (16 points). Also, the calculated Barthel Index shows a severe degree of dependency (35 points out of 100), and the Functional Ambulation Categories scale indicates that the patient falls into the non-functional ambulatory category. The patient is treated with Vitamin D3 (1mg daily).

	Place of measurement	BMD (g/cm²)	Z Score
2022	Right hip	0,636	-2,8
	Left hip	0,608	-3,0
	Spinal cord	0,995	-0,5
2025	Right hip	0,620	-2,9
	Left hip	0,602	-3,2
	Spinal cord	0,890	-1,5

Results
The progression of osteoporosis is evident, with continued loss of bone mass.

Conclusion
Understanding the unique challenges that young individuals face when immobilised is crucial for improving clinical outcomes and supporting the development of preventive strategies that preserve bone integrity throughout life.

P1001

ROMOSOZUMAB: ANALYSIS OF SAFETY AND DIFFERENTIAL EFFECTIVENESS IN SPECIFIC SUBGROUPS: PATIENTS WITH RHEUMATOID ARTHRITIS, DIABETES MELLITUS (DM), CORTICOSTEROIDS-INDUCED OSTEOPOROSIS

M. S. Moreno Garcia[1], R. Gonzalez Mazario[2], M. Robustillo Villarino[3], E. Meriño Ibarra[1], Y. Uson[1], C. Bruscas[4], J. Ulier[1], G. Giner[5], J. C. Cobeta Garcia[6], J. Fragio Gil[2], R. Martin Holguera[7], A. I. Turrion[8]

[1]HOSPITAL MIGUEL SERVET, ZARAGOZA, Spain, [2]HOSPITAL GENERAL, VALENCIA, Spain, [3]HOSPITAL UNIVERSITARIO DE LA PLANA, VILLARREAL, Spain, [4]HOSPITAL DE LA DEFENSA, ZARAGOZA, Spain, [5]HOSPITAL ROYO VILLANOVA, ZARAGOZA, Spain, [6]HOSPITAL ERNEST LLUCH, CALATAYUD, Spain, [7]UNIVERSISDAD PONTIFICIA DE SALAMANCA, SALAMANCA, Spain, [8]COMPLEJO ASISTENCIAL UNIVERSITARIO DE SALAMANCA, SALAMANCA, Spain

Background/Objective: There is limited evidence regarding the effects of 12 months of romosozumab (ROMO) treatment on increasing bone mineral density (BMD) in real-world clinical practice due to its recent approval. This study aimed to describe the effectiveness and safety outcomes of ROMO at 12 months in patients at very high risk of fracture and to investigate its differential effectiveness in specific subgroups: patients with rheumatoid arthritis (RA), diabetes mellitus (DM), corticosteroid-induced osteoporosis, and those who are treatment naive for osteoporosis.
Methods: In this prospective, observational, and multicenter study, data were analyzed for 216 female patients, with baseline and follow-up bone mineral density (BMD) information available for 74 patients. Collected characteristics included osteoporosis (OP) risk factors, cardiovascular risk factors (CVRF), DM, diseas-

es requiring glucocorticoids (GC), RA, and BMD measurements before and after ROMO treatment. Additional data on previous treatments and safety outcomes, including major adverse cardiovascular events (MACE), were collected at 6 and 12 months (Table 1) .

Results: There was a statistically significant increase in column density (8.76%), which was also maintained across all prespecified subgroups, except for the DM subgroup, which showed only a 3.88% increase. Similarly, femur density increased significantly (5.65%), with this improvement observed in all prespecified subgroups except the DM subgroup, where the median increase was 1.65% (Figure 1).
No MACE were documented at 6 months or 1 year. Fourteen patients discontinued treatment, with 11 cases attributed to adverse events, 1 to economic reasons, 1 due to uncertainty about the treatment, and 1 as a result of multidrug use. Adverse events included depression (n=1), headache (n=1), drug intolerance (n=6), flu-like symptoms (n=1), osteonecrosis of the jaw (n=1), and cramps (n=1).

Conclusion: This real-world dataset demonstrates rapid progress after one year of treatment, with significant increases in BMD observed in both the lumbar spine and femoral neck. All analyzed subgroups showed a significant increase in BMD, except for patients with DM. Further studies are needed to evaluate the effect of ROMO on BMD changes in patients with unique characteristics.

Table 1: Demographic characteristics and baseline clinical data.

Parameter		N: patients. (%)
Females, n (%)		216 (100)
Age (years), mean (SD)		69.3 (8.55)

P1002

THE EFFICACY OF FOCUS EXTRACORPOREAL SHOCK WAVE THERAPY ON HAMSTRING TIGHTNESS IN HEALTHY SUBJECTS

M. S. Roongsaiwatana[1], M. S. Padungchaitavi[1], M. S. Chiraadisai[1]

[1]Physical medicine and Rehabilitation Department, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

Objective: To study efficacy of focus extracorporeal shock wave therapy on the flexibility of hamstring muscles in healthy subjects
Study design: Double-blind randomized controlled trial (RCT)
Setting: Rehabilitation Medicine Department, Faculty of Medicine Ramathibodi hospital.
Subjects: Healthy subjects age between 18-65 years with limited hamstring flexibility
Methods: All participants were evaluated by passive knee extension test (PKE) to define the limited hamstring flexibility and later received weekly focus extracorporeal shockwave therapy (F-ESWT) at energy flux density 0.15 mJ/mm^2, frequency of 6 Hz, intensity, 2,000 pulses per session, 1 session per week for 3 weeks) compared with sham F-ESWT. Both groups also received standard static stretching home exercise program. Passive knee extension (PKE), Back-saver sit-and-reach test (BSSR), Sit and reach test

(SRT) and Toe touch test (TT) were evaluated before and 1, 2 and 3 weeks after intervention.

Results: One hundred and twenty-four participants with mean age (SD) of 37.44(12.60) were recruited by randomized controlled males and females equally. At pre- intervention, mean passive knee extension test (PKE) (SD) was 29.22(7.65) and median Back-saver sit-and-reach test (BSSR), Sit and reach test (SRT) and Toe touch test (TT) were -6.2 (-28.60,15.60) cm, -4.90(-27.60,13.70) cm and -5.40(-25.50,8.10) cm, respectively. When comparing between pre-, 1, 2 and 3 weeks post- intervention, the PKE, BSSR, SRT and TT improved significantly in both groups (P<0.05). Even though more improvement in F-ESWT group, there was no statistic significant; except TT (P=0.014)

Conclusion: F-ESWT with home exercise program for flexibility of hamstring muscle is effective in improving the flexibility of hamstring muscles in healthy subjects, but did not provide additional improvement compared with performing standard static stretching alone especially in mild degree of hamstring inflexibility subjects.

Keywords: Focus ESWT, hamstring flexibility, hamstring tightness

ASSESSING THE RISK OF OSTEOPOROSIS AND FRAGILITY FRACTURES IN THE COMMUNITY: IN THE WORLD OSTEOPOROSIS DAY CAMPAIGN

P. Zarepour[1], M. Sanjari[2], N. Fahimfar[2], M. J. Mansourzadeh[2], F. Hajivalizadeh[3], E. Hesari[2], S. Hajivalizadeh[2], K. Khalagi[4], V. Mohseni[2], S. Salehi[1], F. Z. Dehestani[1], M. Darman[3], A. Ostovar[5]

[1]School of Public Health, Department of Epidemiology and Biostatistics, Tehran University of Medical Science, Tehran, Iran, Tehran, Iran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [3]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, Tehran, Iran, Tehran, Iran, [4]Obesity and Eating Habits Research Canter, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [5]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective:

Osteoporosis is one of the most common chronic diseases among the elderly. It is characterized by an increased risk of severe fractures, reduced quality of life, and substantial economic costs. This abstract reports on osteoporosis risk assessment within a national osteoporosis campaign held by the Osteoporosis Research Center and Non-Communicable Disease Office of the Iran Ministry of Health and Municipality.

Material and Methods:

This descriptive study was conducted in the public seminars. Data were collected using the Osteoporosis Risk Check tool from the International Osteoporosis Foundation (IOF). The tool contains ten yes-no questions to assess risk factors for osteoporosis such as age, history of fractures, low body mass index (BMI), height loss of more than 4 cm, and comorbidities. A "yes" answer to any item indicates an increased risk of fractures or osteoporosis. The target population was the general public, who participated in public seminars held in neighborhood halls and health centers. Data were collected before participants entered the seminar. In these three-hour seminars, experienced professors provided information on bone health, osteoporosis, risk factors, fall and fracture prevention, and lifestyle modification. The seminar ended with a question-and-answer session. Data were analyzed with SPSS software using chi-square analysis.

Results

A total of 1,101 individuals participated in the study, of whom 81% were women, 21.8% were over 60, and 56.1% had education levels above high school. Among the participants, 52.6% responded positively to at least one question on the risk check, indicating they were at risk for osteoporosis. About 82% reported familiarity with osteoporosis, but only 20.1% of participants sought a diagnosis and had a bone density test. Additionally, 41.1% of those diagnosed with osteoporosis were currently taking medication, and 78.4% were adhered to their treatment regimens. Also, of those over 60, 3.7% had fractures after age 50, 2.8% had a BMI below 19, and 5.8% had a height reduction of over 4 cm after age 40.

Conclusion

The findings indicate that preventive awareness and diagnostic measures for osteoporosis persist inadequately. Expanding educational campaigns and national screening programs are crucial to improving bone health in the population.

INFORMING AND EDUCATING ABOUT OSTEOPOROSIS AT THE COMMUNITY LEVEL: IN THE WORLD OSTEOPOROSIS DAY CAMPAIGN

P. Zarepour[1], M. Sanjari[2], N. Fahimfar[2], M. J. Mansourzadeh[2], F. Hajivalizadeh[3], E. Hesari[2], S. Hajivalizadeh[2], K. Khalagi[4], V. Mohseni[2], S. Salehi[1], F. Z. Dehestani[1], M. Darman[3], A. Ostovar[5], S. M. Tabatabaee[2], B. Larijani[5]

[1]School of Public Health, Department of Epidemiology and Biostatistics, Tehran University of Medical Science, Tehran, Iran, Tehran, Iran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [3]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, Tehran, Iran, Tehran, Iran, [4]Obesity and Eating Habits Research Canter, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [5]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective: Osteoporosis, as a common bone metabolic disorder, leads to fracture and causes significant morbidity and mortality. However, there is a substantial knowledge gap regarding risk factors and prevention strategies. This abstract reports on osteoporosis awareness status within a national osteoporosis campaign held by the Osteoporosis Research Center, the Non-Communicable Disease Office of the Iran Ministry of Health, and the Iranian Osteoporosis Society.

Material and Methods:

This descriptive study was conducted during awareness campaigns and educational programs, including community-based seminars. These public seminars (October and November 2024) focused on raising awareness through lectures, interactive activities, and expert Q&A sessions.

The target population was the general public, who participated in public seminars held in neighborhood halls and health centers. In these three-hour seminars, experienced professors provided information on bone health, osteoporosis, risk factors, fall and fracture prevention, and lifestyle modification. The seminar ended with a question-and-answer session. Data were collected using a validated questionnaire before participants entered the seminar. The awareness score was categorized according to total value:80% or higher indicates good awareness, between 50% and 80% signifies moderate awareness, and a score below 50% reflects poor awareness. Data were analyzed with SPSS software using chi-square analysis.

Results:

A total of 261 participants attended the seminars. In total, 96.2% were women, with a mean age of 48.86 years. Findings revealed that 15.7% of participants showed a poor level of awareness, 79.5% moderate awareness, and only 4.8% demonstrated good awareness levels. Knowledge about risk factors, such as Calcium and vitamin D deficiency, lack of dietary intake, and smoking, was acceptable, but misconceptions regarding the role of coffee intake and frailty existed. Higher educational attainment was significantly associated with better awareness levels (P >0.021).

Conclusion:

The study underlines the need for comprehensive and targeted educational interventions. Innovative communication strategies and culturally adapted content can effectively improve public awareness and prevention of osteoporosis. Stainable efforts, especially among at-risk groups, are essential to mitigate the disease's burden.

THE FRENCH VERSION OF PHYSICAL ACTIVITY SCALE FOR THE ELDERLY (PASE) – TRANSLATION, CULTURAL ADAPTATION AND VALIDATION

M. Scouvemont[1], F. Humblet[1], S. Bornheim[1], C. Beaudart[2], J. van Beveren[3], V. Tannoia[1], G. Schaff[1], N. Beliy[1], C. Elsen[1], S. Adam[1], C. Schmidt[1], O. Bruyère[1]

[1]University of Liège, Liège, Belgium, [2]University of Namur, Namur, Belgium, [3]Collège Saint-Hadelin, Visé, Belgium

Objective: To translate the Physical Activity Scale for the Elderly (PASE) questionnaire into French, adapt it to the French European culture and validate it.

Material and methods: The PASE was translated and culturally adapted using a 5-step validated process. The investigation of the measurement properties included the internal consistency, test-retest reliability, construct validity and floor and ceiling effects.

Results: The translation faced no major problems, with moderate cultural adjustments. Unfamiliar activities such as American football, shuffleboard or aerobic dancing were adjusted, while common sports like yoga, aqua cycling and electric cycling were added. Validation study involved 89 older participants (median age of 73 (69.5 - 77) years, 58% of women). Moderate internal consistency was found (Cronbach's alpha= 0.571). Test-retest reliability was very good for household activities (ICC= 0.712 (95% CI= 0.496 – 0.845)) and work-related activities (ICC= 0.955 (95% CI= 0.908 – 0.978)) but was lower in the leisure section (ICC= 0.163 (95% CI= - 0.183 - 0.473)), leading to a moderate overall score (ICC= 0.455 (95% CI= 0.125 - 0.608)). This result could be attributed to the weather conditions that were not similar between the two test-intervals[1], which affects leisure activities (most of which take place outdoors)[2]. Construct validity was almost confirmed (66.67% of the ideal 75% hypothesis was validated). No floor or ceiling effects were detected.

Conclusion: The French PASE appears to be a reliable and relatively valid tool for assessing household and work-related activities. However, PASE should be used with caution, especially when assessing leisure time activities, ensuring that the meteorological conditions are consistent between the two reliability tests.

ASSOCIATIONS BETWEEN THE LIVING ENVIRONMENT AND SLEEP THROUGH THE MEDIATION OF THE PHYSICAL ACTIVITY: A SYSTEMATIC REVIEW PROTOCOL

M. Scouvemont[1], V. Tannoia[1], G. Schaff[1], N. Beliy[1], C. Elsen[1], S. Adam[1], C. Schmidt[1], O. Bruyère[1]

[1]University of Liège, Liège, Belgium

Objective: To obtain a comprehensive understanding of the role of physical activity as a mediator variable in the association between the living environment and sleep.
Material and methods: The systematic review protocol has been published on PROSPERO [ID: CRD42024580376]. The PRISMA 2020 guidelines will be followed throughout the process. This systematic review will include both experimental and observational studies in English that focus on how physical activity mediates the relationship between the living environment and sleep in humans, regardless of age, gender or ethnicity. The literature search will be conducted in Medline (via Pubmed), Scopus and Embase, using both controlled language and free text to formulate the search equations. Additional manual searches will also be realized. Studies will be imported into the Covidence software for duplicate removal, and selection will be conducted by two independent reviewers based on titles, abstracts, and full-text articles, providing detailed reasons for exclusion. Data extraction will be performed independently by two reviewers, while the methodological quality of the studies will be assessed using the critical appraisal tools for use in JBI Systematic Reviews.
Results: We expected to obtain the results of the systematic review during 2025.
Conclusion: Identifying elements of the living environment that influence sleep through the mediation of physical activity is essential for public authorities to develop effective strategies in public health, housing, and territory planning. Highlighting the role of physical activity in this association can guide targeted interventions to improve both sleep health and, more broadly, overall health status.

P1008

TUMOUR INDUCED OSTEOMALACIA: ELEVATED SERUM FIBROBLAST GROWTH FACTOR 23 MAY A PREDICTOR FOR THE OCCURANCE OF FUTURE TUMOUR

M. Shalaby[1], H. Eitta[1]

[1]University of Al-Azhar/Rheumatology departement/Al-Hussien Hospital, Cairo, Egypt

Background Tumour induced osteoporosis (TIO) is a rare paraneoplastic disease characterized by decreased renal tubular reabsorption of phosphate, by hypophosphatemia and by low levels of active vitamin D ultimately results in osteomalacia due to chronic hypophosphatemia. Diagnosis of TIO is usually suspected when serum phosphate levels are chronically low in the setting of bone pain, fragility fractures and muscle weakness. It is usually associated with high serum level of fibroblastic growth factor (23FGF23).
Case presentation
A 44 year age female presented with sever agonizing generalized bony aches mainly in the chest, dorsal and lumber spine, also she had gradual progressive muscle aching and weakness in the pelvic girdle with difficulty in walking, getting up from floor as well as shoulder girdle with difficulty in doing normal daily activities. All manifestations occurred and gradually increased after removal of left benign breast mass 3 month earlier. On examination; generally she look ill, suffers from pain and walks with waddling pattern. Neurological examination showed weakness in the shoulder and pelvic girdle muscles (power grade 3+) but no wasting with normal sensation and reflexes. Musculoskeletal examination revealed generalized polymyalgia, tenderness in dorsal and lumber spine, sacroiliac joints, most of the ribs. Also tenderness of the left shoulder joint with limited ROM for both Shoulders. Left knee and Right ankle sowed mild tenderness with full ROM. No Hotness or swelling for the examined joints. Laboratory investigations showed reduced total serum calcium 8.7 mg/dl while the ionized serum calcium was normal 4.12mg/dl , decreased serum phosphorous 1.3 mg/dl , elevation of serum alkaline phosphatase 482 u/l (normal range 35-105) and normal total CPK , serum PTH elevated 385.2 pg/ml and marked decrease in serum vitamin D level 5.16 ng/dl. CA 41.18 U/mL mildly elevated (normal level up to 37 U/mL) and CEA (Carcinoembryonic Antigen) was normal 0.72 (normal level up to 7 ng/ml). DEXA scan showed severe osteoporotic pattern (T score was - 4.1 at lumber spine, -2.9 femur and -2.2 at forearm). Whole body F18-FDG PET/CT report stated absence of any significant blastic/lytic lesions or dense tracer foci could be seen over the surveyed skeleton, but there was left dense left breast parenchyma with bad architecture distortion. She treated with calcitriol and phosphate supplements with gradual improvement. Six months later the patient complained of recurrent abdominal pain with recurrent melena Upper gastroscopy was normal but colonoscopy showed fungating mass proved to be adenocarcinoma of the colon. In conclusion and earning points for clinical practice: patient with high level of FGF23 with manifestation of TIO should be closely monitored and regularly followed up for future malignancy

P1009

ATYPICAL BILATERAL AFF

M. Siddiqi[1], G. Dixon[1]

[1]University Hospitals of Liverpool Group, Liverpool, United Kingdom

Introduction: The aetiology of atypical femoral fractures (AFF) is multifactorial. Though the incidence is very low (1) The propensity for AFFs to be bilateral and in the same location on ipsilateral and contralateral sides suggests that femoral geometry may play a part in its incidence (2). We present a case here in which in our opinion, the geometry of femur was the sole risk factor.

Case Presentation: A 69-year-old active Caucasian woman presented with a fracture of shaft of left femur with all the radiological features of AFF (Fig.1), when she tripped over at home. She was treated with intra-medullary nailing (IMN). She had no obvious risk factors for osteoporosis and was never treated with any bisphosphonate or steroids. Her routine biochemistry including bone turnover markers was normal her BMD showed osteopenia. Though she did not complain of any pain in the contralateral thigh, an x-ray followed by a CT scan of right femur demonstrated a microfracture at almost the same position as the left AFF (Fig.2). She had preventative IMN. It was noticed that she had increased bowing specially in frontal plane(Angle A 13°) (Fig3).

Discussion: Femoral bowing is defined as the angle between two lines along the proximal and distal portions of the femoral shaft in both frontal (angle A) and sagittal plane (angle B) allowing for the quantification of both lateral and anterior bowing angles (3). Sasaki measured the angles in 24 normal controls and found the Angle A to be 4.6±5.1 and Angle B 11.8±3.8 (4)
It is hypothesized that geometry influences AFF risk by increasing mechanical strains at the femoral shaft (3) and these studies suggest that elevated femoral bowing may increase the risk of AFF independent of bisphosphonate exposure (5). A better understanding of how femoral geometry is linked to AFF may allow for clinical risk stratification for patients with osteoporosis on bisphosphonate treatment.

EFFECTIVENESS OF ELECTROTHERAPY IN THE TREATMENT OF PAIN IN KNEE OSTEOARTHRITIS

M. Slouma[1], E. Razgallah, N. Mouhli[2], R. Dhahri[3], R. Maaoui[2], H. Rahali[2], E. Cheour[4], I. Gharsallah[3]

[1]Rheumatology department, military hospital of Tunis, Tunis, Tunisia, [2]Department of Physical Medicine and Functional Rehabilitation, Military hospital of Tunis, Tunis, Tunisia, [3]Department of Rheumatology, Military hospital of Tunis, Tunis, Tunisia, [4]Rabta hospital, Tunis, Tunisia

Objective : to evaluate the effectiveness of TENS in managing pain associated with knee osteoarthritis.
Methods :
A longitudinal study in the rheumatology department included patients diagnosed with knee osteoarthritis according to the 1986 ACR criteria (1).
Patients on non-steroidal anti-inflammatory drugs (NSAIDs), anti-arthritic drugs, those with knee prostheses, or those who had undergone viscosupplementation or corticosteroid injections within the past four months were excluded. Only paracetamol was allowed during the study. Socio-demographic and clinical data were collected.
Progression of responses was evaluated in the three domains of the WOMAC index: pain, stiffness, and function, comparing the period before (T0) and after (T1) the TENS sessions.
Subsequently, all recruited patients underwent a program of 9 sessions of TENS physiotherapy in the physical medicine department, with 3 sessions per week. Statistical analysis was performed using SPSS software.
Results :
Thirty patients with knee osteoarthritis were included in the study. The average age was 57.70 ± 16.37 years [22–87]. The sex ratio (M/F) was 1.3. Hypertension was found in 61%, 37% were diabetic, and 21% had dyslipidemia. The average body mass index (BMI) was 29.13 ± 3.91 kg/m² [22.40–36.70], with 43% being overweight and 33% obese.
The average duration of knee pain was 76.34 ± 131.53 months [6–720]. Genu-varum in 40%, genu-valgum in 27%, and genu-flexum in 7% of patients.
According to the Kellgren and Lawrence radiographic classification, 52.2% of the patients had moderate-stage knee osteoarthritis.
A significant improvement was observed in the WOMAC function domain, with scores decreasing from 386.33 at T0 to 314.33 at T1 ($p = 0.047$).
No significant improvement was noted in the WOMAC pain (T0: 167.87; T1: 142.67; $p = 0.116$), and stiffness (T0: 31.67; T1: 25.67; $p = 0.387$), and weekly paracetamol consumption (T0: 1.77; T1: 1.27; $p = 0.395$).
Conclusion: Our study confirms the widely proven effectiveness of TENS in alleviating osteoarthritic knee pain, and improving stiffness and function.

A CASE OF SEVERE MALE OSTEOPOROSIS: 42-YEAR-OLD MAN WITH HIDRADENITIS SUPPURATIVA AND MULTIPLE VERTEBRAL COMPRESSION FRACTURES – DIAGNOSTIC AND THERAPEUTIC CHALLENGE

M. Sokalska-Jurkiewicz[1], J. Šindelářová[1], M. Klein[1], O. Růžičková[1]

[1]Rheumatology Institute, Prague, Czechia

Objective(s): Osteoporosis, characterized by low bone mass and microarchitectural deterioration of bone tissue, leading to fragility fractures, is the most common metabolic bone disease. However, the incidence of osteoporosis in young men is relatively low. Most cases in young adults are secondary (mostly glucocorticoid use), with less than 10% attributed to idiopathic causes. Treating osteoporosis in younger patients is challenging, and addressing the underlying etiology is crucial.
Material and Methods: This case report describes a 42-year-old male patient treated with adalimumab for hidradenitis suppurativa and spondyloarthritis. He was referred to our osteology outpatient clinic for vertebral compression fractures. The patient complained of back pain and was initially diagnosed with spondyloarthritis, despite being HLA-B27 negative. He was progressively shortening and reported no effect of adalimumab on his back pain. He denied glucocorticoid use and had no other known endocrinological disease.
Results: Initial evaluations - densitometry and X-ray imaging, confirmed osteoporosis and multiple vertebral fractures. Given the severity of the condition, we pursued genetic testing. Meanwhile, as mutation detecting is time-consuming, we opted to initiate anabolic therapy. As condition manifested in adulthood and without concomitant symptoms we excluded osteogenesis imperfecta and among others we suspected mutation of LRP5 gene, which would be resistant to teriparatide. Therefore we decided to start off-label romosozumab therapy. The drug was well tolerated and effective. For more we reconsidered diagnosis of spondyloarthritis - patient is not fulfilling diagnostic criteria.
Conclusion(s): In differential diagnostics of back pain in young male osteoporosis should be considered and densitometry should be performed. In case of detecting low bone density secondary causes, including genetic mutations, should be inves-

tigated. Taking on account young age and long life expectancy anabolic treatment should be the first choice to rebuild bone mass, afterwards antiresorptive drugs should be considered. **Acknowledgments:** Supported by the project (Ministry of Health, Czech Republic) for conceptual development of research organization 00023728 (Institute of Rheumatology)

THE EFFECTS OF TIBIA FRACTURE AND INJECTION OF MESENCHYMAL STEM CELLS INTO FRACTURE AREA ON CHEMICAL COMPOSITION OF DENTIN OF UPPER MOLARS

M. Trufanova[1], V. Luzin[2], I. Soloviova[1], A. Razaryonova[1]

[1]FSBEI HI St. Luka LSMU of MOH of Russia, Lugansk, Russia, Lugansk, Russia, [2]FSBEI HI ST. LUKA LSMU of MOH of Russia, Lugansk, Russia

Objective: Aim of the study is to test chemical composition of dentin of upper molars (DUM) after tibia fracture modeling and injection of mesenchymal stem cells (MSC) into the defect of the tibia at different times after surgery.
Material and Methods: 162 male rats with the body weight of 190-225 g were distributed into 7 groups: group 1 - controls, group 2 - animals with tibia fracture, and groups 3-7 animals with the same tibia fracture that received local injections of 5 million MSC per injection at 3rd, 10th, 15th, 24th and 45th days after surgery. Bone marrow cells were obtained from the tibia and phenotyped according to standard methods. Upon expiration of observation terms (7, 15, 30, 60 and 90 days) the animals were withdrawn from the experiment; DUM prepared for chemical analysis.
Results: In the group 2 calcium/phosphorus ratio in the DUM in the period from the 30th to the 90th day after surgery was lower than those of the group 1 by 6.37%, 8.21% and 7.38%, and calcium level by 60th day - by 3.87%. In the group 3 calcium/phosphorus ratio by 90th day were higher than those of the group 2 by 3.82%, and fluorine level by 60th and 90th day - by 5.29% and 4.49%. In the group 4 calcium/phosphorus ratio and fluorine level in the period from the 30th to the 90th day were higher than those of the group 2 by 5.25%, 7.48% and 6.77%, and by 6.12%, 6.76% and 4.92% respectively. In the group 5 calcium/phosphorus ratio in the period from the 30th to the 90th day was higher than those of the group 2 by 5.80%, 6.78% and 5.83%, and fluorine level by 60th and 90th day - by 4.91% and 4.92%. In the groups 6 and 7 the restoration of the chemical composition of DUM were expressed to a significantly lesser extent.
Conclusions: Administration MSC into the defect of the tibia at different times after surgery was accompanied by a faster recovery of the chemical composition of DUM. The most effective was administration of MSC on the 10th day after surgery.

P1015

APPLICATION OF MACHINE LEARNING AND ITS EFFECTS ON THE PREDICTION OF SARCOPENIA

N. Michalopoulos[1], C. Matzaroglou[1], E. Billis[1], M. Tsekoura[1], E. Dermatas[1]

[1]University of Patras, Rio, Greece

Objective: The study aimed to investigate the variety of Machine Learning (ML) methods and their ability to detect individuals at risk of or suffering from sarcopenia.
Material and Methods: A scoping review was performed. Pubmed databases were searched from July to September 2024 for trials related to the sarcopenia prognosis and artificial intelligence. The key words used were "sarcopenia", "artificial intelligence", "machine learning", "risk factors". All studies were able to identify sarcopenia with moderate to high accuracy values and with different ML methods. The reference lists of systematic review articles and meta-analyses were scanned for any additional references missed from the above databases' search. Only English literature was included for the current review.
Results: In total 11 articles were included. A total of 15.799 participants were included in this review. The machine learning methods that standout were, deep neural networks, LightGBM, Decision Tree, CAT, k-nearest neighbors. 4 studies were performed in Korea, 2 in Mexico, 1 in China, 1 in Italy, 1 in turkey, 1 in USA, and 1 study had data from participants from 3 different countries (England, Jamaica and Singapore). As for the risk factors it is found that the most important were age, body mass index, waist circumference, chronic diseases and some socioeconomic features.
Conclusion(s): These results indicate that ML methods can be used by clinicians for faster and more cost-effective means of identifying sarcopenia. Early and accurate detection of sarcopenia through ML can lead to timely interventions reducing several serious health issues. ML has emerged as a powerful tool in the field of healthcare, offering novel approaches to diagnosing and predicting conditions such as sarcopenia.
Keywords: sarcopenia, machine learning, risk factors

P1016

PREVALENCE AND ASSOCIATED FACTORS OF SARCOPENIA AMONG PATIENTS WITH HYPERTENSION

M. Tsekoura[1], P. Aggelopoulos[2], K. Fousekis[2], P. Sakkatos[2], C. Matzaroglou[2], E. Billis[2], E. Tsepis[2], J. Gliatis[3]

[1]Department of Physiotherapy, University of Patras, Aigio, Greece, [2]Department of Physiotherapy, University of Patras, Rio, Greece, [3]Department of Medicine, University of Patras, Rio, Greece

Objective: To investigate the prevalence rate of sarcopenia and associated factors among older adults with hypertension.
Material and Methods: This was a cross-sectional study of 102 older patients with hypertension aged ≥60 years. Hypertension

was defined by self-reporting of a physician diagnosis or the use of antihypertensive medication. All participants were evaluated for sarcopenia using the European Working Group on Sarcopenia in Older People 2 (EWGSOP2) criteria. Reported determinants (sex, age, sociodemographic characteristics, chronic diseases, fall history) of the participants were obtained through a questionnaire. Anthropometric assessments were performed to measure the patients' weight, height and body mass index (BMI). Body composition was evaluated by bioimpedance analysis (Tanita BC-601). Handgrip strength (HGS) was assessed via a hand held dynamometer (Saehan, Seoul, Korea). Gait speed (4 meters test), and 5 times sit to stand test (5STST) were evaluated also. The association between variables was calculated using Pearson-r correlation coefficients.
Results: The overall prevalence of sarcopenia among older adults with hypertension was 24.5% (n=25). The mean age of the study population was 70.2 ± 5.6 years (age range, 60–93 years). Patients with sarcopenia were older than those without sarcopenia ($p \leq 0.001$). Patients with concurrent hypertension and sarcopenia had a significantly lower HGS, walking speed and a higher incidence of osteoporosis, and fall history ($p < 0.05$) compared to non sarcopenic older adults. Hypertension was associated with HGS ($r=0.59, p \leq 0.001$), 5STST ($r=0.44, p \leq 0.001$) and BMI ($r=0.4, p \leq 0.05$).
Conclusions: This study revealed a high prevalence of sarcopenia among older adults with hypertension (22.4%). Current research confirms that sarcopenia is associated with hypertension. These results may have significant impact in both prevention and treatment techniques for older adults with sarcopenia and hypertension. Future studies should investigate more factors that could influence older adults with hypertension and sarcopenia.
Funding: This paper has been financed by the funding programme "MEDICUS", of the University of Patras", Greece.

P1017

RELATIONSHIP BETWEEN FALL HISTORY AND THE ENHANCED PAPER GRIP TEST AMONG OLDER ADULTS: A PILOT STUDY

M. Tsekoura[1], E. Livieratou[2], P. Chatzistergos[3], E. Tsepis[2]

[1]Department of Physiotherapy, University of Patras, Aigio, Greece, [2]Department of Physiotherapy, University of Patras, Rio, Greece, [3]School of Science and Engineering, University of Dundee, Dundee, United Kingdom

Objective: To investigate the relationship between fall history and the enhanced paper grip test (EPGT).
Material and Methods: A convenient sample of 30 community dwelling adults of both genders agreed to participate in this study. Lower-limb strength was assessed using the EPGT. EPGT force was measured using a dynamometer (Omega engineering, UK). Hand Grip Strength (HGS) was assessed using a hand held dynamometer (Saehan Seoul, Korea). Anthropometric assessments were performed to measure the patients' weight, height and body mass index (BMI). Data on demographic characteristics, health conditions, history of falls, and psychological factors were collected using a pre-tested, structured questionnaire. The association between variables was calculated using Pearson-r correlation coefficients. Ethical approval was secured from University of Patras ethics committee.
Results: The mean age of the study population was 73.6 ± 4.8 years. Mean score on EPGT was 15.2±5.4 N. Out of the total of 30 participants, 12 people (40%) reported having a history of falling. Out of the 12 fallers, 8 were female (66.7%).Older adults with a history of falls appeared to have significantly lower HGS and lower EPGT force. Results record strong correlation for EGPT and HGS ($r=0.6, p \leq 0.001$) and moderate to strong correlation with history of falls ($r=0.41, p \leq 0.001$) and
Conclusions: The present study found statistically significant positive moderate-strong correlations between EPGT force, HGS and history of falls. The proposed EPGT could be used to monitor muscle strength and it may be used for falls-risk assessment. Further research is required to assess the clinical value of this measurement for the prevention of falls in the older population.
Keywords: enhanced paper grip test, muscle strength, falls

LEVEL OF PHYSICAL ACTIVITY AND ITS ASSOCIATED FACTORS AMONG GREEK POSTMENOPAUSAL WOMEN

M. Tsekoura[1], S. Lampropoulou[1], S. Xergia[1], A. Sakellaropoulou[2], A. Gridelas[2], G. Kolokuthas[2], C. Matzaroglou[3], E. Billis[1]

[1]Department of Physiotherapy, University of Patras, Rio, Greece, [2]Elderly Open Care Centers Patras, Rio, Greece, [3]University of Patras, Rio, Greece

Objective: To investigate the relationship between physical activity, quality of life, anxiety and depression in postmenopausal Greek women.
Material and Methods: This cross-sectional clinical study included 219 postmenopausal women. A structured interview schedule was used to collect information on the participants' age, general health status, education level, time since last menstruation, hormonal therapy use, socioeconomic status, and smoking habits. Menopausal status was determined based on a self-report. Osteoporosis diagnosis was confirmed by participants' recent dual-energy X-ray absorptiometry (DXA) measurement. The female participants were asked to fill out the International Physical Activity Questionnaire-short form (IPAQ), the Hospital Anxiety and Depression Scale (HADS), and the EuroQol (EQ-5D-5L) instru-

ment. The Ethics Committee of the University of Patras, Greece, approved the study protocol.
Results: A total of 219 postmenopausal women with an age of 61.4 ± 6.1 years were studied. Out of the total postmenopausal women studied, 64.8% were physically active. The physical activity level of the female participants ranged from 500 to 3358 MET-min/week (mean value of MET-min/week: M = 1383.46 ± 1030.12). A total of 39.7% (n = 87) of the female Greek participants were diagnosed with osteoporosis. Physical activity among postmenopausal Greek women showed a strong correlation with quality of life ($r = 0.5$; $p \leq 0.001$) and age ($r = 0.55$; $p \leq 0.001$) and a medium correlation with the HADS ($r = 0.4$; $p \leq 0.05$).
Conclusions: The majority of the Greek postmenopausal women were physically active. The findings provides important health-related data of a group not previously studied in Greece. In addition results underscore the significance of fostering physical activity and quality of life among postmenopausal women to formulate efficacious therapeutic interventions.
Keywords: physical activity, menopause, anxiety, depression

EVALUATING THE PREDICTIVE POWER OF THE FRACTURE RISK ASSESSMENT TOOL (FRAX): A DECADE-LONG ASSESSMENT OF FRACTURE RISK IN OSTEOPOROTIC PATIENTS

M. U. N. Effendi[1], U. A. Siddiqui[1], A. J. Farooqui[1], M. U. Zaman[2], M. Shekha[3], Z. A. Dandia[3], M. N. Akhtar[4], A. H. Khan[1]

[1]Department of Pathology & Laboratory Medicine, Aga Khan University Hospital, Karachi, Pakistan, [2]Department of Radiology, Aga Khan University Hospital, Karachi, Pakistan, [3]Postgraduate Medical Education, Aga Khan University Hospital, Karachi, Pakistan, [4]Department of Surgery, Liaquat National Hospital, Karachi, Pakistan

Objective: To evaluate the predictive performance of The Fracture Risk Assessment Tool (FRAX) by analyzing its 10-year fracture risk predictions against the actual fracture outcomes observed over a decade-long follow-up period.
Material and Methods: This retrospective cohort study is being conducted at the Department of Pathology and Laboratory Medicine in collaboration with the Department of Radiology, Aga Khan University Hospital, Karachi, Pakistan. The institutional review committee granted an ethical exemption due to its retrospective design. The study includes 750 patients diagnosed with osteoporosis based on Dual-energy X-ray Absorptiometry (DEXA) imaging in 2014, with the FRAX, applied to calculate their 10-year probability of major osteoporotic and hip fractures. Data on demographic characteristics, clinical parameters, DEXA scan results, and FRAX predictions were extracted from medical records. Patients are being followed up for 10 years (2014–2024) to assess fracture occurrences, primarily through telephonic calls. Descriptive analyses summarized the demographic and clinical characteristics of the study population, and the predictive performance of the FRAX was evaluated by calculating sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) using SPSS version 23.
Results: Among 160 patients evaluated, 16 (10.0%) sustained fractures, with the femoral neck being the most common site (n=6, 37.5%). The cohort was predominantly female (152, 96.2%) with a mean age of 59.7 ± 1.35 years, mean weight of 69.8 ± 13.0 kg, and mean height of 153.6 ± 6.91 cm. Prior fracture history was reported by 7 (4.4%) patients, while 8 (5.3%) had a parent with a history of hip fracture. Most patients reported no smoking history (155, 96.9%), no glucocorticoid use (157, 98.1%), no rheumatoid arthritis (157, 98.1%), and no evidence of secondary osteoporosis (145, 90.6%). All patients (100%) reported consuming less than three units of alcohol daily. The FRAX demonstrated a sensitivity of 68.75%, a specificity of 90.91%, a PPV of 45.83%, and an NPV of 96.30%.
Conclusion: Our study's preliminary findings highlight the potential utility of FRAX in identifying patients at low risk of fractures.

P1020

IMPACT OF MULTIPLE MYELOMA ON BONE METABOLISM: INSIGHTS FROM BONE STATUS INDICES

M. U. N. Effendi[1], A. Mahmood[2], F. M. A. Khan[1], F. Jahan[1], H. Majid[1], R. Kausar[1], A. H. Khan[1]

[1]Department of Pathology & Laboratory Medicine, Aga Khan University Hospital, Karachi, Pakistan, [2]Medical College, Aga Khan University, Karachi, Pakistan

Objective: To compare bone status indices between patients with multiple myeloma and healthy controls to assess the impact of multiple myeloma on bone health.
Material and Methods: This analytical cross-sectional study was conducted at the Department of Pathology and Laboratory Medicine, Aga Khan University Hospital, Karachi, Pakistan, following ethical approval from the institutional review board. Patients diagnosed with multiple myeloma during the year 2024 were identified through serum protein electrophoresis and immunofixation electrophoresis. Eligible patients were approached to evaluate their bone status indices (BSIs), including serum levels of Osteocalcin, Procollagen 1 Intact N-Terminal Propeptide (P1NP), and C-terminal telopeptide of type I collagen (β-CTX). BSIs were measured using the Cobas e801 analyzer (Roche Diagnostics) via the electrochemiluminescence immunoassay technique, adhering to the manufacturer's protocols. Data analysis was performed using SPSS version 23. Descriptive statistics were used to summarize patient demographics and BSIs, and comparative analyses were conducted to explore differences in BSIs. A p-value of <0.05 was considered statistically significant.
Results: A total of 46 patients diagnosed with multiple myeloma were included in the study, comprising 29 males (63%) and 17 females (37%). The median age of the patients was 57.5 (46.8–67.8) years. The median levels of BSIs in multiple myeloma patients were as follows: Osteocalcin, 6.64 (3.02–15.5) ng/mL; P1NP, 60.25 (29.7–93.2) ng/mL; and β-CTX, 0.04 (0.02–0.09) ng/mL. For comparison, BSIs were also analyzed in 40 healthy controls.

The median BSI levels in the control group were Osteocalcin, 7.48 (5.8–10.5) ng/mL; P1NP, 45.95 (34.2–54.8) ng/mL; and β-CTX, 0.03 (0.01–0.05) ng/mL. The Mann-Whitney U test was applied to compare the median BSI levels between patients with multiple myeloma and healthy controls. The analysis revealed a statistically significant difference in β-CTX levels ($p = 0.03$) between the two groups, with higher levels observed in multiple myeloma patients. However, no significant differences were observed for Osteocalcin ($p = 0.80$) or P1NP ($p = 0.12$) levels.
Conclusion: Based on the findings, β-CTX levels were significantly elevated in patients with multiple myeloma compared to healthy controls, suggesting altered bone resorption in this population.

DOES GENICULAR NERVE BLOCK IMPROVES QUALITY OF LIFE IN END STAGE OSTEOARTHRITIS?

M. U. Rezende[1], O. P. Camargo[2]

[1]Departament of Orthopedics - HC-FMUSP, São Paulo, Brazil, [2]Department ofOrthopedics - HC-FMUSP, São Paulo, Brazil

Objetivo: Ao tentar oferecer algum conforto aos pacientes com osteoartrite grave do joelho (OAJ) que podem ou não querem ser submetidos à artroplastia total do joelho, comparamos os resultados algofuncionais do bloqueio do nervo genicular com anestésico ou fenol em pacientes com osteoartrite grave do joelho.
Material e Métodos: Trinta e quatro pacientes com Kelgren&Lawrence grau IV grave e Alhback graus 3 a 4, aguardando artroplastia total do joelho, foram submetidos ao bloqueio do nervo genicular de todos os joelhos com OAJ grave. Eles foram randomizados em dois grupos, ou seja, bloqueio por ropivaína e bloqueio por fenol 5% 2ml em cada nervo genicular (inferior-medial, superior-medial e superior-lateral). Os pacientes foram avaliados na inclusão e 1 mês e 3 meses por VAS, WOMAC (1-96), Timed-Up-and-Go (TUG) e teste de sentar e levantar de 30 segundos (30STS).
Resultados: Os grupos foram semelhantes na inclusão para todas as variáveis com IMC de 36,5 ± 8,9 (ropivacaína) e 34,8 ± 8,8. TUG e 30STS não melhoraram devido ao bloqueio do nervo genicular indistintamente pelo método ou em qualquer período de tempo. Ambos os grupos apresentaram melhorias não significativas no WOMAC total e em todos os subconjuntos (Tabela). Os resultados VAS melhoraram 1,38 (grupo Fenol) da linha de base até 1 mês ($p = 0,001$), mas pioraram 1,15 pontos entre 1 e 3 meses (não duradouro) ($p = 0,45$). No grupo anestésico, nenhuma melhoria significativa ocorreu em nenhum momento.
Conclusão: O bloqueio do nervo genicular na OA grave do joelho pode oferecer uma leve melhora na dor por um curto período de tempo com fenol, enquanto quando bloqueado com ropivacaína a melhora não é relevante por um mês.

P1022

THE ASSOCIATION OF FRAILTY INDEX-LABORATORY (FI-LAB) SCORES WITH OSTEOPOROTIC FRACTURE RISK IN OLDER ADULTS: A RETROSPECTIVE COHORT STUDY

M. Ucdal[1], M. Gungor[2], C. Balci[2], B. Balam Dogu[2], M. G. Halil[2], M. Cankurtaran[2], M. Esme[2]

[1]Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkiye, [2]Department of Geriatrics, Hacettepe University Faculty of Medicine, Ankara, Turkiye

Introduction and Objective Osteoporotic fractures represent a significant cause of morbidity and mortality in older adults and are frequently associated with increased frailty. The Frailty Index-Laboratory (FI-lab) is a quantitative tool that assesses frailty by analyzing deviations in routine laboratory parameters. This study aimed to evaluate the association between FI-lab scores and the prevalence of osteoporotic fractures in individuals aged 65 years and older.
Materials and Methods In this retrospective cohort study, 15,814 patients aged ≥65 years were analyzed from the MIMIC 3 database. Of these patients, 3,200 (20.2%) had documented osteoporotic fractures. FI-lab scores were calculated based on 24 routine laboratory parameters, including hematology, biochemistry, inflammatory markers, and liver function tests. Mean FI-lab scores were compared between patients with and without osteoporotic fractures.
FI-lab Calculation Methodology A systematic approach was employed to assess frailty based on laboratory abnormalities. Each parameter was assigned a value of 1 if outside the normal clinical range and 0 if within range. The FI-lab score was calculated by dividing the number of abnormal parameters by the total number of parameters evaluated. The examined parameters were categorized into four main groups: hematology (hemoglobin, white blood cell count, platelet count), biochemistry (albumin, creatinine, glucose, urea, sodium, potassium), inflammatory markers (CRP, ESR), and other tests (liver enzymes, bilirubin, coagulation profiles).
Demographic Data Of the total 15,814 patients included in the study, 64.3% were female. The mean age was 73.5 ± 6.8 years. The study group comprised 3,200 patients (20.2%) with osteoporotic fractures, while 12,614 patients (79.8%) without fractures formed the control group.
Primary Findings Patients with osteoporotic fractures demonstrated a mean FI-lab score of 0.487 ± 0.156, compared to 0.463 ± 0.149 in the control group ($p<0.05$). The odds ratio (OR) was calculated as 1.42 (95% CI: 1.28-1.58)(figure-1). Among laboratory parameters, the most pronounced abnormalities were observed in elevated CRP (52% in fracture group vs. 38% in control group), decreased albumin (48% vs. 32%), and reduced hemoglobin levels (45% vs. 35%)(figure-2).
FI-lab Score Distribution Analysis of FI-lab score distribution revealed that 35% of patients in the fracture group had scores within the 0.4-0.6 range, 28% within 0.2-0.4, and 17% within 0.6-0.8. In the control group, the majority of patients (35%) had scores within the 0.2-0.4 range. Both groups showed 5% of patients with scores

in the 0.8-1.0 range(figure 3).

Conclusions and Recommendations FI-lab has been identified as a valuable predictive tool for assessing frailty and its association with osteoporotic fracture risk in older adults. FI-lab scores above 0.4 show a significant correlation with increased fracture risk. Integration of this scoring system into clinical practice may facilitate the identification of high-risk populations and guide preventive strategies. Future prospective studies may further elucidate the predictive value of FI-lab.

SERUM ANGIOPOIETIN-LIKE PROTEINS CONTENT IN PATIENTS WITH OSTEOARTHRITIS

V. A. Aleksandrov[1], M. V. Nikitin[2], A. V. Aleksandrov[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, VolgogradState Medical University, Volgograd, Russia, [2]National Medical Research Center for Rehabilitation and balneology, Moscow, Russia

Angiopoietin-like proteins (Angptl) are involved in repair and remodeling of damaged tissues, but hyperfunction of some types of Angptl can induce and/or maintain chronic inflammation leading to progression of arthropathies of various genesis.

Purpose of the study:

To determine the correlations of serum levels of Angptl types 3, 4 and 6 with clinical and laboratory characteristics of osteoarthritis and comorbid conditions.

Materials and Methods.

34 patients with osteoarthritis (OA), of whom 5 (14.7%) were males and 29 (85.3%) were females, were included in the study. The average age of the patients was 60.0±7.9 years, the average duration of the disease was 11.8±9.6 years.

Generalized form of OA was observed in 25 people, obesity of various degrees - in 15 people, presence of metabolic syndrome (MS) was found in 10 people. Synovitis was registered in 26.5% of OA patients.

Results and Discussion.

When assessing the activity of the inflammatory process in patients with OA, we focused, first of all, on the presence of synovitis and laboratory indicators of the inflammatory process (ESR and CRP). Analysis of variance showed a significant effect of synovitis and high ESR/CRP on Angptl3 (p=0.04 and p=0.002, respectively), Angptl4 (p=0.02 and p=0.01, respectively) and Angptl6 (p=0.045 and p=0.03, respectively). The influence of these factors on the content of Angptl3 and Angptl6 was statistically insignificant (p>0.05), in contrast to Angptl4 (p=0.007), the levels of which were the highest in patients with synovitis on the background of pronounced inflammation.

MS was diagnosed in 29.4% of OA patients. Angptl3 content in patients with MS was higher than in OA patients without MS (M-W U

test, p=0.034), Angptl6 levels tended to increase in the presence of MS (M-W U test, p=0.06), and Angptl4 indices did not differ significantly in these groups (p>0.05). Obesity was detected in 44% of OA patients. Angptl4 content in obese patients was higher than in OA patients with normal body weight (M-W U test, p=0.025), while Angptl3 and Angptl6 were not significantly different in these groups (p>0.05).

Conclusions.

Obesity and synovitis have a significant effect on Angptl content in patients with OA. The highest Angptl4 values are observed in patients with synovitis on the background of pronounced inflammation (high ESR and CRP).

P1024

PHYSICAL ACTIVITY LIMITATIONS ARE ASSOCIATED WITH FATIGUE AND DEPRESSION IN PATIENTS WITH RHEUMATIC DISEASES

N. V. Aleksandrova[1], M. V. Nikitin[2], V. A. Aleksandrov[3], I. A. Zborovskaya[1], A. V. Aleksandrov[3]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]National Medical Research Center for Rehabilitation and balneology, Moscow, Russia, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Volgograd State Medical University, Volgograd, Russia

Purpose of the study:

To evaluate the effect of physical activity on depression and fatigue in patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE).

Methods:

52 patients with RA and 54 patients with SLE completed a program of additional physical activity (daily dosed walking of 30-60 minutes) during a 4-week rehabilitation cycle.

The total index of kinesiophobia was calculated using The Tampa Scale for Kinesiophobia (TSK) questionnaire, the level of fatigue was evaluated using the VAS screening scale and the FACIT scale. The Beck Depression Inventory (BDI-II) was used to assess the presence of depressive symptoms.

Results and Discussion:

According to the level of physical activity, patients were divided into groups with sedentary lifestyle (less than 5.5 thousand steps per day) and groups with mobile lifestyle (more than 6 thousand steps per day). In the groups with a mobile lifestyle, there was a decrease in fatigue scales (for RA: VAS and FACIT p<0.01; for SLE: VAS p=0.026, FACIT p=0.009), a decrease in psychological (for RA p<0.01; for SLE p<0.001) and physical components of TKS (for SLE p<0.001). At the end of the rehabilitation program, the number of patients with different levels of depression in SLE did not change (p>0.05), while in RA it decreased from 65.4% to 52%. Moreover, a negative correlation of medium strength was established between depression and vitamin D levels (r = -0.38) in patients with RA. It is possible that vitamin D may indirectly participate both in inflammatory processes and in central sensitization, which provokes chronic pain and psychological disorders. Patients with sedentary lifestyle did not show positive changes in depressive symptoms (p>0.05) and fatigue scores (for RA: VAS and FACIT p>0.05; for SLE: VAS p>0.05). In patients with SLE, low physical activity led to increased fatigue on FACIT (p=0.043) and increased level of kinesiophobia (p=0.025), while in RA patients a slight decrease in total TKS score (p=0.036) was mainly due to the psychological component.

Conclusions:

In patients with rheumatic diseases, kinesiophobia and severe fatigue are important barriers to physical activity. Motivating patients to overcome their irrational fear of active movement may help to increase endurance and reduce the risk of depression.

P1025

ASSOCIATIONS BETWEEN BODY COMPOSITION, EXERCISE, DIET, SHORT-CHAIN FATTY ACIDS, AND BONE LOSS IN EARLY POSTMENOPAUSAL WOMEN

M. Vilar Geraldi[1], G. Gregori[1], L. Johansson[2], U. Hjertonsson[1], E. Brättemark[1], M. Lorentzon[1]

[1]Sahlgrenska Osteoporosis Centre, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden., Mölndal, Sweden, [2]Department of Orthopaedics, Sahlgrenska University Hospital, Mölndal, Sweden, Mölndal, Sweden

Objective

The early postmenopausal period is characterized by a rapid loss in bone mineral density (BMD), which emphasizes the importance of lifestyle factors as important predictors and targets for preventive interventions. This study aimed to assess the relationship between bone characteristics and factors like nutrient intake, body composition, physical activity, and plasma SCFAs; and to identify which of these factors predict changes in bone characteristics over 2 years in early postmenopausal women.

Material and Methods

This cross-sectional and longitudinal study involved 223 early postmenopausal Swedish women aged 50 to 60 years who participated and completed the 2-year ELBOW II clinical trial. Appendicular lean mass (ALM), fat mass (FM), and BMD were measured using dual x-ray absorptiometry (DXA), and tibia total volumetric BMD (vBMD) and microstructure by high-resolution peripheral computed tomography (HR-pQCT). Additionally, dietary intake, physical activity levels, and plasma short-chain fatty acids (SCFAs) were evaluated.

Results

In multiple linear regression analyses, weight and body mass index (BMI) were significant predictors for all bone parameters. ALM and FM were associated with BMD, with the strength of these associations varying by bone site. Over the 2-year period, the relative change (Δ) in ALM had a stronger association with bone changes than ΔFM. Women in the lowest tertile of ΔALM (ΔALM: -3.5 kg) and baseline FM (FM: 16.5 kg) experienced approximately 2.7-fold and 4.4-fold significantly greater reductions in total hip BMD and tibia total vBMD, respectively, compared to those in the highest tertiles. No consistent associations were ob-

served for changes in neither macronutrient intake nor physical activity and the degree of bone loss. A positive relationship was found between Δisobutyric acid levels and bone loss, suggesting that gut microbiota metabolites may influence bone health.
Conclusion
Women with greater FM and maintaining/increasing ALM are linked to less development of skeletal fragility, typically seen in early postmenopausal women.

SERUM INFLAMMATORY MARKERS IN OSTEOPOROTIC FRACTURE PATIENTS: A SURVEY IN THE FRACTURE LIAISON SERVICE AT SHAFA YAHYAEIAN ORTHOPEDIC HOSPITAL, TEHRAN, IRAN

M. Zabihiyeganeh[1], A. Mirzaei[2], P. Heidari[3]

[1]Bone and Joint Reconstruction Research Center, Department of Orthopedics, School of Medicine, Iran University of Medical Sciences, Tehran, Iran., Tehran , Iran, [2]Department of Orthopedic Surgery, University of Minnesota Minneapolis, Minnesota, USA, Minnesota , United States, [3]Bone and joint reconstruction research center, Department of orthopedics, School of medicine, Iran University of Medical Sciences, Tehran, Iran, Tehran , Iran

Background: Fracture Liaison Service (FLS) is a healthcare model aimed at preventing re-fractures by diagnosing, investigating, and treating osteoporosis, as soon as possible, in patients with the history of previous osteoporotic fragility fracture. As per the literature, secondary causes of osteoporosis can affect two-thirds of older men, and 30% of postmenopausal women. Monoclonal gammopathy of uncertain significance, Multiple myeloma and chronic infectious diseases are important causes of secondary osteoporosis And patients can present with fragility fracture as a first presentation of underlying disease. Measurement of inflammatory markers, such as ESR (erythrocyte sedimentation rate) and CRP (C-reactive protein), has important role in assessing secondary osteoporosis. The measurement of inflammatory markers, while being easy to measure and affordable, can be helpful in guiding the team to screen for secondary osteoporosis.
Objective: To analyze ESR and CRP levels in patients with osteoporotic fractures and to assess their associations with patients' demographics and clinical characteristics.
Materials and Methods: In this retrospective cross-sectional study, 1979 patients who were enrolled in the FLS clinic of Shafa Yahyaeian Orthopedic Hospital between October 2020 and May 2023 were included. The main outcome was determining the percentage of patients with high ESR and CRP levels and investigating the relationship between these markers and the demographic/clinical variables. The data were analyzed using SPSS version 26 software.
Results: Out of 1979 patients, 32% had elevated ESR levels, and 40% had elevated CRP levels. Females, older patients, those with higher BMI (body mass index), and patients with lower BMD (bone mass density) in the femoral neck, hip, and radius had significantly higher ESR levels. Higher CRP levels were significantly associated with male sex, lower BMI, lower BMD in the radius, and lower serum vitamin D. Necessary investigations were done to rule out the causes of secondary osteoporosis, including malignancy and infection, in patients who had elevated ESR and CRP, and no cases of secondary osteoporosis were found.
Conclusion: Although about one third of our patients had high ESR or CRP, No case of secondary osteoporosis were identified, suggesting not to check inflammatory factors in the acute phase of fracture. The high level of inflammatory factors in the early phase of fracture may be attributed to physiological process of fracture healing.
Keywords: Fracture Liaison Service, inflammatory markers, secondary osteoporosis

HIGH INCIDENCE OF OSTEOPOROTIC FRACTURES IN ADULTS UNDER 65 WITHOUT INDICATIONS FOR BMD TESTING: A CALL TO REEVALUATE SCREENING GUIDELINES

M. Zabihiyeganeh[1], P. Heidari[1], A. Mirzaei[2], F. Farajimoghadam[3]

[1]Bone and joint reconstruction research center, Department of orthopedics, School of medicine, Iran University of Medical Sciences, Tehran, Iran, Tehran , Iran, [2]Department of Orthopedic Surgery, University of Minnesota Minneapolis, Minnesota, USA, Minnesota , United States, [3]Bone and Joint Reconstruction Research Center, Department of Orthopedics, School of Medicine, Iran University of Medical Sciences, Tehran, Iran., Tehran , Iran

Background: Despite the availability of effective interventions, a substantial number of osteoporosis patients remain underdiagnosed and undertreated, particularly those under 65 years of age. This study aimed to assess the incidence of osteoporotic fractures in patients under 65 years referred to a Fracture Liaison Service (FLS) clinic and to evaluate the applicability of current Bone Mineral Density (BMD) testing guidelines.
Methods: We conducted a retrospective review of the medical profiles of patients enrolled in the FLS clinic from April 2022 to March 2024. The primary outcome of the study was the incidence of osteoporotic fractures in individuals under 65 years of age and no BMD indication presented with a fragility fracture to the FLS clinic of our subspecialty orthopedic hospital. The secondary outcome of the study was the frequency of different BMD indications in this population.
Results: Among the 1,248 patients analyzed, 772 (61.9%) were under 65 years. Of these, only 27% had indications for BMD testing according to the International Society for Clinical Densitometry (ISCD) guidelines. Diseases or conditions associated with bone loss were the common BMD indication in this group (n=139, 18%). Diabetes was the most frequent underlying condition, justi-

fying the BMD testing (n=116, 15%).
Conclusions: A significant proportion of patients under 65 years with fragility fractures do not meet current BMD testing criteria, potentially leading to unrecognized osteoporosis and subsequent fractures. This underscores the urgent need to revise osteoporosis screening guidelines to better identify at-risk individuals, thereby reducing the burden of fragility fractures.

P1028

ADVANCEMENTS IN UNDERSTANDING AND MANAGING HYPOPHOSPHATASIA: FROM CLINICAL SPECTRUM AND DIAGNOSIS TO THERAPEUTIC STRATEGIES

M. Zabihiyeganeh[1], R. Shams[1]

[1]Iran University of medical sciences,bone and joint reconstruction center ,shafa orthopedic hospital, Tehran, Iran

Hypophosphatasia (HPP) is a rare, inherited metabolic disorder characterized by mutations affecting the gene responsible for producing the tissue-nonspecific isoenzyme of alkaline phosphatase (TNSALP). This condition spans a wide clinical spectrum, ranging from severe, life-threatening infantile forms to milder adult presentations that primarily affect dental health and bone integrity. Diagnosing HPP involves a combination of clinical observation, radiographic findings, laboratory testing, and genetic screening. Despite its clear clinical markers, the disease often remains unrecognized for extended periods, underscoring the importance of increased vigilance among dentists, orthopedic surgeons, and rheumatologists. The therapeutic landscape, particularly for severe cases in infants, children, and adults, has been significantly enhanced by treatments, such as Asfotase alfa, though questions remain about treatment duration. The past decade has brought forth significant advancements in understanding HPP's pathophysiology, including the pivotal role of persistently low serum alkaline phosphatase (AP) levels, offering new avenues for its management. HPP constitutes a rare genetic disorder with diverse clinical presentations. Characterized by six distinct forms categorized by age of onset and severity—perinatal, infantile, childhood (severe and mild), adult, and odonto—HPP manifests variably, presenting diagnostic challenges. The diagnosis, reliant on clinical, radiographic, and laboratory assessments, entails crucial laboratory criteria, including low serum ALP, elevated urinary PEA, and serum PLP levels. Confirming the diagnosis requires the identification of mutations in the TNAP gene. Genetic testing assumes a pivotal role in confirming HPP diagnoses, elucidating the underlying genetic mutations responsible for TNSALP dysfunction.
This serves a dual purpose: Substantiating the diagnosis and unraveling the intricate interplay between genetic variants and clinical presentations. The primary therapeutic avenue for severe HPP manifestations is Asfotase alfa (Strensiq), serving as a first-line treatment in infants, children, and select adults. Notably, antiresorptive treatments are strictly contraindicated in HPP, as they may exacerbate the underlying pathophysiology and elevate the risk of AFF. This holistic perspective underscores the multidimensional challenges and intricacies of HPP diagnosis and management, necessitating a comprehensive unde standing of its diverse clinical manifestations and therapeutic considerations.

P1030

HIDROXIVITAMIN D DEFICIENCY, OSTEOPENIA, AND LEAN MASS IN KNEE OSTEOARTHRITIS: WHAT IS THE INFLUENCE OF OBESITY IN INDIVIDUALS WITH PAINFUL SYMPTOMS? - A CROSS-SECTIONAL STUDY

N. A. Casonato[1], F. E. Sette[1], M. G. Da Silva[1], I. L. Nóbrega[1], R. F. Tizziotti[1], P. J. F. Venturini[1], G. B. Marques[1], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil

Objective: Obesity is one of the main risk factors for the development of knee osteoarthritis (KOA). Obese individuals may invariably have lower plasma concentrations of vitamin D. This factor may exacerbate painful symptoms resulting from joint overload and the progression of KOA, in addition to playing a fundamental role in metabolism and the properties of the musculoskeletal system. The present study aimed to analyze the association between the presence of obesity and vitamin D levels, painful symptoms, and body components in individuals with KOA.
Methods: Participants aged 40 or older with a clinical diagnosis of KOA were included. Blood samples were collected in the morning after a 12-hour fast for hydroxyvitamin D assessment by a specialized laboratory. Dual-energy absorptiometry (Hologic DXA) defined the presence of obesity and quantified lean and bone mass indices. Painful symptoms were assessed with an Algomed digital pressure algometer (Medoc, Israel) at a point on the medial joint line of the knee with the greatest pain. Analyses were conducted using R Studio with $p < 0.05$ considered significant.
Results: Fifty individuals were recruited: 44% obese and 70% female, with a mean age of 58.5 years. Hydroxyvitamin D levels averaged 27.8 ng/mL, considered insufficient. Bone mass was -0.9, approaching the limits of osteopenia, with lean mass values indicating 6.4 for females and 8.5 for men within the recommended values. Painful symptoms averaged 231,8 kPa reflecting decreased hyperalgesia. A multiple linear regression model revealed that sex ($p<0.01$), hydroxyvitamin D ($p<0.05$), bone mass ($p<0.05$), and lean mass ($p<0.01$) predicted 68% of the presence of obesity in patients with KOA.
Table 1. A linear regression model that explains the obesity association with sex, hydroxyvitamin D, body components and painful symptons

Predictors	ß	SE	t-value	P-value	R^2	R^2 adj
Intercept	6.539	3.426	1.91	0.063	0.709	0.675
Sex	-7.877	1.290	-6.10	<0.001*		
Hydroxyvitamin D	-0.128	0.053	-2.39	0.021*		
Bone mass	-1.270	0.415	-3.06	0.003*		
Lean mass	4.095	0.431	9.49	<0.001*		
Painful symptons	-0.002	0.003	-0.70	0.485		

Dependent variable: Obesity
Independent variables: Sex, hydroxyvitamin D, body components, painful symptons
Abbreviations: SE = Non-standard beta standard error.
Conclusion: Body components, hydroxyvitamin D deficiency, and sex correlate with obesity in patients with KOA, with no significant association with pain symptoms. These findings highlight the need to explore metabolic alterations caused by excess adiposity in the treatment of KOA.

P1031

KNEE OSTEOARTHRITIS AND USE OF MULTIPLE MEDICATIONS: WHAT IS THE INFLUENCE OF THE PRESENCE OF DRUG-DRUG INTERACTION ON THE PRESSURE PAIN THRESHOLD OF THESE INDIVIDUALS?

N. A. Casonato[1], F. E. Sette[1], M. G. Da Silva[1], P. J. F. Venturini[1], J. B. Aily[1], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil

Objective: Pain in knee osteoarthritis (KOA) is associated with symptom severity, and pain drugs are the main treatment. Patients with KOA, especially women, report having multiple comorbidities, which increase their use of other drugs. The presence of drug-drug interactions (DDIs) in this population deserves further investigation. This study examines the association between DDIs and local pressure pain threshold (PPT) in patients with KOA.
Methods: Sixty-four patients (32 women and 32 men) with KOA and aged over 40 years were evaluated. PPT was assessed at the most symptomatic knee (local site). The Drugs.com® database was used to assess the presence or absence of DDIs among drugs used for KOA pain and other comorbidities. The Statistical Package for Social Sciences software was used for all statistical analyzes and the significance level was set at 5%.
Results: Participants' mean age was 58.9 ± 9.3 years. Self-reported comorbidities included systemic arterial hypertension (45.6%) and type 2 diabetes mellitus (24.1%). Drugs.com® identified 15 major (8.2%), 85 moderate (81.7%), and 4 minor (3.8%) DDIs. Women with DDIs had a PPT of 2.3 ± 0.9 kgf/cm² vs. 2.8 ± 0.7 kgf/cm² without DDIs. Men with DDIs had 3.8 ± 1.4 kgf/cm² vs. 4.8 ± 1.5 kgf/cm² without DDIs. Multiple linear regression showed DDIs ($p = 0.008$) and sex ($p < 0.001$) predict 36% of local PPT variability (Tab. 1).
Table 1. A linear regression model that explains the association of Local PPT results with sex, DDIs, and comorbidities

	ß	S.E	*t* value	*p-value*	R^2	R^2 adj
					0.390	0.360
Intercept	4.8089	0.3055	15.74	0.000		
Sex	-1.7567	0.3099	-5.67	<0.001*		
DDI	-0.6580	0.3799	-1.73	0.008*		
Comorbidities	0.2070	0.3932	-0.53	0.600		

Dependent variable: Local PPT
Independent variables: Sex, DDIs, and comorbidities

Conclusion: The presence of DDIs in women may predict worse outcomes of local PPT. These results highlight the relevance of treating comorbidities in women, to achieve better results in the management of pain symptoms in patients with KOA.

P1032

INITIATION OF ANTI-OSTEOPOROSIS MEDICATION, CALCIUM AND VITAMIN D SUPPLEMENTATION AMONG PATIENTS REFERRED TO THE FRACTURE LIAISON SERVICE (FLS)

N. A. Shohor[1], N. S. Francis[1], J. F. Leong[1], S. A. Mokhtar[1], M. K. Yin[2]

[1]Fracture Liaison Service, Orthopedic and Traumatology Department, Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia, [2]Pharmacological Department, Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

INTRODUCTION:
Osteoporosis, characterized by excessive bone loss, poses significant public health challenges for elderly individuals, both men and women. The most alarming complication is that it significantly increases the risk of fractures due to fragile bones. Pharmacological treatment, including antiosteoporosis medications as well as calcium and vitamin D supplementations, is vital in treating fragility fractures.
MATERIALS AND METHODS:
This prospective study conducted from 1st January to 1st July 2024, focusing on elderly patients aged 55 years and above who presented with fragility fractures at our hospital. Identification of these patients was conducted by our Fracture Liaison Service (FLS) Coordinators, excluding those with severe trauma, malignancy, or steroid-induced fractures. Comprehensive demographic data, medication prescriptions, and surgical information were meticulously recorded. Patients were initiated on osteoporosis-related treatment. Prescription and usage of anti-osteoporosis medication, calcium and vitamin D supplementation was observed among patients that were enrolled.
RESULTS AND DISCUSSION:
A total of 87 patients were identified and consulted by the FLS. More than half of the referred patients were Chinese (56.3%, n= 49), followed by Malay (33.3%, n=29) and Indians (10.3%, n=9). Remarkably, 100% of these patients received both calcium carbonate (CaCO3) and vitamin D supplementations. These vitamin

D supplements were inclusive of calcitriol (60.9%, n=53), alfacalcidol (28.7%, n=25), cholecalciferol (6.9%, n=6) and Vitamin D3 (3.4%, n=3) either upon discharge or during follow-up. Among the patients with fragility fractures, 72 (82.8%) patients agreed to initiate anti-osteoporosis medications. Subsequently, the majority opted for anti-resorptive treatment (65.5%) over anabolic therapy (17.2%).

Based on these results, we observed an increase in the percentage of patients opting for anabolic compared to our previous study. This may be due to the education given to the patient and family members to increase knowledge on the pharmacological actions between anabolic and antiresorptive for post-fracture care and minimize the risk for subsequent fractures.

Next, as an FLS center, we administered CaCO3 because it holds the highest percentage of elemental calcium in the body. For Vitamin D, our center offers a variety of choices, thus empowering patients in the treatment options, as some of the medications are not funded by the federal government. The dedication of FLS has resulted in a marked improvement of anti-osteoporosis medication, CaCO3 and Vitamin D supplementation compared to when our center was first established.

CONCLUSION:

The integration of FLS and the collaborative efforts among a multidisciplinary team have significantly improved the management of osteoporosis in our hospital.

P1033

DEMOGRAPHIC AND FRACTURE TYPES ANALYSIS OF FRAGILITY FRACTURE PATIENTS REFERRED TO FRACTURE LIAISON SERVICE (FLS) AT A LEADING MALAYSIAN UNIVERSITY HOSPITAL

N. A. Shohor[1], N. S. Francis[1], J. F. Leong[1], S. A. Mokhtar[1]

[1]Fracture Liaison Service, Orthopedic and Traumatology Department, Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

INTRODUCTION:

Fragility fractures also known as osteoporotic fractures are a significant concern in elderly populations, necessitating a systematic approach to patient assessment and fracture risk management. Gender and racial distribution play a pivotal role in understanding the demographics of patients presenting with such fractures. Furthermore, identifying the types of fractures is crucial for tailoring prevention and management strategies.

MATERIALS AND METHODS:

This study using prospective analysis includes data collected from 150 patients referred to the Fracture Liaison Service (FLS) between January 2024 and November 2024, with two reported deaths. This study focusing on elderly patients aged 55 years and above who presented with fragility fractures at our hospital. Identification of these patients was conducted by our Fracture FLS Coordinators, excluding those with severe trauma, malignancy, or steroid-induced fractures. Patient demographics were categorized by gender and race, while fracture types were analyzed to determine the most prevalent patterns.

RESULTS AND DISCUSSION:

Among 150 patients referred to FLS, 76% (n=114) were female, and 24% (n=36) were male, consistent with the higher prevalence of osteoporosis in women. Racial distribution revealed that 54% (n=81) of patients were Chinese, followed by Malays at 37% (n=56), Indians at 7% (n=11), and other ethnicities at 2% (n=2). Analysis of fracture types demonstrated that hip fractures were the most common, accounting for 69% (n=104) of cases, followed by lower limb fractures at 8% (n=13), and spine fractures at 5.5% (n=8) as well as wrist fractures with similar value. Combination fractures and other minor fracture types collectively represented the remaining 12%.

The predominance of hip fractures underscores the need for early intervention strategies, as these are often associated with significant morbidity and mortality in elderly populations. Tailored prevention programs addressing racial and gender disparities could improve overall outcomes.

CONCLUSION:

The findings highlight the importance of demographic and fracture type data in managing fragility fractures. A targeted approach combining early detection tools like dual-energy x-ray absorption (DEXA) scans and complementary assessments such as the Fracture Risk Assessment Tool (FRAX) score is critical for optimizing care in high-risk groups. The predominance of hip fractures necessitates urgent action to prevent future occurrences, particularly among women and specific racial groups.

P1034

EVALUATION OF THE DIAGNOSIS ACCURACY OF THE ASIAN WORKING GROUP FOR SARCOPENIA 2019 CRITERIA FOR 'POSSIBLE SARCOPENIA IN THAI COMMUNITY-DWELLING OLDER ADULTS

A. Unnanuntana[1], N. Adulkasem[1], A. Asavamongkolkul[1], P. Chotiyarnwong[1], E. Vanitcharoenkul[1]

[1]Department of Orthopaedic Surgery, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Introduction

The term "possible sarcopenia" was introduced in the 2019 Asian Working Group for Sarcopenia (AWGS) guidelines to identify individuals at high risk for sarcopenia in primary care settings. However, limited studies have evaluated the accuracy of this definition. This study aims to validate the "possible sarcopenia" criteria in Thai community-dwelling older adults and explore methods to enhance its effectiveness.

Methods

This study is a secondary analysis of an epidemiological investigation on the prevalence of sarcopenia among Thai older adults conducted from 2021 to 2022. We assessed the performance of the "possible sarcopenia" criteria against sarcopenia diagnoses based on the 2019 AWGS guidelines. To improve performance, we incorporated demographic parameters such as age, sex, height, weight, and body mass index (BMI), comparing their area under the curve (AUC). The parameter with the highest AUC was

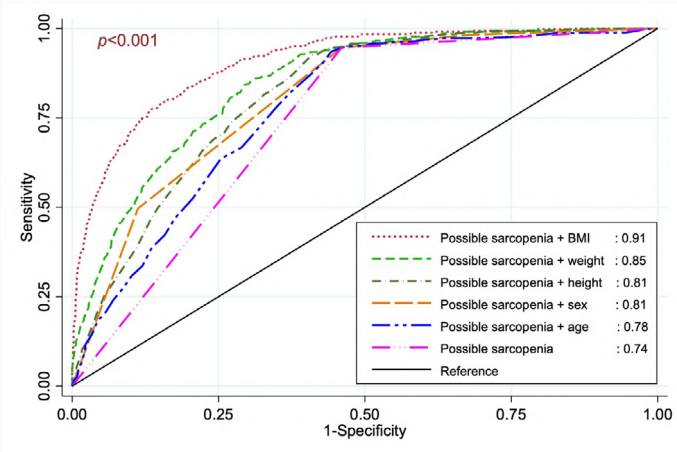
selected for modification of the criteria, and a cut-off value was established to maintain sensitivity above 80% while maximizing specificity.

Results

A total of 2,456 participants were included, with a mean age of 69.0 ± 6.1 years. Of these, 445 (18.1%) were diagnosed with sarcopenia. The "possible sarcopenia" criteria showed a sensitivity of 94.6%, a specificity of 54.0%, and an AUC of 74%. Incorporating BMI improved the AUC by 17%. A BMI below 24 kg/m² may serve as an additional criterion, enhancing specificity to 72.7% while maintaining sensitivity at 89.9%.

Conclusions

The AWGS 2019 "possible sarcopenia" criteria exhibited excellent sensitivity but lacked specificity, resulting in a high false-positive rate. The modified criteria incorporating BMI effectively reduce false positives while preserving high sensitivity, making them more suitable for sarcopenia screening in primary care.



P1035

VITAMIN D METABOLITE RATIO AS A MARKER OF NUTRITIONAL BONE HEALTH IN ADOLESCENTS

N. Al-Daghri[1], S. Sabico[1], E. Cavalier[2], B. Dawson-Hughes[3], Y. Al-Saleh[4], M. N. K. Khattak[1], K. Wani[1], A. Alnaami[1], M. Alokail[1], J. Y. Reginster[1]

[1]King Saud University, Riyadh, Saudi Arabia, [2]University of Liege, Liege, Belgium, [3]Tufts University, Massachusetts, United States, [4]Health Oasis, Riyadh, Saudi Arabia

Background: The vitamin D metabolite ratio (VMR) has recently gained attention as a promising marker of functional vitamin D status in adults and, to some extent, for evaluating bone health in the elderly. However, there is scarcity of evidence as to whether these findings may also apply to younger populations. This study aims to fill this gap.

Methods: The osteomalacia database of the Chair for Biomarkers of Chronic Diseases in King Saud University, Riyadh, Saudi Arabia (SA), is a registry containing clinical information of almost 3000 apparently healthy 12-17-year-old Saudi students from different schools in Riyadh, SA. A total of n=949 age- and body mass index (BMI) matched adolescents (n=513 girls, mean age=14.9 ± 1.8 years, mean BMI=23.0 ± 5.9; n=436 boys mean age=14.9 ± 1.7 years, mean BMI=23.7 ± 5.8) were included in this cross-sectional study. Anthropometric, biochemical [25(OH)D (VD), calcium (Ca), phosphorus, alkaline phosphatase, parathyroid hormone (PTH, n=64), fasting glucose and lipid profile] and dietary Ca data were retrieved from the database. Circulating VD metabolites [24, 25 VD; VD2; VD3; total VD] were assessed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). VMR was calculated as [24,25(OH)D/25(OH)D] × 100. VD deficiency cut-offs were defined at 25(OH)D <50nmol/L, 24,25(OH)VD <3.0nmo/L, VD2 limit of quantification (LOQ) <1.8 and VMR <4% based on proposed cut-offs

Results: Over-all prevalence of VD deficiency was 86.5% and levels of VD metabolites were extremely low for all participants [Low 24, 25(OH)VD at 93.2%; VD2 LOQ<1.8 at 99.7%; Low VMR at 74.9%]. A subset analysis of 64 samples with PTH values revealed significant inverse associations with serum Ca (r=-0.34; p<0.01) and 25(OH)D (r=-0.28; p<0.05). In all VD metabolites, only VMR was significantly associated with serum Ca (r=0.07; p<0.05). With the exception of VD2, all VD metabolites, including VMR, were significantly associated with dietary Ca intake in girls, not boys.

Conclusion: VD metabolites, including VDR, are extremely low in a large subset of Saudi adolescents. VMR's modest but significant associations with serum and dietary Ca in girls suggest that it may be a sexually-dimorphic nutritional marker of bone health in adolescents rather than a marker of functional VD deficiency.

P1036

TEN-YEAR ATHEROSCLEROTIC CARDIOVASCULAR DISEASE RISK SCORE IN POST-MENOPAUSAL WOMEN WITH LOW BONE MINERAL DENSITY

K. Wani[1], S. Sabico[1], N. Veronese[2], A. Al-Masri[1], N. Al-Daghri[1]

[1]King Saud University, Riyadh, Saudi Arabia, [2]Saint Camillus International University of Health Sciences, Rome, Italy

Background: Reports on the association between cardiovascular disease (CVD) risk and bone mineral density (BMD) remain inconsistent and hence more population-based studies on this subject are needed. **Aims:** This study aimed to evaluate the association between bone mineral density (BMD) at the lumbar spine (L1-L4) and femoral neck (right and left) with 10-year atherosclerotic cardiovascular disease (ASCVD) risk scores in Saudi postmenopausal women. **Methods:** A cohort of 1,450 postmenopausal women with risk of bone loss were analyzed using the data from the Chair for Biomarkers of Chronic Diseases (CBCD) Osteoporosis database. BMD at the lumbar spine and femoral neck was assessed via dual-energy X-ray absorptiometry (DXA). Anthropometric and biochemical parameters, including fasting glucose and lipid profiles, were measured. ASCVD risk scores were calculated using the ASCVD Risk Estimator Plus tool. BMD tertiles were examined for their association with ASCVD risk. **Results**: Women with osteoporosis exhibited significantly lower body mass index, waist

and hip circumferences, and metabolic dysfunction markers compared to those with normal BMD. Significant inverse correlations were observed between ASCVD risk scores and BMD at the femoral neck sites in women with osteopenia and osteoporosis. Multivariate logistic regression indicated that women in the lowest BMD tertiles had higher odds of intermediate-to-high ASCVD risk scores, with adjusted odds ratios of 1.90 for the lumbar spine, 2.19 for the right femoral neck, and 2.04 for the left femoral neck. **Conclusions:** The study identified significant associations between lower BMD at the lumbar spine and femoral neck sites and elevated 10-year ASCVD risk scores in postmenopausal women, particularly among those with osteopenia and osteoporosis. These findings demonstrate the importance of assessing cardiovascular risk in women with low BMD to enable early prevention and management strategies.

P1037

EFFECTS OF FIRST-LINE ORAL HYPOGLYCEMICS IN BONE MARKERS OF TREATMENT NAÏVE SAUDI ADULTS: BASELINE CHARACTERISTICS

M. Almosfer[1], S. Sabico[1], N. Veronese[2], N. Al-Daghri[1]

[1]King Saud University, Riyadh, Saudi Arabia, [2]Saint Camillus International University of Health Sciences, Rome, Italy

Background: It has been established that people with type 2 diabetes (T2D) are at higher risk of fracture as compared to the general population. Given the complex interplay of T2D on bone metabolism, findings on the effects of various T2D drugs on bone health and its markers remain inconsistent. This on-going randomized clinical trial (RCT) aims to present the baseline characteristics of participants after randomization and associations of baseline bone markers with measured parameters.
Methods: A total of 63 (55 males and 12 females) newly diagnosed T2D adults were randomized equally (1:1:1) to receive either metformin 1000mg alone (n=21), metformin 1000mg + lifestyle (n=21) and lifestyle alone (n=21) for 6 months. Anthropometrics, lipids, liver, glycemic and renal profiles were assessed routinely. Circulating sclerostin and osteocalcin were measured using commercially available assays. All measurements will be repeated every 3 months. Here we present the baseline data for the 3 treatment groups:
Results: Baseline characteristics showed no significant differences in anthropometrics, lipids, liver, glycemic and liver profiles, including sclerostin and osteocalcin across treatment groups (p-values >0.05). In all subjects, sclerostin was significantly associated with age (r=0.56; p<0.01), creatinine (r=0.46; p<0.01) and urea (r=0.60; p<0.01). On the other hand, osteocalcin was inversely associated with fasting glucose (r=-0.27; p<0.05) and HbA1c (r= -0.40; p<0.05).
Conclusion: The on-going RCT was able to successfully randomize a group of naïve T2D on different first line treatment regimens. The significant associations of sclerostin to markers of renal function and osteocalcin on glycemic profile highlight the extra-skeletal role of these bone markers in human metabolism. The present study will study the effects of first-line T2D treatment in these markers and concomitant changes in the baseline parameters assessed.

P1038

DO MYOKINES INFLUENCE THE ASSOCIATIONS BETWEEN SARCOPENIA-RELATED PARAMETERS AND COGNITIVE FUNCTION IN COMMUNITY-DWELLING OLDER ADULTS?: EXPLORATORY RESULTS FROM THE ENHANCE STUDY

N. Amini[1], L. Lapauw[1], L. Vercauteren[1], J. Dupont[1], S. Dalle[2], K. Koppo[2], S. Verschueren[3], J. Tournoy[1], E. Gielen[1]

[1]Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium, [2]Department of Movement Sciences, KU Leuven, Leuven, Belgium, [3]Department of Rehabilitation Sciences, KU Leuven, Leuven, Belgium

Objectives: This study aimed to explore the association between sarcopenia-related parameters and both global and specific cognitive domains, and whether myokines influenced this association.
Methods: An exploratory, cross-sectional analysis of data from the Exercise and Nutrition for Healthy AgeiNg (ENHANce) study, a 5-armed triple blinded RCT in older adults (≥65 years) with sarcopenia (EWGSOP2-criteria) was performed. Cognitive functioning was assessed by Mini-Mental State Examination (MMSE), Repeatable Battery for the Assessment of Neuropsychological Status (RBANS), Trail Making Test A&B (TMT), Stroop and Maze Test. Muscle mass and function were evaluated by measuring Hand-Grip Strength, Chair Stand Test, appendicular Lean Mass (aLM), Gait Speed (GS) and Short Physical Performance Battery (SPPB). Serum myokines (IGF-1, irisin, myostatin, BDNF) were determined through Enzyme Linked Immunosorbent Assay. Multivariable regression analyses were performed to explore the associations between sarcopenia-related parameters and cognitive functioning, with adjustment for confounders age, sex, body mass index, nutritional status, physical activity and the myokines.
Results : Fifty-eight participants were included in this analysis (76.2±6.7years,♀:65.5%). After adjustment for age, sex, body mass index, physical activity and nutritional status, aLM was significantly associated with MMSE (β=0.207,p=0.040), RBANS Total (β=0.206,p=0.011) and RBANS Attention (β=0.200,p=0.007), SPPB was significantly associated with Maze time (β=-0.306,p=0.024) and GS was significantly associated with TMT A (β=-0.240, p=0.009). After further adjustment for BDNF, the association between aLM and MMSE became non-significant. Adjustment for irisin, myostatin and IGF-1 did not influence the significance of the associations.
Conclusion: This study showed that several sarcopenia-related parameters, such as muscle mass and physical performance, are associated with both global and specific cognitive domains. Furthermore, BDNF may, at least partially, explain the association between muscle mass and MMSE. Additional research with larger sample size is needed to replicate these novel findings.

P1039

EFFECTS OF A HOME-BASED EXERCISE PROGRAM, PROTEINS AND OMEGA-3 SUPPLEMENTATION ON MUSCLE STRENGTH, MUSCLE MASS, PHYSICAL PERFORMANCE AND COGNITIVE FUNCTION IN OLDER ADULTS WITH SARCOPENIA: EXPLORATORY RESULTS FROM A 5-ARMED RCT

N. Amini[1], J. Dupont[1], L. Lapauw[1], L. Vercauteren[1], S. Verschueren[2], J. Tournoy[1], E. Gielen[1]

[1]Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium, [2]Department of Rehabilitation Sciences, KU Leuven, Leuven, Belgium

Objectives:
This 5-armed RCT explores the (combined) effects of an exercise program, protein-and omega-3 supplementation on muscle strength, muscle mass, physical performance and cognitive function in older adults with sarcopenia.
Material & Methods:
Preliminary analysis of the ENHANce RCT data was performed. Participants were randomized into 5 groups: 1) Exercise, 2) Protein, 3) Exercise + Protein, 4) Exercise + Protein + Omega-3, 5) Control group. The primary outcome was the Short Physical Performance Battery (SPPB) score across the 5 groups, at baseline, 12 weeks (W12), and 24 weeks (W24). Secondary outcomes were appendicular lean mass, skeletal muscle index (SMI), handgrip strength, chair stand test, gait speed, and cognitive performance (Repeatable Battery for the Assessment of Neuropsychological Status (RBANS), Trail Making Test A&B, Stroop test, Maze test). Data analysis was performed using linear mixed models according to the intention-to-treat approach.
Results:
Among 58 participants (Ex, n=9; Prot, n=12; Ex+Prot, n=13; Ex+Prot+Omega-3; n=12; Control, n=12), the mean age was 76.19y (±6.59) & 65.52% were female. Ex+Prot group showed a significant SPPB score increase at W12 (1.13 point, 95%CI: 0.07;2.19), but was not significantly different from the Ex group (0.61 point, 95%CI: -0.63;1.86). Time-averaged group difference in SPPB (W12&W24) was not significant (Δ: 0.33, 95%CI -1.09;1.74). Ex+Prot+Omega-3 significantly improved SMI (2% increase, 95%CI: 1.00;1.04) vs. Ex+Prot (1% decrease, 95%CI: 0.98;1.01) after W12. Ex or Prot did not significantly improve sarcopenia outcomes vs. control at any time point. The Ex group showed significant improvements in RBANS Total and Immediate memory vs control group, and the time-averaged group difference was significant (Total; Δ:7.06 point, 95%CI: 1.89;12.23 & Immediate memory; Δ:10.33, 0.73;19.94). Mixed results on cognitive outcomes were found for the other groups.
Conclusion:
The combination of exercise and protein supplementation showed significant improvements in SPPB, but this was not significantly different from exercise only. Omega-3 on top of exercise and protein supplementation may have an additive effect on muscle mass. Results of the interventions on cognitive outcomes were mixed. Further research in a larger sample size is needed to confirm our findings.

P1040

THE FIRST-EVER MALTESE STUDY ON THE EPIDEMIOLOGY AND OUTCOMES OF FRAGILITY FRACTURES

N. Aquilina[1], C. Vassallo[1], Z. Attard[1], M. Galea Sillato[1], A. Borg[1]

[1]Rheumatology Unit, Ministry for Health, Malta, Msida, Malta

Objective
The aim of this study was to identify trends in prevention and management of osteoporotic fractures, including adherence to established screening recommendations, as this had never been studied locally.
Material and Methods
Data was handled through GDPR regulations. All fractures of the hip, vertebrae, humerus, radius, ulna and pelvis, occuring in individuals over the age of 18, between March and May 2024, were identified using imaging archiving software. These were then filtered for fragility based on electronic case record (ECR) documentation. Epidemiologic data were collected for the cohort, as well as whether eligible patients had been screened by means of a dual energy X-Ray absorptiometry (DEXA) scan prior to their fracture or not. A 6-month follow-up period was assigned to the patient cohort, and at the end of this study period their ECRs were reviewed once more to retrieve the osteoporosis management outcomes.
Results
A total of 543 fragility fractures were eligible for analysis. The majority of patients were female (n=406). Male patients had a younger mean age at time of fracture compared to females (69.9 vs 75.1). 441 patients met international screening recommendations, yet only 36.3% of patients had a DEXA scan pre-fracture (n=160). These were predominantly females, with only 4 of the 86 eligible males having had a DEXA scan. 62 of the 160 screened patients had osteoporotic DEXA results, yet only 24.2% (n=15) were managed with calcium and vitamin D and/or antiresorptives and/or anabolic agents. After the fracture, 4% had a DEXA requested (n=23), 12.9% had calcium and vitamin D prescribed (n=70), and 4.6% had an antiresorptive or anabolic agent prescribed (n=25). A lacuna was also identified in patients on glucocorticoids, as only 48% (n=12) had been screened with a DEXA scan prior to their fracture.
Conclusion
This study demonstrates poor use of screening tools and suboptimal management of osteoporotic fractures. The results of this study raised concern and brought about a number of changes in clinical practice, namely the establishment of a dedicated fracture liaison service, as well as education of other specialties about the management of osteoporosis.

P1041

DO RHEUMATOLOGISTS MANAGE GLUCOCORTICOID-INDUCED OSTEOPOROSIS BETTER THAN NON-RHEUMATOLOGISTS?

N. Aquilina[1], C. Vassallo[1], Z. Attard[1], M. Galea Sillato[1], A. Borg[1]

[1]Rheumatology Unit, Ministry for Health, Malta, Msida, Malta

Objective
Glucocorticoid-induced osteoporosis (GIOP) is a diagnosis which unites specialties. The aim of this audit was to compare screening and management strategies between various specialties where long-term oral glucocorticoids are prescribed.
Material and Methods
Data was handled through GDPR regulations. Patients over the age of 18 on longterm oral corticosteroids were defined as having had at least 3 months of a steroid dose equivalent to 5 mg daily of prednisolone or more. Rheumatology, Respiratory Medicine, Neurology and Gastroenterology physicians were then asked to identify patients meeting this definition, over the span of 3 months. Data was derived from 24 teams (6 per specialty) so as to eliminate bias. Electronic case records were then analysed, looking for any screening tests, as well as osteoporosis management strategies. Patients on steroid inhalers were excluded.
Results
The majority of long-term steroid patients belonged to Rheumatology (n=25), followed by Respiratory Medicine (n=12), Neurology (n=9) and Gastroenterology (n=6). With regards to screening, 100% of rheumatology patients underwent a dual energy X-Ray absorptiometry (DEXA) test within 1 year of starting treatment. On the other hand, respiratory medicine (50%), neurology (22.2%) and gastroenterology (16.7%) showed subpar screening rates. In terms of calcium and vitamin D prophylaxis, 100% of rheumatology patients received this, as opposed to 16.7% of respiratory patients, 11.1% of neurology patients, and 0% of gastroenterology patients.
In the screened patients who were diagnosed with GIOP, shortcomings were also identified. 83.3% of osteoporotic rheumatology patients received antiresorptives or anabolic agents (n=15 out of 18), while only 1 patient from respiratory medicine and 1 patient from neurology received such treatment. The single gastroentrology patient was also not managed using such pharmacotherapy. During the study period, 12 patients sustained an osteoporotic fracture (rheumatology = 7, respiratory = 3, neurology = 2, gastroenterology = 0). 100% of rheumatology patients who sustained an osteoporotic fracture were managed with antiresorptives, as opposed to 0% of respiratory and neurology patients.
Conclusion
In Malta, Rheumatologists excel when compared to non-Rheumatologists in the management of GIOP. This audit highlights the need for further liaison and communication between specialties, and the adoption of a multidisciplinary bone health initiative.

P1042

DAIRY INTAKE PATTERNS IN 50 YEARS AND OLDER IRANIAN POPULATION: INSIGHTS FROM A NATIONWIDE SURVEY

S. Sarrafzadeh[1], N. Behgam[1], O. Tabatabaei-Malazi[2]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Background: Consuming dairy products plays a crucial role in bone health among individuals. Considering the significance of dairy consumption for those aged 50 and older, this study seeks to evaluate the dairy intake habits of individuals 50 years old and above within the Iranian population.
Methods: Analysis was conducted using data from the 2021 WHO STEPwise approach to NCD risk factor surveillance (STEPS) survey, focusing on participants aged 50 and older (n=10883). Dairy consumption was categorized into three groups: less than once a day, one to two times a day, and more than three times a day. The study examined differences in these dietary habits in relation to gender, residence, and educational level. The Mann-Whitney U test and Jonckheere–Terpstra test for trend were utilized. STATA (v17) was applied for analysis.
Results: Overall, the result shows that dairy consumption is low among our target population. Approximately 60.9% of participants consumed dairy less than once a day, while 36.2% consumed 1-2 times a day, and only 2.9% reported consuming dairy three times a day or more. Gender did not significantly influence dairy consumption patterns (P-value = 0.683). Rural residents had a significantly higher dairy intake. The proportion of consuming three times and more was 4.6% and 2.4% in rural and urban areas, respectively (P-value < 0.001). Participants with lower education levels showed slightly higher dairy consumption; 3.2%, 2.8%, and 2.3% of people with 'less than 7 years', '7 to 12 years' and '12 years and more' of education, respectively, consume dairy three times or more (P-value < 0.001). This may due to the fact that less educated people live more in rural areas more and people in rural area tend to consume more dairy.
Conclusions: As the population of Iran continues ages, the prevalence of geriatric diseases, particularly osteoporosis, has become increasingly significant. Our findings highlight the necessity of paying special attention to dairy consumption, as it plays a critical role in bone health. Therefore, it is essential to implement policies to increase dairy intake among the elderly population.
Keywords: dairy intake, nutrition, bone, osteoporosis, old people

P1043

ABALOPARATIDE RAPIDLY IMPROVES BONE MINERAL DENSITY SUGGESTING PROMISE FOR PREOPERATIVE BONE HEALTH OPTIMIZATION

N. Vanderwerker[1], P. Anderson[1], S. Mosiman[1], D. Krueger[1], N. Binkley[1], J. Bernatz[1]

[1]University of Wisconsin Madison School of Medicine and Public Health, Madison, United States

Objective(s)
To evaluate the efficacy of subcutaneous abaloparatide (ABL) on markers of bone remodeling and bone mineral density (BMD) at 3, 6, and 12 months in men and women with osteoporosis.
Material and Methods
Lumbar spine, total hip and femoral neck BMD and bone turnover biomarker (CTX and P1NP) data from two randomized controlled trials assessing efficacy of 80 µg subcutaneous ABL on bone formation, at timepoints noted above, were utilized (n= 399). Mixed models were used to model mean percent change in BMD and the median percent change in turnover markers from baseline.
Results

Table 1: Percent Change from Baseline by Timepoint

Month	Men	Women
Femoral Neck BMD		
3	1.8	1.5
6	1.9	2.6
12	3.4	3.6
Hip BMD		
3	1.3	1.8
6*	1.7	2.8
12*	2.4	3.9
Spine BMD		
3	4.2	4.4
6*	6.7	7.9
12	9.5	10.7
CTX		
1	-2.8	2.7
3	28.3	24.6
6	49.0	36.8
12	35.0	24.2
P1NP		
1	130.7	133.7
3	93.3	102.4
6	109.7	114.5
12	80.9	68.1

BMD: Bone Mineral Density; CTX: C-terminal Peptide; P1NP: Procollagen Type I N-Propeptide

*Significant difference between men and women at p≤0.01

Conclusion(s)
ABL increased BMD at all measured sites at 3, 6, and 12 months in both men and women. Bone turnover marker data were concordant with the BMD data. Previous research demonstrated that total hip BMD increases as little as 1.42% at 24 months results in significant risk reduction of all clinical fractures.[1] In this analysis, ABL treatment met or exceeded this threshold at all timepoints in women and at 6 and 12 months in men. This rapid response may reduce or eliminate surgical delay while still providing improved bone status. Thus, ABL shows promise for use in bone health optimization prior to elective orthopedic surgery in patients with osteoporosis.

ABALOPARATIDE INCREASES DISTAL FEMUR BMD POST TOTAL KNEE ARTHROPLASTY

N. Binkley[1], D. Krueger[1], G. Borchardt[1], B. Nickel[1], P. A. Anderson[1]

[1]University of Wisconsin School of Medicine and Public Health, Madison, United States

Objectives: Osteoporosis is common in total joint replacement patients and increases risk for adverse outcomes. Existing data indicate that total knee arthroplasty (TKA) leads to rapid distal femur bone loss. We hypothesized that abaloparatide (ABL) would mitigate this loss. The study's purpose was to evaluate the effect of ABL begun prior to TKA on distal femur BMD.
Materials and Methods: Female and male TKA candidates age ≥ 55 yrs were enrolled in this open-label 18-mo study. Those with clinical osteoporosis, defined as T-score ≤ -2.5 or < -1.0 if prior low-trauma fracture, received daily ABL. Subjects with osteopenia, but without fracture, comprised an untreated control (CON) group. BMD was measured by DXA at the L-spine, total hip, radius and 2 distal femur regions of interest (ROIs) placed at 15% and 25% of femur length at screening (~3 mo pre-TKA), 1-week pre-TKA, 6-mo and 15-mo post-TKA. Groups were compared at baseline by t-test. For this completers analysis (n = 21 ABL/27 CON) BMD change at all measured sites was assessed by ANOVA.
Results: At baseline (n = 58; 29 ABL/29 CON) sex, mean (SD) age and BMI did not differ between ABL and CON groups; 3 vs. 6 male, 70.5 (7.2) vs. 68.6 (7.1) years and 31.3 (6.1) vs. 31.0 (4.7) kg/m^2 respectively. ABL group baseline BMD was lower ($p \leq 0.05$) at all sites except the L-spine. ABL was dosed for 96 (60) days prior to TKA. In the CON group, BMD declined ~1-2.5% ($p < 0.05$) at the 15% and 25% ROI by 15-mo post TKA.
Distal femur BMD increased at the 15% and 25% sites in ABL group from baseline and differed from CON ($p < 0.05$) at pre-surg, 6 and 15 mo post-surg (Table). L-spine and total hip BMD also increased by 6-mo in the ABL group (Table). BMD percent change at 15% and 25% distal femur ROIs was ~double in the surgical

compared to non-surgical leg, (up to 4%; p > 0.05), but did not differ at the total hip.

Conclusion: In osteoporotic TKA recipients, ABL increased BMD at the distal femur, L- spine and total hip compared with osteopenic controls. Abaloparatide improves BMD in osteoporotic patients undergoing TKA. The decrease in distal femur BMD after TKA among controls was less than previously reported, thus, further study to clarify the effect of TKA on distal femur BMD is needed.

BMD % Difference from Baseline Between ABL and CON Groups

CHANGES IN BODY COMPOSITION ASSESSED WITH BIOELECTRICAL IMPEDANCE IN TRANSGENDER PATIENTS AFTER 12 MONTHS OF AFFIRMATIVE HORMONE THERAPY IN A HEALTH INSTITUTION IN COLOMBIA

N. C. Camargo[1], M. A. R. Rueda[1], A. S. Sierra[1], D. A. Andrade[1], L. F. Forero[1]

[1]FUNDACION UNIVERSITARIA DE CIENCIAS DE SALUD, BOGOTA, Colombia

Objetivo: Describir los cambios en la composición corporal en pacientes transgénero que recibieron hasta 12 meses de terapia hormonal afirmativa y fueron atendidos en el Hospital San José (Bogotá – Colombia) entre 2019 – 2023.

Materiales y métodos: Estudio descriptivo de una cohorte histórica de pacientes mayores de 18 años en terapia hormonal afirmativa por al menos 12 meses de forma continua y evaluados con impedancia bioeléctrica. Los parámetros fueron obtenidos mediante un equipo OMRON modelo HBF-514C, incluyendo IMC (Índice de Masa Corporal), porcentajes de músculo, grasa total y niveles de grasa visceral. Cada uno de los anteriores fueron extraídos de mediciones tomadas antes del inicio del tratamiento (día cero) y posteriormente agrupados en intervalos de (0-3 meses), (3-6 meses), (6-12 meses). Los datos fueron recolectados de las historias clínicas de los pacientes atendidos desde junio de 2019 hasta junio de 2023 en seguimiento por el servicio de endocrinología del Hospital de San José en Bogotá, Colombia. Se excluyeron los pacientes que suspendieron la terapia hormonal, iniciaron terapia hormonal automedicada antes de las mediciones de las variables de interés, diagnóstico previo de trastornos alimentarios no controlados, enfermedad coronaria y apnea del sueño. Se comparó el punto cero con un año mediante la prueba de Wilcoxon. Los cambios en todas las mediciones a lo largo del tiempo se exploraron con la prueba de Friedman y, en caso de diferencias, se realizó un análisis post hoc con la prueba de Durbin Conover.

Todas las pruebas de hipótesis se realizaron con un alfa de 0,05 y un 95% de confianza. La información fue procesada y analizada en el software estadístico Jamovi® versión 2.3.

Resultados: Cincuenta y nueve pacientes con una mediana de edad de 23 años (RIC 21-29) cumplieron los criterios de selección, el 64% de los pacientes (n=38) eran hombres transgénero. El 100% (n=59) tenía diagnóstico de disforia de género confirmado por un equipo multidisciplinario. La mediana del IMC fue de 23,3 kg/m2 (RIC 20,4-25,0) y la mediana del peso fue de 60,3 kg (RIC=53,2-71,0).

Las mujeres transgénero habían recibido estrógenos conjugados 76,1%, valerato de estradiol 9,52%, parches de estradiol 9,52% y estradiol en aerosol 4,76%. El cien por ciento (n=38) de los hombres transgénero recibieron undecanoato de testosterona como tratamiento.

Todos los pacientes transgénero solo mostraron aumentos estadísticamente significativos en el IMC (p=0,031) sin variación relevante en otras variables al realizar pruebas t. Los hombres transgénero mostraron cambios con aumentos en los niveles de masa muscular cuando se compararon los resultados a los 0 meses y a los 6-12 meses (p=0,001) sin modificación en la masa grasa y la grasa visceral. Por otro lado, las mujeres transgénero presentaron ganancia en la masa grasa y disminución en la masa muscular cuando se compararon los resultados a los 0 meses y a los 6-12 meses (p=0,005) y (p=0,004) después de doce meses de tratamiento.

Discusión: En nuestro estudio podemos confirmar lo descrito en la literatura mundial; después de 12 meses de terapia hormonal afirmativa, se evidencian aumentos en los porcentajes de masa muscular en hombres transgénero y de masa grasa en mujeres transgénero, acercándose a la distribución corporal típica de hombres y mujeres cisgénero.

WEIGHT, HEIGHT, BMI AND THEIR ASSOCIATION WITH FRACTURE RISK: AN INTERNATIONAL META-ANALYSIS

N. C. Harvey[1], H. Johansson[2], E. V. McCloskey[3], E. Liu[4], L. Vandenput[5], M. Lorentzon[5], W. D. Leslie[6], J. A. Kanis[2], Frax Meta-Analysis Cohort Group[2]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [2]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom, [3]MRC Versus Arthritis Centre for Integrated research in Musculoskeletal Ageing, Mellanby Centre for Musculoskeletal Research, University of Sheffield, Sheffield, United Kingdom, [4]South Australian Health and Medical Research Institute (SAHMRI), Adelaide, United Kingdom, [5]Sahlgrenska Osteoporosis Centre, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [6]Department of Medicine, University of Manitoba, Winnipeg, Canada

Objectives

In a recent Mendelian Randomisation analysis height was causally associated with incident fracture independently of body mass index (BMI) [ref]. Any implications of this finding for risk assessment are not clear. In this international meta-analysis, we investigated the independent predictive value of weight, height and BMI for incident fracture in women and men.

Materials and methods

The interim analysis dataset comprised individual records of 672,282 women and men from 38 cohorts with information on weight, height, BMI and incident fractures. The total follow-up time was 7.1 million person-years. We investigated associations between baseline measures (as continuous variables) and risk of major osteoporotic fracture (MOF) using an extended Poisson model in each cohort. The covariate adjustments were age and duration of follow-up. Results from the different cohorts were merged using the inverse-variance weighted β-coefficients in random effects models.

Results

After adjustment for age, time since baseline and height, higher BMI was associated with lower risk of incident MOF in both women [hazard ratio (HR) (95% CI) per 1 kg/m^2: 0.97 (0.96-0.99)] and men [0.98 (0.97-1.00)] (Table). Similar BMI associations were demonstrated when adjusted for weight instead of height in women [HR (95% CI) per 1 kg/m^2: 0.96 (0.95-0.98)] and men [0.97 (0.94-1.01)]. When height was adjusted for age, follow-up time and BMI there were no statistically significant associations with incident MOF [women HR (95% CI) per 1 cm: 1.00 (1.00-1.01); men 1.00 (0.99-1.01)]. The same was true for weight [women HR (95% CI) per 1 kg: 1.01 (1.00-1.01); men 1.00 (1.00-1.01)].

Conclusions

In one of the largest ever meta-analyses undertaken to date, higher BMI was associated with lower major osteoporotic fracture risk when adjusted for height and weight. In contrast, neither height nor weight adjusted for BMI was statistically significantly related to incident fracture risk. These findings will inform the next iteration of the FRAX® calculator.

Table. Hazard ratios for hip and major osteoporotic fracture (MOF) [+ 95% confidence intervals] by baseline height, weight and BMI per 1 unit change (cm, kg and kg/m^2) (adjusted for age and follow-up time). Associations in bold denote p<0.05

		Outcome: MOF
BMI adjusted for height	Women	**0.97 (0.96-0.99)**
	Men	**0.98 (0.97-1.00)**
Height adjusted for BMI	Women	1.00 (1.00-1.01)
	Men	1.00 (0.99-1.01)
BMI adjusted for weight	Women	**0.96 (0.95-0.98)**
	Men	0.97 (0.94-1.01)
Weight adjusted for BMI	Women	1.01 (1.00-1.01)
	Men	1.00 (1.00-1.01)

Objective:
Osteoporosis remains a critical healthcare challenge in Iran, imposing an economic burden of 2165 million US$ purchasing power parity 2020 (1). To mitigate the elevated risk of secondary fractures following an initial osteoporotic fracture, the Fracture Liaison Service (FLS) program, endorsed by the International Osteoporosis Foundation (IOF), was launched in 2020 as "Osteopod." This initiative focuses on systematic patient identification, treatment initiation, and long-term monitoring. This abstract shows the current status of this prevention program in Iran.

Material and Methods:
A collaborative team from the Ministry of Health (MOH) and the Endocrinology and Metabolism Research Institute (EMRI) at Tehran University of Medical Sciences developed Iran's national Osteopod protocol in 2019, aligned with IOF guidelines. The protocol emphasizes a four-step framework: identifying at-risk patients, investigating lifestyle and fall risks, initiating evidence-based treatments, and following up through a dedicated digital platform. The software tracks patient outcomes, including falls, fractures, and mortality, while enabling nationwide data collection for research. EMRI-led workshops train clinic personnel to standardize practices. Continuous feedback has refined the protocol and software, supporting nationwide scalability.

Results:
Five Osteopod clinics are now operational in Tehran, Gorgan, Sari, Shiraz, and Hamedan, with all five recognized on the IOF's Best Practice Map. These clinics have earned gold, silver, and bronze medals for adherence to global standards. To date, 4,700 patients (68.1% women; mean age 65.9 years) have been registered. Analysis of fracture types revealed the following distribution: hip fractures (23.3%), vertebral fractures (1.4%), and other fractures (75.4%). Among the "other fractures," the most common sites were the radius (25.6% of total fractures), and humerus (12.3%), with the remaining 37.5% comprising other fracture sites (see Figure 1). The mean age of patients with hip fractures was significantly higher than those with other fracture types (72.5 vs. 63.6 years, p<.001).

Conclusions: The Osteopod program has successfully transitioned from pilot to national expansion, demonstrating scalability within Iran's healthcare system. Collaboration between MOH and EMRI has enabled standardized, multidisciplinary care for osteoporosis patients, reducing secondary fracture risks. With all five clinics achieving IOF recognition and a growing patient registry, the program serves as a model for low- and middle-income countries. Future efforts will prioritize further geographic expansion, integration with primary care, and research leveraging the program's comprehensive database.

PREVALENCE AND RISK FACTORS OF VERTEBRAL FRACTURES IN IRANIAN OLDER ADULTS: FINDINGS FROM IRANIAN MULTICENTER OSTEOPOROSIS STUDY (IMOS)

E. Hesari[1], N. Fahimfar[1], M. Sanjari[1], A. H. Aghakhani[1], K. Khalagi[1], M. J. Mansourzadeh[1], S. Akbarpour[2], S. Hajivalizadeh[1], A. Ghazbani[1], A. Ostovar[1], B. Larijani[3]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran, Iran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Understanding vertebral fractures (VF) is crucial, as a person who has experienced one fracture is at greater risk for future fractures, and many vertebral fractures occur without clinical symptoms. This study aimed to estimate the prevalence of VF and identify the associated risk factors within a representative population-based sample.

Material and Methods: This cross-sectional study, conducted as part of the Iranian Multicenter Osteoporosis Study (IMOS 2021-2022), involved participants aged 50 and older. The study employed dual-energy X-ray absorptiometry (DXA) to measure bone mineral density (BMD) and utilized vertebral fracture assessment (VFA) techniques to identify the presence of vertebral fractures (VFs). Osteoporosis was defined according to established criteria, specifically as a T-score of ≤ -2.5 in either the hip or lumbar spine. Additionally, the trabecular bone score (TBS) was evaluat-

ed in the lumbar spine using the TBS iNsight™ software. Furthermore, we employed multiple logistic regression models to analyze the relationship between vertebral fractures and a range of associated risk factors.

Results: The study included 1,441 (54.4% women) participants, who underwent VFA. A total of 623 VFs were identified, with 330 in women and 293 in men. The overall prevalence of VFs was 43.2% (95% CI: 40.6% - 45.8%), with a prevalence of 43.9% in men and 53.7% in women (P=0.079). Among women, 52.7% of the fractures were classified as mild, 37.6% as moderate, and 5.36% as severe. In men, the corresponding figures were 60.7%, 34.7%, and 4.6%, respectively. The types of fractures observed included wedge fractures (61.6% in women, 65.5% in men), biconcave fractures (31.2% in women, 30.5% in men), and crush fractures (7.2% in women, 4.1% in men). Key factors associated with VFs in women included age (OR: 1.01, 95% CI: 1.00-1.02, P: 0.039), current or former smoking (OR: 1.35, 95% CI: 1.00-1.83, P: 0.049), and history of fall (OR: 1.24, 95% CI: 1.02-1.51, P: 0.026). In contrast, for men, having more than 12 years of education was a significant predictor of lower odds of the VF (OR: 0.57, 95% CI: 0.41-0.79, P: 0.001).

Conclusion: This study reveals a notable prevalence of vertebral fractures, particularly among women. These findings highlight the need for tailored prevention strategies to target VFs, especially the non-clinical ones.

Objective

The Procollagen Type 1 N-terminal Propeptide (P1NP) serves as a vital biomarker for evaluating bone formation. This study aimed to establish P1NP levels to improve diagnostic and therapeutic approaches for assessing bone health.

Materials and Methods

A systematic literature search was conducted across various databases up to April 15, 2023, targeting articles that measured serum P1NP levels in healthy individuals aged 50 and older. After eliminating duplicates, two reviewers assessed the titles and abstracts of potentially relevant studies. Data were collected on authorship, publication year, sample size, laboratory kits utilized, participants' fasting status, sex, and serum P1NP levels using a pre-designed data sheet. The risk of bias was evaluated using the Newcastle-Ottawa checklist, and pooled mean P1NP levels were calculated with Stata software, while statistical heterogeneity was analyzed via Cochran's Q test and the I^2 statistic.

Results

From an initial pool of 11,011 studies, 49 met the inclusion criteria after screening and removing 4,227 duplicates. The pooled P1NP levels were found to be 39.6 ng/mL for males and 48.5 ng/mL for females, resulting in a combined level of 46.5 ng/mL. In fasting conditions, P1NP levels were 40.0 ng/mL for males and 49.7 ng/mL for females. Funnel plot analysis indicated potential publication bias, yet the overall quality of the studies was deemed generally strong.

Conclusion

This study underscores the importance of determining sex-specific P1NP values, revealing that elevated P1NP levels in women are linked to an increased risk of osteoporosis.

P1051

INCIDENCE OF FALL-RELATED FRACTURE IN WOMEN OVER 50 YEARS: INSIGHTS FROM A BONE DENSITOMETRY CLINIC

M. Bakhtiari[1], K. Karimi[2], N. Fahimfar[1], M. Sanjari[1], V. Mohseni[1], M. J. Mansourzadeh[1], E. Nasli-Esfahani[3], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran , Iran, [2]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [3]Diabetes Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran , Iran

Objective: The aim of this study is to investigate the cumulative incidence of fractures in women over 50 years of age who underwent bone mineral density (BMD) measurements in a clinic within one year.

Methods: We collected data from the bone mineral densitometry clinic in Tehran, Iran between 2022 and 2023. Demographic information, previous medical history, BMD status and body mass index (BMI) were extracted from the participants' medical records. Information on fractures in the last year and receiving osteoporosis medication was collected through telephone interviews. The incidence of fall-related fractures was calculated in all women, based on the BMI and BMD status.

Findings: A total of 373 eligible women with a mean age of 64.7±7.2 years were included in the study. Osteoporosis and osteopenia were detected in 80 (21.4%) and 199 (53.3%) of the women, respectively. The overall incidence of new fall-related fractures among the participants during the one- year period was 5.09% (95%CI: 3.31-7.85). Regarding the BMD status, the highest number of fall-related fractures was observed in the osteopenia group in eight cases (4.02%, 95%CI: 2.01-7.84). In terms of BMI, 2.27% (95%CI:0.73-6.83) of the normal-weight women, 7.01% (95%CI:3.91-12.20) of the overweight group, and 5.95% (95%CI:2.49-13.54) of the obese group reported fall-related fractures during one year. A higher, but not statistically significant, incidence rate was observed in the group eligible for osteoporosis treatment (7.92%, 95%CI:4.0-15.0) in comparison to the other group (4.04%, 95%CI: 2.24-7.16). The incidence of fall- related fractures was higher in women on hormone therapy (9.2% ,95%CI:4.63-17.32), than in the others (3.8%, 95%CI:2.13-6.82).

Conclusion: Considering the incidence and complications of fractures in elderly populations, encouraging timely diagnosis, medication adherence and maintaining a healthy behavior can significantly contribute to reducing fracture rates in this high-risk population.

Keywords: Fracture incidence, elderly women, osteoporosis, fall

Objective: This study aimed to assess the cost-effectiveness of a Fracture Liaison Service (FLS) program compared to current practice in Iran, from a healthcare system perspective.

Material and Methods: The target population was patients aged 50 years or older with recent sentinel fragility fractures. Data were collected using various resources, including previously published literature, treatment guidelines, and hospitals. A state-based microsimulation model with a lifetime horizon and the perspective of the healthcare system was designed to estimate the cost-effectiveness of an FLS compared to current practice by simulating costs and quality-adjusted life years (QALYs (. In this study sentinel and subsequent fractures were categorized into hip, spine, or major fractures at other sites. Treatment pathways for patients under current practice and FLS were compared using incremental cost-effectiveness ratios (ICERs).

Results: For patients aged 50 years and older with a sentinel fragility fracture, FLS was associated with an additional cost of $177 and a gain of 0.05 QALYs compared to current. Consequently, the ICER was estimated at $3,662 per QALY gained, which is below the willingness-to-pay (WTP) threshold of one GDP per capita ($4,503 per QALY), indicating that FLS is cost-effective relative to current practice. Furthermore, simulations involving patients with a recent fracture showed that FLS led to a reduction of 60 fractures and 6.7 deaths due to fractures per 1,000 patients compared to current practice. The one-way sensitivity analysis indicates that the relative risk of fracture reduction with anti-osteoporosis medication, cost of medication treatment, discount rate, and hip and other fracture treatment costs have the most impact on the ICER. The acceptability curves show that at the WTP threshold of one GDP per capita of Iran, 69% of the simulations indicate that the

FLS was cost-effective compared to current practice. When the WTP threshold increased to two GDP per capita, the probability of the FLS strategy being cost-effective rose to nearly 100%.
Conclusion: The findings of this study demonstrate that FLS is cost-effective compared to current practice in Iran. Given the significant incidence of osteoporotic fractures and the increasing aging population in Iran, these results underscore the potential of FLS to enhance patient outcomes.

P1053

THE PREVALENCE OF CO-OCCURRENCE OF FEAR OF FALLING AND AVOIDANCE BEHAVIORS DUE TO FALLS IN PEOPLE AGED 50.

K. Karimi[1], N. Fahimfar[1], M. Sanjari[1], F. Nemati[2], V. Mohseni[1], K. Khalagi[3], A. Ostovar[1], B. Larijani[4]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran , Iran, [2]School of public health, Tehran University of Medical Sciences, Tehran, Iran, [3]Obesity and Eating Habits Research Center Endocrinology and Metabolism Molecular Cellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran , Iran, [4]Endocrinology and Metabolism Research Center Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran , Iran

Objective: This study aims to determine the prevalence of co-occurrence of fear of falling (FOF) and falling avoidance behaviors (FFAB)in people over 50 years of age.

Methods: This cross-sectional study was conducted on individuals over 50 years of age who performed bone mineral density (BMD) in a BMD clinic in Tehran, Iran, between 2022 and 2023 . The demographic data of individuals was collected from their medical records. The validated FOF questionnaire with seven questions (total score: 0-16) and the FFAB questionnaire with 14 questions (total score: 0-54) were used considering the standard cut-off points for categorization. High fear of falling, and high fall-avoidance behaviors were defined as score>15, and score>20, respectively. Data on other variables of interest and fall experiences in the past year were collected through telephone interviews with the participants.

Results: Of the 425 (87.2% women) participants with the mean age of 64.2 years,), 93 (21.8%; 95%CI: 18.2-26.0) reported FOF, and 68 people (16.0%: 12.8-19.8) reported FFAB. In all, 52 (12.2%: 9.4-15.7) participants reported high levels of fear of falling and avoidance behavior at the same time. This co-occurrence was higher in men (17.3%) than in women (11.5%) but the difference was not statistically significant (p=0.233). The co-occurrence was also more prevalent in individuals aged over 70 years (32.9%: 24.2-43.1), compared to people aged 60-70 years (8.0%: 5.1-12.4) and who aged 50-60 years (2.8%: 1.0-8.3). People taking medication for type 2 diabetes were more likely to report this co-occurrence than others (16.3%: 11.8-22.4, p=.014). Also, participants with cardiovascular diseases showed a higher prevalence compared to the healthy ones (37.8%: 22.3-56.) vs. (10.3%:7.7-13.7), p<0.001). Visual and hearing impairments increased the likelihood of this co-occurrence compared to the general population by respectively, p<0.001). Spontaneous falls in the past year and living alone also increased the likelihood of FOF and FFAB co-occurrence by (26.3%:18.4-36.0) and 21.3% (95%: 12.7-33.), respectively, p<0.001).
Conclusion: The simultaneous occurrence of a high fear of falling and fall-avoidance behavior is notably prevalent among individuals older than 60 years. The high prevalence of this co-occurrence is linked to cardiovascular disease, diabetes medication, sensory impairments, and past falls experiencing.
Key word; Fall, FOF, Avoidance behavior, elderly, cooccurrence

Yanovsky NAMS of Ukraine, Kyiv, Ukraine, [10]Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine, [11]Donetsk National Medical University, Kropyvnytskyi, Ukraine

Background. Glucocorticoid-induced osteoporosis (GIOP) is a bone metabolic disease caused by chronic glucocorticoid (GC) use. It is one of the leading causes of secondary osteoporosis, which significantly increases the risk of low-trauma fractures and impacts disability and mortality among patients. Although few studies on GIOP epidemiology and treatment have been conducted in Ukraine, national guidelines for GIOP management have been lacking until now.
The **aim** was to create national guideline for the diagnosis, prevention, and treatment of GIOP based on an analytical review of modern literature, raising awareness among the Ukrainian medical community, enhancing GIOP management, and reducing the

disease's socio-economic impact.
Materials and Methods. To develop this guideline, a team of 18 leading Ukrainian experts from various fields was formed. Six experts from the Working Group analyzed current literature on GIOP epidemiology, risk factors, diagnosis, prevention, treatment, and monitoring. Evidence was synthesized using the GRADE system, while the quality of recommendations was critically assessed with the AGREE II tool. Two rounds of voting were performed in 2024.
Results. The current guideline comprises 12 key statements covering GIOP screening, diagnosis, prevention, and treatment. It highlights the importance of educating the Ukrainian medical community and patients about the risks of chronic GC use. The document provides detailed recommendations for assessing osteoporotic fracture risks in GC users (using FRAX and DXA) and outlines modern, locally available GIOP diagnosis (DXA, USD, etc.) and treatment methods.
Conclusion. The first Ukrainian guideline for GIOP management offers a significant national framework for screening, diagnosis, prevention, and treatment of this disease. The Board of the Ukrainian Association of Osteoporosis endorses it for implementation in clinical practice by physicians across various specialities.

THE ANTHROPOMETRIC EQUATIONS FOR SCREENING OF LOW APPENDICULAR SKELETAL MUSCLE MASS IN OLDER UKRAINIANS

N. Grygorieva[1], A. Musiienko[1], N. Zaverukha[1], N. Koshel[1], A. Pysaruk[1]

[1]D. F. Chebotarev Institute of Gerontology National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

Background. Sarcopenia, a prevalent age-related condition, contributes to increased disability and reduced life expectancy of older subjects. Current sarcopenia guidelines employ assessment of muscle mass by measuring the appendicular skeletal muscle mass (ASM) using dual-energy X-ray absorptiometry (DXA) or bioelectrical impedance analysis. However, the limited availability of DXA in Ukraine hinders in-time sarcopenia diagnosis. Previous studies proposed different ASM prediction equations based on demographic and anthropometric data, offering a more accessible and cost-effective alternative for improving sarcopenia diagnosis. However, similar equations have not been present for Ukrainians until now.
This study **aimed** to create and validate ASM prediction equations for the Ukrainian population using simple demographic and anthropometric indices.
Materials and Methods. The study included 1,606 adults aged 60-91 years. Subjects were randomly divided into 2 groups: a model development group (n=1406, 1,262 women and 144 men) and a cross-validation group (200 women). ASM was measured by DXA (Hologic), and anthropometric parameters included body weight, height, and waist and hip circumferences. Demographic data included participants' age and menopausal status for women. Using multiple regression analysis, ASM was treated as the dependent variable, while demographic and anthropometric variables were independent.
Results. The final ASM equations for both sexes (1), males (2) and females (3) were created:
ASM (1)=0.165×weight (kg)+0.096×height (cm)−4.939×gender*−0.0205×age (years)+1.877
Note. * - 1 - females and 2 - males.
ASM (2)=0.191 weight (kg)+0.141×height (cm)−0.077×age (years)−9.406
ASM (3)=0.161×weight (kg)+0.089×height (cm)−0.013×age (years)−7.067
The models showed high multiple correlation (R1=0.90, R2=0.84 and R3=0.84) and determination coefficients ($R^2$1=0.81, $R^2$2=0.71, $R^2$3=0.71, for all equations p<0.00001). In the cross-validation group, the difference between calculated and DXA ASM indices was most minor for formula 3 (Min-Max: [-4.7–2.2]).
Conclusion. The developed ASM prediction equations demonstrated substantial prognostic accuracy and can significantly enhance sarcopenia diagnosis in the Ukrainian population.

P1056

SARCOPENIA AND BONE HEALTH PARAMETERS IN POSTMENOPAUSAL WOMEN WITH DIFFERENT TYPES OF OSTEOPOROTIC FRACTURES

N. Grygorieva[1], A. Musiienko[1], D. Kurylo[1], A. Iniushina[1]

[1]D. F. Chebotarev Institute of Gerontology National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

The research **aim** was to study sarcopenia and bone health parameters depending on the presence of various osteoporotic fractures in postmenopausal women.
Materials and Methods.
In the single-centre study, we examined 139 females aged 51-87 years (mean age 69.2±7.8 years), divided into three groups: 1 - healthy subjects without any previous fractures (n=50), 2 - patients with previous forearm fractures (FFs, n=39) and women with previous vertebral fractures (VFs, n=50).
Anthropometric measurements, including height, weight, and body mass index, were obtained using standard clinical methods. Muscle strength was evaluated using hand dynamometry and the "sit-to-stand" test. Muscle mass (appendicular muscle mass (ALM) and appendicular muscle mass index) was determined using dual-energy X-ray absorptiometry (DXA, Hologic). The diagnosis of sarcopenia was confirmed using EWGSOP2 criteria. Also, by DXA, we measured bone mineral density (BMD) in the lumbar spine (LS), femoral neck (FN), total hip (TH) and radius as well as

trabecular bone score (TBS).

Results.

The examined did not differ in age, main anthropometric parameters (height, weight and body mass index) and menopausal status (menopause age and duration of postmenopausal period). However, the increased risk of confirmed sarcopenia was revealed in the patients with VFs (OR=2.71, 95% CI: 1.02-7.20; p = 0.045) but not in subjects with FFs (OR=0.60, 95% CI: 0.18-1.95; p=0.40). FN and TH BMD were significantly lower in patients with various osteoporotic fractures (FN BMD - group 1: 0.70±0.14; group 2: 0.63±0.10; group 3: 0.61±0.09 g/cm^2, respectively, F=9.96; p=0,00009) whereas LS BMD and TBS were reliable lower only in subjects with VFs (LS BMD - group 1: 0.89±0.19; group 2: 0.83±0.16; group 3: 0.80±0.14 g/cm^2, respectively. TBS - group 1: 1.23±0.10; group 2: 1.21±0.08; group 3: 1.17±0.10 un., respectively). We did find significant differences in radius BMD and ALM parameters depending on the presence and types of osteoporotic fractures. Also, we did not reveal reliable differences in muscle strength parameters between patients from the study groups.

Conclusion.

Patients with VFs have lower bone strength and quality, as well as an increased risk of sarcopenia compared to subjects without previous fractures, which should be counted in their management.

P1057

AWARENESS LEVELS AMONG INDIAN FEMALES ABOUT POST MENOPAUSAL OSTEOPOROSIS: A CROSS-SECTIONAL STUDY FROM NORTHERN INDIA

N. Gupta[1], A. Khosla[1]

[1]Centre for Arthritis and Rheumatological diseases in Delhi, Delhi, India

Background

Osteoporosis can be prevented by imparting knowledge to the general population. To address this, we assessed the knowledge among the population by a survey involving female population aged 25-45 years.

METHODS

Between May 2024 and November 2024, a cross-sectional study was done in Delhi, India. A total of 2000 healthy females aged 25-45 years, all graduate participated in the study. The Osteoporosis Knowledge Assessment Tool (OKAT) was used to assess the knowledge of osteoporosis amongst the females.

Results

The mean age was 33.1±2.7 years. The mean score for osteoporosis awareness was 7 out of 20 points. A total of 1698 (85%) had no knowledge about osteoporosis with most of them scoring 2-3 points on OKAT scale.

Conclusions

Even among educated women of Pitampura, Delhi knowledge, attitudes, and behaviors about osteoporosis were found to be quite low. In addition, education and mass communications are needed to increase awareness among women about improving bone health.

P1058

RELAPSED PAGET'S DISEASE OF THE BONE: CLINICAL PRESENTATION, PREDICTORS AND THERAPEUTIC RESPONSE

N. Kapoor[1], K. E. Cherian[1], T. V. Paul[1]

[1]Christian Medical College, Vellore, Vellore, India

Background and Objectives: Bisphosphonate therapy has revolutionised the management of Paget's disease of bone. However, 3 to 15% of these patients have been reported to relapse during follow-up. We describe the clinical presentation of patients with Relapsed Paget's Disease of Bone(RPDB), their predictors and response to therapy, from a single quaternary centre in southern India.

Material and Methods: This observational study analysed the clinical features, biochemical profile, and treatment outcomes of patients diagnosed to have RPDB from 2010 to 2016. A diagnosis of RPDB was made in previously treated patients with a documented remission who had biochemical worsening(elevated serum alkaline phosphatase) with or without clinical(recurrence of bony pain) and radiological deterioration, during follow up. The data was captured through the hospital Computerized Hospital Information and Processing System. The predictors of relapse were derived in comparison to 41 patients without relapse from a previously published series from our centre(Cherian et al, 2018). An ethics approval was obtained for this study.

Results: A total of 7 patients(6 men) were diagnosed to have RPDB. The mean(SD) age at diagnosis was 69.1(16.3) years. 28.7 percent(2/7) were asymptomatic. Pain was the predominant presenting symptom and all RPDB patients had a polyostotic involvement. 85.7 percent(6/7) were initially treated with oral bisphosphonates. The mean(SD) duration of developing relapse after initial treatment was 55(27.3) months. In comparison to those who did not relapse(n=41), patients with RPDB were significantly older, were treated with oral bisphosphonates and had a lower serum 25(hydroxy) vitamin D($p<0.01$). All RPDB attained remission with intravenous bisphosphonates.

Conclusion: RPDB can occur after several months of initial treatment and hence warrants long term follow-up. Patients who relapse were likely to be older, those treated with oral bisphosphonates and who have a lower vitamin D level.

P1059

THE UTILITY OF KNEE JOINT DXA (DUAL-ENERGY X-RAY ABSORPTIOMETRY) IN POSTMENOPAUSAL WOMEN WITH SEVERE OBESITY AND KNEE OSTEOARTHRITIS – A NOVEL ASSESSMENT STRATEGY

N. Kapoor[1], T. V. Paul[1], K. E. Cherian[1]

[1]Christian Medical College, Vellore, Vellore, India

The utility of knee joint DXA (Dual-energy X-ray Absorptiometry) in postmenopausal women with severe obesity and knee osteoarthritis – A novel assessment startegy

Background
Obesity is a major reversible public health problem of the 21st century associated with significant morbidity and mortality. Traditionally, it has been proposed that obesity is protective for the bone. However, those with severe obesity have poor bone quality, a higher risk of hip fracture, poor fracture healing, and an increased knee osteoarthritis risk, further contributing to poor quality of life. Protocols for knee DXA scans have been published before. However, the impact of severe obesity on knee BMD and its relation to severe osteoarthritis has not been studied, and the study helps address this research gap.
Aims and objective
To assess the impact of osteoarthritis severity on BMD at the knee joint in post-menopausal women with severe obesity. To also study the Dual Energy X-ray Absorptiometry (DXA) derived parameters at conventional sites in addition to the trabecular bone score and hip structural analysis in this study population.
Material and Methods
The study included 160 subjects - 80 ambulatory postmenopausal women who have morbid obesity cases, whose characteristics were compared with 80 age-matched postmenopausal women who have normal BMI. The prevalence of osteoporosis, low trabecular bone score (an index of degraded microarchitecture), and hip structural analysis of postmenopausal women were studied and compared to age-matched women with normal BMI. The impact of osteoarthritis on BMD at the knee joint with DXA scan in those with or without knee osteoarthritis was assessed separately. The osteoarthritis grading was assessed using WOMAC scoring and ACR criteria.
Results
The mean (SD) age of our study population was 55.7(5.4) years and the mean BMI was 40.1(4.2) kg/m2. In this study, the mean age of menopause was 45 years. The physical activity of the study subjects as assessed using GPAQ and quantified as MET (metabolic equivalent) in minutes. The mean (SD) MET score in the study population was 1062(191). The mean (SD) time spend sedentarily among cases was 161(80) minutes per day. 92.7% of the study population had pre-diabetes or type 2 diabetes mellitus and was on treatment. 41/80(51%) of the subjects had Vitamin D deficiency (<20 ng/mL). The mean value (SD) of 25(OH) Vitamin D was 22.01(10.4) pg/ml in cases and 23.6(9.3) in control group. The markers of bone resorption (CTX—429.5(225.4) vs 628.3(304.8) pg./ mL; P 0.102) and bone formation (P1NP—55.1(23.1) vs 62.1(29.7) ng/mL; P .102) were lower among postmenopausal women with morbid obesity as compared to age matched controls with normal BMI. The mean BMD at total Hip in cases were 0.715 (0.115) g/cm2, at lumbar Spine 0.984(.138) g/cm2. Mean (SD) TBS values in cases 1.095(0.181) & 1.143(0.059) in controls($p < 0.05$). The buckling ratio for the NN, FS and IT were 10.29 (3.33) ,2.75(0.53) &11.32 (2.48) which is statistically higher from that of controls. As per ACR Criteria 88.7% (71/80) of the study subjects has osteoarthritis knee. The severity of osteoarthritis was assessed by the radiological Kellgren and Lawrence scoring system. The cases were divided as with less severe and more severe Knee Osteoarthritis on the basis of the WOMAC score. The median WOMAC was 25. The cases were comparable for their baseline parameters. The mean (SD) BMI of cases with more severe OA were 42.7(5.6) kg/m2 & that of cases with less severe OA was 37.8(3.3) kg/m2. The BMD characteristics at the upper tibia (left and right) were significantly lower in cases with more severe osteoarthritis of the Knee Joint.
Conclusion
Post-menopausal women with morbid obesity have poor bone health in terms of bone density, trabecular bone score, and hip geometry and warrant periodic screening. Knee DXA can be considered as a surrogate to assess the severity of knee osteoarthritis. Further studies are needed to study its utility in predicting, diagnosing, and studying the impact of treatment.

P1060

ASSOCIATION BETWEEN FRACTURE RISK ASSESSED WITH FRACTURE RISK ASSESSMENT TOOL (FRAX) AND CHAIR STAND TEST IN GERIATRIC WOMEN

N. Kirilov[1], S. Vladeva[2], S. Todorov[3], F. Bischoff[4]

[1]Department of Orthopedics and Traumatology, University Hospital "Dr. Georgi Stranski, Medical university of Pleven, Pleven, Bulgaria, [2]Department of Health Care, Faculty of Medicine, Trakia University, 6007 Stara Zagora, Bulgaria, Stara Zagora, Bulgaria, [3]UMBAL "Heart and Brain" Pleven – Clinic of Orthopedics and Traumatology, Pleven, Bulgaria, Pleven, Bulgaria, [4]IPSMP Rheumatology, 6000 Stara Zagora, Bulgaria, Stara Zagora, Bulgaria

Objective: Fractures are a major concern among elderly women, driven by age-related declines in bone density and functional mobility (1). The Fracture Risk Assessment Tool (FRAX) estimates 10-year fracture probabilities, while the Chair Stand Test evaluates lower body strength and mobility. This study aims to explore the association between FRAX-calculated fracture risk and Chair Stand Test performance to enhance fracture risk prediction.
Material and Methods:
This study examined the association between fracture risk and functional mobility using the Chair Stand Test (5XSST). 83 participants over 60 years were instructed to stand up and sit down from a chair five times consecutively as quickly as possible. Based on their performance, participants were categorized into two groups: 5XSST < 12.9 seconds (s) and 5XSST ≥ 12.9 s. Fracture risk was

assessed using the FRAX tool, which estimates 10-year probabilities of major osteoporotic (MOF) and hip fractures (HF). The relationship between 5XSST performance and FRAX scores was analyzed to identify variations in fracture risk across the two groups.
Results:
Out of 83 participants, 51 women (61.5%) had 5XSST < 12.9 s and 32 women (38.5%) had 5XSST ≥ 12.9 s. The mean age of the participants was 73 ± 5.3 years, and the mean BMI was 25.6 ± 4.3 kg/m². FRAX scores for MOF differed significantly ($p < .001$) across Chair Stand Test groups. Women with 5XSST ≥ 12.9 s had the higher mean FRAX score for MOF (24.39%), compared to those with 5XSST < 12.9 s (14.95%). Similarly, FRAX scores for HF also showed significant differences ($p < .001$) among Chair Stand Test groups. Women with 5XSST ≥ 12.9 s had the higher mean FRAX score for HF (10.03%), compared to those with 5XSST < 12.9 s (3.67%).
Conclusion:
The findings underscore the potential value of the 5XSST as a simple, practical tool for identifying individuals at higher risk of fractures, which could aid in early intervention strategies aimed at improving bone health and reducing fall-related risks.

P1061

MIDDLE-AGED AND ELDERLY PATIENTS' PERCEPTIONS OF REHABILITATION TREATMENT AND FUNCTIONAL RECOVERY AFTER DISTAL RADIUS FRAGILITY FRACTURES: A QUALITATIVE STUDY

Y. Nie[1], N. Liu[1]

[1]Peking University Third Hospital, Beijing, China

Objective 1.To investigate patients' perceptions of rehabilitation treatment and functional recovery following distal radius fragility fractures through semi-structured interviews. 2.To provide novel insights for establishing best practice guidelines for conservative treatment and early postoperative rehabilitation of distal radius fragility fractures.
Methods A sample of 23 cases diagnosed with distal radius fragility fractures was collected from the Departments of Rehabilitation Medicine and Orthopedics at Peking University Third Hospital between October 2022 and January 2023. Using a semi-structured interview guide developed based on a review of relevant literature, semi-structured interviews were conducted with the sample. Audio and textual data were collected and subsequently transcribed and analyzed using MAXQDA2022 software for qualitative data analysis. The aim was to explore patients' perceptions regarding rehabilitation treatment and functional recovery post-fracture.
Results The study included a total of 23 participants, comprising 2 males (aged 53-56) and 21 females (aged 49-78). Through three levels of coding analysis, 50 initial categories, 14 main categories, and 5 themes were identified (1.The importance of fall risk assessment and prevention in middle-aged and elderly individuals;2.The significance of early intervention and continuous guidance in rehabilitation treatment;3.The importance of active participation by patients and their families in rehabilitation treatment;4.The necessity of providing psychological support therapy for middle-aged and elderly patients with DRF;5.The necessity of regularly assessing the functional status of the affected shoulder joint).
Conclusions This study indicates that early rehabilitation intervention and continuous guidance are perceived by middle-aged and elderly patients with distal radius fragility fractures as significantly beneficial for functional recovery and quality of life improvement. It is recommended that rehabilitation treatment for these patients comprehensively consider multiple factors, including pain, wrist joint function, psychological aspects, patient engagement, and shoulder joint function. Additionally, fall risk assessment and stratification should be conducted, and a multidimensional, personalized rehabilitation strategy should be employed to promote comprehensive recovery and facilitate an early return to normal life.

P1062

VALIDATION OF THE CHINESE VERSION OF THE QUALITY OF LIFE QUESTIONNAIRE FOR DISTAL FOREARM FRACTURE

Y. Nie[1], N. Liu[1]

[1]Peking University Third Hospital, Beijing, China

Background: To evaluate the reliability and validity of the Chinese version of the IOF-Wrist scale in patients with distal radius fractures (DRF), a systematic validation study was conducted.
Methods: A total of 144 DRF patients were recruited for the analysis of internal consistency reliability, test-retest reliability, and criterion validity. Internal consistency was assessed using Cronbach's α, test-retest reliability was evaluated with intraclass correlation coefficients (ICC) calculated using a one-way random-effects model, and criterion validity was verified by analyzing correlations with VAS, DASH, and EQ-VAS.
Results: The overall Cronbach's α of the scale was 0.888, with 0.660 for the symptom domain and 0.855 for the function domain. The total score of the scale showed a single-measure ICC of 0.937 (95% CI: 0.892–0.964) and an average-measure ICC of 0.967 (95% CI: 0.943–0.981), $P < 0.001$. The criterion validity analysis demonstrated high correlations ($P < 0.01$) between the IOF-Wrist domains and the reference scales: 0.836 with VAS pain for the pain domain, 0.720 with DASH symptoms for the upper limb symptom domain, 0.887 with DASH function for the upper limb function domain, and 0.880 with EQ-VAS for the overall health status domain.
Conclusions: The Chinese version of the IOF-Wrist scale demonstrates good reliability and validity, making it an effective tool for assessing pain, function, and quality of life in DRF patients.

P1063

RISK FACTORS FOR BONE MINERAL DENSITY DISORDERS IN POSTMENOPAUSAL WOMEN

L. S. Abboskhujaeva[1], N. M. Alikhanova[2], G. G. Akramova[1], M. M. Shakirova[2], F. A. Takhirova[2]

[1]Republican Specialized Scientific-and-Practical Medical Centre of Endocrinology named after academician Yo.Kh.Turakulov under the Ministry of Health of the Republic of Uzbekistan, Tashkent, Uzbekistan, [2]Institutes of Health and Strategic Development. Tashkent, Uzbekistan, Tashkent , Uzbekistan

Objective: Postmenopausal bone loss associated with estrogen deficiency is a major contributing factor to osteoporosis.
Material and Methods: To assess the prevalence of bone mineral density (BMD) disorders, a survey and examination of 172 women aged over 50 and under 70 years in Tashkent were conducted. A standardized questionnaire was completed for each participant, recording personal data, osteoporosis risk factors, laboratory results, and spine and proximal femur X-ray densitometry data. The average age of the participants was 58.5±6.7 years, the average age of menopause onset was 48.8±4.1 years, and the average BMI was 29.2±5.1 kg/m².
Results. It was found that nearly one-third (32.0%) of women experienced pain in various areas, while fractures were reported by 11.6% of participants. Family history of fractures was present in 14.5% of cases. Calcium and vitamin D supplements were taken by 16.9% and 37.8% of women, respectively, with the average daily calcium intake being 527.4±182.1 mg, and vitamin D intake 14,226±29,047 IU.
Almost half (47.1%) of the women consumed a sufficient amount of dietary calcium, while more than one-third (36.0%) excluded dairy products from their diets. In the overall cohort, just over half (53.5%) led an active lifestyle, while 27.9% were physically inactive.
When asked if they wore open clothing (short-sleeved tops and skirts above the calves), 67.4% answered "yes," 17.4% preferred moderately open clothing, and 15.1% wore fully covered clothing. More than one-third (34.9%) of the surveyed women consumed coffee, strong tea, and carbonated beverages, exceeding three cups per day.
Conclusion(s): Thus, one in three surveyed women has one or more risk factors for developing osteoporosis.

P1064

INTERLEUKIN-4 AND INTERLEUKIN-13 MODULATION IN ATOPIC DERMATITIS AND ITS ASSOCIATION WITH OSTEOPOROSIS

G. G. Mitroi[1], N. M. Bugălă[2], S. A. Preda[3], M. R. Mitroi[4], D. M. Albulescu[5], A. Boicea[6], G. Mitroi[7]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [5]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [7]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania

Objective :Atopic dermatitis (AD) is a chronic inflammatory skin disease, primarily driven by Th2 cytokines like interleukin-4 (IL-4) and interleukin-13 (IL-13), which cause inflammation and impair skin barrier function. Recent treatments like JAK inhibitors (abrocitinib) and biologics (Dupilumab) targeting these cytokines effectively manage AD. However, the impact of long-term modulation on bone health, especially osteoporosis, is unclear. Osteoporosis, characterized by bone mass loss and increased fracture risk, has been linked to chronic inflammation, but the role of IL-4/IL-13 in bone metabolism requires further exploration.
Case Report - A 52-year-old woman with a 20-year history of AD experienced worsening symptoms despite using topical treatments. She was started on Dupilumab, leading to significant skin improvement. However, after six months, she reported new back pain, and a DEXA scan confirmed osteoporosis (T-score of -2.6). Her lab results showed normal calcium and vitamin D, but elevated bone turnover markers, with no other secondary causes for osteoporosis. The temporal link between Dupilumab use and bone loss raised concerns about IL-4/IL-13 inhibition affecting bone health [1-17].
Conclusions This case suggests a potential link between IL-4/IL-13 modulation in AD and osteoporosis development. Monitoring bone density in AD patients on long-term immunomodulatory therapy is crucial, especially in those at risk of osteoporosis, to prevent complications through early intervention and screening.

DUPILUMAB THERAPY IN ATOPIC DERMATITIS AND THE ONSET OF OSTEOPOROSIS

G. G. Mitroi[1], N. M. Bugălă[2], S. A. Preda[3], M. R. Mitroi[4], G. Mitroi[5], A. Boicea[6], D. M. Albulescu[7]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [5]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [7]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania

Background: Dupilumab, a monoclonal antibody that blocks interleukin-4 (IL-4) and interleukin-13 (IL-13), is approved for moderate-to-severe atopic dermatitis (AD), asthma, and chronic rhinosinusitis. It effectively reduces inflammation by inhibiting the IL-4 receptor, improving symptoms in AD patients. While generally safe, its long-term impact on bone health remains unclear. Osteoporosis, characterized by decreased bone density and increased fracture risk, may be influenced by inhibiting IL-4/IL-13, as they play protective roles in bone metabolism. This report discusses a rare case of osteoporosis in a patient undergoing Dupilumab therapy.

Case Report A 45-year-old male with severe AD, unresponsive to conventional therapies, was started on Dupilumab. Over a year, his symptoms improved significantly, with fewer flare-ups and enhanced skin healing. However, after 18 months, he developed musculoskeletal discomfort. A DEXA scan revealed osteoporosis (T-score of -2.8), with no history of steroid use, thyroid disorders, or other secondary causes. Normal vitamin D and calcium levels, alongside elevated bone resorption markers, pointed to a potential link between Dupilumab and bone metabolism disruption.

Conclusions This case suggests a possible connection between Dupilumab therapy and osteoporosis. While Dupilumab effectively controls AD by blocking IL-4/IL-13, it may impact bone health in long-term users. Regular bone density monitoring and early interventions, especially in at-risk patients, are recommended to mitigate potential bone loss. Further studies are needed to clarify the effects of IL-4/IL-13 inhibition on bone metabolism.

ATOPIC DERMATITIS AND OSTEOPOROSIS: A CASE REPORT ON THE POTENTIAL LINK BETWEEN CHRONIC INFLAMMATION AND BONE HEALTH

G. G. Mitroi[1], N. M. Bugălă[2], S. A. Preda[3], D. M. Albulescu[4], A. Boicea[5], G. Mitroi[6], M. R. Mitroi[7]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [5]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [7]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania

Background Atopic dermatitis (AD) is a chronic skin disorder driven by a Th2-dominated immune response with elevated cytokines like interleukin-4 (IL-4), interleukin-13 (IL-13), and IgE. Though AD is primarily seen as a skin disease, there is evidence suggesting that chronic inflammation associated with AD may affect bone health. Osteoporosis, characterized by reduced bone mineral density (BMD) and increased fracture risk, has been linked to inflammation that accelerates bone resorption.

Case Report A 38-year-old woman with a 25-year history of AD presented with worsening symptoms and increased corticosteroid use over the past year. Her AD primarily affected flexural areas, with flare-ups managed by corticosteroids and antihistamines. Over time, she also experienced joint pain, particularly in her back and hips. A DEXA scan revealed a T-score of -2.5, consistent with osteoporosis. Her calcium and vitamin D levels were normal, but elevated bone turnover markers indicated increased bone resorption. Prolonged corticosteroid use, reduced physical activity, and chronic AD-related inflammation were considered major contributors to her osteoporosis [1-17]

Conclusions This case highlights the possible link between chronic AD and osteoporosis, where systemic inflammation and corticosteroid use may disrupt bone remodeling. Clinicians should monitor bone health in AD patients, especially those with long disease histories or frequent corticosteroid use. Early screening and interventions, such as calcium and vitamin D supplementation and exercise, can help prevent osteoporosis and reduce fracture risks in these patients.

EXPLORING THE LINK BETWEEN CHRONIC ATOPIC DERMATITIS AND OSTEOPOROSIS: A CROSS-SECTIONAL STUDY

G. G. Mitroi[1], N. M. Bugălă[2], S. A. Preda[3], D. M. Albulescu[4], A. Boicea[5], G. Mitroi[6], M. R. Mitroi[7]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [5]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [7]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania

Background: Atopic dermatitis (AD) is a chronic skin disorder driven by a Th2-dominant immune response, leading to eczema and barrier dysfunction. Though primarily dermatological, AD's systemic inflammation may impact other organs, including bones. Osteoporosis, marked by reduced bone density and increased fracture risk, has been associated with chronic inflammatory diseases. This study explores the prevalence of osteoporosis in chronic AD patients and its contributing factors, including disease duration, severity, and corticosteroid use.

Materials and Methods: This 12-month cross-sectional study included 120 moderate-to-severe AD patients aged 30-65, compared with 120 healthy controls. Patients had a diagnosis of AD for over 5 years and a history of exacerbations requiring systemic treatment. AD severity was measured by the Eczema Area and Severity Index (EASI), and bone mineral density (BMD) was assessed using DEXA scans. Multivariate regression models analyzed the association between AD and bone health.

Results: Osteoporosis prevalence was higher in AD patients (25%) than controls (10%) ($p < 0.01$), and osteopenia was more frequent (40% vs. 22%). AD patients with longer disease duration (>10 years) and higher EASI scores had a greater likelihood of osteoporosis (OR: 2.8; 95% CI: 1.6-4.9). Systemic corticosteroid use in the past 2 years was also linked to increased bone loss ($p < 0.05$). Elevated C-reactive protein (CRP) levels in AD patients with osteoporosis supported the role of chronic inflammation in bone resorption. No significant differences were found in calcium and vitamin D levels between AD patients and controls[1-17]

ATOPIC DERMATITIS AND OSTEOPOROSIS: A CASE REPORT OF CHRONIC INFLAMMATION LEADING TO BONE LOSS

G. G. Mitroi[1], N. M. Bugălă[2], S. A. Preda[3], D. M. Albulescu[4], A. Boicea[5], G. Mitroi[6], M. R. Mitroi[7]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [5]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [7]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania

Background : Atopic dermatitis (AD) is a chronic skin condition characterized by eczema, pruritus, and barrier dysfunction. Emerging evidence suggests that AD's systemic inflammation may contribute to osteoporosis, marked by reduced bone mineral density (BMD) and increased fracture risk. Inflammatory cytokines like interleukin-4 (IL-4) and interleukin-13 (IL-13), which drive AD, may promote osteoclast activity and bone resorption.

This case report explores the potential link between long-standing AD and osteoporosis.

Case Report : A 40-year-old woman with a 15-year history of moderate-to-severe AD presented with worsening skin symptoms and new-onset back pain. Despite intermittent topical corticosteroid use, she experienced frequent exacerbations that required oral corticosteroids. Her physical activity had decreased due to discomfort from her skin and joint symptoms. Examination revealed widespread eczematous lesions, primarily in flexural areas.

A dual-energy X-ray absorptiometry (DEXA) scan showed a lumbar spine T-score of -2.6, consistent with osteoporosis. Lab results indicated normal serum calcium, vitamin D, and parathyroid hormone levels, but slightly elevated C-reactive protein (CRP), reflecting ongoing systemic inflammation.The patient's osteoporosis was likely due to a combination of chronic AD-related inflammation, corticosteroid use, and decreased physical activity. She was prescribed calcium and vitamin D supplements, advised to engage in weight-bearing exercises, and referred to an endocrinologist for further management. Her AD treatment plan was adjusted to reduce corticosteroid reliance and explore alternative therapies for better inflammation control [1-17]

THYROID DISEASE AND OSTEOPOROSIS

D. M. Albulescu[1], A. Boicea[2], N. M. Bugălă[3], G. Mitroi[4], G. G. Mitroi[5], M. R. Mitroi[6], S. A. Preda[7]

[1]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [5]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [7]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Objective: Hyperthyroidism can induce secondary osteoporosis. The mechanism of thyroxine osteoporosis involves the action of excess thyroid hormones on both osteoblasts and osteoclasts, stimulating their activity, but especially osteoclasts, resulting in the loss of bone mass. . Overt hyperthyroidism is defined as TSH and high triiodothyronine (T3) and/or free thyroxine (FT4), subclinical hyperthyroidism is defined as low TSH and normal T3 and FT4 concentrations. Untreated hyperthyroidism can cause cardiac arrhythmia, heart failure, osteoporosis, and adverse pregnancy outcomes. It can lead to weight loss, and is associated with increased mortality.

Methods: The study included 74 patients: 36 with thyroxine osteoporosis, age–39-61 years, 38 with postmenopausal osteoporosis in euthyroidism, age between 46-70 years. Clinical (anamnesis and objective examination) and paraclinical criteria were used to establish the etiological diagnosis. The research on bone metabolism was carried out by studying biochemical markers of bone turnover: markers of bone formation (osteocalcin, serum alkaline phosphatase), markers of bone resorption, terminal C telopeptides of type I procollagen (CrossLaps), and calciuria. Hormonological investigations revealed thyroxine osteoporosis: TSH, FT3, FT4, TRAb, LH, FSH, PRL, Estradiol, and progesterone. Postmenopausal osteoporosis cases: LH, FSH, Estradiol, progesterone, TSH, and FT4. Evaluation of bone mineral density by dual X-ray absorptiometry (DEXA) in patients with thyroxine osteoporosis induced by different clinical forms (Graves Basedow disease, autonomous thyroid nodule, multi-hetero-nodular-toxic goiter) of thyrotoxicosis, as well as in those with postmenopausal osteoporosis.

Results: Osteocalcin values for patients with thyroxine osteoporosis were 27.92 ± 19.47 ng/ml (an increase of approximately 60% compared to normal values premenopause). This shows a significant stimulation of bone formation by the excess thyroid hormones. For patients with postmenopausal osteoporosis the values were 17.29 ± 9.12ng/ml (close to the normal postmenopausal values 18.4±9.5ng/ml). Variations were correlated with the number of years since the onset of menopause. Postmenopause, following estrogen deficiency, bone remodeling increases in postmenopausal women to 0.506 ± 0.255ng/ml. The CrossLaps values determined in patients with thyroxine osteoporosis were between 0.304 ± 0.887 ng/ml (approximately 80% higher than the normal premenopausal values). For patients with postmenopausal osteoporosis, the values were 0.277 ± 0.842 ng/ml (close to the normal postmenopausal value of 0.251±0.761ng/ml)[1-17].

Conclusions: Analyzing the results obtained for subjects with thyroxine osteoporosis, it was observed that excess thyroid hormones induced an acceleration of both osteoformation and bone resorption, with a positive effect on bone resorption. Evaluation of the results of different therapeutic approaches: synthetic antithyroid drugs, radiotherapy, surgical treatment in combination with antiosteoporotic medication on bone mineral density.

THYROTOXICOSIS AND OSTEOPOROSIS

D. M. Albulescu[1], A. Boicea[2], N. M. Bugălă[3], G. Mitroi[4], G. G. Mitroi[5], M. R. Mitroi[6], S. A. Preda[7]

[1]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [5]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [7]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Thyrotoxicosis represents a complex of clinical manifestations induced by the presence of excess thyroid hormones at the tissue and receptor levels. This condition is considered a cause of endocrine osteoporosis. In thyrotoxicosis, both trabecular and cortical bone are affected, and the mechanism seems to be induced by increased resorption by accelerating local turnover

Objective: To identify cases of thyrotoxicosis and evaluate thyroid hormone status and bone mineral density.

Methods: 56 cases with thyrotoxicosis were included in the study: Graves-Basedow disease (22), toxic multi-nodular goiter (20), and toxic plummer adenoma (16), aged–22-64 years. In all cases, TSH, T4, FT4, T3, FT3, ATPO, and ATG levels were studied. Thyroid ultrasound was performed to highlight the dimensions of the gland, homogeneous/inhomogeneous appearance, presence of nodules, and type of vascularization. Exophthalmometry, EKG, EMG as well as bone mineral density by dual X-ray absorptiometry (DEXA) were also performed

Results: Osteodensitometry revealed osteoporosis in all cases with Graves-Basedow disease, toxic plummer adenoma, and in 5 of the cases with toxic multi-nodular goiter (83.9% of the cases studied).

Conclusions: Hormonological, immunological, and osteodensitometric evaluations are required in all cases of thyrotoxicosis. The institution of therapy with synthetic antithyroid drugs, beta-blockers, and immunosuppressants in combination with antiresorptive medication contributes to increasing bone mass and reducing fragility fractures. Thyrotoxicosis affects both trabecular and cortical bone, and the mechanism appears to be related to increased resorption by accelerating local turnover[1-17]

BONE ENDOCRINE ORGAN

D. M. Albulescu[1], A. Boicea[2], N. M. Bugălă[3], G. Mitroi[4], G. G. Mitroi[5], M. R. Mitroi[6], S. A. Preda[7]

[1]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [5]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [7]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Osteoporosis is a systemic, multifactorial, silent, and endemic skeletal disease characterized by decreased bone mass, damage to the microarchitecture of the bone tissue, increased bone fragility, and increased fracture risk. The bone is the beneficiary of the greatest informational and operational game, ensured first by the balance of the osteoforming hormonal mixture and then by other factors such as nutritional and mechanical factors. Recent research has revealed the multifaceted role of bone not only in structure but also as a complex endocrine organ that produces hormones responsible for the self-regulation of bone metabolism. Circulating osteocalcin increases insulin secretion, lowers blood glucose levels, and decreases visceral adipose tissue levels. Various cytokines, hormones, and growth factors can modu-

late osteocalcin production by modulating signaling pathways or by interacting with transcription factors acting on the promoter region of the osteocalcin gene (BGLAP gene on chromosome 1q25–q31). Osteocalcin has been reported to function as a hormone that regulates glucose metabolism, testosterone synthesis, muscle mass, brain development and function, and parasympathetic tone In men, it has also been shown to improve testosterone production by the testicles. Neuropeptide Y is produced by various cell types, including osteocytes and osteoblasts, and there is evidence to suggest that peripheral NPY is important for the regulation of bone formation. Hormonal disturbances are often associated with abnormal levels of bone turnover markers. These include commonly used bone formation markers (bone alkaline phosphatase, osteocalcin, and procollagen I N-propeptide) and resorption markers (serum collagen type I telopeptides, urinary collagen type I N-telopeptides, and tartrate-resistant acid phosphatase type 5b). However, bone is not exclusively composed of bone tissue. Bone marrow adipose tissue, an endocrine organ often compared to visceral adipose tissue, is found between trabeculae of the bone cortex. It secretes a diverse range of hormones, especially lipids, cytokines, and other factors, that exert various local and systemic effects[1-17].

Conclusions: The bone plays an important role in endocrine metabolism. Further research is needed to determine the exact relationship between bones, secreted hormones, and other endocrine organs. Determining their exact effects may be of great importance for the diagnosis and treatment of osteoporosis and obesity.

BONES AND HORMONES

D. M. Albulescu[1], N. M. Bugălă[2], A. Boicea[3], G. Mitroi[4], G. G. Mitroi[5], M. R. Mitroi[6], S. A. Preda[7]

[1]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [5]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [7]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Far from being an inert envelope surrounding the bone marrow, thus protecting hematopoiesis and the development of the immune system, bone is a complex organ that constantly changes under the control of hormones, cytokines, and the central and sympathetic nervous systems, and functions as an endocrine organ. As in other complex organs, bone function is controlled by a range of specialized cell types, which are on the bone surface or within the mineralized matrix. Research advances over the past decade have shed light on the various hormones that influence this process and modulate bone metabolism and structural integrity. More recently, novel and non-traditional functions of hypothalamic, pituitary, and adipose hormones and their effects on bone homeostasis have been proposed. This review highlights the recent work on physiological bone remodeling and discusses our current knowledge of the systemic interplay of factors that regulate this interplay. In this review, we provid a summary of literature on the relationship between bone physiology and hormones, including kisspeptin, neuropeptide Y, follicle-stimulating hormone (FSH), prolactin (PRL), adrenocorticotropic hormone (ACTH), and thyroid-stimulating hormone (TSH).), growth hormone (GH), leptin, and adiponectin levels. Discovering and understanding this new functionality will reveal a new layer of physiological circuitry [1-17].

Conclusions Thus, we hypothesize that there is a pituitary-bone and pituitary-fat axis that, when disrupted, causes diseases such as obesity and osteoporosis, which could potentially be used to target new therapies for these conditions

THE INTERACTION BETWEEN NPY AND SEX HORMONES IN THE CONTROL OF BONE HOMEOSTASIS

D. M. Albulescu[1], N. M. Bugălă[2], A. Boicea[3], G. Mitroi[4], G. G. Mitroi[5], M. R. Mitroi[6], S. A. Preda[7]

[1]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [5]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [7]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Sex hormones play a fundamental role in the maintenance of bone mass and etiology of osteoporosis. The expression of estrogen and androgen receptors on bone cells and the response of bone cells to sex steroid treatment in vitro highlights the importance of the direct action of these hormones on bone homeostasis. However, indirect evidence of action is much less appreciated, suggesting that estrogen signaling in the brain contributes to skeletal regulation. The NPY family of peptides and receptors influence numerous homeostatic processes and represent a complex and extensive regulatory apparatus. Its actions in bone to modulate osteoblast activity, and potentially osteoclastic activity, appear to be consistent and potent, with changes in both the central and peripheral aspects of this regulatory network [1-17].

Conclusion: Obviously, currently, interactions between the skeleton and energy homeostasis have was defined, thus providing a correlation between the body weight and bone mass. However, ongoing studies suggest additional interactions involving endocrine pathways, glucose homeostasis, and local actions in the bone, such as mechanical loading. Excitingly, the constant development of pharmacological agents and analytical tools points to continued analysis of NPY biology and new opportunities for biological and therapeutic understanding.

Objectives: Osteoporosis is the most common metabolic bone disease and is characterized by reduced bone mineral density (BMD). Osteoporosis can be defined as silent suffering due to a lack of symptoms and increase in the number of cases. Osteoporosis occurs mainly in elderly people, where the main complication is the occurrence of fractures, especially balance bills. This study aimed to evaluate bone mineral density in a group of both female and male patients to determine the incidence of osteoporosis caused by tobacco use [1-17].

Methods: A total of 140 patients (45 female and 95 male) aged 35–78 years were included in this study. Osteoporosis was diagnosed based on the assessment of bone mineral density (BMD) measured by X-ray absorptiometry X with double energy, osteocalcin, and beta cross-laps.

Results: From all the cases studied, approximately 60% of the patients (F 28% and M 32%) presented a T-score value between -2.5 SD and -5.5 SD, and 15% (F 7% and M 8%) presented a T score value between -1 SD and -2 SD; beta crosslaps with the values in the female sex <1ng/ml and in the male sex < 0.65ng/ml; osteocalcin in the female sex between 10-35 ng/ml, and for males between 11-40 ng/ml. The serum nicotine level in female smokers (123 + 25.6 µmol/L) was higher than that in male smokers (98 ± 33.8 µmol/L).

Conclusions: Osteoporosis is more common in females, but its incidence in males is observed to be slightly increasing. Smoking is a known risk factor for osteoporosis.

P1075

IS THERE A HIGHER PREVALENCE OF OSTEOPOROSIS IN PATIENTS WITH BENIGN PAROXYSMAL POSITIONAL VERTIGO?

S. A. Preda[1], N. M. Bugălă[2], D. M. Albulescu[3], A. Camen[1]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania

Objectives: Benign paroxysmal positional vertigo (BPPV) is a prevalent vestibular disorder, particularly in older adults, and is characterized by episodes of vertigo. This study aims to investigate the potential association between BPPV and osteoporosis [1-11].

Material and Methods: The study included 15 patients diagnosed with BPPV, aged between 55 and 75 years. Comorbidities were analyzed: 10 patients were diagnosed with osteoporosis (66.6%), 4 (26.6%) with chronic urinary infections, and 6 (40%) with associated ENT pathology.

Results: Data from this study align with existing literature. Pooled analysis of the literature revealed a significantly higher risk of osteoporosis in the BPPV group compared to controls (odds ratio [OR], 1.73). The findings suggest that patients with BPPV have a higher prevalence of osteoporosis than those without.

Conclusions: The study highlights a potential link between BPPV and osteoporosis, suggesting the need for further research to understand the mechanisms underlying this association and its clinical implications.

DEPOT-STEROID INJECTIONS FOR ALLERGIC RHINOSINUSITIS INCREASE THE RISK OF OSTEOPOROSIS?

S. A. Preda[1], D. M. Albulescu[2], N. M. Bugălă[3], A. Boicea[4]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania

Objectives: This study aims to investigate whether depot-steroid treatment for allergic rhinosinusitis increases the risk of steroid-related diseases, including osteoporosis [1-11].

Material and Methods: The study included 124 patients diagnosed with allergic rhinosinusitis between 2018 and 2022. All participants received depot-steroid injections over varying time intervals: 37 patients (29.8%) for 5 years, 24 (19.3%) for 4 years, 21 (16.9%) for 3 years, 22 (17.7%) for 2 years, and 20 (16.3%) for 1 year. Steroid use was defined as receiving at least one injection between April and July. The study examined the relative risk of adverse outcomes such as osteoporosis, infections, diabetes, and tendon ruptures.

Results: No significant differences were observed in the incidence of infections or osteoporosis across the treatment groups.

Conclusions: Depot-steroid injections for allergic rhinosinusitis do not appear to significantly increase the risk of osteoporosis or infections. However, further studies with larger sample sizes are warranted to confirm these findings.

INFLAMMATION AS A MEDIATOR OF THE ASSOCIATION BETWEEN OSTEOPOROSIS AND HEARING LOSS IN OLDER SUBJECTS: A POPULATION-BASED STUDY

S. A. Preda[1], D. M. Albulescu[2], N. M. Bugălă[3], A. Boicea[4]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania, [3]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania

Objectives: With aging populations, the prevalence of hearing loss and osteoporosis is rising. Previous studies have suggested a link between these conditions, but the underlying pathophysiological pathway remains unclear. This study aimed to evaluate the potential association between hearing loss and osteoporosis in an older population and to assess whether this relationship varies with inflammatory status [1-11].
Material and Methods: We examined the association between osteoporosis and self-reported hearing loss in 110 subjects aged 75 and older, with no exclusion criteria. Bone density was measured using calcaneal quantitative ultrasound, and osteoporosis was defined as a T-score ≤ -2.5 standard deviations. Inflammatory status was assessed using high-sensitivity C-reactive protein (hs-CRP) levels.
Results: Hearing loss was found to be associated with osteoporosis (67%). This association was significantly influenced by hs-CRP levels ($p = 0.015$), indicating a role for inflammation. No significant variation was observed with sex ($p = 0.982$).
Conclusions: In elderly individuals, hearing loss is associated with osteoporosis, and this relationship appears to be mediated by higher levels of inflammation. These findings highlight the need for further research into inflammatory pathways as potential targets for intervention.

RELATIONSHIP BETWEEN OSTEOPOROSIS AND OSTEOPENIA AND HEARING IMPAIRMENT IN POSTMENOPAUSAL WOMEN

S. A. Preda[1], N. M. Bugălă[2], D. M. Albulescu[3], A. Camen[1]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania

Objectives: Osteoporosis and osteopenia are progressive conditions marked by reduced bone density, particularly in postmenopausal women. This study aims to assess auditory function in postmenopausal women diagnosed with osteopenia or osteoporosis [1-11].
Material and Methods: The study involved 38 postmenopausal women aged 50–70 years with urological disease. Participants included 11 women newly diagnosed with osteoporosis, 15 with osteopenia, and 13 healthy controls. Audiological assessments comprised pure-tone audiometry (both conventional and extended high-frequency), speech audiometry, and impedance audiometry.
Results: Hearing thresholds were poorer across all frequencies in the osteoporosis group compared to both the osteopenia and control groups. Additionally, speech recognition and discrimination scores were significantly lower in the osteoporosis group.
Conclusions: Osteoporosis and osteopenia are significant risk factors for hearing and vestibular dysfunction in postmenopausal women. Regular monitoring of auditory and vestibular function through audiological assessments is recommended for these individuals.

P1079

ASSOCIATION BETWEEN CHRONIC INFLAMMATORY SKIN DISEASES AND OSTEOPOROSIS: THE ROLE OF SYSTEMIC INFLAMMATION

S. A. Preda[1], N. M. Bugălă[2], D. M. Albulescu[3]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania

Objectives: Chronic inflammatory skin diseases, such as psoriasis and atopic dermatitis, have systemic inflammatory components that may contribute to the development of comorbid conditions, including osteoporosis. This study aimed to investigate the relationship between chronic inflammatory skin diseases and bone health, focusing on the potential mediating role of systemic inflammation [1-11].
Material and Methods: A total of 85 patients with chronic inflammatory skin diseases (45 with psoriasis and 40 with atopic dermatitis) and 40 age- and sex-matched controls were included in the study. Bone mineral density (BMD) was assessed using dual-energy X-ray absorptiometry (DEXA) at the lumbar spine and femoral neck. Systemic inflammation was evaluated by measuring serum levels of C-reactive protein (CRP) and interleukin-6 (IL-6). Patients with secondary causes of bone loss were excluded.
Results: Patients with chronic inflammatory skin diseases had significantly lower BMD at the lumbar spine (T-score: -2.3 ± 0.4) and femoral neck (T-score: -2.1 ± 0.3) compared to controls (T-score: -1.0 ± 0.3 and -0.9 ± 0.2, respectively, $p < 0.01$). Elevated CRP and IL-6 levels were observed in patients with skin diseases and were inversely correlated with BMD ($r = -0.45$, $p = 0.002$). Psoriasis patients with severe disease (Psoriasis Area Severity Index > 10) exhibited the highest prevalence of osteoporosis (35%), followed by those with atopic dermatitis (25%).
Conclusions: This study identifies a significant association between chronic inflammatory skin diseases and reduced bone density, highlighting systemic inflammation as a potential mediator. Dermatological patients with chronic inflammatory conditions should be screened for osteoporosis, and anti-inflammatory treatment strategies may reduce the risk of bone loss.

VITAMIN D DEFICIENCY IN PATIENTS WITH CHRONIC SKIN DISEASES: A RISK FACTOR FOR OSTEOPOROSIS

S. A. Preda[1], N. M. Bugălă[2], D. M. Albulescu[3]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Anatomy, Craiova, Romania

Objectives: Vitamin D deficiency, commonly observed in patients with chronic skin diseases such as vitiligo, eczema, and psoriasis, may contribute to the development of osteoporosis. This study aimed to evaluate the prevalence of vitamin D deficiency in dermatological patients and its potential impact on bone health [1-11].
Material and Methods: A cross-sectional study was conducted with 120 patients diagnosed with chronic skin diseases (40 with psoriasis, 40 with vitiligo, and 40 with eczema) and 50 healthy controls. Serum 25-hydroxyvitamin D [25(OH)D] levels were measured, and bone mineral density (BMD) was assessed using dual-energy X-ray absorptiometry (DEXA) at the lumbar spine and femoral neck. A 25(OH)D level <20 ng/mL was classified as de-

ficient.
Results: Vitamin D deficiency was significantly more prevalent in patients with chronic skin diseases (72%) compared to controls (36%, $p < 0.001$). Patients with vitamin D deficiency exhibited lower BMD at the lumbar spine (T-score: -2.2 ± 0.5) and femoral neck (T-score: -2.0 ± 0.4) compared to those with sufficient levels (T-score: -1.2 ± 0.3 and -1.0 ± 0.2, respectively, $p < 0.01$). Among dermatological conditions, patients with psoriasis showed the highest prevalence of osteoporosis (30%), followed by those with eczema (25%) and vitiligo (20%).
Conclusions: Vitamin D deficiency is highly prevalent in patients with chronic skin diseases and is associated with a greater risk of osteoporosis. Screening for vitamin D deficiency and bone health in dermatological patients is recommended, alongside supplementation strategies to reduce the risk of bone-related complications.

TREATMENT OF IBANDRONIC ACID ASSOCIATED WITH K2 VITAMINE IN OSTEOPOROSIS FROM DELAYED PUBERTY

G. G. Mitroi[1], G. Mitroi[2], M. R. Mitroi[3], N. M. Bugălă[4], A. Camen[5]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [4]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [5]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Discovering frequently feminine cases with delayed puberty (hypogonadotrop or hypergonadotrop hypogonadism), is motivating the therapeutically broaching of hypogonadism osteoporosis that is installed more precocious compared with menopause [1-7].
OBJECTIVES: Gonadal insufficiency diagnosis and its etiology , the DMO evaluation, initiating differentiated therapeutically measures by rapport with the evolutive stage of bone mass deficit (osteoporosis /osteopenie) and with hypogonadism etiology .
MATERIAL AND METHODS:Were included in the study 22 cases with delayed feminine puberty with ages 16 to 23.At all cases DMO was evaluated by dual absorbtiometry with X rays (DEXA). The therapeutically options were aiming to non-pharmacological undertake:a diet with a positive level of Calcium and D vitamin, modifying the life style and easy physical exercises.Pharmacological therapy was applied at cases with osteoporosis which administrated antiresorptive agent-ibandronic acid in 150 mg doses at 30 days) in association with 45 mg K2 vitamine(MK7 or MENACHINONA-7)/day.
Results: Osteoporosis was confirmed at 9 cases.The efficiency of the treatment with ibandronic acid in association with K_2 vitamine,after 12 months of therapy, was superior then the separately bisfosfonates therapy.It was remarked an increase of DMO with 4,7 % at lumbar spine level and with 3,5% at femoral cervix level compared to 4.3% and 2.3% reported for ibandronic acid.
Conclusions: The study is confirming the efficiency association of ibandronic acid with K2 vitamine in delayed feminine puberty.
K_2 vitamine-latest discovery in terms of vitamins, is the most bio-available and bio-active form,which increases the efficiency of biofosfati treatment.

STUDY OF BIOCHEMICAL MARKERS OF BONE TURNOVER AND BONE MINERAL DENSITY IN TURNER SYNDROME

G. G. Mitroi[1], G. Mitroi[2], M. R. Mitroi[3], N. M. Bugălă[4], A. Camen[5], A. Boicea[6]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [4]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [5]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [6]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania

All formation errors of embryonic gonad were grouped under the name of gonadal dysgenesis. In the etiology of gonadal dysgenesis, the role of sexual chromosomes is well established because is conditioning the development of the gonad and implicit of enzymatic battery which is ensuring a biosynthesis of sexual hormones. Alteration of gonadogenesis process (the morphological dysgenesis) has multiples implications: perturbation of hormonal biosynthesis process, alteration of structure reactivity on gonadic hormones and , under clinical aspect, the perturbing of sexualisation process. The exclusion from the organism economy of sexual hormones is seriously influencing the bone structure, being the principal cause of osteoporosis [1-7].
OBJECTIVES : Identification of cases with Turner syndrome with feminine phenotype, hormonal evaluation on gonadotrope axis and the study of bone mineral density and biochemical markers of bone turnover.
MATERIAL AND METHODS: The study were performed on 15 cases with Turner syndrome with ages between 12-19 years.In the same time with karyotype study of ovarian(estradiol,progesterone) and gonadotropic hormones(LH,FSH) were evaluated the biochemical markers of bone turnover (serum Osteocalcin and Cross Laps) and bone mineral density were appreciated by dual absorbtiometry with X rays (DEXA).
RESULTS: It was highlighted osteoporosis on 8 cases, osteopenie at 4 cases(SCOR T=-2.5DS) , and for the remnants patients (3) biochemical markers and mineral bone density were in normal limits.
CONCLUSIONS: 1The study of biochemical markers of bone turnover and mineral bone density is mandatory for all cases with Turner syndrome cytogenetic confirmed.
The precocious diagnosis of osteoporosis/osteopenie , is claiming the estro-progestative hormonal substitution which represent the therapeutically attitude from the main intention.
Hormonal substitution associated with therapeutically means specific to bone remineralisation is preventing the apparition of fragility fractures.

EVALUATION OF BIOCHEMICHAL MARKERS OF BONE TURNOVER IN PREMATURE OVARIAN INSUFFICIENCY

G. G. Mitroi[1], G. Mitroi[2], M. R. Mitroi[3], N. M. Bugălă[4], A. Boicea[5]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [4]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [5]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania

In premature ovarian insufficiency or the syndrome of pauper ovaries, the follicular dower is much reduced and as a result is the deficiency of ovarian hormonopoiesis. As the number of follicles is lower the ovary`s life span is reduced, making the clinical spectrum to be characterized through the absence of puberty sexuality total or partial until the precocious installation of climacterium [1-7].
OBJECTIVES: The identification of ovarian failure secondary amenorrhea cases caused by premature ovarian insufficiency.Is demonstrated that the perturbation of hormonal secretion which controls the bone homeostasis, ratio bone formation-resorption is damaged and thus, bone mass decreases and causes osteoporosis.
MATERIAL AND METHODS: The study was performed on 78 patients whose ages ranged from 18-47 years.Hormonal investigations focused on the study of FSH, LH, PRL, estradiol, progesterone and also on the biochemical markers of bone turnover (osteocalcin and Cross Laps). Bone mineral density (BMD) was measured by absorbtiometry dual with X ray (DEXA).
RESULTS: Hormonal doses showed low levels of estradiol and progesterone, instead of gonadotropic that hormones were above the normal upper limit between 210-390 mUI/ml. There were also showed low levels for biochemical markers of bone turnover at half of the studied cases.BMD measurements revealed the presence of osteoporosis at 37cases - which represents 47.4% and 7 cases with osteopenie.BMD values correlate with biochemical markers of bone turnover.
CONCLUSIONS: 1.Evaluation of BMD and biochemical markers of bone turnover in premature ovarian failure must be done regularly after amenorrhea appearance, to identify patients who rapidly lose bone mass and are at increased risk of osteoporosis/osteopenia 2. Estrogen-progesterone substitution is the main and first treatment in premature ovarian failure to prevent osteoporosis/

osteopenia, metabolic and visceral complications. 3. Patients with osteoporosis will receive antiresorptive agents or proformative medication to prevent fragility fractures.

THE STUDY OF DENTAL MODIFICATIONS IN CHRONICLE TETANY -RELATION WITH OSTEOPOROSIS

G. G. Mitroi[1], G. Mitroi[2], M. R. Mitroi[3], A. Boicea[4], N. M. Bugălă[5]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania, [5]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania

OBJECTIVES: Chronic tetany is individualized as clinical form of tetany through intense trophic disorders occurring as a result of tetany subtle over time worsening , with or without symptoms of acute tetany. Chronic tetany presents subtle tetany symptoms that can occur amid bouts of muscle stiffness, but the trophic disorders of tetany subtle, barely sketched, become, by their multiplicity and intensity, the dominant clinical picture [1-7].

MATERIAL AND METHODS: The study was performed on 34 patients (18 men and 16 women) whose ages ranged from 19-42 years.Paraclinical investigations focused on the study: phospho-calcium metabolism (total blood calcium, calcium ion, urinary calcium, phosphorus blood, blood magnesium) electrophysiological investigations (EMG, EEK, EKG), evaluation of circulating PTH in selected cases, ultrasound and parathyroid CT,radiological exploration of long bones.

RESULTS: Through enamel and dentin alterations show up many signs of dystrophy dental, teeth are losing their luster and become mat or coated,sometimes dirty yellow,with gray or black ribbed. Their strength is diminished, abrasion surfaces eroding overmuch. Appear numerous cavities side .The side edges of the tooth erode,the tooth taking aspect of a nail or screw appearance. Finally the whole dental crown disappears .In some cases - 3-highlighted parathyroid hyperplasia.Imagistical explorer of long bones could highlight in 3 cases with parathyroid hyperplasia and fibrocystic bone lesions.

CONCLUSIONS: 1 Chronical tetany is the most common clinical form of primary hypoparathyroidism (surgical, drastically, infiltrative, idiopathic autoimmune-)

2. Treatment targets aimed eliminating the causes and correcting hypocalcemia

THE STUDY OF OSTEOPOROSIS INCIDENCE IN THE SYNDROME OF PAUPER OVARIES

G. G. Mitroi[1], M. R. Mitroi[2], G. Mitroi[3], N. M. Bugălă[4], A. Boicea[5]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [4]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [5]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania

At patients with premature ovarian insufficiency or the syndrome of pauper ovaries, the follicular dower is much reduced and as a result is the deficiency of ovarian hormonopoiesis. As the number of follicles is lower the ovary`s life span is reduced, making the clinical spectrum to be characterized through the absence of puberty sexuality total or partial until the precocious installation of climacterium [1-7].

OBJECTIVES: The identification of ovarian failure secondary amenorrhea cases caused by premature ovarian insufficiency. During the perturbation of hormonal secretion which controls the bone homeostasis, ratio bone formation-resorption is damaged and thus, bone mass decreases and causes osteoporosis.

MATERIAL AND METHODS: The study was performed on 64 patients whose ages ranged from 19-43 years.Hormonal investigations focused on the study of FSH, LH, PRL, estradiol, progesterone.The patients underwent utero-ovarian pelvic sonography. Bone mineral density (BMD) was measured by absorbtiometry dual with X ray (BMD) at the spine, pelvis and radius. The biochemical markers of bone turnover studied were serum osteocalcin and Cross Laps by ELISA.

RESULTS: Hormonal doses showed low levels of estradiol and progesterone, instead of gonadotropic that hormones were above the normal upper limit between 210-390 mUI/ml. BMD measurements revealed the presence of osteoporosis at 29 cases - which represents 45.31% of all cases investigated.BMD values correlate with biochemical markers of bone turnover.

CONCLUSIONS: .Evaluation of BMD and biochemical markers of bone turnover in premature ovarian failure must be done regularly to identify patients who rapidly lose bone mass and are at increased risk of osteoporosis.Estrogen-progesterone substitution is the main and first treatment in premature ovarian failure to prevent osteoporosis/osteopenia, metabolic and visceral complications. Patients with osteoporosis will receive antiresorptive agents or proformative medication to prevent fragility fractures.

TREATMENT OF IBANDRONIC ACID ASSOCIATED WITH MENAQUINONE-7 IN HYPOGONADIC OSTEOPOROSIS

G. G. Mitroi[1], N. M. Bugălă[2], M. R. Mitroi[3], G. Mitroi[4], A. Boicea[5]

[1]University of Medicine and Pharmacy Craiova , Department of Dermatology Clinic, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy, Department of Otorhinolaryngology, Craiova, Romania, [4]University of Medicine and Pharmacy, Department of Urology, Craiova, Romania, [5]University of Medicine and Pharmacy, Department of Medicine and Professional Diseases, Craiova, Romania

Discovering frequently cases with hypogonadism (feminine or masculine), is motivating the therapeutically broaching of hypogonadism osteoporosis that is installed more precocious in comparing with the menopause-one[1-7].

Objectives: Gonadal insufficiency diagnosis and its etiology , the DMO evaluation, adopting differentiated therapeutically measures in rapport with the evolutive stage of bone mass deficit (osteoporosis /osteopenie) and with hypogonadism etiology .

MATERIAL AND METHODS: In the study we included 67 cases with hypogonadotroph and hypergonadotroph hypogonadism with ages 12 to 37.At all cases DMO was evaluated by dual absorbtiometry with X rays (DEXA).The therapeutically options were aiming to: non-pharmacological undertake (a diet with a positive level of Calcium and D vitamin, modifying the life style and easy physical exercises).Pharmacological therapy was applied in all cases with osteoporosis that received antiresorptive agent-ibandronic acid in 150 mg doses at 30 days) in association with 45 mg vitamine K2 (MK7 or MENACHINONA-7)/day.

Results: Osteoporosis was confirmed at 39 cases.The efficiency of the treatment with ibandronic acid in association with K_2 vitamine,after 12 months of therapy, was superior then the separately bisfosfonates therapy.It was observed an increase of DMO with

4,4 % at lumbar spine level and with 2,6% at femoral cervix level compared to 4.2% and 2.1% reported for ibandronic acid.

Conclusions: The study is confirming the efficiency of association between ibandronic acid and menachinona 7 in hypogonadism osteoporosis.

MK7(K_2 vitamine)-latest discovery in terms of vitamins, is the most bio-available and bio-active form,which increases the efficiency of biophosphonates therapy.

THE INFLUENCE OF HYPERSECRETION OF STH IN THE GROWTH AND DEVELOPMENT OF THE DENTO-MAXILLARY APPARATUS

M. I. Gheorghiu[1], N. M. Bugălă[2], C. C. Nistor[1], R. I. Marinescu[3]

[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Secretory disorders of the endocrine glands have a significant impact on the development and functioning of the dentomaxillary apparatus because of the complex interactions between the endocrine system and the processes of craniofacial growth. The articles in the specialized literature reveal, in recent years, an increase in the prevalence of dentomaxillary anomalies class III Angle and implicitly those of class III/1 Angle (true mandibular pronation). Hypersecretion of STH causes juvenile acromegaly with repercussions for the growth and development of the dentomaxillary apparatus. Hypersecretion of the pituitary somatotropic hormone (STH) influences both endochondral and desmal growth. Thus, in the age period of 6-16 years, the hypersecretion of STH generates an exaggerated growth of the skeleton with the appearance of mandibular pronation associated with macroglossia, one as the most serious orthodontic condition. Early intervention and treatment that control STH levels are essential to limit these effects. In severe cases, a multidisciplinary approach (endocrinology, orthodontics, and maxillofacial surgery) is crucial.[1-10]

THE INFLUENCE OF STH HYPOSECRETION IN THE GROWTH AND DEVELOPMENT OF THE DENTO-MAXILLARY APPARATUS

R. I. Marinescu[1], N. M. Bugălă[2], C. C. Nistor[3], M. I. Gheorghiu[3]

[1]University of Medicine and Pharmacy of Craiova, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

The pituitary gland ensures hormonal balance in the body and influences metabolism and reproduction as well as the growth and development of the entire body. Hyposecretion of STH can negatively influence the development and functioning of the dentomaxillary apparatus. Thus, the hyposecretion of STH until the age of 6 years, at the level of the dentomaxillary apparatus, causes an insufficient development of the jaws with the appearance of dental inclusions and dentoalveolar incongruities with dental crowding. Between 6 and 16 years of age, the hyposecretion of STH causes, at the level of the dentomaxillary apparatus, the appearance of mandibular retrognathion, and insufficiently developed alveolar arches with the appearance of inclusions and dental malpositions. After the age of 16 years, hyposecretion of STH leads to demineralization in the alveolar arches associated with tooth loss.

Thus, orthodontic treatment for the correction of malocclusions must be associated with monitoring of STH secretion by endocrinologists. Interdisciplinary collaboration between endocrinologists, orthodontists, dentists, and psychologists is essential, offering the patient the best solutions for the general state of health and implicitly for the dentomaxillary apparatus[1-10]

ASPECTS OF EXPLOSIVE CARIES IN PATIENTS WITH OSTEOPOROSIS

M. I. Gheorghiu[1], N. M. Bugălă[2], R. I. Marinescu[3]

[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy of Craiova, Craiova, Romania

For the study, 36 patients diagnosed with osteoporosis were selected. Patients were examined and based on well-established clinical signs, both incipient carious lesions and explosive carious lesions were highlighted. Moreover, the study also allowed an association with diet, smoking, but also with a series of gastro-duodenal or endocrine diseases. Patients had varied treatment for osteoporosis, which influenced the presence and evolution of existing caries.

THE INFLUENCE OF SYSTEMIC DISEASES IN THE EVOLUTION OF ODONTO-PERIODONTAL DISEASES

M. Nicolescu[1], N. M. Bugălă[2], M. I. Gheorghiu[1], R. I. Marinescu[3], I. C. Petcu[3]

[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Examining the mouth cavity can reveal signs of underlying systemic disease and provide information about general health. Autoimmune, hematologic, endocrine, and neoplastic processes are among the systemic disorders that manifest orally. Changes in the salivary and parotid glands, tongue abnormalities, and mouth ulcers are all signs of autoimmune illness. Depending on the etiology, patients with hematologic diseases may present with glossitis or gingival bleeding. Depending on the underlying condition, oral alterations linked to endocrine disorder can vary. Metastatic lesions affecting the mouth cavity's soft and bone structures are examples of neoplastic alterations. Dental erosions that result in halitosis or mouth pain can be seen in patients with long-term conditions such eating disorders and gastroesophageal reflux. Dentists' comprehensive history-taking and physical examinations can help identify the underlying cause of oral alterations and enable doctors to intervene earlier[1-10].

THE ROLE OF VITAMINS AND FLUORIDES IN THE FORMATION AND EVOLUTION OF JAW BONES

I. C. Petcu[1], N. M. Bugălă[2], C. C. Nistor[3], M. Nicolescu[3], R. I. Marinescu[1]

[1]University of Medicine and Pharmacy of Craiova, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

For healthy dentition and oral tissues to grow, develop, maintain, and repair, the right nutrients must be available. Deficits in calcium, fluoride, protein, vitamins A, C, and D, folate, and other B complex vitamins are especially pertinent to dental practice. Scurvy, cleft palate, enamel hypoplasia, poor mineralization, caries, and other pathoses are all caused or exacerbated by a deficiency of these nutrients, which impact almost every structure in the oral cavity. Individuals with bad behaviors can also exhibit damage to their teeth; for instance, a diet high in sugars will encourage caries and demineralization. A bad diet can also lead to diabetes, which is linked to oral candidiasis and periodontitis.
The dentist can ask patients about their eating habits and offer advice to promote a healthy lifestyle if they are aware of these linkages [1-10].

NUTRITIONAL ASPECTS IN ROMANIAN ADOLESCENTS

I. C. Petcu[1], N. M. Bugălă[2], R. I. Marinescu[1]

[1]University of Medicine and Pharmacy of Craiova, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania

The transition to processed foods in Romanian diets has led to a rise in vitamin and mineral deficiencies in teenagers, which can affect growth and health and frequently show up as oral sores. In order to provide guidance and avoid long-term problems, this review study sought to investigate the relationship between nutritional inadequacies and teenage dental health. Because oral health and nutritional inadequacies are linked, integrated healthcare is necessary. Holistic approaches and early treatments can enhance results and lessen long-term consequences. Regular dental exams and thorough health education are crucial for both prevention and treatment, improving health in all populations [1-10].

VASCULAR CHANGES AT THE DENTAL PULP LEVEL IN DIABETES

I. T. Dascălu[1], N. M. Bugălă[2], I. C. Petcu[3], R. I. Marinescu[3]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Diabetes mellitus significantly raises the risk of myocardial infarction, stroke, and amputation—the conditions that cause the majority of morbidity and death. In the development or progression of diabetic macroangiopathy, raised high shear blood vis-

cosity with decreased erythrocyte deformability and elevated low shear blood viscosity with erythrocyte aggregation may be significant and perhaps treatable variables. Diabetes-related metabolic problems lead to vascular dysfunction and blood rheological alterations, which make this patient population more susceptible to atherosclerosis. Atherosclerosis is caused by vortices with oscillating shear stress and decreased shear stress. The development of atherosclerosis and the effects of plaque erosion or rupture in diabetes may be made worse by abnormalities in platelet function and elevated blood coagulability[1-10].

LONG-LASTING SYSTEMIC GLUCOCORTICOIDS THERAPY AND CHRONIC APICAL PERIODONTITIS

I. T. Dascălu[1], N. M. Bugălă[2], M. Nicolescu[3], I. C. Petcu[4]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [4]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Relying on higher life expectancy, especially in aged peoples is increasing the number of dental patients affected by systemic medical conditions. As the global prevalence of chronic apical periodontitis in humans is higher in subjects with systemic conditions (63% vs 52%) that explain why corticosteroids medication may rise the issue of their side effects in evolution of chronic apical lesions [1].

Glucocorticoids are steroid hormones used as analogues of endogenous cortisol commonly used as anti-inflammatory drugs. There are involved in the synthesis of macromolecules. Though the effect of glucocorticoids comes out between a couple of hours or days it should be stressed that their clinical efficiency was still proved after the descending of their plasma level.

The side effects of glucocorticoids, directly related of dose and treatment duration, rely on the inhibitory effect on the immune system, inflammatory response and induction of bone resorption. [2,3]

Acting as modifiers of genuine biological response of host, glucocorticoids endorse infection, osteopenia and osteoporosis. At the tissues level the chronic main adverse effect of glucocorticoids results in embarrassment of fibroblast proliferation and successive type I collagen synthesis and deposition, inhibition of blood capillaries formation, lowering the osteoblasts function in parallel with enhancing the osteoclasts number and activity.

These chronic deleterious outcomes of long lasting glucocorticoids treatment suggest worsen changes in evolution and treatment prognosis of already installed chronic apical periodontitis as the pulp necrosis and bone loss are accelerated. [4]

Accordingly, the use of an apical lesion model in Wistar rats proved that prednisone accelerated the dental pulp necrosis. Furthermore, prednisone treatment increased the rate of chronic apical lesion formation by accelerating the chronic inflammatory cell invasion dependent on pro-inflammatory cytokines. Both collagen type I and type III were also reduced by prednisone. In contrast, significantly increased the number of TNF-α and TRAP immunopositive cells in the apical area of the induced animal lesion model.

On the other hand unlike the typical oral microorganisms in the presence of periodontal pathogens the corticosteroid therapy proved to be an aggravating factor of chronic apical lesion[5,6]. Experimental orthodontic movement under long-lasting corticoid therapy in rats showed extended orthodontic movement surface and associated bone erosion

Stimulating the osteoblast and osteocyte apoptosis and subsequent bone loss glucocorticoids are also in charge with increasing the osteoclasts survival and activity. Moreover, by increasing the expression of RANKL (receptor activator of nuclear factor K ligand) glucocorticoids are also stimulating the pre-osteoclasts, driving to reducing number of bone matrix-forming cells and enhancing the ability of chronic apical lesion in local bone resorption [7-10].

P1096

CHRONIC APICAL PERIODONTITIS IN DIABETIC TYPE 2 PATIENTS

I. T. Dascălu[1], N. M. Bugălă[2], M. I. Gheorghiu[3], S. M. S. Petrescu[1]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Commonly the apical bone resorption associated to chronic apical periodontitis is the synergistic outcome of the inflammatory elicited bacterial LPS (lipopolysaccharide) and immune response of the host. Actually the bone loss is initiated following the RANKL (receptor activator of nuclear factor K ligand) expression in osteoblasts which bind to RANK (receptor activator of nuclear factor K) of osteoclasts. The bone resorption is modulated by OPG (osteoprotegerin) receptors competitor with RANK.[1]
However, for triggering the bone matrix resorption is mandatory the involvement of MMPs (metalloproteinases), such as MMP-9, in order to facilitate the osteoclasts adhesion to bone interface. Furthermore, other molecular signals sent to PTH (parathyroid gland hormone) and PTHrP (parathyroid hormone-related protein) activate the RANKL/RANK coupling to initiating the aimed bone resorption.
However in a study of chronic apical periodontitis in diabetic type 2 patients compared with normoglycaemic ones there were not found significant differences by analyzing the immunoexpression of biomarkers RANK, PTHrP and MMP-9 involved in the bone loss process. In addition it seems that the effective glycaemic control in diabetic patients was crucial in preventing an enhanced apical bone resorption.
Diabetic patients have a higher incidence of dental caries and chronic apical periodontitis than non-diabetics of similar ages. High glycohemoglobin HbA1c levels drive to increased incidence of chronic apical periodontitis asking endodontic treatment. [2,3]
The impaired PMN (polymorphonuclear leukocytes) in uncontrolled blood glucose level facilitates the extension of pulp inflammation. The symptomatic irreversible pulpitis seems to be significantly higher in diabetic patients younger than 40 years than in non-diabetic patients.
Whether some other endocrine diseases such as hyperparathyroidism may modify the response to pulp sensibility tests it was supposed that some similar clinical outcomes may also present the diabetic patients due to the different biochemical factors running in diabetic pulp tissue[4].
Actually no significant differences were related between diabetic and non-diabetic patients in responses to electric and cold pulp tests. However, it was observed that aging provoked a significant reduced response to cold tests in diabetics' maxillary premolars. It seems that the obliterating endarteritis and the limited collateral blood circulation in elderly as well as the degrading antioxidant systems are cooperating in that respect[5].
Irreversible pulpitis and chronic apical periodontitis either primary or post-treatment persistent commonly require root canal treatment. [6]. Though chronic apical periodontitis are strongly associated with type 2 diabetes there are still controversies regarding the occurrence of post-treatment apical lesions in diabetic patients.
A recent meta-analysis revealed a higher prevalence of post-treatment chronic apical periodontitis in type 2 diabetes patients especially in cases of previous apical lesions. Moreover, the pathologic condition leads to poorer resolution of apical located chronic lesion[7-10].

MELATONIN IS IMPROVING CHRONIC APICAL PERIODONTITIS RESOLUTION

I. T. Dascălu[1], N. M. Bugălă[2], C. C. Nistor[3], R. I. Marinescu[4]

[1]University of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania, [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, Craiova, Romania, [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [4]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Apical osteolytic lesion that characterizes the chronic apical periodontitis is an immune response to root canal infection relying on disturbed redox balance which triggers the local tissue damage. Reactive oxidative species (ROS) confined to the apical lesion progressively diffuse into blood stream negatively affecting systemic health.[1]
Melatonin is a hormone synthesized mostly in the pineal gland that improves the insulin sensitivity and exhibits anti-inflammatory effects. Regarding the chronic apical periodontitis, it was reported that melatonin reduces both the inflammation and local apical bone loss [2].
The large protective capacity of melatonin against free radicals is mirrored in increasing the activity of some antioxidant enzymes such as glutathione reductase, superoxide dismutase and glutathione peroxidase.
On the other hand, melatonin ameliorates insulin resistance by restoring the pathway of Akt phosphorylation. Accordingly it may

be hypothesized that melatonin should reverse some systemic disturbances related to plasma concentration of glucose and pro-inflammatory cytokines as well as insulin resistance.[3]
The well known pro-inflammatory cytokine TNF-α is upregulated in exudates harvested from root canals of teeth with chronic apical periodontitis and even in irreversible pulpitis that finally result in pulp necrosis.
However it was proved that fortunately melatonin ameliorates periodontal conditions by reducing the depth of periodontal pockets as well as the plasma concentration of TNF-α and IL-1β in both gingivitis and acute pulpitis.
Is noteworthy that chronic apical periodontitis supports insulin resistance, higher levels of pro-inflammatory cytokines such as TNF-α, IL-1β and IL-6 along with decrease of IL-10 and prejudices the transduction of insulin tissue signaling.
Accordingly melatonin is considered a potent antidiabetic agent as influences the insulin secretion and can be therapeutically used for the prevention of insulin resistance. [4]
The positive findings of melatonin improving effects in rat experimental model on insulin resistance induced by chronic apical periodontitis, plasma concentration of cytokines TNF-α, IL-1β and IL-10 suggests a translational survey to humans to mitigate the side effects of chronic apical periodontitis [5].
On the other hand, looking to the future, melatonin might be a promising adjuvant in regenerative endodontics due to its proved effects on biological and immunomodulatory properties of dental pulp stem cells [6-10].

HISTOLOGICAL STRUCTURE OF THE SHAFT OF TIBIA IN DIABETIC RATS AFTER REPEATED FRACTURE OF THE TIBIA

N. Mosyagina[1], D. Astrakhantsev[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia, Lugansk, Russia

Objective. Objective of the study is to investigate histological structure of the shaft of tibia in diabetic rats after repeated fracture of the tibia
Material and Methods. Female rats (n=72, m=155 g) were distributed into three groups. Group 1 comprised intact animals. Group 2 comprised non-diabetic animals with 2-mm openings in metadiaphyseal areas of the femur and the tibia as a model of fracture. Tibia surgery was performed after complete healing of femur fracture. Group 3 comprised animals with diabetes caused by adipogenic diet and surgeries identical to those of group 2. Observation terms were 7, 15, 30, and 60 days. On expiration of each term tibiae were collected and undamaged areas of tibiae shafts were prepared for histological study. Morphometry of HE stained cross-sections of the shafts included measurements of outer circumferential lamellae (OCL), osteonic layer (OL), and inner circumferential lamellae (ICL)
Results. In animals of the group 2 as compared to the group 1 OCL exhibited compensatory widening in all observation terms – by 5.12%, 5.04%, 4.61%, and 5.72% respectively. ICL also increased by the 7th, the 15th, and the 30th day – by 6.62%, 5.36%, and 6.59%. OL on the contrary narrowed in the period from the 7th to the 30th day by 5.20%, 7.83%, and 8.91% respectively. In the group 3, in comparison with the group 2 OCL narrowed in all observation terms by 7.61%, 7.46%, 6.32%, and 6.53%. ICL also exhibited narrowing in the same period – by 7.82%, 4.68%, 6.21% and 6.53%. OL narrowed as well – by 4.02%, 4.09%, 7.46, and 9.15%. Unlike those of group 2, these values testify for absence of recovery.
Conclusions. In non-diabetic animals repeated fracture resulted in deranged cortical bone remodeling accompanied by compensatory hypertrophy. In diabetes, all layers of the cortical bone exhibited narrowing throughout of the whole study, which testifies for severe derangement of bone remodeling without signs of restoration.

P1099

AGE-RELATED FEATURES OF THE HISTOLOGICAL STRUCTURE OF THE LOWER INCISOR IN WHITE RATS UNDER CONDITIONS OF CHRONIC RENAL FAILURE

A. Kiselev[1], V. Luzin[1], N. Mosyagina[1], G. Reshet'ko[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia, Lugansk, Russia

Objective: Chronic renal failure (CRF) is often the cause of osteodystrophy. Morphological state of the dental system in conditions of CRF has been studied fragmentarily. Morphogenesis of the lower incisor (LI) under these conditions hasn't been studied at all.
Material and Methods: 216 male rats of three age groups: infantile, mature and senile, which were divided into two groups. Group 1 – intact animals. Group 2 – rats with CRF. At the end of the experiment, the LI were isolated and histological sections were prepared.
Results: In the 2nd group from the 7th to the 90th day of the experiment, the width of the odontoblast layer was less than the values in the 1st group by 5.63%, 6.65%, 6.65% and 7.44%, the width of the predentin layer - by 4.47%, 5.17%, 6.61%, and 7.89%, the width of the dentin layer - by 4.57%, 6.07%, 8.74% and 9.04%, and the mesiodistal size of the LI - by 3.47%, 4.06%, 4.51%, and 5.46%. In

mature rats morphofunctional activity of the odontoblasts of the LI also decreased but from the 15th day. In juvenile rats, the width of the odontoblast layer from day 15 to day 90 was less than the values in 1st group by 4.29%, 5.64%, and 6.88%, and the width of the predentin layer, the width of the dentin layer and the mesiodistal size of the LI by days 30 and 90 were less by 4.45%, and 5.41%, by 3.66% and 6.95%, and by 4.43%, and 4.97%. In senile rats with CRF, the width of the predentin and dentin layers from the 7th to the 90th day lagged behind the values of 1st group by 5.00%, 5.60%, 6.34%, and 7.79% and by 4.36%, 6.74%, 6.41%, and 8.07%, the width of the odontoblast layer from the 15th to the 90th day - by 4.26%, 5.08%, and 6.54%, and the mesiodistal size of the LI by the 50th and 90th days - by 2.97% and 3.25%.
Conclusion: Experimental CRF in rats of different age groups is accompanied by suppression of dentinogenesis in the LI. These changes are observed earlier in infantile animals and senile rats and later in mature rats.

P1100

THE EFFECTS OF LOCAL AND SYSTEMIC CALCIUM SOURCES ON CHEMICAL CONTENT OF BONE REGENERATE IN DIABETIC RATS AFTER REPEATED FRACTURE

N. Mosyagina[1], A. Skriabina[2], D. Astrakhantsev[1], E. Skriabina[3]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia, Lugansk, Russia, [2]Lausanne University Hospital, Lausanne, Switzerland, [3]FSBEI HI ST. LUKA LSMU of MOH of Russia, Rivne, Ukraine

Objective: The study is aimed at analysis of chemical content of bone regenerate formed after administration of local and systemic calcium sources in diabetic rats with repeated fracture.
Material and Methods: The experiment involved 96 female rats (m=155 g). Animals were distributed into four groups. Group 1 - intact animals. Group 2 - rats with diabetes and 2-mm openings in metadiaphyseal areas of the femur and the tibia as a model of repeated fracture. Group 3 - diabetic animals with repeated fractures and OK-015 implants. Group 4 - rats identical to those of group 3 treated with Calcemine Advance. Observation terms were 7, 15, 30, and 60 days. The content of the mineral component, organic substances and water was determined by the percentage-spring method.
Results. In group 2 compared with group 1, an imbalance of the main fractions of bone tissue was observed. In group 3 compared with group 2, water share decreased by 7 by 11.12% followed by an increase on 30 and 60 days by 17.09% and 15.59%. The organic matter share decreased from the 7th to the 60th day by 12.44%, 23.01%, 13.40% and 4.63%, which may indicate a temporary restoration of the chemical composition. The minerals share increased on the days 7 and 15 by 18.13% and 23.57%, and decreased later on the days 30 and 60 by 5.31% and 9.21%. In group 4, compared with group 3, a share of water decreased on the days 30 and 60 by 11.67% and 9.82%. The share of organic matter increased only on the 7th day by 4.83%, and minerals share decreased on the 15th day by 3.58% and increased on the days 30 and 60 by 10.45% and 8.69% respectively.
Conclusions. In case of repeated fracture in Type 2 diabetes, instability of the chemical composition of the regenerate is observed. Implantation of OK-015 results in temporary restoration of the balance of main bone fractions. Combined Calcemin Advance and OK-015 action leads to restoration of the chemical composition in later terms, which is the most optimal result.

P1101

MEASURING BONE DENSITY BY CALCANEAL QUANTITATIVE ULTRASOUND BASED-STRATEGY (QUS)

N. Muratovic[1], M. Muftic[2], F. Muftic[2]

[1]Eurofarm Policlinic, Sarajevo, Bosnia & Herzegovina, [2]"MHS" Private Practice for Physical Therapy and Rehabilitation, Sarajevo, Bosnia & Herzegovina

Objectives
When assessing the risk of osteoporotic fractures, quantitative ultrasonography (QUS) is an alternative to dual-energy x-ray absorptiometry (DXA scan) for bone mineral density (BMD) measurement. QUS is not recommended for decision-making regarding the start of treatment or follow- up of osteoporosis. Bone density can be studied non-invasively using QUS. The benefits of this technique are affordable and portable instruments, the patient is not exposed to radiation, and it is safe. The study evaluated the spectrum of age and gender structure, clinical entity (healthy population, osteopenia, osteoporosis), body mass index (BMI), and comorbidity.
Methods and Materials
The study is prospective, descriptive and analytic. The study evaluated the spectrum of age and gender structure, clinical entity (healthy population, osteopenia, osteoporosis), body mass index (BMI) and comorbidity. Analyses were conducted in "MHS" Private Practice for Physical Therapy and Rehabilitation. We included the total of 80 patients, 75 female and 5 male, who answered the Osteoporosis Risk Assessment Questionnaire and underwent calcaneal quantitative ultrasonography. The Osteoporosis Risk Assessment Questionnaire includes 19 questions. Comparison was made between our results and the results from PubMed database for published research studies and review papers in English language.
Results
The study included 80 patients, 5 male and 75 female patients. The entities important for osteoporosis assessment and diagnosis are gender, menopause if female, prolonged corticosteroid use, cigarette consumption and T score. The majority of patients who are exposed to corticosteroid use, cigarette consumption and early menopause have a great risk of developing osteoporosis and thus have lower values of T score.
Discussion and Conclusions
The correlation of osteoporosis and osteopenia with all the factors that were analyzed in the study (gender, age, early menopause, corticosteroid use, cigarette, and alcohol consumption, and decrease in height) plays an important role in diagnosis and

treatment. Results from this study suggest that QUS can be used to assess osteoporosis risk and should be a part of routine gynecologic, physical, and family medicine examinations.

PREVALENCE OF VITAMIN D DEFICIENCY AND PERCENTILE VALUES FOR SERUM VITAMIN D CONCENTRATIONS IN IRANIAN CHILDREN AND ADOLESCENTS: A POPULATION-BASED STUDY

N. Namazi[1], M. Qorbani[2], R. Heshmat[3], R. Kelishadi[4]

[1]Diabetes Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Non-communicable Diseases Research Center, Alborz University of Medical Sciences, Karaj, Iran, Karaj, Iran, [3]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [4]Child Growth and Development Research Center, Research Institute for Primordial Prevention of Non-Communicable Disease, Isfahan University of Medical Sciences, Isfahan, Iran, Isfahan, Iran

Objectives: Reference values for determining vitamin D deficiency can vary based on ethnicity, age, and region of residence. This study aimed to assess the prevalence of vitamin D deficiency and establish reference intervals for serum vitamin D levels among Iranian children and adolescents.
Materials and Methods: This nationwide cross-sectional study involved 2596 students aged 7 to 18 years. A parametric method was employed to define age-specific reference values by generating smooth centile curves and explicit formulas for centile estimates and standard deviation scores, stratified by sex and region of residence.
Results: Serum 25-hydroxyvitamin D deficiency (<30 ng/mL) was observed in approximately 70% of participants. The percentage of girls and boys with vitamin D levels (VDL) between 10 and 30 ng/mL was 58.5% and 62%, respectively, while VDL fell below 10 ng/mL in 11.3% of girls and 9.9% of boys. Significant differences in VDL were noted between rural and urban residents ($P < 0.05$). Children aged 7 to 12 years had higher serum VDL than adolescents aged 13 to 18 years (26.96 ± 8 ng/mL vs. 26.04 ± 10 ng/mL, $P = 0.007$). The estimated reference intervals for circulating 25(OH)D levels, corresponding to the 5th and 95th percentiles, were 11.45 to 48.40 ng/mL for boys and 9.51 to 47.69 ng/mL for girls. Significant variations in VDL were also observed across different age groups ($p<0.05$).
Conclusion: This study established reference intervals for serum vitamin D levels across various age groups, taking into account sex and region. Additionally, we found that vitamin D deficiency affects approximately 70% of Iranian adolescents and children. Therefore, implementing appropriate interventions to maintain bone health and prevent future osteoporosis should be prioritized.

DEVELOPMENT OF A NOVEL DIETARY QUESTIONNAIRE TO EVALUATE KEY NUTRIENTS ESSENTIAL FOR BONE AND MUSCLE HEALTH

N. Namazi[1], N. Fahimfar[2], K. Mobaraki[2], M. J. Mansourzadeh[2], K. Khalaji[2], A. Ostovar[2]

[1]Diabetes Research Center, Endocrinology and Metabolism Clinical Sciences Institude, Tehran University of Medical Sciences, Tehran, Iran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objectives: Due to the importance of dietary assessment in the prevention and management of osteoporosis and sarcopenia, and considering the time-consuming nature of food frequency questionnaires (FFQs), the development of a shorter questionnaire with acceptable validity and reliability is prioritized. Accordingly, we aimed to develop a shorter dietary questionnaire and examine its validity and reliability in the elderly.
Methods & Materials: This pilot study involved 100 individuals over the age of 50 who participated in a multi-center osteoporosis study (IMOS). Participants completed a 168-item Food Frequency Questionnaire (FFQ) through face-to-face interviews, and after a two-week interval, a novel questionnaire was filled out. A 24-hour urine sample was also collected to measure calcium levels. The correlations of nutrients essential for bone and muscle health in two questionaries were examined to assess validity, and reliability was evaluated based on expert feedback.
Results: Correlations between two questionnaires on energy intake, carbohydrate, protein, fat based on intraclass correlation (ICC) were 0.65, 0.59, 0.68, respectively ($P<0.001$ for all). ICCs for key nutrients including calcium, phosphorus, and magnesium were 0.78, 0.75, 0.54, respectively ($P<0.001$ for all). The correlations between vitamin D intake and serum levels of vitamin D for both questionnaires were weak ($P=0.5$ for both). Cronbach's alpha was also more than 0.70.
Conclusion: The novel short-form dietary questionnaire demonstrates acceptable validity and reliability in assessing total energy, macronutrients, and nutrients essential for bone and muscle health in the elderly. However, since the primary source of vitamin D is sunlight, using dietary questionnaires to estimate vitamin D levels is not practical; therefore, serum vitamin D measurement is recommended.

TOTAL PROTEIN INTAKE AND PROTEIN SOURCES IN A POPULATION AT RISK OF OSTEOPOROSIS

N. Namazi[1], P. Jalali[2], N. Fahimfar[2], M. J. Mansourzadeh[2], K. Khalaji[2], A. Ostovar[2]

[1]Diabetes Research Center, Endocrinology and Metabolism Clinical Sciences Institude, Tehran University of Medical Sciences, Tehran, Iran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objectives: Protein intake can have a detrimental impact on the prevention of osteoporosis and sarcopenia, depending on various factors, including the sources of protein. Therefore, in this population-based study, we aimed to clarify the total intake of protein and the prominent source at both national and subnational levels in Iran.

Methods and Materials: In this population-based survey, Iran was divided into five strata based on osteoporosis risk factors, and one to two provinces were selected from each stratum. The participants (n=1,272) were individuals over 50 years of age who were at risk of osteoporosis. To assess dietary intake, a 168-item Food Frequency Questionnaire was utilized.

Results: Based on protein intake, the study population was categorized into 3 groups (<0.8, 0.8-1.2, >1.2 g/kg/day). The majority of participants (≈46%) fell in the middle (0.8-1.2g/kg/day) category. This pattern was also consistent across sex and age groups, place of residence, educational and socioeconomic status. Compared to men, women consumed more protein (median: 0.95 vs 1.05 g/kg/day, $p < 0.001$). The dietary animal-to-plant protein ratio was 0.9 (interquartile range of 0.65, 1.24). The top four food sources for providing total protein were dairy, refined grain, whole grain, and red meat (53% of total protein intake). The prominent protein source was plant protein (52%) and refined grains contributed around 28% of this protein source (14% of total protein intake) in both men and women.

Conclusion: The current population-based study revealed that the prevalence of insufficient protein intake (<0.8 g/kg/day) was 32.5% in elderly Iranian women and 18.2% in men. Approximately 13% of total energy intake was derived from protein, with 52% sourced from plant-based proteins and 47% from animal sources. Consequently, healthcare policymakers should prioritize addressing insufficient protein intake, particularly in regions with a high prevalence, by implementing effective interventions to prevent osteoporosis and sarcopenia.

P1106

CONSIDERATIONS IN DIGITAL INTERVENTIONS FOR MUSCULOSKELETAL AGEING: INSIGHTS FROM PATIENT AND PUBLIC INVOLVEMENT

N. R. Fuggle[1], B. Dennison[1], G. Bevilacqua[1], F. Laskou[1], L. D. Westbury[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objectives

This study aimed to explore the perceptions, barriers, and facilitators associated with adopting digital interventions for musculoskeletal health in UK older adults. By engaging older adults in evaluating two digital health platforms, DocHQ and ReMaker, the study sought to understand how such technologies can be tailored to improve accessibility, adherence, and health outcomes while addressing equity challenges.

Materials and Methods

A Patient and Public Involvement and Engagement (PPIE) workshop was conducted in June 2024 at the MRC Lifecourse Epidemiology Centre. Five older adults participated, receiving an educational presentation on musculoskeletal ageing, followed by live demonstrations of DocHQ (which offers AI-powered physiotherapy with real-time feedback) and ReMaker Move (which uses wearable technology to measure physical performance). Their feedback was recorded, transcribed, and thematically analysed. Key themes included continuity of care, accessibility, personalisation, and motivation.

Results

Participants valued the remote accessibility and instant feedback of the interventions, particularly for overcoming barriers such as limited mobility and hospital access. DocHQ and ReMaker devices provided valuable strength and movement assessments, promoting independence and motivation. Issues around access to technology, digital literacy, and cost were raised. Participants emphasised the need for continuity of care with clinicians, personalised exercises, and the potential benefits of periodic human interaction to sustain motivation and ensure safety.

Conclusions

Digital interventions like DocHQ and ReMaker hold promise for enhancing musculoskeletal health in older adults. To ensure equitable access and benefit, strategies must address barriers related to technology accessibility, digital support, and cost. Integrating these tools with personalized clinician support could improve adherence, mitigate health disparities, and promote musculoskeletal health across diverse populations.

P1107

DEXA SCAN FINDINGS AND THE ROLE OF FRAX IN MANAGING FRAGILITY FRACTURE PATIENTS AT A LEADING MALAYSIAN UNIVERSITY HOSPITAL

N. S. Francis[1], N. A. Shohor[1], J. F. Leong[1], S. A. Mokhtar[1]

[1]Fracture Liaison Service, Orthopedic and Traumatology Department, Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

INTRODUCTION:
Bone mineral density (BMD) is most commonly assessed through dual-energy x-ray absorption (DEXA) scans, which is widely recognised as the gold standard screening method for evaluating the risk of fragility fractures. This method is deemed as the preferred diagnostic tool for osteoporosis and is ideally performed on the hip and lumbar spine. BMD results are typically reported as T-scores, which represent deviations from the average bone density of a healthy, young adult. A T-score of -1 and above indicates normal bone density, a T-score between -1 and -2.5 is indicative of osteopenia, while a T-score of -2.5 or below indicates osteoporosis. While BMD remains a valuable diagnostic tool, the Fracture Risk Assessment Tool (FRAX) calculator offers a practical, accessible alternative for assessing fracture risk in settings where DEXA scans are unavailable or for patients where immediate screening is not feasible.

MATERIALS AND METHODS:
This study utilised a prospective design, conducted for a duration of 1.5 years; from January 2023 to July 2024. The inclusion criteria consisted of elderly Fracture Liaison Service (FLS) patients with fragility fractures, aged 55 years and above, who were scheduled for a BMD scan as outpatients. We excluded patients with severe trauma, malignancies or steroid-induced fractures. The hip T-score derived from the DEXA scan was chosen to determine their classification into normal, osteopenia or osteoporosis categories.

RESULTS AND DISCUSSION:
A total of 146 patients were included in the study, n=87 for the whole of 2023 and n=59 within the first six months of 2024. The age profile revealed that majority of patients who came for screening were aged between 71 and 80 years (45.9%, n=67), with the smallest group (1.4%, n=2) aged 51 to 60 years. Gender distribution on the other hand divulged that women represented the majority (87.7%, n=128), while the men constituted (12.3%, n=8). The predominance of females was expected given the osteoporosis trends.

Analysis of the DEXA scan results showed that 18.5% of patients exhibited normal bone density. Osteopenia was observed in 49.32% of patients, while 32.19% were classified as osteoporotic. This highlights that half of our study patients were osteopenic.

According to Clinical Practice Guidelines, (CPG) in 2022, DEXA readings are not a vital component in the initiation of anti-osteoporosis therapies but could serve as a monitoring tool instead. Patients on these therapies should be assessed for their treatment response. Hence, at the osteopenia stage, DEXA could serve as preventive strategy. The FRAX tool on the other hand could complement the evolving approach to osteoporosis management.

CONCLUSION:
Our findings underscore the importance of integrating FRAX with DEXA scans for a comprehensive approach to osteoporosis management, especially in high-risk populations to identify those who are prone to osteoporosis-related fractures. This dual strategy can ensure that none of the patients are under-treated and prevents any delay in the initiation of anti-osteoporosis medication.

P1108

MANAGEMENT TRENDS AND TIMING OF SURGICAL INTERVENTION IN ELDERLY PATIENTS WITH HIP FRACTURES: A RETROSPECTIVE ANALYSIS

N. S. Francis[1], N. A. Shohor[1], J. F. Leong[1], S. A. Mokhtar[1]

[1]Fracture Liaison Service, Orthopedic and Traumatology Department, Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

INTRODUCTION:
Hip fractures pose a major health challenge among elderly populations, often necessitating either surgical intervention or conservative treatment. Understanding the timing of surgical intervention and the distribution of conservative cases is vital for improving patient outcomes. This study explores the distribution of surgical versus conservative management trends in patients with hip fractures and evaluates the time to surgery for those undergoing operative treatment.

MATERIALS AND METHODS:
This study utilised a retrospective design, conducted throughout the entire year of 2024 from January to December. The inclusion criteria consisted of patients referred to the Fracture Liaison Service (FLS) throughout the year specifically for hip fractures which resulted in a total of 104 patients. Data analysis included the proportion of patients receiving surgery as compared to those who were managed conservatively and the time intervals from hospital admission to surgical intervention. The duration to surgery was categorised into four intervals: 0–3 days, 4–7 days, >7–14 days and >14 days, with an additional category for cases where the time to surgery was uncertain.

RESULTS AND DISCUSSION:
Out of the 104 patients, 83% (n=86) underwent surgery, while 17% (n=18) were treated conservatively. Among the surgical patients, 50% underwent surgery within 0–3 days, 24.4% within 4–7 days and 22.1% within >7–14 days. None of the patients had to wait longer than 14 days for surgery, however 3.5% had uncertain surgery timelines. These findings highlight that half of the patients received timely surgical intervention as they were treated within 3 days, following the stipulated timeframe provided by our hospital. Conservative management cases were reflective of either patient's treatment preferences or due to comorbidities which led to them being unfit for surgery. Current clinical guidelines underscore the importance of early surgical intervention to reduce complications, improve recovery and mobility as well as decreasing the risk of mortality.

CONCLUSION:
The study highlights that the majority of patients with hip fractures predominantly undergo surgical treatment, with a significant proportion receiving early intervention. This underscores the importance of prompt surgical decision-making in order to achieve optimal outcomes. Opposingly, for patients managed conservatively, tailored approaches remain essential. Further research is warranted to explore the long-term impacts of both surgical and conservative treatment modalities in this osteoporotic population.

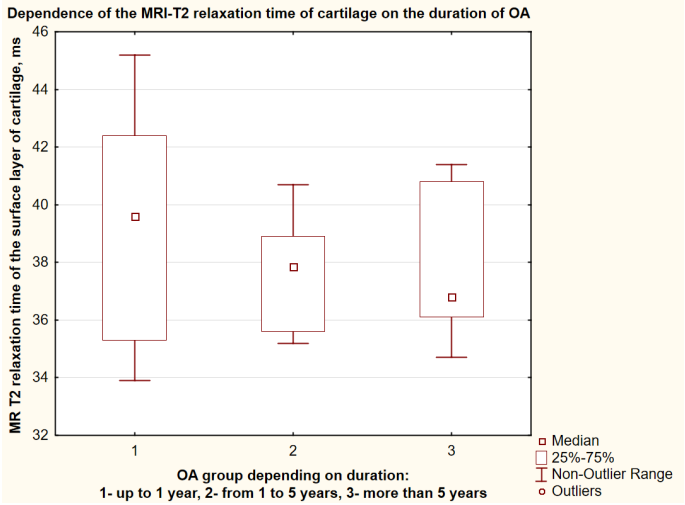
P1109

MRI -T2 MAPPING OF CARTILAGE IN PATIENTS WITH OSTEOARTHRITIS OF THE KNEE JOINTS OF VARYING DURATION

N. Savushkina[1], L. Alekseeva[1], E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], E. Sharapova[1], A. Halmetova[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

The purpose of the study. To determine the T2 relaxation time of articular cartilage (total, deep and surface layer) during MRI examination depending on the duration of osteoarthritis (OA).
Materials and methods. The prospective study for the period 2023-2024 included 45 women aged 35-75 years, with a reliable diagnosis of OA (ACR) of knee joints of stage I-III, who signed informed consent. The average age of the patients was 52.7±11.0 years, BMI was 28.9±7.7 kg/m2, and the median duration of the disease was 2 [1; 4] years. All patients were divided into three groups: group 1 (n=20) - patients with short-term OA (up to 1 year); group 2 (n=12) - patients with OA lasting from 1 year to 5 years; group 3 (n=13) - patients with OA lasting more than 5 years. years old. Quantitative signs of T2 relaxation time of articular cartilage (total, deep and surface layers) were evaluated in all groups during MRI examination. Statistical processing of the material was carried out using Statistica 10.0.
Results. In group 1, the MRI-T2 relaxation time in the deep cartilage layer was 34.0 [31.3; 34.9] ms, in the surface layer - 39.6 [35.3; 42.4] ms, in the total - 35.0 [31.7; 36.7] ms. In group 2, the MR-T2 relaxation time in the deep cartilage layer was 33.5 [31.9; 35.3] ms, in the surface layer - 37.8 [35.6; 38.9] ms, in the total - 34.6 [33.8; 35.2] ms. In group 3, the MR-T2 relaxation time in the deep cartilage layer was 34.5 [32.2; 35.3] ms, in the surface layer - 36.8 [36.1; 40.8], in the total - 36.1 [34.5; 38.0] ms. There were no statistically significant differences in the assessment of quantitative indicators of T2 relaxation time in all cartilage layers in the three groups. However, we noted a tendency to increase the T2 relaxation time in the surface layer of cartilage in patients with knee joint OA with a disease duration of up to 1 year (Figure 1).
Figure 1. Dependence of MRI-T2 relaxation time of the surface layer of cartilage on the duration of OA



Conclusion. The results obtained show a tendency to increase the T2 relaxation time in the superficial cartilage layer in patients with knee joint OA of short duration (up to 1 year), which may allow us to consider this indicator as one of the signs of disease progression in the future, and requires further study and comparison with clinical data.

P1110

THE RELATIONSHIP OF DEEP CARTILAGE LESIONS WITH ANTHROPOMETRIC AND LABORATORY PARAMETERS IN PATIENTS WITH KNEE OSTEOARTHRITIS OF VARIOUS DURATION

N. Savushkina[1], L. Alekseeva[1], E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], E. Sharapova[1], A. Halmetova[1], D. Kudinskij[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

The purpose of the study. To determine the influence of anthropometric and laboratory parameters on the development of deep cartilage lesions (DCL) in patients with osteoarthritis (OA) of the knee joints (KJ).
Materials and methods. A prospective study included 45 women with a diagnosis of OA (ACR) of KJ stage I—III (Kellgren — Lawrence). The age of the patients was 52.7±11.0 years, the body mass index was 28.5 ± 7.4 kg/m2, and the duration was 2 [1;4] years. All underwent magnetic resonance imaging (MRI) using WORMS: 0 - normal thickness and signal, 1 - normal thickness, increased signal; 2 - focal defect with a width of <1 cm not to the full depth; 3 - multiple partial defects not to the full depth, alternating with areas of normal thickness <75% of the area; 4 - Diffuse (≥ 75% of the area) partial thickness loss; 5 - multiple areas of total thickness loss <75% of the area; 6 - diffuse (≥75% of the area) loss of total thickness. The presence of DCL was established in the case of belonging to grades 4-6 in accordance with the above gradation. Statistical processing of the material was carried out using Statistica 10.0.
Results. Depending on the presence or absence of DCL, all patients were divided into 2 groups: 22% with DCL (n=22) and 78%

without it (n=35). Individuals with DCL were comparable in age, pain level according to VAS and WOMAC, as well as duration of NSAID and SYSADOA use with patients without DCL. Patients with DCL had a longer duration of the disease (10 [3;13] and 1 [0.8;3] years, p=0.001), higher weight (87.5 [80;101] and 70 [60;88.5] kg, p=0.04), body mass index (BMI) (32.1 [30.5;41.5] and 25.4 [22.2; 30.9] kg/m2, p=0.02) and triglyceride levels (1.7 [1.1;2.2] and 0.9 [0.7;1.3] mmol/l, p=0.02). In patients with short-term OA, it was found that multiple areas of partial and complete cartilage defects were detected in more than 50% of cases (Table 1).

Table 1 - Gradation of KJ cartilage damage depending on the duration of OA

Gradation of cartilage damage by WORMS	Duration of OA <1 year, n=20	The duration of OA >1 year, n=25
0	-	-
1	n=1 (5%)	n=1 (4%)
2	n=7 (35%)	n=3 (12%)
3	n=11 (55%)	n=12 (48%)
4	n=1 (5%)	n=8 (32%)
5	-	n=1 (4%)
6	-	-

Conclusion. DCL is associated with OA duration, increased weight, BMI and hypertriglyceridemia. GPH is detected even in patients with OA duration no more than 1 year, which makes MRI WORMS an extremely important method for detecting structural cartilage defects even in the presence of short-term pain in the KJ.

P1111

THE RELATIONSHIP OF MULTIPLE CARTILAGE DEFECTS WITH PRO-INFLAMMATORY CYTOKINES IN OSTEOARTHRITIS OF THE KNEE JOINTS OF SHORT DURATION

N. Savushkina[1], L. Alekseeva[1], E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], E. Sharapova[1], A. Halmetova[1], D. Kudinskij[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

The purpose of the study. To determine the relationship of cartilage damage with laboratory changes in osteoarthritis (OA) of the knee joints (KJ) of short duration.

Materials and methods. A prospective study for the period 2023-2024 included 69 women who met the ESKOA criteria, which are currently being developed and tested, with knee joint OA and X–ray stage I-II (Kellgren — Lawrence), who signed the informed consent. The average age of the patients was 44.8±8.0 years (from 35 to 66), the body mass index (BMI) was 25.5 ± 5.0 kg/m2, and the duration of knee pain was 0.8 [0.5; 1] years. All underwent magnetic resonance imaging (MRI) using WORMS: 0 - normal thickness and signal, 1 - normal thickness, increased signal; 2 - focal defect with a width of <1 cm not to the full depth; 3 - multiple partial defects not to the full depth, alternating with areas of normal thickness <75% of the area; 4 - Diffuse (≥ 75% of the area) partial thickness loss; 5 - multiple areas of total thickness loss <75% of the area; 6 - diffuse (≥75% of the area) loss of total thickness. Statistical processing of the material was carried out using Statistica 10.0.

Results. According to the WORMS grading, patients corresponded to the following categories: 0 – 1.5% of cases (n=1), 1 – 6% (n=4), 2 – 33% (n=23), 3 – 52% (n=36), 4 – 7% in (n=5); none of the patients had cartilage lesions corresponding to categories 5 and 6 according to WORMS MRI. Depending on the presence of multiple partial and/or complete cartilage defects according to WORMS MRI, all patients were divided into 2 groups: group 1 (n=48, 59%) with these defects and group 2 (n=28, 41%) without them. Patients in both groups were comparable in age, duration of the disease, BMI, waist and hip size, pain levels according to VAS and WOMAC, ESR and CRP, as well as duration of NSAID and SYSADOA administration. In group 1, there were higher levels of interleukin-6 (IL-6) compared with group 2 (0.28 [0.04; 0.36] pg/ml versus 0.03 [0.01; 0.08] pg/ml; p=0.005). The Spearman correlation analysis confirmed positive correlations (p <0.05) between the presence of multiple cartilage defects and higher IL-6 values (r=0,4).

Conclusion. In our study, it was shown that in patients with OA duration of no more than 1 year, more than 50% of cases already have multiple cartilage defects according to WORMS MRI. This study also demonstrated that the presence of more than 1 partial cartilage defect is associated with higher IL-6 levels, which may possibly indicate a significant role of inflammation in the development of OA.

P1112

EARLY KNEE OSTEOARTHRITIS: KEY PREDICTORS OF PAIN

A. Khalmetova[1], A. Lila[1], E. Taskina[1], L. Alekseeva[1], N. Savushkina[1], N. Kashevarova[1], E. Strebkova[1], O. Alekseeva[1]

[1]Research Institute of Rheumatology, Moscow, Russia

Objective: to investigate key risk factors associated with pain in early-stage knee osteoarthritis (OA).

Materials and Methods: The study included 109 women aged 35–70 with knee pain for ≤1 year and minimal radiographic changes (Kellgren-Lawrence 0–II, no significant JSN). Anthropometric data, medical history, clinical examination results, and scores (VAS, WOMAC, KOOS, overall health) were documented. Radiography, ultrasound, and laboratory tests were performed.

Results: pain intensity ≥40 mm on the VAS was observed in 15% of patients (n=16). These patients were older (52.5 (42; 62.5) vs. 44 (38; 52) years, p=0.02), had higher BMI (28 (25; 31.6) vs. 24 (21; 28) kg/m², p=0.04), worse total WOMAC scores (1245 (872; 1510) vs. 248 (90; 410) mm, p<0.001), lower total KOOS scores (44 (37; 67) vs. 79 (63; 88)%, p<0.001), and poorer overall health (60 (47; 80) vs. 29.5 (10; 50) mm, p<0.001). Synovitis (50% vs. 13.9%, p<0.001), history of synovitis (75% vs. 31.1%, p=0.008),

and US-detected osteophytes (50% vs. 10.75%, p<0.001) were more frequent. Metabolic syndrome (MetS) (56.25% vs. 25.8%, p=0.03) was also more common.

Discriminant analysis revealed significant risk factors for pain (Table 1): physical function (PF) (WOMAC), synovitis, osteophytes, and MetS. A predictive formula was developed:

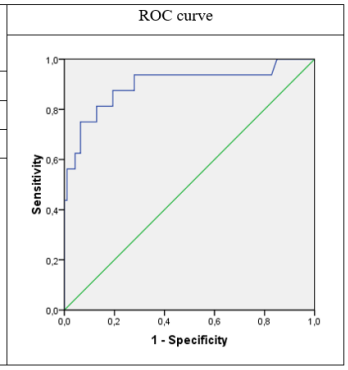
(0.012 × PF) + (3.03 × MetS) + (3.38 × osteophytes) + (2.14 × synovitis) ≥ 14.1.

Here, PF are measured in mm; MetS is coded as 0 (absent) or 1 (present); US-detected osteophytes and synovitis as 1 (absent) or 2 (present).

The formula demonstrated high predictive accuracy (90.8%), confirmed by ROC analysis (AUC: 0.898, 95% CI: 0.794–1.002).

Table 1. Coefficients of the discriminant function for pain prediction in early-stage knee

Factors	Coefficients
Physical function (WOMAC)	0.012
US-detected osteophyte	3.38
Metabolic syndrome	3.03
Synovitis	2.14



Conclusions: Pain in early-stage knee OA is linked to functional impairments (WOMAC), synovitis, US-detected osteophytes and MetS.

P1113

THERAPEUTIC OPTIONS FOR TARGETING INFLAMMATORY OSTEOARTHRITIS

E. Taskina[1], A. Lila[1], L. Alekseeva[1], N. Kashevarova[1], E. Sharapova[1], E. Strebkova[1], N. Savushkina[1], A. Khalmetova[1], V. Nesterenko[1]

[1]Research Institute of Rheumatology, Moscow, Russia

Objective: to investigate the efficacy and safety of olokizumab (OKZ) in patients with knee osteoarthritis (OA) with synovitis, persistent pain, and ineffectiveness of previous conservative therapy.

Materials and Methods: the study included 15 patients with stage II–III knee OA who met ACR criteria, had pain ≥50 mm on the VAS, synovitis, and treatment failure. Patient age ranged from 54 to 75 years; disease duration was 1–23 years. Over 12 weeks, patients received three subcutaneous injections of OKZ (64 mg). Effectiveness was assessed by changes in pain intensity (VAS, WOMAC, KOOS), DN4 outcomes, and EQ-5D quality of life. GHA via VAS, physician/patient efficacy ratings, and the need for NSAIDs were also considered. All patients underwent laboratory testing.

Results: therapy significantly reduced pain on VAS (65 (55–75) mm to 38 (19–42) mm, p=0.001) and improved KOOS scores: pain (44.4 (33.3–55.6)% to 63.9 (50–66.7)%, p<0.01), symptoms (50 (35.7–57.1)% to 64.3 (53.6–67.9)%, p<0.05), daily living (47.1 (35.3–50)% to 57.8 (51.5–70.6)%, p=0.003), and quality of life (25 (12.5–43.8)% to 43.8 (31.3–70.6)%, p<0.05). Quality of life by EQ-5D improved from 0.52 (-0.02–0.52) to 0.52 (0.52–0.68), p=0.01. GHA improved from 55 (40–60) mm to 70 (60–75) mm, p=0.001, hsCRP (2.9 (1–4) mg/L to 0.35 (0.2–0.95), p<0.005) and ESR (13 (4–22) mm/h to 2 (2–4), p<0.005) also decreased significantly.

Adverse events (AE) were reported in 4 patients. Two discontinued OKZ due to serious AEs: bilateral pneumonia of unknown etiology requiring hospitalization and allergic dermatitis affecting hands, chest area, and back. In 2 cases, ALT elevations were observed but did not require treatment.

Conclusion: OKZ demonstrated significant symptomatic and anti-inflammatory effects in patients with the inflammatory phenotype of OA. Further research is needed to confirm its efficacy and safety.

P1114

ASSOCIATION OF LEPTIN WITH EARLY-STAGE KNEE OSTEOARTHRITIS

E. Taskina[1], A. Khalmetova[1], L. Alekseeva[1], A. Lila[1], N. Kashevarova[1], N. Savushkina[1], E. Strebkova[1], E. Sharapova[1], K. Mikhailov[1]

[1]Research Institute of Rheumatology, Moscow, Russia

Objective: to evaluate the relationship between hyperleptinemia and clinical, instrumental, laboratory parameters in patients with early-stage knee osteoarthritis (OA).

Material and Methods: the study included 50 women (mean age: 44.6±7.3 years, range 35–64; BMI: 25.3±5.1 kg/m²) with knee pain for ≤1 year and minimal radiographic changes (Kellgren-Lawrence 0–II, no significant JSN). Anthropometric data, medical history, clinical examination, and pain scores (VAS, WOMAC, KOOS) were recorded. Radiography and lab tests were performed.

Results: hyperleptinemia (leptin ≥11.1 ng/mL) was found in 37 patients (74%). Patients were divided into two groups by leptin levels (Table 1). Groups were similar in age but differed in BMI, waist, and hip circumference (p<0.05). Hyperleptinemic patients had higher WOMAC pain scores (p=0.04), smaller medial JSW (p<0.001), more frequent MetS (p=0.02), more MetS components (p=0.01), and higher fasting glucose (p=0.01).

Table 1. Comparative characteristics of patients with and without hyperleptinemia

Parameter	Patients with Hyperleptinemia (n=37)	Patients without Hyperleptinemia (n=13)	p-value
Age, years, Me	44 (40; 52)	39 (36; 45)	0.06
BMI, kg/m², Me	26.3 (23; 29)	21 (19.7; 22)	<0.001
Waist circumference, cm, Me	82 (75; 90)	70 (70; 74)	<0.001
Hip circumference, cm, Me	101 (98; 107)	94 (90; 96)	<0.001
Pain (WOMAC), mm, Me	60 (30; 140)	30 (10; 40)	0.04
MetS, %	32.4	0	0.02
MetS components, Me	1 (1; 2)	1 (0; 1)	0.01
Medial JSW, mm, Me	3.9 (3.4; 4.3)	4.5 (4.3; 4.8)	<0.001
Glucose, µmol/L, Me	5.3 (5; 5.7)	5 (4.9; 5.3)	0.01

Leptin correlated with WOMAC pain (r=0.3, p=0.04), BMI (r=0.6, p<0.001), waist (r=0.6, p<0.001), hip circumference (r=0.4, p<0.001), hyperglycemia (r=0.4, p=0.01), MetS (r=0.3, p=0.01), and MetS components (r=0.4, p=0.004). Leptin was inversely correlated with medial JSW (r=−0.5, p<0.001).
Conclusions: hyperleptinemia in women with early-stage knee OA is associated with higher WOMAC pain scores, narrower medial JSW, and metabolic disturbances. Understanding the mechanisms linking hyperleptinemia to OA is essential for developing preventive and therapeutic strategies.

P1115

THE IMPACT OF METABOLIC SYNDROME ON CLINICAL MANIFESTATIONS OF EARLY-STAGE KNEE OSTEOARTHRITIS

A. Khalmetova[1], A. Lila[1], E. Taskina[1], L. Alekseeva[1], N. Savushkina[1], N. Kashevarova[1], E. Strebkova[1], E. Sharapova[1]

[1]Research Institute of Rheumatology, Moscow, Russia

Objective: to evaluate the impact of metabolic syndrome (MetS) on the clinical manifestations of early-stage knee osteoarthritis (OA).
Materials and Methods: the study included 93 women aged 35–64 with knee pain for ≤1 year and minimal radiographic changes (Kellgren-Lawrence 0–II, no significant JSN). Anthropometric data, medical history, clinical examination results, and scores (VAS, WOMAC, KOOS, overall health) were documented. All patients underwent laboratory testing.
Results: MetS was diagnosed in 18% of patients (n=17). Based on the presence or absence of MetS, patients were divided into two age-matched groups. Patients with MetS showed higher rates of hypertension (p < 0.001), hypertriglyceridemia (p = 0.002), low HDL (p = 0.004), elevated LDL (p = 0.01), hyperglycemia (p < 0.001), and obesity (p < 0.001). They also had higher VAS pain scores (p = 0.01), total WOMAC (p = 0.04), and overall health scores (p = 0.01), along with worse KOOS Pain (p = 0.04) and activities of daily living (ADL) (p = 0.04).

Table 1. Comparative characteristics of patients with and without metabolic syndrome

Parameter	Patients with MetS (n=17)	Patients without MetS (n=77)	p-value
Arterial hypertension, %	53	5	<0.001
Hypertriglyceridemia, %	29	3	0.002
Reduced HDL, %	29.4	4	0.004
Elevated LDL cholesterol, %	88	57	0.01
Hyperglycemia, %	29	0	<0.001
Obesity, %	53	4	<0.001
Pain VAS (mm), Me	45 [15; 60]	20 [10; 40]	0.01
Total WOMAC (mm), Me	640 [140; 790]	244 [84; 395]	0.04
Overall health (mm), Me	40 [35; 55]	21 [10; 50]	0.01
KOOS Pain, %, Me	78 [56; 86]	83 [75; 92]	0.04
KOOS ADL, %, Me	78 [68; 90]	90 [76; 96]	0.04

Spearman analysis showed positive correlations of MetS with VAS pain (r = 0.3, p = 0.01), total WOMAC (r = 0.2, p = 0.04), and overall health (r = 0.3, p = 0.01), and negative correlations with KOOS Pain (r = -0.2, p = 0.04) and ADL (r = -0.2, p = 0.04).
Conclusion: the presence of MetS is associated with more severe clinical manifestations of early-stage knee OA. Addressing metabolic disturbances may contribute to reducing pain intensity and improving outcomes for patients with early-stage OA.

P1116

PREDICTORS OF INFLAMMATORY PHENOTYPE KNEE OSTEOARTHRITIS PROGRESSION

E. Strebkova[1], E. Taskina[1], N. Kashevarova[1], N. Savushkina[1], A. Khalmetova[1], E. Samarkina[1], L. Alekseeva[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Purpose: to determine the factors of inflammatory phenotype knee osteoarthritis (OA) progression
Methods. The prospective study included 51 patients aged 40-75 with knee OA (according to ACR criteria) stages I-III (Kellgren J.- Lawrence J) who signed informed consent. The average age was 54.1 ± 11.1 and the duration of OA was 3.5 (1-11) years. The average BMI was 32.4 ± 7.6 kg/m2. Persistent knee synovitis, confirmed by ultrasound data, was the main parameter for determining the inflammatory phenotype of OA. The duration of the study is 3 years.

Results. During the follow–up period, progression of knee OA was noted in 19.6% of patients (n=10). Patients were divided into 2 groups (Table 1), according to the presence or absence of OA progression. The patients in both groups did not differ in age (p=0.19) and duration of OA (0.15). Worse pain scores were determined by WOMAC and its other components in patients with knee OA progression. When comparing the groups, patients with knee OA progression showed higher rates of systemic inflammation (increasing the level of CRP), hyperleptinemia, and increased production of extracellular cartilage matrix destruction markers (matrix metalloproteinase–9 (MMP-9)). Spearman's correlation analysis showed that the knee inflammatory OA progression is associated with knee pain according to WOMAC (r=0.58, p=0.004), multimorbidity (r=0.52, p=0.03) and hyperleptinemia (r=0.54, p=0.009).

Table 1. Comparative clinical and laboratory characteristics of patients with and without knee OA progression

Parameter	Knee OA progression n = 10	No knee OA progression n = 41	p
Pain WOMAC, мм, Me	255 [238,5; 275]	179,5 [100; 220]	0,007
Total WOMAC, мм, Me	1107,5 [1000,5; 1338,5]	824,5 [505; 1100]	0,05
MPP-9, ng/ml, Me	4 [1,14; 13,0]	1,4 [0,4; 4]	0,02
CRP, mg/l, Me	6,9 [1,9; 9,8]	1,5 [0,7; 3,0]	0,04
Leptin, ng/ml, Me	82,4 [67,2; 128,2]	37,2 [25,7; 48,0]	0,001

Conclusions. The main predictors of the inflammatory phenotype knee osteoarthritis progression are: pain, increased leptin levels, and multimorbidity. Therapeutic interventions aimed at these factors will improve the course of the inflammatory phenotype of knee OA.

P1117

THE EFFECT OF BONE METABOLISM MARKERS ON THE COURSE KNEE OSTEOARTHRITIS

E. Strebkova[1], N. Kashevarova[1], E. Taskina[1], N. Savushkina[1], E. Sharapova[1], A. Khalmetova[1], E. Samarkina[1], O. Alekseeva[1], N. Demin[1], D. Kudinskij[1], L. Alekseeva[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to study the effect of bone metabolism markers (Cathepsin K and runx2) on the course of knee osteoarthritis (OA)
Material and Methods. The prospective study included 352 patients with knee OA (according to ACR criteria) X-ray stage I-III (Kellgren J.- Lawrence J) who signed informed consent. The average age was 58.3 ± 9.3 years, the duration of OA was 6.0 [2;12] years. Cathepsin K was detected in 56 patients, runx2 in 89. The duration of the study is 3 years.
Results: 73.2% of patients had an increase in the expression of the Cathepsin K gene, and 80.0% had an increase in the expression of the runx2 gene. A comparative analysis showed that patients with Cathepsin K gene expression had lower KOOS scores (48 [34; 58] vs. 60 [48; 78] points, p=0.024 and higher DN4 scores (3 [2; 4] vs. 1 [0; 3] points, p=0.01). The Spearman correlation analysis confirmed positive correlations (p < 0.05) between the expression of the Cathepsin K gene and DN4 (r=0,37, p=0.007) and negative correlations with the total KOOS scores (r=-0,33, p=0.02). Patients with runx2 gene expression had higher values of synovial membrane thickness according to ultrasound (US) (3.0 [2.7; 3.2] vs. 2.4 [2.1; 2.7] mm, p=0.0005), lower values of total hip BMD: (0.90 [0.79; 0.95] vs. 0.99 [0.90; 1.0] (g/cm2), p=0.02) and of total hip T-score: (-0.3 [-1.2; 0.1] vs. 0.4 [-0.3; 0.8], p=0.03). The Spearman correlation analysis confirmed positive correlations (p < 0.05) between the expression of the runx2 gene and the thickness of the synovial membrane (US) and negative correlations with total hip BMD and the total hip T-score (Table 1)

Table 1 – Correlation coefficients of runx2 gene expression with OA risk factors and progression

Parameter	r	p
Synovial membrane thickness (US), mm	0,40	0,0003
Total hip BMD, (g/cm2)	-0,31	0,02
Total hip T-score	-0,31	0,02

Conclusions. Increased expression of Cathepsin K and runx2 genes may contribute to the degradation of the cartilage matrix during the OA progression. Cathepsin K and runx2 can serve as new molecular targets not only for assessing the OA progression, but also for the development of new drugs for the OA treatment aimed at reducing pain and inflammation.

P1118

THE EFFECT OF HYPERURICEMIA IN THE METABOLIC PHENOTYPE OF KNEE OSTEOARTHRITIS

E. Strebkova[1], E. Taskina[1], N. Kashevarova[1], N. Savushkina[1], E. Sharapova[1], K. Mikhailov[1], O. Alekseeva[1], E. Samarkina[1], L. Alekseeva[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to evaluate the effect of hyperuricemia (HU) on the course of knee osteoarthritis (OA) associated with metabolic syndrome (MS).
Material and Methods. The prospective study included 111 patients aged 40-75 with knee OA (according to ACR criteria) stage I-III (Kellgren J.- Lawrence J) and MS, who signed informed consent. The average age was 61 (54; 67.5), the duration of OA was 6 years (3; 14.5). The uric acid level of more than 360 mmol/l was determined as HU. The duration of the study is 3 years.
Results. Patients with OA were divided into 2 groups according to the presence or absence of HU (Table 1). Patients with the metabolic phenotype of OA with and without HU were comparable in age and duration of OA. In patients with the metabolic phenotype of OA and HU, worse indicators of the course of OA were deter-

mined: higher VAS pain, knee varus deformity and hypotrophy of the quadriceps femoris muscle were more often recorded, as well as more severe functional insufficiency (use of walking aids). During laboratory and instrumental examination, patients in the group with HU had a lower thickness of posterior lateral cartilage and higher levels of matrix metalloproteinase-3 (MMP-3).

Table 1 – Comparative characteristics of patients with knee OA and MS depending on the presence/absence of HU

Parameter	Patients with MS and without HU (n=62)	Patients with MS and HU (n=49)	P
BMI, kg/m², Me	31,4 [27,9; 35,4]	33,5 [30,85; 37,8]	0,009
Knee VAS pain >40 mm, %	62,9	80,85	0,042
Knee varus deformity, %	14,5	34,8	0,014
Using a walking stick, %	8,2	24,4	0,02
Hypotrophy of the quadriceps femoris muscle,%	33,9	55,1	0,025
Thickness of posterior lateral cartilage mm, Me	1,6 [1,5; 1,7]	1,6 [1,5; 1,6]	0,017
MMP-3, Me	16,5 [12,1; 22,4]	23,9 [16,3; 28,4]	0,035

Conclusions. HU in patients with the metabolic phenotype OA is an additional factor contributing to a more severe course of OA. In this regard, it is necessary to develop therapeutic measures for metabolic OA aimed at correcting urate metabolism, which will help reduce the risk of severe OA.

P1119

PREDICTORS OF KNEE OSTEOARTHRITIS PROGRESSION WITH A SHORT DURATION OF THE DISEASE (LESS THAN 5 YEARS)

E. Strebkova[1], E. Taskina[1], N. Kashevarova[1], N. Savushkina[1], E. Sharapova[1], A. Khalmetova[1], O. Alekseeva[1], D. Kudinskij[1], N. Demin[1], L. Alekseeva[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

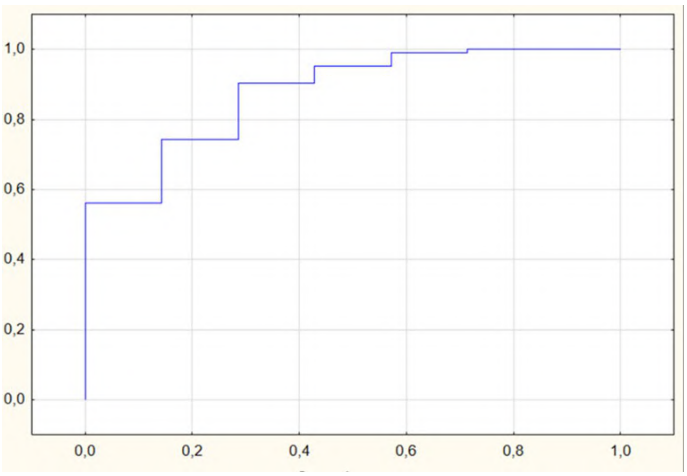
Objective: to determine the factors of knee osteoarthritis (OA) progression with a short duration of the OA (less than 5 years).

Material and Methods. The prospective study included 218 patients with knee OA (according to ACR criteria) of stage I-III (Kellgren J.- Lawrence J) who signed informed consent. The average age was 53.5 [46.0; 61.0] years. The duration of the study is 3 years.

Results. During the follow—up period, progression of knee OA was noted in 25% of patients. Patients were divided into 2 groups according to the presence or absence of OA progression. The patients of both groups did not differ in age (p=0.45) and duration of OA (p=0.45), however, patients from the progression group had statistically significantly higher values: BMI (p= 0.002), knee VAS pain (p=0.0001), WOMAC pain (p=0.0002), WOMAC functional insufficiency (p=0.002), lumbar spine bone mineral density (BMD) (p=0.03); diabetes mellitus was more often diagnosed (p=0.0094), knee varus deformity (p=0.02), knee synovitis (according to ultrasound) (p=0.003) and osteitis in the medial tibia (according to MRI) (p<0.001). As a result of correlation and discriminant analysis, the following risk factors for the progression of OA with a short duration of OA were identified: knee pain, BMI, osteitis in the medial tibia, lumbar spine BMD. To clarify the prognosis of OA progression, as well as to illustrate the predictive power of the factors included in the multifactorial model during discriminant analysis, a ROC curve was constructed (Fig. 1). The area under the ROC curve reflects the accuracy of the forecast and is 0.88 in the model used (the range 0.8–0.9 corresponds to a very good quality model).

Conclusions. A prospective study showed that high BMI, knee pain, osteitis in the medial tibia, and high lumbar spine BMD determine the risk of knee OA progression in patients with a short duration of the OA.

Figure 1 - ROC - curve of the sensitivity/specificity ratio for predicting the knee OA progression (area under the curve = 0.88)



P1120

THE EFFECT OF COLECALCIFEROL ON THE COURSE OF KNEE OSTEOARTHRITIS

N. Kashevarova[1], E. Strebkova[1], E. Taskina[1], E. Sharapova[1], N. Savushkina[1], S. Glukhova[1], O. Alekseeva[1], D. Kudinskij[1], E. Samarkina[1], L. Alekseeva[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to study the effect of colecalciferol on the course of knee osteoarthritis (KOA)

Material and Methods. The study included 171 patients aged 40-75, with a reliable diagnosis of KOA stages I-III according to Kellgren-Lawrence, who signed informed consent. The mean age was 53.5 ± 9.94, BMI 29.8 ± 6.4kg/m², and KOA duration 3 [1, 7] years.

Results. Normal vitamin D levels (≥ 30 ng/ml) were found in 62 patients (36.3%): group 1. Reduced vitamin D levels (< 30ng/ml) was found in 109 patients: insufficiency (20-30ng / ml) - 66

(38,6%) - group 2; deficiency (<20ng/ ml) -43 (25,1%) -group 3. Patients from the groups were similar in terms of age and KOA duration, but patients in groups 2 and 3 had significantly higher body weight, BMI, VAS pain, WOMAC, worse patient's general health status and KOOS data. They were more likely to have hip OA and hand OA, clinically diagnosed knee synovitis, flat foot and quadriceps hypotrophy. Fewer patients were engaged in physical therapy, took calcium and vitamin D supplementation, and had concomitant conditions such as coronary heart disease, hypertriglyceridemia and hypertension. Also, these patients were significantly more likely to have higher concentrations of CRP, leptin, glycated hemoglobin, glucose, and alkaline phosphatase. Ultrasound examination revealed smaller sizes of cartilage tissue more often on both the anterior medial and anterior lateral surfaces of the knee; MRI showed osteitis in the medial femur and tibia more often ($p < 0.05$ for all values). Spearman's correlation analysis confirms the relationship between vitamin D deficiency and the following indicators (Table 1).

Table -1 Correlation coefficients between vitamin D deficiency and OA-related factors

Parameter	r	p
BMI	-0,35	0,002
OA stage	-0,26	0,002
Synovitis	-0,25	0,003
VAS pain	-0,29	0,04
WOMAC pain	-0,29	0,04
Total KOOS	0,23	0,02
The size of cartilage on the anterior medial surface	0,20	0,04
Osteitis in the medial femur	-0,29	0,01
Osteitis in the medial tibia	-0,12	0,02

Conclusions. Vitamin D deficiency/ insufficiency is associated with a more severe course of KOA. Therapeutic measures aimed at restoring the level of colecalciferol, and these factors can improve the course of the KOA.

P1121

THE EFFECT OF BONE MINERAL DENSITY OF THE AXIAL SKELETON ON THE KNEE OSTEOARTHRITIS COURSE

N. Kashevarova[1], E. Strebkova[1], E. Taskina[1], N. Savushkina[1], E. Sharapova[1], A. Khalmetova[1], L. Alekseeva[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the effect of bone mineral density (BMD) on the course of knee osteoarthritis (OA).

Material and Methods. The study included 352 patients aged 40-75, with a reliable diagnosis of KOA (ACR) stages I-III according to Kellgren-Lawrence, who signed informed consent. Of these, 164 had low BMD (osteoporosis / osteopenia), while 188 had normal levels. The average age was 58.3 ± 9.3 years, BMI was 29.5 ±5.4 and the median duration of OA was 6 (2-12) years. Individual cards were filled out for each patient including anthropometric data, medical history, clinical examination, assessment of VAS pain, WOMAC, KOOS, DN4, patient's general health status (GHS). All patients had laboratory tests, standard DEXA, knee X-rays and knee US.

Results. A comparative analysis showed that patients with osteoporosis/osteopenia and norm were comparable in age and duration of OA, however, patients with low BMD had a higher VAS pain (50 [40; 65] versus 40 [25; 58] mm, p=0.03), worse GHS values (47 [34; 55] versus 35 [15; 55] mm, p=0.003), worse KOOS values (50 [38; 58] versus 68 [44; 85] points, p=0.004), smaller osteophyte sizes in the medial femoral and tibial bones (2.0 [1.3; 3.8] versus 4.7 [2.0; 6.7] mm, p = 0.02 and 1.4 [0.8; 2.5] versus 2.4 [1.5; 3.9] mm, p = 0.02), a more pronounced thickness of the knee synovial membrane (US) (3.0 (2.8; 3.2) versus 2.9 (2.4; 3.1), p = 0.01), high values of alkaline phosphatase (85.0 [77.0; 94.0] versus 70.0 [56.0; 84.0] IU/l, p=0.0007) and glycated hemoglobin (5.6 [5.2; 5.9] versus 5.3 [4.8; 5.7] %, p=0.005). The Spearman correlation analysis confirmed positive associations ($p < 0.05$) between the low BMD and worse GHS values, the thickness of the synovial membrane (US), glycated hemoglobin, alkaline phosphatase, and negative relationships with the total KOOS, the osteophyte sizes in the medial femoral and tibial bones (according to X-ray) (Table 1).

Table 1 – Correlation coefficients between the "osteoporotic" phenotype and OA risk factors

Parameter	r	p
KOOS, points	-0,27	0,004
GHS, mm	0,20	0,03
The thickness of the synovial membrane (US), mm	0,24	0,01
The osteophyte sizes in the medial femur, mm	-0,30	0,02
The osteophyte sizes in the medial tibia, mm	-0,29	0,03
Glycated hemoglobin, %	0,29	0,004
Alkaline phosphatase, IU/l	0,31	<0,0001

Conclusions. Patients with the "osteoporotic" phenotype have a more severe course of OA: higher pain, knee synovitis was more often detected, worse values GHS and KOOS than in patients with normal BMD.

P1122

PREDICTORS OF KNEE OSTEOARTHRITIS PROGRESSION (LONG-TERM PROSPECTIVE STUDY)

N. Kashevarova[1], E. Strebkova[1], E. Taskina[1], N. Savushkina[1], E. Sharapova[1], A. Khalmetova[1], L. Alekseeva[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to identify the main risk factors for the knee osteoarthritis (OA) progression

Material and Methods. A 3-year prospective study included 352 patients with a reliable knee OA (ACR) stages I-III (Kellgren J.-Lawrence J), aged 40-75, average age was 58.3 ± 9.3, BMI – 29.5 ± 5.4 kg/m2, median duration of OA was 6 [2-12] years, who signed the informed consent. An individual card was filled out for each patient, including anthropometric indicators, medical history and clinical examination data, assessment of knee pain according to VAS, WOMAC, KOOS, DN4, and the patient's general health status (GHS). All patients underwent laboratory diagnostics, standard knee X-ray, knee ultrasound (US), knee MRI and DEXA.

Results. During the follow-up period, knee OA progression was noted in 22% of patients. Patients divided into two groups according to absence/presence knee OA progression. Patients in both groups did not differ in age (p>0.05) and duration of OA (p>0.05). Patients with knee OA progression had statistically significant higher BMI values (31.7±6.5 vs. 28.4±5.9 kg/cm2, p = 0.02), knee VAS pain (58.1±16.4 versus 49.2±15.8 mm, p = 0.003), knee varus deformity was more often detected (37.5% versus 22.9%, p<0.05), synovitis (US) was more often detected (3.2 [2.9; 3.4] versus 2.8 [2.4; 3.2] mm, p = 0.01), osteitis in the medial tibia (MRI) (65.4% vs. 21.1%, p=0.001), higher femoral neck and lumbar spine BMD (DEXA) (63.1% vs. 44.3% and 43.5 vs. 34.3%, respectively). The Spearman correlation analysis revealed significant associations (p < 0.05 for all cases) between knee OA progression and the following factors (Table 1).

Table 1 – Spearman correlation analysis between knee OA progression and the following factors (correlation coefficients)

Parameter	r	p
BMI	0,32	0,03
Knee VAS pain	0,42	0,02
Knee varus deformity	0,30	0,02
Femoral neck BMD	0,36	0,03
Knee synovitis (US)	0,37	0,03
Osteitis in the medial tibia	0,32	<0,0001

Conclusions. As a result of the study, risk factors associated with the knee OA progression have been identified. Timely therapeutic measures aimed at these factors can improve the course of knee OA.

P1123

THE EFFICACY OF BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN PATIENTS WITH GENERALIZED OSTEOARTHRITIS

L. Alekseeva[1], E. Taskina[1], N. Kashevarova[1], E. Strebkova[1], N. Savushkina[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

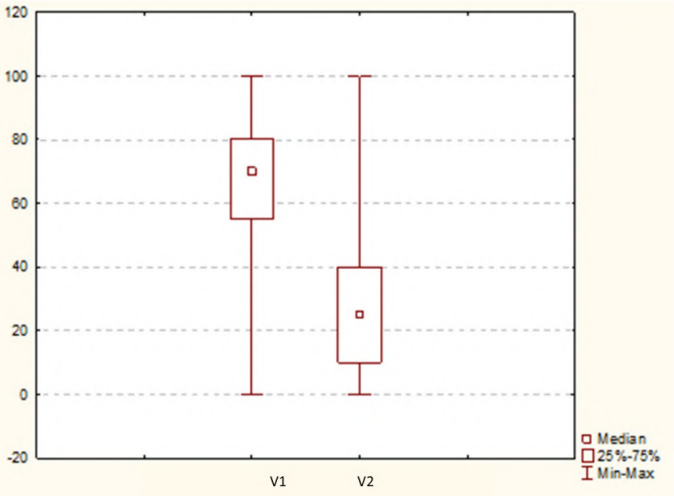
Objective. To evaluate the efficacy of SYSADOA (bioactive concentrate of small marine fish (BCSMF) containing chondroitin sulfate, amino acids, peptides, sodium, potassium, calcium, magnesium, iron, copper and zinc ions) in patients with generalized osteoarthritis (OA) in the multicenter observational study.

Materials and methods. The study included 22,525 patients with OA, including 1,694 with generalized OA (affecting three or more groups of joints). The following localizations were taken into account: hands, knee, hip and spine. The median age was 67 (60-72) years, and the body mass index (BMI) was 28.4 (25.7-31.6) kg/m2, the duration of the OA was 96 (60-132) months. BCSMF was prescribed 1 ml intramuscular daily No. 20 or 2 ml intramuscular every other day No. 10. The duration of the study is from 20 to 31 days, the number of visits is 2: visit 1 (V1) – the beginning of therapy, visit 2 (V2) – within 10 days after the completion of the 1st course of treatment. The effectiveness of treatment was assessed by the dynamics of pain (VAS), assessment of quality of life according to the EQ-5D and patient's general health status (GHS) according to VAS.

Results. Against the background of one course of the BCSMF there was a significant decrease in pain (at the beginning of the study – 70 (55-80) and at the end of therapy – 25 (10-40) mm, p<0.0001, Fig.1), improved quality of life according to EQ-5D (0.52 (from -0.02 to 0.59) and 0.76 (from 0.62 up to 1.0), p<0.0001) and GHS (50 (30-60) and 80 (60-90) mm, p<0.0001, respectively). A decrease in the need for NSAIDs was revealed: 79.9% took NSAIDs at the beginning of therapy, 68.3% at the end (relative risk, RR = 1.17, 95 CI 1.12 – 1.22, p<0.0001). Good response to treatment (pain reduction by 50% or more) it was detected in 64.5% of patients; 89.7% had a reduction in VAS pain of less than 40 mm. Older age, female sex (RR = 1.08, 95 CI 1.02 – 1.16, p=0.02), longer duration of the disease, worse values for EQ-5D, III-IV X-ray stages of the OA (RR = 1.32, 95 CI 1.19 – 1.48, p=0.000), coronary heart disease (RR = 1.21, 95 CI 1.07 – 1.37, p = 0.003), chronic heart failure (RR = 1.61, 95 CI 1.33 – 1.95, p < 0.0001) and obesity (RR = 1.4, 95 CI 1.23 – 1.58, p < 0.0001) were associated with a lower effect of the therapy in generalized OA (pain reduction by less than 50%).

Conclusion. The use of BCSMF in generalized OA has shown the expediency of its widespread use in clinical practice. To increase the effectiveness of therapy, it is necessary to take into account factors that reduce the analgesic effect of the BCSMF.

Fig.1 Dynamics of pain (according to VAS) in generalized OA therapy



P1124

THE EFFICACY OF BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN PATIENTS WITH HIP OSTEOARTHRITIS

L. Alekseeva[1], E. Taskina[1], N. Kashevarova[1], E. Strebkova[1], N. Savushkina[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

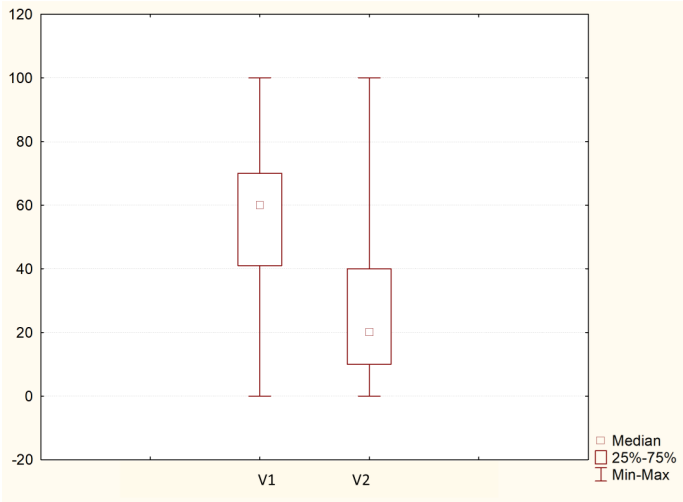
Objective. To evaluate the efficacy of SYSADOA (bioactive concentrate of small marine fish (BCSMF) containing chondroitin sulfate, amino acids, peptides, sodium, potassium, calcium, magnesium, iron, copper and zinc ions) in patients with hip osteoarthritis (OA) in the multicenter observational study.

Materials and methods. The study included 6666 patients with hip OA (according to criteria ACR). The median age was 59 (50-67) years, body mass index (BMI) was 27.1 (24.7- 29.7) kg/m2, and the duration of the hip OA was 60 (24-96) months. The duration of the study is from 20 to 31 days, the number of visits is 2: visit 1 (V1) – the beginning of therapy, visit 2 (V2) – within 10 days after the completion of the 1st course of treatment. BCSMF was prescribed 1 ml intramuscular daily No. 20 or 2 ml intramuscular every other day No. 10. The effectiveness of treatment was assessed by the dynamics of pain (VAS), assessment of quality of life according to the EQ-5D and patient's general health status (GHS) according to VAS.

Results. On the background of one course of the BCSMF, there was a significant decrease in pain (V1 – 60 [33; 70] and V2 – 20 [10; 40] mm, p<0.0001, Fig.1), an improvement in the quality of life according to EQ-5D (V1 – 0.52 [0.06; 0.69] and V2 – 0.8 [0.69; 1] points, p<0.0001) and GHS (V1 – 50 [30; 65] and V2 – 80 [60; 90] mm, p<0.0001). Respectively, the median reduction in pain (according to VAS) was 57.1% and the improvement of GHS (according to VAS) was 40%. Against the background of therapy, the need for NSAIDs decreased: at the beginning of therapy, 67.9% of patients received NSAIDs, at the end of treatment 64.9% (relative risk (RR) = 1.09, 95% CI 1.04 - 1.15, p<0.0001). Good response to therapy (pain reduction by 50% or more) it was detected in 63.6%; a decrease in VAS pain of less than 40 mm was observed in 83.3% of patients. Older age, female sex, longer duration of OA, worse values for EQ-5D, III-IV X-ray stages (RR = 1.19, 95 CI 1.02 – 1.14, p < 0.0001), coronary heart disease (RR = 1.43, 95 CI 1.33 – 1.55, p < 0.0001), chronic heart failure (RR = 1.61, 95 CI 1.42 – 1.83, p < 0.0001) and obesity (RR = 1.09, 95 CI 1.01 – 1.18, p < 0.0001) were associated with a lower effect of hip OA therapy (pain reduction by less than 50%).

Conclusion. The use of BCSMF in hip OA demonstrates its effectiveness and the possibility of widespread use in clinical practice. Consideration and modification of factors related to the analgesic efficacy of the BCSMF will improve the results of OA therapy.

Fig. 1 – Dynamics of pain (according to VAS) in hip OA therapy



P1125

URIC ACID AND FUNCTIONAL MUSCLE STATUS IN RHEUMATOID ARTHRITIS PATIENTS

O. Dobrovolskaya[1], M. Kozyreva[1], N. Demin[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to study the association of uric acid (UA) levels with skeletal muscle mass, strength and physical performance in women with rheumatoid arthritis (RA).

Material and methods. 130 women (median age 61 [53; 66] years) with confirmed RA who signed informed consent were examined. The study was approved by the local ethics committee. A clinical and laboratory examination was performed, including an assessment of muscle strength, physical performance. Dual-energy X-ray absorptiometry according to the "whole body" program was done.

Results. The median UA level was 262.8 [197.4; 310.5] μmol/l, the incidence of hyperuricemia was 9.2%. Positive correlations of UA with the total lean mass index (r=0.32, p<0.001), appendicular lean mass index (r=0.24, p=0.006) were established. These associations were confirmed in multiple linear regression analysis (b*=0.38, p<0.001 and b*=0.29, p<0.001, respectively). There was no association between the level of UA and RA parameters (duration of the disease, glucocorticoid intake, RF and ACCP se-

ropositivity, ESR, CRP and DAS28 index), as well as with muscle strength. A negative correlation between the level of UA and parameters of physical performance was found.
Conclusion. The frequency of hyperuricemia was 9.2% in women with RA. Multiple regression analysis confirmed an independent association between lean mass and UA level.

P1126

BODY COMPOSITION AND MUSCLE FUNCTIONAL STATUS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS

O. Dobrovolskaya[1], M. Kozyreva[1], A. Feklistov[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to evaluate the body composition and functional status of skeletal muscles in women with RA, depending on the presence of treatment with biological disease-modifying antirheumatic drugs (bDMARDs).
Materials and methods. The study included 138 women (mean age 60.8±8.6 years) with confirmed RA who received bDMARDs (tumor necrosis factor α inhibitors – 18, rituximab – 30, abatacept – 19), and 71 patients treated with methotrexate. A clinical and laboratory examination, evaluation of body composition using dual-energy X-ray densitometry and tests to assess muscle strength and physical performance were carried out.
Results. Muscle mass, fat mass and BMD did not differ depending on the type of DMARDs. When evaluating muscle strength and physical performance of skeletal muscles, it was found that muscle strength did not differ depending on the type of DMARDs. At the same time, gait speed ≤0.8 m/s was less frequently determined among women receiving bDMARDs compared with those taking methotrexate ($p<0.001$). Significant correlations have been established between the presence of bDMARDs therapy and physical performance, assessed by the results of a short physical performance battery ($\tau=0.14$, $p=0.035$) and gait speed ($\tau=0.20$, $p=0.003$). Logistic regression analysis confirmed the relationship between bDMARDs therapy and the functional state of the skeletal muscles.
Conclusion. There were no differences in the body composition depending on the type of DMARDs. Therapy with bDMARDs was associated with a better functional status of skeletal muscles, estimated by gait speed and a short physical performance battery compared with methotrexate-only therapy.

P1127

URIC ACID AND BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS PATIENTS

O. Dobrovolskaya[1], N. Demin[1], E. Samarkina[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to assess the frequency of hyperuricemia (HU) and association of uric acid (UA) level with bone mineral density (BMD) in postmenopausal women with rheumatoid arthritis (RA).
Material and methods. 173 postmenopausal women with RA (aged 40-75 years) enrolled in the study. All patients underwent clinical and laboratory examination to determine the level of UA in the blood serum (spectrophotometry in fresh specimens; Cobas C311 analyzer). The level of MK>360 mmol/l was taken as HU. Dual-energy X-ray absorptiometry (DXA, Lunar prodigy, GE, USA) was performed to measure the BMD of lumbar spine (LS), femoral neck (FN) and total hip (TH). The study was approved by the local ethics committee.
Results. Median age of patients with osteoporosis (OP) and patients without OP was 62 [57; 68] and 61 [55; 68] years, respectively ($p>0.05$). UA serum level in patients without OP was more than in persons with OP (278.3 [241.8; 329.1] μmol/l and 259.3 [198.9; 307.7] μmol/l, respectively; $p<0.05$). HU was identified in 4.5% patients with OP and in 17.9% women without OP ($p<0.05$). UA correlated with LS ($r=0.32$, $p<0.001$), FN ($r=0.22$, $p<0.05$), TH ($r=0.27$, $p<0.001$) and duration of postmenopause ($r=0.26$, $p<0.001$). In logistic regression analysis the normal level of UA was a protective factor for OP in postmenopausal women with RA (OR 0.55 95%CI 0.33-0.90, $p=0.017$).
Conclusion. UA serum level in women without OP was higher than in patients with OP ($p<0.05$). HU was 3.9 times more often in persons without OP compared to those with OP. A high level of UA was a protective factor for low BMD and the presence of OP.

P1128

URIC ACID AND APPENDICULAR LEAN MASS IN WOMEN WITH RHEUMATOID ARTHRITIS

N. Toroptsova[1], O. Dobrovolskaya[1], N. Demin[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to assess the frequency of hyperuricemia (HU) and uric acid (UA) association with appendicular lean mass (ALM) in women with rheumatoid arthritis (RA).
Material and methods. 207 women with RA (aged 40-75 years) were enrolled in the study. The level of uric acid (UA) >360 μmol/L was taken as HU. Sarcopenia was diagnosed according to criteria European Working Group on Sarcopenia in Older People (EWGSOP2, 2018). Muscle strength was assessed in all patients with grip strength and 5-chair stand test. Dual-energy X-ray absorptiometry (DXA, Lunar prodigy, GE, USA) was performed to measure the appendicular lean mass. Uric acid level in the blood serum

was determined by spectrophotometry (Cobas C311 analyzer). The study was approved by the local ethics committee.

Results. Mean age of patients with sarcopenia (SP) and patients without SP was 61.1±8.7 and 59.0± 8.5 years, respectively (p>0.05). UA serum level in patients without SP was more than in persons with SP (276.6±79.9 μmol/L and 249.2±75.4 μmol/L, respectively; p=0.034). HU was identified in 4.4% patients with SP and in 11.9% women without SP (p>0.05). UA correlated with ALM (r=0.20, p=0.018) and ALM index (r=0.26, p=0.001), age (r=0.31, p<0.001), body mass index (r=0.35, p<0.001) and duration of post menopause (r=0.22, p=0.008). Univariate linear regression revealed the association among UA with ALM (b=0.22, p<0.001) and ALM index (β=0.24, p<0.001).

Conclusion. UA serum level in women without SP was higher than in patients with SP (p=0.034). HU was 2.7 times more often in persons without SP compared to those with SP. Higher values of muscle mass corresponded to higher UA rates in women with RA.

P1129

ASSOCIATION OF ANTICITRULLINATED ANTIBODIES WITH CHRONIC HELICOBACTER PYLORI INFECTION IN RHEUMATOID ARTHRITIS

N. V. Aleksandrova[1], L. N. Shilova[2], V. A. Aleksandrov[3], I. Y. Alekhina[4], A. V. Aleksandrov[3]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Volgograd State Medical University, the Department of Hospital Therapy, Volgograd, Russia, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Volgograd State Medical University, Volgograd, Russia, [4]Stavropol State Medical University, the Department of Hospital Therapy, Stavropol, Russia

Different mechanisms associated with Helicobacter Pylori (H. pylori) may cause loss of cellular tolerance and promote autoantibody formation in patients with autoimmune rheumatic diseases.

Purpose of the study:

To evaluate the association of chronic H. pylori infection with seropositivity for antibodies to cyclic citrullinated proteins in patients with rheumatoid arthritis (RA).

Materials and Methods.

A clinical and laboratory examination of 92 women with RA (66% seropositive for antibodies to cyclic citrullinated peptide, 58% for antibodies to modified citrullinated vimentin) was performed. Antibodies to cyclic citrullinated peptide (anti-CCP), modified vimentin (anti-MCV), antibodies to H. pylori (anti-H.pylori-IgG) and total antibodies to H. pylori CagA antigen (anti-CagA) were determined by enzyme immunoassay.

Results and Discussion.

Laboratory confirmation of chronic H. pylori infection was obtained in 68.5% of RA patients, with 40% of them testing positive for anti-CagA. The research of laboratory parameters in RA patients with the presence of H. pylori demonstrated an increase in inflammatory markers (ESR, CRP) and studied autoantibodies. When RA patients highly positive for both anti-CCP and anti-MCV were combined, a significant predominance of patients with chronic H. pylori infection was observed in this group (p=0.012). The data of multivariate regression analysis showed a high specific contribution of H.pylori among the factors influencing the levels of anti-CCP (beta=0.25) and anti-MCV (beta=0.23) in the serum of RA patients. Anti-CCP levels in RA patients with anti-CagA(+) were significantly higher not only compared to the group of patients seronegative for anti-H.pylori-IgG, but also compared to patients with anti-H.pylori-IgG but negative for anti-CagA (p<0.001 and p<0.02, respectively).

Conclusions.

Autoreactive B-cells actively producing antibodies to citrullinated proteins in RA may be affected by H. pylori.Additional studies are required to investigate possible clinical and laboratory associations that may influence treatment tactics for anticitrullinated antibody-positive RA patients with positive anti-CagA determinations.

P1130

POSSIBILITY OF USING ANGIOPOIETIN-LIKE PROTEINS TYPES 3 AND 4 AS MARKERS OF INFLAMMATORY PROCESS ACTIVITY IN PSORIATIC ARTHRITIS

N. V. Golovina[1], L. N. Shilova[1], V. A. Aleksandrov[2], I. Y. Alekhina[3], A. V. Aleksandrov[2]

[1]Volgograd State Medical University, the Department of Hospital Therapy, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, VolgogradState Medical University, Volgograd, Russia, [3]Stavropol State Medical University, the Department of Hospital Therapy, Stavropol, Russia

Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease of the bone and joint system that develops in patients with psoriasis.

Research aimed at improving the diagnosis and prognosis of PsA has focused on finding potential biomarkers, among which angiopoietin-like proteins (Angptl) are of definite clinical interest.

Purpose of the study:

To investigate the possibility of using Angptl types 3 and 4 as markers of PsA activity.

Forty-five PsA patients, including 20 (44.4%) men and 25 (55.6%) women, predominantly middle-aged (30 to 59 years) (53.3%), with disease duration of more than 5 years (57.8%) and high (DAS > 3.7) disease activity (66.6%) were involved in the study.

All patients underwent clinical and laboratory examination, which also included determination of serum levels of Angptl types 3 and 4 by enzyme-linked immunoassay.

Results and Discussion.

In PsA patients, the mean Angptl3 level was 1078 ± 348 pg/mL and Angptl4 level was 386 ± 173 pg/mL.

A number of statistically significant (p<0.05) correlations of Angptl levels with a number of clinical and laboratory parameters were found: Angptl3 with triglyceride levels (r=0.31) and ESR (r=0.29); Angptl4 with disease duration (r=0.31) and uric acid levels (r=0.58).

Single-factor analysis of variance showed no association between PsA activity and Angptl levels (Newman-Keuls test; p>0.05 for all types). When performing two-factor analysis of variance with addition to PsA activity (factor 1) of patients with high indicators of inflammatory reaction (increased values of ESR and CRP, n=23) (factor 2), the data on mutual influence of these factors only on Angptl3 content were obtained (p=0.01).
In the group of patients with high level of inflammatory reaction (high levels of COE and CRP) there were significant differences in Angptl3 content between patients with moderate and low activity of PsA (Newman-Keuls test; p=0.008). This fact may be required when differentiating PsA patients according to the degree of disease activity on the background of severe inflammation.
Conclusions.
Further study of the role of Angptl in the pathogenesis of PsA will allow to further investigate the mechanisms of the inflammatory process and may create preconditions for the development of targeted drugs.

P1132

PHYSICAL ACTIVITY AND PERSISTENCE OF SUPRA-THRESHOLD DEPRESSIVE SYMPTOMS IN OLDER ADULTS: A TEN-YEAR COHORT STUDY

N. Veronese[1], F. S. Ragusa[2], L. Smith[3], M. Barbagallo[2], L. Dominguez[4], R. Monastero[2], A. Dara[5], S. Sabico[5], N. Al-Daghri[5]

[1]Unicamillus University, Rome, Italy, [2]university of palermo, Palermo, Italy, [3]Anglia Ruskin University, Cambridge, United Kingdom, [4]University of Kore, Enna, Italy, [5]King Saud University, Ryhad, Saudi Arabia

Objective: Few multination-based studies have examined the longitudinal association between PA (physical activity) and persistence of supra-threshold depressive symptoms (SDS) in older people. This cohort study aimed to assess the influence of PA on persistence of SDS.
Materials and methods: Data were obtained from the Population Survey of Health, Ageing and Retirement in Europe (SHARE). The cohort was composed of individuals with SDS at baseline. Depressive symptoms were ascertained using the EURO-D scale, with a value over 4 indicatives of SDS.
Results: The study included 6,631 participants with SDS. After adjusting for nine different covariates at baseline and the changes of PA level during the follow-up period, compared to very low PA, moderately high (OR=0.82; 95%CI: 0.69-0.98; p=0.03), and high (OR=0.80; 95%CI: 0.66-0.95; p=0.01) PA levels were associated with significantly reduced persistence of depressive symptoms. In a propensity score analysis, matching low and high PA level for baseline scores of EURO-D, people with high PA levels reported a lower EURO-D of 0.53 points (p<0.0001).
Conclusions: Among adults with depression, higher levels of PA were associated with a reduced persistence of depression. These real-world data complement evidence on efficacy of exercise as a treatment for depression and can inform clinical guidelines.

P1133

LONG-TERM IMPACT OF PHYSICAL ACTIVITY ON MORTALITY IN ADULTS WITH MULTIMORBIDITY: A 12-YEAR COHORT LONGITUDINAL STUDY FROM THE SURVEY ON HEALTH, AGING, AND RETIREMENT IN EUROPE

N. Veronese[1], F. S. Ragusa[2], M. Barbagallo[2], L. Dominguez[3], L. Smith[4], S. Sabico[5], N. Al-Daghri[5]

[1]Unicamillus University, Rome, Italy, [2]university of palermo, Palermo, Italy, [3]University of Kore, Enna, Italy, [4]Anglia Ruskin University, Cambridge, United Kingdom, [5]King Saud University, Ryhad, Saudi Arabia

Background: While physical activity (PA) is known to reduce mortality in the general population, this relationship in individuals with multimorbidity (≥ two chronic conditions) is unclear. This longitudinal study aimed to investigate whether there is a long-term association between PA levels and mortality rates over a 12-year period in adults with multimorbidity.
Methods: Data were obtained from eight waves of the Survey of Health, Ageing and Retirement in Europe (SHARE), from 28 European countries. PA levels were self-reported via computer-assisted personal interviews. Mortality during the follow-up period was assessed using data obtained from caregivers through end-of-life interview. Multimorbidity was identified based on the presence of two or more 15 self-reported chronic diseases/conditions. Cox's regression analysis, adjusted for potential confounders, was used to assess the association between PA level and mortality.
Results: The study included 9,216 participants with multimorbidity (mean age 69±10.1 years; 58.7% were women). Among those with multimorbidity, individuals with high PA level were significantly younger, more frequently men, less impaired in activities of daily living, less educated, and less frequently obese than those with very low level of PA (p<0.0001 for all comparisons). Over the 12 years of follow-up, mortality incidence was three times higher in individuals with multimorbidity and very low PA levels than those with multimorbidity and high levels of PA. After adjusting for confounders, the risk of mortality was significantly lower for participants with moderately low PA levels (HR=0.64; 95% CI: 0.59-0.71; p<0.0001), moderately high PA levels (HR=0.53; 95% CI: 0.47-0.60; p<0.0001), and high PA levels (HR=0.49; 95% CI: 0.43-0.55; p<0.0001) compared to those with very low PA levels.
Conclusions: Findings from the present study suggest that people with multimorbidity who had lower levels of PA were three times more likely to die prematurely after 12 years than adults with multimorbidity and higher levels of PA at baseline. These findings underscore the importance of promoting physical activity in adults with multimorbidity to reduce the risk of premature mortality. Future longitudinal research is required to confirm/refute our findings. Further, intervention studies are needed to understand whether increasing levels of physical activity in this population subsequently reduces mortality risk.

P1134

THE CLINICAL EFFICACY OF PLATELET-RICH PLASMA IN ARTHROSCOPIC ROTATOR CUFF REPAIR

N. Zurita[1], P. Fuentes[2], A. Ortin[1]

[1]Arthrosport. Cllinicas Quironsalud of Alicante, Alicante, Spain, [2]Arthrosport. Clinicas Quironsalud of Alicante, Alicante, Spain

INTRODUCTION

The efficacy of platelet-rich plasma (PRP) in the arthroscopic treatment of rotator cuff injuries has been published in the literature due to the importance of biological mechanisms in tendon healing processes after surgery.

However, the results we found in the literature are very different due to the lack of consensus in the formulation of PRP.

Objetives: Therefore, to minimize these differences, we determined the formulation of PRP according to the DEPA and MARSPILL classifications and the application process to evaluate whether PRP promotes and improves the effects of arthroscopic rotator cuff repair.

MATERIAL AND METHODS

We conducted a retrospective and observational study establishing a series of cases and controls. We obtained a sample of 200 patients treated with arthroscopic technique for full thickness rupture of the SPE tendon by double-row suture. 100 were treated with PRP at the end of surgery (case group) and 100 were not treated with PRP (control group).

We formulated the PRP obtaining a number of platelets between 200-400,000 /mm3, without leukocytes and red blood cells, in a medium with calcium and activated with thrombin.

We placed the PRP at the end of surgery under direct vision by intraosseous infiltration at the level of the humeral footprint, at the tendon-bone contract interface after suturing and in the body of the SPE tendon. All patients were followed up for 5 years.

RESULTS

Treatment with PRP showed a better result in pain control in the short term ($P < 0.005$). However, in the medium and long term these differences are progressively reduced.

In the functional assessment of the shoulder, after applying the Constant scale, statistically significant differences were found in favor of PRP compared to the control treatment.

Finally, during the medium and long term follow-up, the rate of re-tearing in the PRP group was lower than in the control group.

CONCLUSIONS

According to our study, standardization of PRP formulation is necessary for proper reproducibility of the results of different outcomes. The PRP formulation of the present study significantly reduces the rate of postoperative re-tears in the medium and long term. However, it only demonstrated clinically significant effects on the improvement of postoperative pain in the short term.

P1135

IS A COMPREHENSIVE GERIATRIC ASSESSMENT USEFUL IN OLDER PEOPLE WHO ARE DIAGNOSED WITH A HEMATOLOGICAL MALIGNANCY?

F. Akagündüz[1], N. Şentürk Durmuş[2], Y. Yasin[2], Z. R. Beşışık Yılmaz[2], C. Alkaç[2], B. Can[2], A. Tufan[2]

[1]MD Department of Internal Medicine, Marmara School of Medicine, Marmara University, Pendik, 34890, Istanbul, Türkiye, Istanbul, Turkiye, [2]MD, Department of Internal Medicine, Division of Geriatrics, Marmara University Medical School, Pendik, 34890, Istanbul, Türkiye, Istanbul, Turkiye

Objective: The number of patients diagnosed with hematological malignancies over the age of 65 is increasing due to the ageing population and the characteristics of hematological diseases. These patients should be assessed using a Comprehensive Geriatric Assessment (CGA) before deciding on the treatment to follow. The aim of this study was to evaluate the effect of CGA, geriatric syndromes and other scales on in-hospital and 1-year follow-up mortality in patients with hematological malignancies who had a pre-treatment consultation with the geriatric department.

Materials and Methods: The study included adults aged 65 years and older with a diagnosis of hematological malignancy. Patients' demographics, comorbidities, geriatric syndromes and treatment modalities were collected. All patients were evaluated by a geriatrician for CGA. The hospitalisation status, the duration of hospitalisation, the in-hospital mortality rate and the one-year follow-up mortality rate were recorded.

Results: In-hospital mortality was 23.8% (n:20) and mortality at 1 year was 33.3% (n:28). In-hospital mortality was associated with frailty (hazard ratio (HR):41.19, 95% confidence interval (CI): [2.74-618.39]; p=0.007) and the presence of sarcopenia risk (HR:0.08, CI:0.01-0.94, p=0.044). Being male, not having received the COVID-19 vaccination, having a higher HOF score and having a lower albumin level were associated with mortality at 1 year follow-up (p=0.016, p=<0.001, p=0.016, respectively).

Conclusions: In older adults, frailty is associated with prolonged hospital stay, adverse drug reactions and increased mortality. Vaccination programmes should be completed in geriatric patients with hematological malignancies, as mortality is higher in patients who have not received the COVID-19 vaccine.

EVALUATION OF SARCOPENIA IN POSTMENOPAUSAL PATIENTS APPLYING TO THE OUTPATIENT CLINIC

A. Yılmaz[1], N. Şentürk Durmuş[2], Y. Yıldız[2], Z. R. Beşışık Yılmaz[2], C. Alkaç[2], B. Can[2], A. Tufan[2]

[1]MD Department of Internal Medicine, Marmara School of Medicine, Marmara University, Pendik, 34890, Istanbul, Türkiye, Istanbul, Turkiye, [2]MD, Department of Internal Medicine, Division of Geriatrics, Marmara University Medical School, Pendik, 34890, Istanbul, Türkiye, Istanbul, Turkiye

Objective: Sarcopenia is a multifactorial skeletal muscle disease commonly observed in the geriatric population, influenced by hormonal changes that occur during the postmenopausal period. It negatively affects the functionality of individuals and reduces their quality of life.. This study aims to evaluate the sarcopenia status of postmenopausal women.
Materials and Methods: In our study, a total of 300 postmenopausal women were included. Sarcopenia was defined based on the EWGSOP2 definition. Probable, confirmed, and severe sarcopenia were collectively categorized under the term "sarcopenia,".
Results: Of the evaluated patients, 44.7% (n=134) were found to be sarcopenic. Among the sarcopenic group, 47.8% (n=64) were under the age of 65, while 52.2% (n=70) were geriatrics. The number of chronic diseases, the number of medications used, and the status of polypharmacy were significantly higher in the sarcopenic group (p=0.005, p=0.036, p=0.011). Levels of albumin, testosterone, and IGF-1 were found to be lower in the sarcopenic group (p=0.022, p=0.004, p=0.034). Postmenopausal sarcopenia related to older age (Odds Ratio (OR): 1.07, 95% Confidence Interval (CI): 1.04-1.10 , p<0.001), the presence of osteoporosis (OR: 0.80, 95% CI: 0.39-0.95, p=0.034), and the existence of vasomotor symptoms (OR: 0.43, 95% CI: 0.24-0.76, p=0.004).
Conclusion: Our study highlights the importance of awareness regarding sarcopenia among specialists providing healthcare services to postmenopausal patients. It underscores the significance of initiating preventive and treatment strategies for at-risk patients before they reach the geriatric stage.

P1137

CLINICAL CHARACTERISTIC AND FACTORS ASSOCIATED WITH MAJOR OSTEOPOROTIC FRACTURES IN THE QATARI POPULATION

O. Alsaed[1], A. Lutf[1], F. Alam[1], N. Abdulla[1], S. Alebbi[1], A. Poil[1], G. Kim[1], A. Padmakumari[1], R. Abualsuod[1], A. Yasin[1], H. Hamad[1], D. Shalatouni[1], S. Alemadi[1]

[1]Hamad Medical Corporation, Doha, Qatar

Introduction:
Identifying the clinical characteristics and factors associated with fragility fractures is crucial for estimating fracture risk. This aligns with the concept of using the fracture risk assessment tool (FRAX®). Most identified risk factors are derived from cohorts that do not represent Arab ancestry, and it remains uncertain whether these risk factors differ from those in other populations.
Aim: Describe the demographic and clinical characteristics, as well as identify the factors associated with major osteoporotic fractures (MOF) in the Qatari population over a three-year period from 2017 to 2019.
Methods:
Major osteoporotic fractures (MOF), including compression spine fractures, proximal humerus fractures, and distal radius fractures, were identified retrospectively in Qatari individuals aged 40 years and older who underwent X-rays of the humerus, shoulder, wrist, lumbar spine, or thoracic spine at Hamad Medical Corporation (HMC) and Primary Health Care (PHC) facilities in Qatar from January 1, 2017, to December 31, 2019. The electronic medical records (EMR) from both institutions are integrated into a single cloud software system (Cerner®). The EMR of the identified individuals were reviewed by the study investigators to collect data on MOF, demographic information, and clinical characteristics, including age, gender, comorbidities, and medications (such as glucocorticoids, aromatase inhibitors, and anti-epileptic drugs). Patients with fractures resulting from high-energy trauma, as well as those with isolated greater tuberosity or avulsion fractures of the humerus, were excluded from the study. Descriptive analysis and bivariate logistic regression analysis were performed using SPSS.
Results:
A total of 9,617 subjects underwent at least one X-ray of the wrist, shoulder, humerus, lumbar spine, thoracic spine, or thoracolumbar spine during the study period. The mean age of the participants was 57.1 years (±11.9), with females representing 67% of the study population. The average body mass index (BMI) was 33.1 kg/m².
Among the 9,617 individuals, 403 (4.19%) sustained at least one fracture, and 43 subjects experienced multiple fractures during the study period. Of these fractures, 369 (82.7%) were attributed to low-energy trauma. The mean age at the time of experiencing a fragility fracture was 66.8 years (±12.2), with 74% of these cases being female. The most prevalent type of fragility fracture was spinal fractures, totaling 153 cases (41.5%), followed by distal radius fractures at 136 (36.9%) and proximal humerus fractures at 80 (21.7%).
Chronic liver disease was found to have the strongest association with major osteoporotic fractures (MOF), with an odds ratio (OR) of 7.999, followed by epilepsy (OR 3.558) and the use of glucocorticoid medications (OR 3.311). Additional risk factors associated with MOF are summarized in Table 1.
Conclusion:
Most of the identified risk factors for fragility fractures in this Qatari population align with those found in global populations. However, some risk factors did not demonstrate an increased risk of major osteoporotic fractures, which may be attributed to the small number of subjects affected by these conditions.

Table1: demographic and clinical characteristics associated with major osteoporotic fractures including compression spine frac-

tures, proximal humerus fractures, and distal radius fractures (bivariate analysis)

	Fracture n=369	No fracture n=9214	P value	OR (95%CI)
Female	273(74.0%)	6199(67.3%)	0.007	1.383(1.092-1.752)
Age, mean (SD)	66.8(12.2)	56.9 (11.7)	0.000	1.064 (1.055-1.073)
BMI kg/m^2, mean (SD)	30.8 (6.7)	32.5 (76)	0.000	0.958 (0.940-0.976)
Diabetes mellitus, no (%)	178(48.2%)	3207(34.8%)	0.000	1.746(1.417-2.151)
Primary hyperparathyroidism, no (%)	3(0.8%)	42(0.5%)	0.325	1.790(0.552-5.802)
Hyperthyroidism, no (%)	0	7(0.1%)	1.000	---
Chronic kidney disease, no (%)	31(8.4%)	444(4.8%)	0.002	1.812(1.239-2.649)
Chronic liver disease, no (%)	6(1.6%)	19(0.2%)	0.000	7.999(3.176-20.149)
Coronary artery disease, no (%)	11(3%)	79(0.9%)	0.000	2.501(0.319-19.589)
Ischemic stroke, no (%)	8(2.2%)	53(0.6%)	0.000	3.830(1.808-8.116)

SAFETY OF ANTI-OSTEOARTHRITIS MEDICATIONS: OUTCOMES OF A SYSTEMATIC LITERATURE REVIEW OF POST-MARKETING SURVEILLANCE STUDIES

G. Honvo[1], L. Lengelé[2], M. Alokail[3], N. Al-Daghri[4], J.-Y. Reginster[3], O. Bruyère[1]

[1]Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium, [2]Metabolism and Nutrition Research Group, Louvain Drug Research Institute, UCLouvain, Université catholique de Louvain, Sint-Lambrechts-Woluwe, Belgium, [3]Protein Research Chair, Biochemistry Department, College of Science, King Saud University, Riyadh, Saudi Arabia, [4]Chair for Biomarkers of Chronic Diseases, College of Science, King Saud University, Riyadh, Saudi Arabia

Objective: To identify all the published post-marketing safety surveillance (PMS) studies on anti-osteoarthritis (OA) medications, and to describe the characteristics and the main findings of these studies.
Methods: This study followed the Cochrane guideline for systematic reviews (SR) of interventions. The Medline, CENTRAL, Scopus, and TOXLINE databases were comprehensively searched from inception to November 2023, to include all PMS studies on any anti-OA medications. The outcomes of the review were any adverse events (AEs) reported in the included studies.
Results: From 16,990 records retrieved from literature search, 59 articles were included. Most studies investigated non-steroidal anti-inflammatory drugs (NSAIDs, 27 studies, 28 reports) and intra-articular hyaluronic acid (IAHA, 16 studies). Symptomatic slow-acting drugs for osteoarthritis (SYSADOAs) were assessed in 7 studies, and corticosteroid injections in 4 studies. Opioids and "herbal mixtures and other compounds" each were investigated respectively in 3 and 2 studies. Most studies were cohort studies (n = 44), others were case reports or case series (n = 12), randomized controlled trials (RCTs, 2 reports of a same trial), or case-control study (n = 1). The most commonly reported AEs with NSAIDs from cohort studies, RCTs, and case-control studies were gastrointestinal (GI) and/or cardiovascular (CV) AEs. Where comparisons between NSAIDs were made, the overall literature shows a better or similar safety profile for celecoxib (at a daily dose of 200 mg) compared to other NSAIDs in regards with the GI, CV, and renal events. Other anti-OA medications with most commonly reported AEs were: IAHA (injection site pain); diacerein (GI AEs and reddish urine); avocado–soybean unsaponifiables (GI AEs); non-pharmaceutical grade glucosamine and chondroitin (allergic reactions, GI disorders); opioids (hip fracture associated with long-term tramadol use among older adults; and GI and nervous system disorders with hydrocodone); corticosteroid injections (increased risk of OA progression); herbal mixtures and other compounds (GI AEs). There were case reports or case series of specific AEs with various anti-OA medications that require further investigations in well designed cohort studies before any definitive conclusions.
Conclusions: This SR of PMS studies confirms previous evidence on the safety of anti-OA medications from meta-analyses of phase 3 RCTs. Beyond the findings reported, the limitations of this research highlight the urgent need of a reporting guideline for PMS studies.

P1139

CLINICAL RESULTS OF MENISCAL REPAIR WITH FIBRIN CLOT AUGMENTATION OF DEGENERATIVE HORIZONTAL TEAR

V. Lykhodii[1], O. Burianov[1], Y. Rybchenko[1], T. Pshenychnyi[2], V. Lianskorunskyi[1]

[1]Bogomolets National Medical University, Kyiv, Ukraine, [2]SI, Institute of Traumatology and Orthopedics by NAMS of Ukraine, Kyiv, Ukraine, Kyiv, Ukraine

Objective: clinical assessment of fibrin clot (FC) augmented meniscal repair in in patients with degenerative medial meniscus tear and concomitant 1st and 2nd K-L knee osteoarthritis. Meniscal preservation surgery is important step to prevent rapid development of knee osteoarthritis. The outcomes of meniscal repair surgery depend on several surgical factors, such as quality of meniscus tissue, type of meniscal tear etc. FC augmentation is inexpensive method which could potentially improve healing of meniscal tear.
Methods: patients with degenerative posterior horn horizontal tear are divided into main group (n_m=21) – meniscal repair with FC augmentation and comparison group (n_c=36) – meniscal repair. During arthroscopy we remove free flaps of meniscus and put the fibrin clot inside the horizontal cleavage meniscal tear. Meniscal repair includes all-inside technique applying circumferential stitches using knee scorion. For FC preparation we use 30-40ml

of patient's blood. During step of dry arthroscopy, we insert FC and tie sutures knots. Patients underwent routine clinical follow up 6 month and 1 year after surgery using Lysholm score, Tegner score, Knee injury and Osteoarthritis Outcome Score (KOOS).
Results: the mean age in patients of the main group was 51.4±4.9, comparison group – 49.8±4.5years (p=0.2). BMI in the main group was 29.6±2.3, comparison group – 28.8±1.9 (p=0.18). In the main group were 14(66.7%) females and 7(33.3%) males and in the comparison group were 25 (69.4%) females and 11 (30.63%) males (p=0.8).
Before surgery, the score on the Lyscholm scale in patients of the main group (n_m=21) was 60.3±4.1, in the comparison group (n_c=36) - 58.4±5.2 points (p=0.1). The score on the Tegner scale before surgery, in patients of the main group (n_m=21) was 4.2±1.1, in the comparison group (n_c=36) – 4.3±0.8 points (p=0.7). Before surgery, the score on the KOOS in patients of the main group (n_m=21) was 63.4±4.1 points, in the comparison group (n_c=36) - 61.7±5.2 points (p=0.1). The score on the Lyscholm scale 6 months post-op in patients of the main group (n_m=21) was 87.2±4.0, in the comparison group (n_c=36) - 89.3±3.7 points (p=0.06). The result on Tegner scale 6 months post-op in patients of the main group (n_m=21) was 5.2±1.0 and in the comparison group (n_c=36) - 5.1±0.8 points (p=0.6). The KOOS 6 months after surgery in patients of the main group (n_m=21) was 89.7±4.7 and in the comparison group (n_c=36) - 92.0±5.1 (p=0.09).There was no difference in clinical results after 6 months of operation.
One year after surgery, the score on the Lyscholm scale in patients of the main group (n_m=21) was 90.3±3.2 , in the comparison group (n_c=36) - 87.6±3.7 points (p=0.02). One year after surgery, the score on the Tegner scale in patients of the main group (n_m=21) was 5.3±1.2 , in the comparison group (n_c=36) - 5.3±0.9 points (p=0.9). One year after surgery, the score on the KOOS in patients of the main group (n_m=21) was 92.2±3.1 , in the comparison group (n_c=36) - 89.8±4.8 points (p=0.02). There was difference in clinical outcomes 1 year post-op follow up. The number of revision surgery during period of follow-up was 3 (14.3%) in main group (n_m=21) and 7(19.4%) in comparison group (n_c=36).
Conclusion: meniscal repairing of degenerative horizontal tear with fibrin clot augmentation shows similar clinical outcomes during 6 months after surgery comparing with meniscal repair alone, but after 1 year after surgery patients with FC augmentation show better clinical result with lower rate of revision surgery. FC augmentation could increase healing rate and decrease level of revision second look arthroscopy.

P1140

OSTEOPOROSIS AND BONE BIOMARKERS

G. O. Cioroianu[1], R. A. Cioroianu[1], C. M. Ionele[1], O. C. Rogoveanu[1]

[1]University of Medicine & Pharmacy of Craiova, Craiova, Romania

Introduction: Bone health can be assessed using measurable indicators of bone metabolism known as bone biomarkers.
Methods: We evaluated 20 patients which presented risk factors for osteoporosis by measuring Osteocalcin (OC), Procollagen type 1 N-terminal propeptide (P1NP) and beta-CrossLaps (β-CTx) from venous blood. Patients who presented modifications of these biomarkers were subsequently assessed by dual-energy X-ray absorptiometry (DXA) of the lumbar spine.
Results: Of the 20 evaluated patients, 13 showed changes in the measured bone biomarkers. Further, following the DXA assessment, we found that 7 patients had osteopenia, with the mean T-score being -1.9, presenting a minimum value of -2.3 and a maximum value of -1.1, and 4 patients had osteoporosis, with the mean T-score being -2.7, presenting a minimum value of -2.9 and a maximum of -2.6.
Conclusion: Measurement of such bone biomarkers could represent valid screening methods for osteoporosis.

P1141

COMBINED USE OF LASER THERAPY AND NONSTEROIDAL ANTI-INFLAMMATORY DRUGS IN PAIN MANAGEMENT OF THE SMALL JOINTS OF THE HANDS IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. O. Cioroianu[1], A. C. Predeanu[1], A. Florescu[1], O. C. Rogoveanu[1]

[1]University of Medicine & Pharmacy of Craiova, Craiova, Romania

Introduction: Rheumatoid arthritis is a chronic inflammatory condition of autoimmune origin that particularly affects the small joints of the hands. The disease causes pain and functional impotence in patients and over time can lead to joint destruction and deformity.
Methods: The aim of the study was to evaluate the effectiveness of using low-level laser therapy (LLLT) and non-steroidal anti-inflammatory drugs (NSAIDs) combined on pain symptomatology control in patients with rheumatoid arthritis.
Results: 14 patients previously diagnosed with rheumatoid arthritis were included, all affected by pain in the small joints of the hands. Pain intensity was assessed using the Visual Analogue Scale (VAS) (0-100 mm), presenting an average of 66.5 mm. The patients underwent physical therapy treatment consisting of LLLT at the radio-ulnar-carpal, metacarpophalangeal and proximal interphalangeal joints, as well as pharmacological treatment with NSAIDs for 10 days. At the end of the treatment period, the patients were re-evaluated, the mean VAS scale presenting the value of 54.3 mm, meaning a decrease of 18.3% from the initial value.
Conclusion: The use of low-level laser therapy and nonsteroidal anti-inflammatory drugs can help control pain symptoms regarding the small joints of the hands in patients with rheumatoid arthritis.

P1142

WEIGHT IMPORTANCE IN OSTEOARTHRITIS OF THE KNEE

G. O. Cioroianu[1], R. A. Cioroianu[1], S. Bănicioiu-Covei[1], O. C. Rogoveanu[1]

[1]University of Medicine & Pharmacy of Craiova, Craiova, Romania

Introduction: Osteoarthritis is the most common arthropathy of the knee joint. Although this was considered a purely degenerative condition, the presence of inflammatory elements have been recently identified in the pathogenesis of the disease. Being a weight bearing joint, obesity is one of the most important risk factors concerning this condition.
Methods: We evaluated 28 patients using musculoskeletal ultrasonography that we divided into 4 groups according to the body mass index (BMI) as follows. The first group was composed of 5 patients with BMI < 24.9 kg/m^2, the second group consisted of 7 patients with 25 kg/m^2 < BMI < 29.9 kg/m^2, the the third group was formed of 10 patients with 30 kg/m^2 < BMI < 34.9 kg/m^2, and the last group had a total of 6 patients with BMI ≥ 35 kg/m^2.
Results: Following the ultrasonographic examination, we found joint changes in 20% of the patients in the first group, in 28.6% of the patients in the second group, in 60% of the patients in the third group and in 83.3% of the patients in the last group.
Conclusion: In a society where the incidence of obesity and metabolic disorders are continuously increasing, these also present a negative impact on osteo-articular health. A higher BMI being associated with an increased risk of developing knee osteoarthritis.

P1143

CHANGES IN BONE MINERAL DENSITY AND THE NEED TO MOBILIZE PATIENTS WITH HEMIPLEGIA AFTER STROKE

M. S. Bulugea[1], O. Taisescu[1], A. C. Predeanu[1], O. C. Rogoveanu[1]

[1]University of Medicine & Pharmacy of Craiova, Craiova, Romania

Objective: The relationship between post-stroke immobility and the reduction in bone density presents significant health concerns, particularly regarding fracture risks and subsequent complications in stroke survivors. It was observed that the duration of immobilization plays a central role in changes to bone density.
Methods: A study was conducted involving 25 acute stroke patients. Initially, there were 11 wheelchair-bound patients and 14 ambulatory patients. The assessment method used was bilateral proximal femur measurements through dual-energy X-ray absorptiometry (DXA). The initial assessment took place approximately 8 days post-stroke, and a follow-up evaluation was conducted after one year. Notably, 5 patients who were initially wheelchair-bound achieved walking capability within 4 months.
Results: The one-year bone mineral density (BMD) changes revealed various patterns. Among the permanently wheelchair-bound patients, a reduction of 11% in BMD was observed on the paretic side, while the non-paretic side exhibited a 4% decrease. In the group of patients who regained walking ability, there was a 7% reduction on the paretic side and a 2% reduction on the non-paretic side. For the continuously ambulatory patients, the paretic side showed a 2% reduction, and the non-paretic side showed no significant change.
Conclusion: These findings underscore the importance of early mobilization in post-stroke rehabilitation. The significant bone density loss seen in immobile patients, particularly on the paretic side, indicates that prolonged immobility heightens fracture risk. The research supports the integration of early walking rehabilitation in stroke recovery protocols to help maintain bone mineral density.

P1144

EFFICIENCY OF A PHYSICAL PROGRAM IN THE MOBILITY OF PATIENTS DIAGNOSED WITH POSTMENOPAUSAL OSTEOPOROSIS

M. S. Bulugea[1], A. C. Predeanu[1], S. Bănicioiu-Covei[1], T. Sas[1], O. C. Rogoveanu[1]

[1]University of Medicine & Pharmacy of Craiova, Craiova, Romania

Objective: A first step in trying to improve the functional status of the patient with postmenopausal osteoporosis should be to approach a physical exercise program divided into balance exercise, resistance training and gait rehabilitation exercise. Through the present study we managed to evaluate the effect of a 10-week exercise program on the functional outcomes of patients aiming to improve muscle strength and balance.
Methods: The study includes 72 female patients assessed via Dual-Energy X-ray Absorptiometry (DXA) diagnosed postmenopausal osteoporosis who were randomized into two groups: exercise group and control group. The patients in the exercise group are 35 in number and participated in a 10 week exercise program, which consisted of resistance training, balance exercise and gait training, while patients from control group are 37 in number and had not participated in any exercise program during the intervention period. The examinations performed were as follows: Sit-to-Stand Test (STS), One-Leg Stance Test (OLST), and Timed Up and Go Test (TUG) were assessed at baseline, as well as at 5 and 10 weeks post-treatment.
Results: Statistically significant improvements were observed in all measured parameters in the exercise group after 5 and 10 weeks, respectively. At the end of the study period, a significant difference was observed in the progress of the two groups. The OLST showed a significant change only in the exercise group across all experimental periods. After 5 weeks, there were no statistically significant changes in any of the monitored parameters in the control group. However, after 10 weeks, the exercise group demonstrated improved scores in the Sit-to-Stand (STS) and Timed Up and Go (TUG) tests.
Conclusion: A physical exercise program consisting of balance exercises, resistance training, and gait training can play a crucial role in improving activities of daily living (ADL) and reducing patients' fear of falling.

P1145

METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE-KEY ELEMENT IN THE PROGRESSION OF OSTEOPOROSIS?

D. B. Harosa[1], C. M. Ionele[1], O. C. Rogoveanu[1], I. Rogoveanu[1]

[1]University of Medicine & Pharmacy of Craiova, Craiova, Romania

Key words: metabolic dysfunction-associated fatty liver disease, osteoporosis, hepatokines.

Introduction: Metabolic dysfunction-associated fatty liver disease (MAFLD) is characterized by the accumulation of triglycerides in hepatocytes in the absence of alcohol consumption or other potential causes of hepatotoxicity. Osteoporosis is a disorder of bone metabolism characterized by a reduction in bone density along with changes in bone structure, associated with an increased risk of fractures. Although it is known that patients with MAFLD are at higher risk of developing osteoporosis, the role of hepatokines, proteins synthesized by the hepatocytes with a hormonal role, is incompletely elucidated. Understanding the pathophysiologic mechanisms of hepatokines regarding the development of osteoporosis could provide new options in terms of diagnostic and therapy for future patients.

Materials and Methods: A study was conducted on a total of 15 patients aged 57-68 years diagnosed with MAFLD and Osteoporosis. To compare the results we used a control group of 15 patients aged 55-65 years diagnosed with Osteoporosis, without MAFLD or other chronic liver diseases. The degree of osteoporosis was objectified using DEXA analysis. Hepatokines (Fetuin A, FGF21, LECT2, Hepassocin) were identified in patients serum using Elisa kits. Subsequently, the serum hepatokine levels were correlated with the DEXA score in both groups.

Results: After analyzing the data, we observed that the serum levels of Fetuin A and FGF21 were twice higher in the study group compared to the control group, while the results for LECT2 and Hepassocin were approximately equal in both groups. T-score of DEXA analysis was also higher in the study group compared to the control group (-3.1 versus -2.7).

Conclusions: The results suggest a potential involvement of hepatokines in the pathophysiology of osteoporosis. However, further studies are needed to establish this hypothesis and to assess how the hepatokines influence negatively or positively the progression of bone demineralization.

P1146

OSTEOPOROSIS AND SYSTEMIC INFLAMMATION LEVELS IN CHRONIC PANCREATITIS PATIENTS

C. C. Bigea[1], M. A. Cîrstei[1], O. C. Rogoveanu[1], C. M. Ionele[1], I. Rogoveanu[1]

[1]University of Medicine & Pharmacy of Craiova, Craiova, Romania

Keywords: chronic pancreatitis, osteoporosis, vitamin D deficiency, systemic inflammation.

Introduction: Chronic pancreatitis (CP) leads to pancreatic exocrine insufficiency which may lead to maldigestion and malnutrition. However, the pathogenesis of low bone mineral density (BMD) has not been characterized. The pathophysiology of secondary osteoporosis in CP is multifactorial, highly related to age and due to exocrine pancreatic insufficiency (EPI) with maldigestion of fat-soluble vitamins including vitamin-D, which has a significant role in the process of bone formation. Therefore, we sought to investigate an association between BMD, systemic inflammation and vitamin D deficiency.

Materials and methods: Twenty-one CP patients (76% male, mean age 51 years (range, 45-72) of whom 76% were smokers) and twenty-one matched controls were recruited from Craiova County Hospital. BMD by dual-energy X-ray absorptiometry at the hip/femoral neck and lumbar spine was measured along with vitamin D (25-hydroxyvitamin D, 25OHD), parathyroid hormone (PTH), interleukin 6 (IL-6), C-reactive protein (CRP), fibrinogen and erythrocyte sedimentation rate (ESR). The data were analyzed focusing particularly on those who experienced exacerbations within the past year. Smoking status was also noted.

Results: 75% of the CP pacients had osteoporosis. Patients had lower 25OHD compared with controls and higher inflammatory markers, including higher Il-6 levels. Using analysis of variance, patients with osteoporosis and CP had higher inflammation (hsCRP), PTH, and IL-6 and lower 25OHD. Moreover, all these patients were smokers.

Conclusion: BMD was abnormal in CP. An association between chronic pancreatitis, low 25-OHD, systematic inflammation (evaluated by hsCRP, fibrinogen, ESR and IL-6) was shown. Those patients with osteoporosis and pancreatitis had the highest systemic inflammation and all of them were smokers. Patients with chronic pancreatitis (CP) may have a higher prevalence of osteoporosis than the general population thereby increasing the risk of bone fracture so should be screened for vitamin D deficiency and corrected with fat soluble vitamin supplementation.

P1148

COMPARISON OF THE COMPREHENSIVE GERIATRIC ASSESSMENT OF OLDER PATIENTS RECEIVING DIFFERENT OSTEOPOROSIS TREATMENT

F. Isıkgil[1], O. Deniz[2]

[1]Bursa City Hospital, Department of Internal Medicine, Bursa, Turkiye, [2]Bursa City Hospital, Palliative Care Unit, Geriatric Medicine Clinic, Bursa, Turkiye, Bursa, Turkiye

Objective: Population ageing is a global phenomenon. The phenomenon of population ageing will lead to an increased proportion of age-associated chronic diseases, including osteoporosis and fractures, and their consequences. The purpose of the present study is to compare the comprehensive geriatric assessment (CGA) of geriatric patients with different osteoporosis treatment choices.

Material and Methods: Osteoporosis was diagnosed by dual energy x-ray absorptiometry. A comprehensive geriatric assessment

included the following: Basic and instrumental activities of daily living, mini nutritional assessment, mini-mental state examination, geriatric depression scale, SARC-F questionnaire, timed up and go test. The diagnosis of probable sarcopenia was made according to the criteria of the European Working Group on Sarcopenia in Older People. Fracture and their localizations were noted.
Results: The study included 125 older patients treated for osteoporosis. Sixty-seven patients were treated with *bisphosphonates,* 40 with denosumab, and 18 with teriparatide. The mean age of the participants was 77,6 ± 8 years; 82% were female. Duration of osteoporosis was higher in those treated with both denosumab and teriparatide than those with *bisphosphonates. Hand grip strength was the highest in the bisphosphonates group. Fracture prevalence was the highest in the teriparatide group. When patients* were categorized into two groups (oral vs. parenteral), the parenteral treatment group had a higher fracture and probable sarcopenia prevalence, and lower calf circumference. Acoording to a comprehensive geriatric assessment parenteral treatment group was more frail than the oral treatment group.
Conclusion: The particular features and potential of the CGA make it useful in managing older patients with osteoporosis. It may give rise to an appropriate, tailored treatment plan for older patients.

P1149

DECISION SUPPORT IN ELECTRONIC HEALTH RECORDS AS TOOL TO IMPROVE CARE FOR WOMEN WITH OSTEOPOROSIS

O. Derevianko[1], T. Rumyantseva[1], D. Fomin[1]

[1]Fomin Clinic, Moscow, Russia

Background & Aims: Osteoporosis remains a significant global public health issue, with a growing number of individuals at risk for fractures due to decreased bone density. Despite its high prevalence, osteoporosis is often underdiagnosed and undertreated, largely due to knowledge gaps among healthcare professionals. This abstract explores the role of education in improving the management of osteoporosis across various medical specialties. While specialists such as endocrinologists, rheumatologists, and orthopedists are the primary healthcare providers involved in the diagnosis and treatment of osteoporosis, there is an increasing need for general practitioners (GPs), geriatricians, and internal medicine doctors to have a more in-depth understanding of the disease. This is particularly critical given the aging population and the potential for osteoporosis-related fractures to lead to significant morbidity and mortality. The aim of our study was to explore the quality of osteoporosis care experienced by women in Russia in Fomin Clinic in 12 cities in Russia and how it could be improved with the help of Electronic Health Record with decision support. Methods: 1617 Electronic Health Records of women with osteoporosis before and after the start of the decision support (802 and 815, respectively) were analyzed and rated on a 100-point scale (diagnostics, nutrition, physical activity, treatment recommendations). The decision support system based on Guidelines of Russian Endocrinology Association, Russian Osteoporosis Association, International Osteoporosis Foundation . Results: The average score before using decision support was 43, and after doctors started to use it the average score after 6 months of using became 89. Conclusions: Electronic Health Record with decision support is great tool which improves quality of care for women with osteoporosis and refines the diagnosis and treatment of osteoporosis in different cities in Russia.

P1150

ONLINE COURSE - A NEW OPTION IN IMPROVING OSTEOPOROSIS MANAGEMENT THROUGH DOCTOR EDUCATION

O. Derevianko[1]

[1]Fomin Clinic, Moscow, Russia

Background and Aims
Online courses play a critical role in enhancing the quality of diseases management among healthcare professionals, particularly doctors. Given the increasing prevalence of osteoporosis globally, it is essential for clinicians to stay updated on the latest diagnostic methods, treatment options, and management strategies. Online educational platforms provide a flexible, accessible, and cost-effective way for doctors to engage with evidence-based content, case studies, and expert-led discussions. These courses offer opportunities for continuous learning, allowing healthcare providers to improve their knowledge of osteoporosis pathophysiology, risk factors, and the latest pharmacological interventions. Moreover, online courses facilitate the development of practical skills in patient management, empowering doctors to tailor interventions based on individual patient needs. As a result, these educational initiatives contribute significantly to improved patient outcomes, reduced fracture rates, and overall better quality of care in osteoporosis management.
Methods
Online course "Osteoporosis School" by endocrinologist Olga Derevianko based on Guidelines of Russian Association on Osteoporosis and International Osteoporosis Foundation consist of 12 part e-Learning series wich provide health professionals an evidence-based approach to the care of women with osteoporosis in a multidisciplinInary environment. 44 doctors were tested before and after the course.
The questions included the topics of diagnosis, treatment, nutrition and physical activity in osteoporosis.
Results
Doctors improved their results in tests rated on a 100-point scale after the course - from 64 to 96 points.
Conclusions
Online course is a great option in improving osteoporosis management through the training of medical personnel.

P1151

ASSESSMENT OF SERUM OSTEOPONTIN, OSTEOPROTEGERIN AND BONE-SPECIFIC ALP AS MARKERS OF BONE TURNOVER IN PATIENTS WITH DISORDERS OF THYROID FUNCTION IN NIGERIA, SUB-SAHARAN AFRICA

O. E. Olukoyejo[1], O. A. Ajose[2], A. K. Ajeigbe[2], N. R. Njeze[3], T. A. Adedeji[2], O. S. Smith[1], J. Akande[4]

[1]DEPARTMENT OF CHEMICAL PATHOLOGY, OBAFEMI AWOLOWO UNIVERSITY TEACHING HOSPITAL, ILE-IFE , Nigeria, [2]DEPARTMENT OF CHEMICAL PATHOLOGY, OBAFEMI AWOLOWO UNIVERSITY, ILE-IFE , Nigeria, [3]DEPARTMENT OF RADIOLOGY, UNIVERSITY OF NIGERIA, NSUKKA, NSUKKA, Nigeria, [4]LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO, Nigeria

Background/Objective: Thyroid dysfunctions, the second commonest endocrine disorders worldwide, is a cause of metabolic bone diseases (MBD). These metabolic bone complications are often subtle but manifest as bone pains with increased risk of fractures. The gold standard for diagnosis, Dual Energy X-ray Absorptiometry, is costly, and not readily accessible in this environment. However, bone biomarkers have shown prospects in assessing alterations in bone remodeling, and have not been studied in this environment. Hence, the need for this novel work on the selected cluster of biomarkers in the West African Sub-region. The aim of the study is to evaluate serum levels of bone-specific ALP (BALP), osteopontin (OPN) and osteoprotegerin (OPG) turnover markers in thyroid dysfunctions.
Methodology: This is a cross-sectional study, involving 40 patients with thyroid dysfunctions, aged 20 to 51 years, and 38 matched euthyroid controls. Patients were further stratified into hyperthyroid and hypothyroid groups. BALP, OPN and OPG, alongside the routine bone markers of serum total calcium (TCa) and ionized calcium (ICa) were assayed for all patients and controls, using ELISA technique and ion-selective electrode respectively while inorganic phosphate (IP) was assayed with automated photometry.
Results: The hyperthyroid and hypothyroid groups had significantly increased median serum BALP (30.40 and 26.50) ng/ml and significantly lower median OPG (0.80 and 0.80) ng/ml than the controls (10.81 and 1.30) ng/ml respectively, $p < 0.05$. However, serum OPN in the hyperthyroid and hypothyroid groups were significantly higher and lower respectively, when compared to the controls (11.00 and 2.10 vs 3.70) ng/ml respectively, $p < 0.05$. Both patient groups had significantly higher mean TCa, ICa and IP than the controls (2.49 ± 0.28, 1.27 ± 0.14 and 1.33 ± 0.33) mmol/l and (2.41 ± 0.04, 1.20 ± 0.04 and 1.15 ± 0.16) mmol/l vs (2.27 ± 0.11, 1.17 ± 0.06 and 1.08 ± 0.16) mmol/l respectively, $p < 0.05$.
Conclusion: Patients with thyroid dysfunctions have metabolic imbalance of all studied bone markers, suggesting a higher bone turnover. The routine bone markers will be an invaluable tool for monitoring bone health in them, while the less readily available markers can be introduced as supplementary tools. Moreover, BALP, OPN and OPG were found to be the strongest independent predictors of MBD in thyroid dysfunctions.

P1152

CORRELATION OF BONE TURNOVER MARKERS WITH DURATION OF THYROIDAL ILLNESS IN PATIENTS WITH OVERT HYPERTHYROIDISM IN NIGERIA, SUB-SAHARAN AFRICA

O. E. Olukoyejo[1], O. A. Ajose[2], A. K. Ajeigbe[2], N. R. Njeze[3], T. A. Adedeji[2], V. O. Ogra[1], J. O. Kolawole[4], C. Olowu[5]

[1]DEPARTMENT OF CHEMICAL PATHOLOGY, OBAFEMI AWOLOWO UNIVERSITY TEACHING HOSPITAL, ILE-IFE , Nigeria, [2]DEPARTMENT OF CHEMICAL PATHOLOGY, OBAFEMI AWOLOWO UNIVERSITY, ILE-IFE , Nigeria, [3]DEPARTMENT OF RADIOLOGY, UNIVERSITY OF NIGERIA, NSUKKA, NSUKKA, Nigeria, [4]DEPARTMENT OF CHEMICAL PATHOLOGY, LAGOS STATE UNIVERSITY TEACHING HOSPITAL, IKEJA, Nigeria, [5]UNIVERSITY OF WEST VIRGINIA, WEST VIRGINIA, United States

Background/Objectives: Overt hyperthyroidism has been known to cause profound derangements in the levels of biochemical bone turnover markers in patients not commenced on the appropriate anti-thyroid medications on time, with accompanying attendant metabolic bone complications, as most patients present late in this environment. Little or no work has been done to unravel the impact of this delay in initiating management, especially in Sub-Saharan Africa. This study is therefore set out and aimed at correlating the traditional (conventional) bone turnover markers of total calcium (Tca), ionized calcium (Ica), inorganic phosphate (Ip), and some relatively newer markers with the duration of thyroidal illness in these patients.
Materials/Methods: This is a cross-sectional study, involving 37 patients with a diagnosis of primary hyperthyroidism, aged 20 to 51 years, and 38 matched euthyroid controls. Patients who were on thyroid medications or other drugs that can affect bone turnover, or who have had thyroid surgery or radiotherapy and patients with any other chronic medical conditions that can simultaneously affect bone turnover were all excluded. Self-administered questionnaire was used to obtain their socio-demographic data and medical history, including the duration of their thyroidal illness. Serum samples were assayed in all patients and controls for Osteopontin (OPN), Osteoprotegerin (OPG) and Bone-specific ALP (BALP), using ELISA technique. Tca and Ica were assayed using a direct ISE while Ip was assayed with automated photometry. Spearman Correlation was used to determine the relationship between the markers and the duration of thyroid illness.
Results: Only serum Tca and Ica demonstrated statistically significant positive correlations with the duration of thyroid illness ($r = 0.327$, $p = 0.048$; $r = 0.388$, $p = 0.018$ for Tca and Ica respectively), while Ip, OPN, OPG and BALP showed no statistically significant correlations ($r = -0.102$, $p = 0.550$; $r = 0.033$, $p = 0.845$; $r = -0.176$, $p = 0.296$; $r = -0.057$, $p = 0.740$ respectively).
Conclusion: The traditional bone markers of total calcium and ionized calcium should be routinely done in patients presenting with overt hyperthyroidism, especially in those presenting late, with delayed diagnosis, so as to optimize bone health in them. However, in resource-limited settings, any of these two can suffice in such late-presenters.

P1153

THE IMPORTANCE OF DETERMINING ANTIBODIES TO ELASTIN AND ELASTASE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS WITH CARDIOVASCULAR SYSTEM PATHOLOGY

O. Emelianova[1], A. Trofimenko[1], O. Rusanova[1], N. Emelianov[2], S. Spicina[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Federal State Budgetary Educational Institution of Higher Education «Volgograd State Medical University», Volgograd, Russia

Introduction. Elastin is the main protein component of which elastic fibers are composed. Elastases participate in the exchange of elastin. Damaging factors of various origins cause the production of autoantibodies to its components, leading to inflammation and, subsequently, to tissue destruction. Antibodies to elastin and elastase are predictors of the development of vascular pathology in systemic lupus erythematosus.
Objective. To identify the relationship between the level of antibodies to elastin and elastase in patients with systemic lupus erythematosus and cardiovascular disease
Materials and methods. The serum of 30 donors, 46 with systemic lupus erythematosus SLE, was studied. The diagnosis of SLE was verified using the ACR diagnostic criteria in the 1997 edition. AT to elastin and elastase were determined in the blood serum by the indirect enzyme immunoassay (ELISA) using magnetosorbents (according to the method of I.P. Gontar). The results were expressed in units of optical density (e.o.p.).
Results. When studying the blood serum of healthy individuals, the level of AT to elastin, the upper limit of the norm, was 0.104 e.o.p., and to elastase 113e.o.p. Elevated levels of AT to elastin were detected in 27 (50.8%) patients with SLE, averaging (0.138±0.067) e.o.p., and to elastase (82.6%), on average - (0.154±0.076) e.o.p. Elevated antibody levels were associated with cardiac and vascular lesions. At the first stage of activity of systemic lupus erythematosus, antibodies to elastin were within (0.104 ± 0.010) e.o.p. with cardiac lesions (0.112 ± 0.006) e.o.p.; to elastase - (0.116 ± 0.008), with cardiovascular lesions - (0.124 ± 0.006). In the second degree of activity of antibodies to elastin (0.128±0.006) e.o.p., in case of heart damage, respectively (0.136±0.007) e.o.p.; to elastase (0.148±0.004)e.o.p, in case of cardiovascular damage – (0.157±0.005)e.o.p. In patients with the third degree of SLE activity, AT to elastin (0.154±0.004) e.o.p., in case of cardiovascular damage – (0.168±0.005)e.o.p.; to elastase (0.172±0.008)e.o.p, in case of cardiovascular damage – (0.185±0.008)e.o.p.
Conclusions. The conducted studies revealed a relationship between the level of AT to elastin, elastase and cardiovascular damage. This fact indicates that antibodies to elastin and elastase are specific predictors of the development of vascular pathology in SLE.

P1154

DIAGNOSTIC AND PATHOGENETIC SIGNIFICANCE OF AUTOANTIBODIES TO FIBRONECTIN IN THE OCCURRENCE OF AUTOIMMUNE INFLAMMATION IN PATIENTS WITH RHEUMATIC DISEASES

O. Emelianova[1], S. Spicina[2], O. Rusanova[1], A. Trofimenko[1], N. Emelianov[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Federal State Budgetary Educational Institution of Higher Education «Volgograd State Medical University», Volgograd, Russia

Introduction. Fibronectin (FN) is known for its polyvalent properties, due to the presence in its molecule of specialized regions – domains that have a high affinity for collagen, fibrin, bacterial walls, etc. The formation of antibodies to FN, as studies show, plays an important role in the pathogenesis of rheumatic diseases, since it can be the cause of the weakening of a number of important functions of this glycoprotein.
Objective. Study of the clinical and pathogenetic role of antibodies to fibronectin in patients with systemic lupus erythematosus and systemic scleroderma using antigen immobilization technology on polyacrylamide granules with magnetic properties.
Materials and methods. The serum of 30 healthy individuals, 53 SLE patients and 34 patients with SSD was studied. In the group of SLE patients, 10 people (19%) had stage I disease activity, 32 (60%) – II and 11 (21%) – the maximum stage of pathological process activity. The SLAM and SLEDAL indices were also calculated. Among patients with SSD, 18 people (53%) had stage I disease activity, and 16 (47%) had stage II. According to the nature of the disease course, patients were distributed as follows: with SSD, 22 people (65%) had a subacute course and 12 people (35%) had a chronic course of the disease. With SLE, the acute course of the disease was observed in 4 patients (7%), subacute - in 37% of patients (70%) and chronic - in 12 (23%). Antibodies to FN were determined by the enzyme immunoassay using magnetosorbents (IGAP) (modified by I.P. Gontar)
Results. When studying the blood serum of healthy individuals, AT to FN was 0.03±0.01 e.o.p. Elevated levels of AT to FN were detected in 20 (41%) patients with SLE and in 11 (32%) patients with SSD. In patients with SLE, the level of AT to FN reliably depended on the activity of the pathological process. In case of damage to the cardiovascular and musculoskeletal systems, the percentage of detection of AT to FN in SLE increased to 68 and 74%, respectively. In SSD, high titers of AT to FN were associated with damage to the cardiovascular ($p<0.05$) and nervous systems ($p<0.001$). Most likely, an increase in the concentration of serum AT to FN in SLE is a consequence of generalized hyperproduction of antibodies, the intensity of which increases proportionally to the degree of disease activity. Violation of the antithrombotic functions of FN as a result of blockade of the active centers of the molecule by antibodies can contribute to the development and progression

of vascular pathology in SSD and SLE (coronaryitis and cerebral vasculitis).
Conclusions. Thus, the determination of antibodies to FN using IGAP allows us to expand our existing understanding of the pathogenesis of SLE and SSD and can be used to improve the immunodiagnostics of these diseases.

P1155

THE ROLE OF AUTOANTIBODIES TO TYPE II COLLAGEN AND FIBRONECTIN IN THE DESTRUCTION OF CONNECTIVE TISSUE IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Emelianova[1], A. Trofimenko[1], O. Rusanova[1], C. Spicina[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Federal State Budgetary Educational Institution of Higher Education «Volgograd State Medical University», Volgograd, Russia

Introduction. The basis of the pathogenesis of rheumatoid arthritis (RA) is currently considered to be the development of immunological reactions to components of connective tissue, mainly to its main protein – collagen. The leading role in this is given to type II collagen, which is predominantly found in articular cartilage. Fibronectin (FN) is a secretory product of connective tissue cells. Various etiologic factors induce the production of autoantibodies to the main components of connective tissue, leading to a pronounced inflammatory reaction with subsequent destruction of connective tissue.
Objective. To identify the relationship between the level of antibodies to FN, KII type and the destruction of connective tissue in patients with rheumatoid arthritis
Materials and methods**.** Serum from 30 donors and 120 RA patients was studied. Minimal activity I was observed in 16 people (13.3%), moderate II – in 68 (56.6%), and maximum – in 46 (38.3%) patients. The articular form of the disease was diagnosed in 71 (59.1%) patients, the articular-visceral form – in 49 (40.8%). Antibodies to type II collagen (AT to KII) and FN were determined by the enzyme immunoassay method modified by I.P. Gontar. The results obtained were expressed in units of optical density (e.o.p.).
Results. Elevated levels of AT to FN were detected in 53.6% of RA patients, and AT to KII were observed in 86% of patients. Moreover, the studied indicator correlated with the degree of disease activity ($p<0.01$). Obviously, this allows us to consider AT to KII and FN as a serological marker of RA. When determining AT to KII in groups with articular and articular-visceral forms, there were no fundamental differences, which indicates a specific dependence of the content of these antibodies on damage to cartilage tissue and their leading role in the pathogenesis of RA. A relationship was established between the level of antibodies to FN and the clinical features of the disease. The maximum values of the studied antibodies were detected in patients with Raynaud's syndrome ($p<0.05$) and RES damage ($p<0.01$).
Conclusions. Determination of antibodies to articular collagen type II and FN may indicate the degree of destructive process of connective tissue in RA.

P1156

PARTICULARITIES OF UVEITIS IN SPONDYLOARTHRITIS

O. Farhat[1], D. Khalifa[1], R. Fakhfakh[1], N. Elamri[1], H. Hachfi[1], K. Baccouche[1], E. Bouagina[1]

[1]Rheumatology, Farhat Hached Hospital, Sousse, Tunisia

Introduction:
Uveitis is a frequent extra-articular manifestation in patients with spondyloarthritis. This study aims to assess the epidemiological, clinical and therapeutic features of uveitis in spondyloarthritis.
Materials and methods:
This is a monocentric, retrospective study carried out in a rheumatology department, including the cases of patients followed up for spondyloarthritis diagnosed according to ASAS 2009 criteria and who presented with uveitis, collected over a 15-year period.
Results :
Of the 56 patients included in the study, 12 developed uveitis during follow-up, representing a prevalence of 21.4%. The mean age of these patients was 44.41 years [31-54]. The sex ratio F/H was 0.33. Uveitis was revelatory of the diagnosis in 4 cases (33.3%). Uveitis was unilateral in 7 cases, bilateral in 2 and flip-flop in 3. It was anterior in 12 cases (%) and intermediate in only 1. Synechiae were present in 5 cases (%). No patient developed retinal vasculitis. The average number of relapses was 2 per year. Local corticosteroid therapy was prescribed in all cases, with recourse to general corticosteroid therapy in 4 cases. Immunosuppressants were prescribed in 3 cases.
Conclusion:
Ocular involvement is frequent in spondyloarthritis, hence the importance of regular monitoring to ensure early and appropriate management and improve the visual prognosis of these patients.

P1157

PREVALENCE OF OSTEOPOROSIS IN HEALTHCARE WORKERS

O. Farhat[1], D. Khalifa[1], R. Fakhfakh[1], N. Elamri[1], H. Hachfi[1], K. Baccouche[1], E. Bouagina[1]

[1]Rheumatology, Farhat Hached Hospital, Sousse, Tunisia

Introduction:
Osteoporosis is a diffuse skeletal disease characterized by a decrease in bone strength, leading to an increased risk of fracture. Because of the physical nature of their work and their often long working hours, healthcare workers can be particularly vulnerable to this pathology.
The aim of this study was to investigate the prevalence of osteoporosis in nursing staff and to analyze the risk factors.
Patients and methods:
We conducted a cross-sectional study among healthcare profes-

sionals working in the Farhat Hached Hospital in Sousse. Bone mineral density (BMD) was measured by X-ray absorptiometry (DXA) at the lumbar spine and hip.

Results:

Eighty participants were included, with a clear female predominance (95.3%). Mean age was 61 years [38-85]. Among the participants, 87.2% were postmenopausal at a mean age of 48.2 years [40-56]. A hip fracture in one of the parents was observed in 23.3% of cases. Osteoporosis was observed in 22.1% of cases at lumbar level and in 18.6% of cases at the hip, with a mean T-score of -3.11DS and -2.88DS respectively. 41.9% of participants had lumbar osteopenia and 39.5% had femoral osteopenia. Risk factors significantly associated with osteoporosis were advanced age (p=0.04), early menopause (p=0.008) and a history of hip fracture in one of the parents (p=0.02).

Conclusion:

This study highlights a notable prevalence of osteoporosis among healthcare personnel, particularly among women and elderly individuals. These results underline the importance of targeted preventive and awareness-raising measures to promote bone health among this population exposed to specific professional risks.

P1158

OSTEOPOROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS : PREVALENCE AND ASSOCIATED FACTORS

O. Farhat[1], R. Fakhfakh[1], D. Khalifa[1], N. Elamri[1], H. Hachfi[1], K. Baccouche[1], E. Bouagina[1]

[1]Rheumatology, Farhat Hached Hospital, Sousse, Tunisia

Introduction:

Systemic lupus erythematosus (SLE) is a chronic auto immune disease that can affect several organs and systems, including the musculoskeletal system, with consequences for bone health.

Our aim was to investigate the prevalence of bone density abnormalities in lupus patients and to identify associated risk factors.

Patients and methods:

This was a retrospective study carried out in the Rheumatology Department of Sousse over a period of 20 years , involving 46 cases of lupus patients followed up,meeting ACR criteria and who were screened by bone densitometry(DXA)

Results:

There were 38 women and 8 men. Duration of disease progression was 68.64 [6-192].High-dose corticosteroid therapy was prescribed in 36 patients. Osteoporosis was noted in 14 patients in the lumbar spine (10cases) and femoral neck (4cases). Seven patients had osteopenia and 25 had normal bone mineral density (BMD). Vertebral fracture was reported in 4 patients with osteoporosis. The mean age was 39 years in the osteoporosis group, 50 in the osteopenia group and 34 in the normal BMD group. The analytical study of factors associated with osteoporosis showed a higher frequency in patients with a longer duration of disease progression(p=0.03) and in those with a lower BMI (p=0.04).

On the other hand, we did not find a significant association between the existence of osteoporosis and age,the use of high dose corticosteroids, the presence of a biological inflammatory syndrome and the frequency of cardiovascular risk factors.

Conclusion:

Patients with SLE are often confronted with alterations in their bone status that can lead to bone fragility and an increased risk of fractures. Associated factors include low BMI and the duration of the disease.

P1159

LOOP DIURETICS IN CHRONIC HEART FAILURE THERAPY AND FUNCTIONAL DISORDERS OF BONE TISSUE

O. M. Ignatyev[1], O. I. Panyuta[1]

[1]Odesa National Medical University, Odesa, Ukraine

In the most countries the prevalence of chronic heart failure (CHF) among the adult population in general 1.5–5.5%. According to epidemiological data, almost 75–80% of all cases of CHF are caused by coronary heart disease (CHD) or arterial hypertension (AH) by itself or in combination. The prognosis of survival for patients with CHF worsens with the progression of this disease, which prompts treatment of CHF, including diuretics, as early as possible. A connection between cardiovascular diseases and a high risk of bone loss may be presented 2 ways. First, it was established that reduced bone mineral density (BMD) was a predictor of CHF. Also, a relationship between the use of loop diuretics, BMD decrease and the risk of fractures was shown in many studies. However, the task of controlling bone tissue status for patients with CHF remains unresolved.

The purpose of the study was to assess the effect of loop diuretic therapy on phosphorus-calcium metabolism in patients with chronic heart failure and moderately reduced ejection fraction.

Materials and Methods. The research has a prospective nature. On the basis of the Odesa Regional Clinical Medical Centre, a clinical and laboratory examination of 109 male patients aged from 65 to 74 years (mean age – 67.4±2.7) was carried out. Among them, 86 patients had CHF stage "C: with a moderately reduced left ventricular EF functional class III according to NYHA, which occurred against the background of CHD and arterial hypertension (AH) and were divided into groups: the 1st group included 41 patients who received constant basic therapy for CHF; The 2nd group consisted of 45 patients who were on constant basic CHF therapy and used loop diuretics (torasemide 10–20 mg/day or furosemide 40–80 mg/day) during the last year. The control group or group III consisted of 23 patients who had no complaints or clinical abnormalities from the cardiovascular and bone systems. All patients underwent a complete clinical examination, objective examination according to generally accepted methods. Phosphorus-calcium exchange indices were assessed by determining total and ionized calcium, phosphorus, parathyroid hormone (PTH), 25-hydroxyvitamin D (25(OH)D) in blood serum.

Results of the study and their discussion. The mean age of patients in the 1st group was 68.7±2.8 years, in the 2nd group – 68.1±2.1, and in the 3rd group – 67.9±2.4 years. Therefore, according to age indices, all groups of examined men were ho-

mogeneous (p>0.05). Based on the results of the analysis of risk factors for the development and progression of CHF, the following factors were identified in the study groups: AH, CHD, obesity, excess body weight, dyslipidemia, permanent form of arterial fibrillation, impaired glucose tolerance.

The study of indices of phosphorus-calcium metabolism did not reveal a significant (p>0.05) increase in the level of total and ionized calcium in the blood serum of patients with hypertension and coronary heart disease complicated by CHF. The content of total calcium in the 1st group was 2.26±0.03 mmol/l (p>0.05), in the 2nd group – 2.24±0.02 mmol/l (p>0.05) , in the 3rd group – 2.29±0.02 mmol/l. Ionized calcium in the 1st group – 1.23±0.02 mmol/l (p>0.05), in the 2nd group – 1.22±0.01 mmol/l (p>0.05), in the 3rd group – 1.25±0.02 mmol/l. Phosphorus level in patients of the 1st and the 2nd groups was significantly reduced – 0.84±0.01 mmol/l (p>0.05) and 0.96±0.02 mmol/l (p>0.05), respectively, compared to the 3rd group – 1.12±0.02 mmol/l. A significant difference was found between the level of phosphorus in the 1st and the 2nd groups (p<0.05), a lower level of phosphorus was recorded in men of the 1st group.

Deficiency of vitamin D and IVD, a significantly higher (p<0.05) level of PTH and a low level of phosphorus demonstrate the presence of disturbances in phosphorus-calcium metabolism and indicate the presence of an imbalance in the system of hormonal regulation of calcium homeostasis in patients with AH and CHD complicated by CHF.

Conclusion. Basic therapy of chronic heart failure in combination with loop diuretics for a long time has a negative effect on the state of mineral density of bone tissue, indices of bone remodeling and phosphoruscalcium metabolism. Vitamin D deficiency is an independent risk factor for the severe course of chronic heart failure and requires timely diagnosis and correction.

P1160

A DUAL CHALLENGE: THE IMPACT OF FIBROMYALGIA ON THE MANAGEMENT OF RHEUMATOID ARTHRITIS

O. Jomaa[1], O. Neifar[1], M. Ardhaoui[1], S. Abedallatif[1], R. Sarraj[1], M. Braham[1], M. Younes[1]

[1]Tahar Sfar Hospital, Mahdia, Tunisia, Mahdia, Tunisia

Introduction

Rheumatoid arthritis (RA) is chronic inflammatory arthritis leading to progressive joint destruction and significant functional disability. It can coexist with fibromyalgia, exacerbating the disease's progression and further diminishing the patients' quality of life. The objective of this study is to determine the prevalence of fibromyalgia in RA patients and identify associated factors.

Methods

This cross-sectional study included patients with RA diagnosed according to the ACR/EULAR 2010 criteria. Clinical characteristics, the Disease Activity Score 28 (DAS28), and the Health Assessment Questionnaire (HAQ) were assessed. Fibromyalgia screening was conducted using the FiRST questionnaire, with a score of ≥5/6 considered as the threshold. The Widespread Pain Index (WPI), Symptom Severity Scale (SSS), and the total score were also calculated, with a total score ≥13 confirming the diagnosis of fibromyalgia.

Results

A total of 46 patients were included, with a sex ratio of 0.17, a mean age of 52 ± 3.5 years, and an average disease duration of 13.7 ± 1.86 years. RA was seropositive in 73.9% of cases and erosive in 97.8%. Treatments included methotrexate (73.9%), oral corticosteroids (76.1%), and biologics (60.9%). Additionally, 95.7% of patients were using analgesics. The average DAS28 score was 4 ± 0.4, and the average HAQ score was 1.6 ± 0.2.

The prevalence of fibromyalgia, as assessed by the FiRST questionnaire, was 82.6%, with an average FiRST score of 5.8 ± 0.9. The mean WPI was 16.3 ± 1, the mean SSS was 6 ± 0.6, and the average total score was 21.5 ± 1. Among the patients, 78.3% had a total score ≥13, confirming the diagnosis of fibromyalgia.

In our cohort, fibromyalgia was significantly associated with nocturnal awakenings ($p < 0.001$), Visual Analog Scale (VAS) ($p = 0.017$), and disease activity ($p < 0.001$). The WPI score correlated with age ($p = 0.001$, $r = 0.5$) and HAQ ($p = 0.018$, $r = 0.38$). The SSS score correlated with DAS28 ($p < 0.001$, $r = 0.6$) and HAQ ($p = 0.004$, $r = 0.54$).

Conclusion

This study highlights the high prevalence of fibromyalgia in RA patients, with significant impacts on disease progression and quality of life. Fibromyalgia is associated with disease activity and severity, underscoring the importance of systematic screening for comprehensive and tailored management.

P1161

COMPARATIVE DETECTION OF VERTEBRAL FRACTURES IN WOMEN AT RISK FOR OSTEOPOROSIS: INSIGHTS FROM VERTEBRAL FRACTURE ASSESSMENT AND RADIOGRAPHY

O. Jomaa[1], M. Braham[1], O. Neifar[1], M. Ardhaoui[1], R. Sarraj[1], M. Younes[1]

[1]Tahar Sfar Hospital, Mahdia, Tunisia, Mahdia, Tunisia

Background

Vertebral fractures (VFs) are prevalent but often underdiagnosed complications of osteoporosis due to their asymptomatic presentation or misinterpretation as benign back pain. While standard radiography remains the reference standard for VF detection, Vertebral Fracture Assessment (VFA) performed via dual-energy X-ray absorptiometry (DXA) offers a low-radiation alternative integrated into routine bone densitometry. This study compares the sensitivity of VFA and standard radiography in identifying VFs in women at risk for osteoporosis.

Methods

A cross-sectional study was conducted involving 37 women with risk factors for osteoporosis. Clinical data were collected, and bone mineral density (BMD) was measured at the lumbar spine and femoral neck using DXA. VFs were detected using both standard radiography and VFA, and fractures were classified by anatomical location (thoracic or lumbar spine). Detection perfor-

mance of the two imaging modalities was compared.

Results

The mean age of participants was 59.8 ± 9.9 years, with 86.5% reporting back pain. A history of prior fractures was noted in 32.4% of the cohort. The mean T-score was −2.1 ± 1.1 at the spine and −1.2 ± 0.8 at the femoral neck. Osteoporosis was diagnosed in 43% of patients (43% postmenopausal osteoporosis, 5.4% corticosteroid-induced osteoporosis), while 18.9% had normal BMD. Indications for performing VFA included age >60 years and T-score < −2 (13.5%), history of prior VFs (32.4%), height loss ≥4 cm (5.4%), and long-term corticosteroid use (37%). Standard radiography identified VFs in 35.1% of patients, with a total of 25 fractures detected: 18.9% had a single VF, 8.1% had two VFs, and 8.1% had three or more VFs. The fractures were predominantly located in the thoracic spine (27%) and lumbar spine (16.2%). In contrast, VFA detected VFs in 51.3% of patients, identifying a total of 37 fractures: 21.6% had a single VF, 18.9% had two VFs, and 10.8% had three or more VFs. VFA demonstrated greater sensitivity in detecting thoracic fractures (45.6%) compared to lumbar fractures (13.5%). Overall, VFA was significantly more sensitive than radiography in identifying VFs (p = 0.004), particularly thoracic fractures (p = 0.004), with no significant difference in detection rates for lumbar fractures (p = 1).

Conclusion

VFA demonstrates superior sensitivity compared to radiography in detecting vertebral fractures, particularly in the thoracic spine. Its integration into DXA offers a low-radiation, efficient, and accessible diagnostic approach for osteoporosis-related fracture detection. Combining VFA with radiography may enhance diagnostic accuracy, leading to improved fracture detection, better management of osteoporosis, and ultimately better patient outcomes.

OBESITY AND RHEUMATOID ARTHRITIS: UNRAVELING THE COMPLEX CONNECTION

O. Jomaa[1], O. Neifar[1], M. Ardhaoui[1], R. Sarraj[1], M. Braham[1], M. Younes[1]

[1]Tahar Sfar Hospital, Mahdia, Tunisia, Mahdia, Tunisia

Introduction

Obesity is a condition characterized by an excess of body fat. Overweight and obesity in the context of chronic inflammatory arthritis are associated with increased morbidity and mortality. The aim of this study was to evaluate the impact of overweight and obesity on the presentation and activity of rheumatoid arthritis (RA).

Patients and Methods

This was a retrospective comparative study including patients with RA who were followed over a three-year period (2019-2022). Clinical, biological, and radiological data, as well as body mass index (BMI) and disease activity scores (DAS28 VS and DAS28 CRP), were collected and analyzed.

Results

Ninety-five patients were included in the study. The mean age of the patients was 55.14 ± 13.4 years, with a sex ratio of 0.21. The mean disease duration of RA was 42 months (range 1 month to 240 months). Of the patients, 2.1% were underweight (BMI < 19 kg/m²), 38.8% had a normal weight (BMI between 19 and 25 kg/m²), 43.2% were overweight (BMI between 25 and 30 kg/m²), 13.7% had moderate obesity (BMI between 30 and 35 kg/m²), and 2.1% had severe obesity (BMI > 35 kg/m²).

Overweight was associated with a higher incidence of extra-articular manifestations (p = 0.011), particularly dry eye syndrome (p = 0.038), and more severe disease activity, as defined by a DAS28 CRP > 5.1 (p = 0.022). Obesity in RA patients was associated with hypertension (p = 0.037), hallux valgus deformity (p = 0.004), and positive antinuclear antibody (p = 0.03). Furthermore, obese patients had a higher prevalence of osteoporosis compared to non-obese patients (p = 0.008).

Conclusion

Our study revealed a notable prevalence of overweight and obesity among RA patients. These conditions were associated with increased comorbidities, heightened extra-articular manifestations, and exacerbated disease activity. This highlights the importance of adequate management of overweight and obesity in patients with RA.

P1163

WEIGHT MATTERS: THE IMPACT OF BODY MASS ON FALL RISK AND FEAR OF FALLING IN RHEUMATOID ARTHRITIS PATIENTS

O. Jomaa[1], O. Neifar[2], M. Jguirim[3], M. Ardhaoui[2], R. Sarraj[2], M. Braham[2], M. Younes[2], I. Bejia[3]

[1]Tahar Sfar Hospital, Reumatology depatment, Mahdia, Tunisia, [2]Tahar Sfar Hospital, Rheumatology department, Mahdia, Tunisia, [3]Fattouma Bourguiba Hospital, Rheumatology depatment, Monastir, Tunisia

Introduction

Falls represent a major health concern in patients with rheumatoid arthritis (RA) due to joint involvement, decreased mobility, and postural instability. This study aims to assess the association between body mass index (BMI) and fall risk in RA patients.

Material and Methods

This study included RA patients, classified into three groups based on BMI: normal weight, overweight, and obese. Fall risk was assessed using the Sternal Push Test (SPT) and Walking and Talking Test (WTT). The Tinetti Test (TT) evaluated gait and balance, with scores <23 indicating a high fall risk. The Falls Efficacy Scale International (FES-I) assessed fear of falling, with with scores greater than 10 indicating heightened concern.

Results

The cohort included 51 patients with a mean age of 54 ± 2.7 years and an average BMI of 28.2 ± 1.2 kg/m². Among them, 37.3% were overweight, 31.4% were obese, and 31.3% had normal weight. In the obese group (n = 16), 56.3% reported a history of fractures, and 62.5% experienced at least one fall in the preceding year. Notable comorbid risk factors in this group included psychological disorders (43.8%), antihypertensive therapy (12.5%), urinary

dysfunction (68.8%), spinal osteoarthritis (93.8%), knee joint involvement (93.8%), and foot deformities (68.8%). A positive SPT was observed in 43.8%, and 25% demonstrated a positive WTT. The mean TT score was 24.7 ± 2.5, with 31.3% scoring below 23, indicating high fall risk. The mean FES-I score was 12.7 ± 4, with 68.8% reporting significant fear of falling.

In the overweight group (n = 19), 26.3% had a history of fractures, and 68.4% reported at least one fall in the past year. Common risk factors included psychological disorders (36.6%), antihypertensive therapy (31.6%), urinary dysfunction (68.4%), spinal osteoarthritis (89.5%), knee involvement (78.9%), and foot deformities (63.2%). Positive SPT and WTT findings were noted in 42% and 36.8% of patients, respectively. The mean TT score was 24.7 ± 2.5, with 52.6% scoring below 23. The average FES-I score was 12.7 ± 4, with 78.9% expressing significant fear of falling.

Patients in the overweight and obese categories had a significantly higher fall incidence compared to those with normal weight ($p < 0.001$), with 92% of patients prone to falls being either overweight or obese. Furthermore, these patients exhibited a greater prevalence of urinary dysfunction ($p = 0.036$), knee joint involvement ($p = 0.033$), fractures ($p = 0.04$), and fear of falling ($p = 0.001$). BMI was negatively correlated with TT scores ($r = -0.575$, $p = 0.01$) and positively correlated with FES-I scores ($r = 0.416$, $p = 0.008$) and the number of fractures ($r = 0.377$, $p = 0.02$).

Conclusion

Obese and overweight RA patients exhibit a significantly increased risk of falls, fractures, gait and balance impairment, and heightened fear of falling. Given the elevated risk, weight management should be prioritized in this population to mitigate fall risk, reduce fracture incidence, and enhance overall quality of life.

P1164

EFFICACY OF MOOD FACTOR IN PATIENTS WITH COMPLEX REGIONAL PAIN SYNDROME

O. Kuculmez[1]

[1]Baskent University Alanya Hospital Department of Physical Medicine and Rehabilitation, Antalya, Turkiye

Objective:

Complex Regional Pain Syndrome is a condition characterized by pain and dysfunction in the somatomotor, somatosensory, and sympathetic nervous systems (1). There are physicological sympthoms such as fear, anxiety, anger, depression and failure to cope nearby functional limitation and pain (2,3). It raises the question of whether patients' anxiety during the outpatient clinic causes these symptoms, or whether patients with anxiety and depression are more prone to this pathology (4-7). This study aimed to explore efficacy of mood factor in patients with Complex Regional Pain Syndrome.

Materials and methods:

The study included 131 patients with a history of trauma or operation. 70 patients diagnosed with Complex Regional Pain Syndrome and 61 patients were revealed in control group. Demographic information was recorded and participants were evaluated with, Visual Analog score, Beck Anxiety Inventory, Beck Depression Inventory and Short Form-36.

Results:

There were 62 male and 69 female patients and the avarage age of patients was 44,53± 14,17. There was no significant difference between demographic properties. There was no significant difference in term of anxiety (p=0,582) and depression scores (p=0,258) between patients with Complex Regional Pain Syndrome and control group. There were significantly higher Visual Analog Scores (p=0,001) in patients with Complex Regional Pain Syndrome. The subscores of Short form-36; pain level (p=0,033), social function (p=0,041)and physical role (p=0,001) were worse in in patients with Complex Regional Pain Syndrome. There was no difference in other subscores of Short form-36 between two groups.

Conclusion:

This findings suggest that basic mood of the patient does not seem to play role in Complex Regional Pain Syndrome to occure. These mood changes may be only result of the dissease as pain level, social function and physical role were determined worse in theese patients. There is a need for further studies that includes larger sample group, detailed mood and charactheristic tests.

Key Words: anxiety, complex regional pain syndrome, depression, mood, reflex sympathic dystrofia

EVALUATION OF THE IMPACT OF EMOTIONAL FACTORS ON OBESITY AND GENERAL WELL-BEING

O. Kuculmez[1], E. Kabacaoglu[2]

[1]Baskent University Alanya Hospital Department of Physical Medicine and Rehabilitation, Antalya, Turkiye, [2]Baskent University Alanya Hospital, Department of Chest Disease, Antalya, Turkey, Antalya, Turkiye

Objective:
Obesity is a health problem that is often present and coexists with anxiety and can be found with psychological eating styles such as emotional eating, addictive eating state and overeating. Emotions and eating are both a natural and recurring part of our daily lives. Research suggests that emotional factors influence the quantity and quality of food eaten, and food intake can have emotional consequences. Food intake is related to both energy balance regulation and reward and taste effects. The aim of this study was to evaluate the impact of emotional factors on obesity and general well-being.

Materials and methods:
It was a cross-sectional study. The patients revealed as overweighted and healty volunters who attended to Baskent University were included in the study. Patients younger than 18 and older than 65 years, who have uncontrolled systemic disease and pregnants were excluded from the study. Demographic information was recorded and participants were evaluated with Obesity-related well-being questionnare and Emotional eater questionnare.

Results:
Totally 203 Patients were analyzed. There were 77 male and 126 female patients and the avarage age of patients was 38,60± 12,77. There was no significant difference between demographic properties. It was detected that females and younger volunteers have lower body mass index ($p<0.05$). Obese volunteers have higher Obesity-related well-being questionnare scores including higher socialsubdimesion ($p<0.05$). Additionally, normal weighted volunteers hava lower Emotional eater questionnare scores ($p<0.05$).

Conclusion:
This findings suggest that obese people have had much more emotional eating behaviour. Although they have been overweighted, their well-being and sociality scores were much more higher. Further studies are needed to shed light on the issue.

P1166

THE PROGNOSIS AND EARLY DIAGNOSTICS OF THE POSTMENOPAUSAL OSTEOPOROSIS

O. M. Ignatyev[1], T. O. Yermolenko[1], M. I. Turchin[1]

[1]Odesa National Medical Universiti, Odesa, Ukraine

The aim of the work is to optimize the early diagnostics of the postmenopausal (PM) osteoporosis (OP). **Materials and methods.** 125 postmenopausal women in the age group of 51 to 60 years old (56,2 ± 0,9) have been examined. The examinations such as clinical examination, colposcopy, the measurement of the pH of the vaginal content (Lashema, Czech Republic), ultrasound densitometry (Aloka OS - 100) have been made. The estradiol (E) in the blood and the biochemical markers of the bone resorption – BCrossLaps(CTX) («Elecsys» 2010) have been determined. **Results and discussion**. It has been revealed that 86.8% of postmenopausal women with urogenital disorders had signs of atrophy of the mucous membrane of vagina, 41% of patients had urogenital disorders combined with complaints on the bone system, 77.5% of women with urogenital disorders had the accelerated resorption of bone tissue. An inverse correlation between CTX and concentration of E in the blood (r = - 0482; p <0001), St ind. and the duration of the menopause (r = - 0997; p <0001), between St ind. and appearance of the urogenital disorders (r = - 0574, p <0.01) has been found. **Conclusions.** Women with the clinical appearances of hypoestrogenia in the urogenital system and with urogenital disorders are in a high risk group for the development of PM OP and its complications. The urogenital disorders caused by the hypofunction of ovaries are the predictor of the development of abnormalities of bone remodeling in the menopause. The prediction and early di-

agnosis of PM OP will give the possibility to appoint a timely therapy in the preclinical stage of the disease and thereby improve the quality of bone tissue, reduce the risk of the fractures and improve the quality of life.

P1167

ALENDRONIC ACID IN THE TREATMENT OF OSTEOPOROSIS IN YOUNG MAN WITH MULTIPLE FRACTURES CAUSED BY CUSHING'S DISEASE: CASE REPORT

O. Mytrokhina[1]

[1]Dnipro state medical university, Dnipro, Ukraine

Cushing's disease is an endocrine disorder that results from excess cortisol production. Cortisol disrupts bone metabolism, leading to decreasing bone density (osteoporosis) and an increasing risk of fractures. Osteoporotic fractures are widely recognized as a common and important cause of disability and death in postmenopausal women, but are relatively poorly understood in men. Alendronate significantly increases bone mineral density and reduces the incidence of osteoporotic fractures, including vertebral and hip fractures, in postmenopausal women, but there are few data on its usage in men.

Case report: A 25-year-old patient complains of pain in the spine and sacral region. Considers himself ill for about 1.5 years, when he took notice of weight gain, red painful striae on the thighs, and high blood pressure. At the same time, he noted an increase in pain in the spine and sacral region. Examination revealed fractures of the Th4, Th5, Th6, Th7 vertebrae, sacral and pubic bones. The growth of cortisol's level in the urine (997 mcg/24) and blood serum (42.4 mcg/dl), a decrease in vitamin D (17.19 ng/ml) were noted. The diagnosis of pituitary adenoma was confirmed by MRI. According to X-ray densitometry, the bone mineral density (BMD) in the lumbar spine was -3.3 SD (according to the T-score). After neurosurgical intervention, the patient was prescribed alendronic acid 70 mg once a week, vitamin D 4000 IU per day. After 6 months of treatment, normalization of vitamin D levels was noted, BMD improved -2.1 SD (according to the T-score). After another 6 months, bone mineral density reached -1 SD (according to the T- score).

Conclusion: Alendronate increased bone mineral density, which indicates its effectiveness in the treatment of men with osteoporosis.

P1168

MONOCLONAL GAMMOPATHY IN CHRONIC INFLAMMATORY ARTHRITIS: EXPLORING CLINICAL, BIOLOGICAL PROFILES, AND DISEASE PROGRESSION

O. Neifar[1], Z. Gassara[1], C. Abid[1], A. Feki[1], H. Hela[1], S. Baklouti[1]

[1]Hedi Chaker Hospital, Sfax, Tunisia

Introduction

Monoclonal gammopathies are biological abnormalities characterized by the presence of a monoclonal immunoglobulin produced by clonal plasma cells. These anomalies can arise in association with chronic inflammatory conditions, such as spondyloarthritis (SpA) and rheumatoid arthritis (RA), necessitating careful management and routine monitoring to improve prognosis and prevent complications. This study aimed to investigate the clinical and biological characteristics of gammopathy in patients with SpA and RA, with a particular focus on its progression and long-term outcomes.

Patients and Methods

This retrospective study was conducted over 23 years (2000–2023) and included patients diagnosed with SpA according to the ASAS 2009 criteria or RA according to the EULAR 2010 criteria, who developed monoclonal gammopathy during follow-up. Clinical, biological, therapeutic, and evolutionary data were collected and analyzed.

Results

The study included 15 patients: 6 with SpA (40%) and 9 with RA (60%). Among SpA patients, the sex ratio was 5. Peripheral SpA was present in 33.3% of cases, axial SpA in 16.7%, and combined axial and peripheral SpA in 50%. Extra-articular manifestations included Crohn's disease (16.7%), psoriasis (16.7%), and uveitis (16.7%). HLA-B27 was positive in 16.7% of cases. Treatments included NSAIDs (83.3%), sulfasalazine (50%), methotrexate (33.3%), and biologics (33.3%). The mean age at SpA diagnosis was 46 ± 2 years, while the mean age at gammopathy diagnosis was 49 ± 3 years, with an average interval of 2.8 years between the two diagnoses. The gammopathy type was IgG kappa in 5 cases (83.3%) and IgA lambda in 1 case (16.7%). Three patients (50%) had monoclonal gammopathy of undetermined significance (MGUS), and three (50%) had multiple myeloma. The mean follow-up duration was 4.8 ± 2.3 years. MGUS cases remained stable, whereas among patients with multiple myeloma, 2 responded to chemotherapy and autologous stem cell transplantation with remission, while 1 patient died. Among RA patients, the sex ratio was 0.8. Seropositive RA was present in 66.7% of cases, and erosive disease in 66.7%. Treatments included sulfasalazine (33.3%), methotrexate (55.6%), biologics (11.1%), and corticosteroids (88.9%). The mean age at RA diagnosis was 54.6 ± 4.3 years, while the mean age at gammopathy diagnosis was 63 ± 4 years, with an average interval of 7.2 ± 3.2 years between the two diagnoses. The gammopathy type was IgG kappa in 5 cases (55.6%), IgG lambda in 1 case (11.1%), IgA lambda in 1 case (11.1%), and biclonal (IgG and IgA lambda) in 1 case (11.1%). MGUS was ob-

served in 66.7% of cases (6 patients), and multiple myeloma in 33.3% (3 patients). The mean follow-up duration was 5.2 ± 1.5 years. Among MGUS cases, 5 (83.3%) remained stable, while 1 evolved into indolent myeloma. Among patients with multiple myeloma, 1 responded favorably to chemotherapy and autologous stem cell transplantation.

Conclusion

The majority of patients with SpA or RA and monoclonal gammopathy are diagnosed at the MGUS stage, with IgG kappa being the predominant subtype, and a stable clinical course. However, the potential progression to malignant conditions, particularly multiple myeloma, highlights the necessity for ongoing monitoring to effectively manage these risks.

P1169

ETIOLOGICAL SPECTRUM OF NON-DEGENERATIVE SPINAL CORD COMPRESSION IN RHEUMATOLOGY: ANALYSIS OF 58 CASES

O. Neifar[1], Z. Gassara[1], C. Abid[1], R. Jebri[1], A. Feki[1], H. Fourati[1], S. Baklouti[1]

[1]Hedi Chaker Hospital, Sfax, Tunisia

Introduction

Spinal cord compression (SCC) is a potential complication of various conditions encountered in rheumatology, often associated with poor prognosis. This study aims to describe the etiological profile of SCC cases managed in a rheumatology department.

Patients and Methods

This retrospective study included patients hospitalized for SCC over 33 years (1990–2023). Traumatic SCC, degenerative causes (disc herniation and cervical spondylotic myelopathy), and intradural causes (schwannomas and meningiomas) were excluded.

Results

Fifty-eight patients were included, with a male-to-female ratio of 1.5 and a mean age of 63 years. Compression was thoracic in 58.2%, lumbar in 41.3%, and cervical in 10.3%. The etiologies identified were multiple myeloma (MM) in 16 cases (27.5%), bone metastases (BM) in 13 cases (22.4%), infectious spondylodiscitis (ISD) in 21 cases (36.2%), skeletal fluorosis in 4 cases (6.8%), Paget's disease in 3 cases (5.1%), and primary bone tumors in 1 case (1.7%).

Among the patients with multiple myeloma, the subtypes identified included IgG (50%), IgA (25%), and light-chain MM (25%). Compression was thoracic in 43.7% and lumbar in 56.2%. All 16 patients received corticosteroids, 10 underwent decompressive radiotherapy, and 4 were considered for laminectomy.

In cases of bone metastases, compression was thoracic in 53.8% and lumbar in 46.1%. The primary tumor sites were pulmonary in 4 patients, renal in 2 patients, gastrointestinal in 3 patients, breast in 1 patient, prostate in 1 patient, and undetermined in 2 patients. All 13 patients received corticosteroids and decompressive radiotherapy.

For infectious spondylodiscitis, the etiologies included tuberculosis in 42.8% of cases, brucellosis in 23.8%, and pyogenic infections in 33.3%. Compression was thoracic in 57.1%, lumbar in 38%, and cervical in 4.7%. Surgery was necessary for 23.5% of patients, and corticosteroids were administered in 57.1% of cases.

All 4 cases of skeletal fluorosis presented with cervical compression. The cause was hydrotelluric exposure in all cases, with imaging showing diffuse osteosclerosis and interosseous membrane ossification. MRI revealed ossification and hypertrophy of the posterior longitudinal ligament. Two patients underwent decompressive cervical laminectomy.

Paget's disease was identified in 3 cases, with thoracic and lumbar compression.

The single case of a primary bone tumor was a chordoma with cervical compression. Management included tumor excision followed by radiotherapy.

Conclusion

Excluding degenerative vertebral disorders, SCC can result from a variety of conditions, primarily malignancies and infections. In our series, infectious spondylodiscitis was the leading cause of SCC, followed by multiple myeloma and vertebral metastases.

P1170

AN INSIGHT INTO SEPTIC ARTHRITIS OF THE BONY PELVIS: A STUDY OF 11 CASES

O. Neifar[1], Z. Gassara[1], A. Feki[1], R. Jebri[1], S. Ben Jmeaa[1], H. Fourati[1], S. Baklouti[1]

[1]Hedi Chaker Hospital, Sfax, Tunisia

Introduction

Infections of the pelvic bones and joints are rare and present significant diagnostic and therapeutic challenges due to their varied clinical presentations. This study aims to describe the clinical, paraclinical, and prognostic features of cases of infectious sacroiliitis and septic arthritis of the pubic symphysis observed in a rheumatology department.

Patients and Methods

We conducted a retrospective study including patients hospitalized in our department for infectious sacroiliitis or septic arthritis of the pubic symphysis over a 13-year period (2010–2023). Clinical, biological, radiological, therapeutic, and outcome data were collected and analyzed.

Results

Our study included 11 patients: 10 cases of infectious sacroiliitis and 1 case of septic arthritis of the pubic symphysis. Among the sacroiliitis cases, the sex ratio was 1:1, with a mean age of 40 ± 19 years. The mean symptom duration was 175 days (range: 5–480 days). The main presenting symptoms were gluteal and lower back pain (90%) and hip pain (10%). Associated symptoms included fever (50%), night sweats (30%), and general health deterioration (30%). The sacroiliac involvement was unilateral in 90% of cases (50% right-sided, 40% left-sided) and bilateral in 10%.

An infection source was identified in 50% of cases: pulmonary (2 cases), genital in the postpartum context (1 case), urinary (1 case), and cutaneous (1 case). One patient reported previous tuberculosis exposure. Elevated inflammation markers were found in 80% of cases, with a mean C-reactive protein (CRP) level of 53 ± 19 mg/L and an erythrocyte sedimentation rate (ESR) of 63 ± 16

mm. Sacroiliac X-rays were abnormal in 60% of cases. MRI or CT scans were performed in all cases, revealing soft tissue involvement in 70%. Hip osteoarthritis was associated in 20% of cases. Biopsy was performed in 90% of cases, contributing to diagnosis in 30%. Infectious sacroiliitis was caused by pyogenic bacteria in 70% of cases and non-pyogenic bacteria in 30% of cases (*Brucella* species in 20% and Mycobacterium tuberculosis in 10%). Isolated pyogenic pathogens included Staphylococcus species (2 cases), Gram-negative bacilli (1 case), and Streptococcus species (1 case). All patients received appropriate antibiotics based on the identified pathogens, with a mean duration of 63 ± 18 days for pyogenic infections and 9 months for brucellosis and tuberculosis. The outcome was favorable in 90% of cases, with one reported death.

The case of septic arthritis of the pubic symphysis involved a 16-year-old boy presenting with bilateral gluteal pain along with fever. The infection source was cutaneous. X-rays revealed lysis of the left pubic bone, while MRI showed arthritis of the pubic symphysis with an associated soft tissue abscess. A CT-guided biopsy identified Staphylococcus aureus in the microbiology exam. A 60-day course of appropriate antibiotics resulted in a favorable outcome.

Conclusion

Our study showed that infectious sacroiliitis and septic arthritis of the pubic symphysis remain rare diagnostic entities. MRI and CT-guided biopsy are pivotal for diagnosis. The prognosis is generally favorable with appropriate antibiotic treatment.

P1171

EXPLORING THE BURDEN OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS IN POLYMYALGIA RHEUMATICA: PREVALENCE AND ASSOCIATED FACTORS

O. Neifar[1], O. Jomaa[1], M. Ardhaoui[1], R. Sarraj[1], M. Braham[1], M. Younes[1]

[1]Tahar Sfar Hospital, Mahdia, Tunisia, Mahdia, Tunisia

Introduction

Polymyalgia rheumatica (PMR) is the most common inflammatory rheumatic disease affecting older individuals. The current cornerstone of treatment is long-term oral glucocorticoid therapy. However, management of these patients is often complicated by comorbidities such as osteoporosis. The aim of our study was to determine the prevalence of glucocorticoid-induced osteoporosis in patients with PMR and to investigate the factors associated with its occurrence.

Patients and Methods

We reviewed the medical records of patients diagnosed with PMR in the rheumatology and internal medicine departments during the period between 2012 and 2023. Data including demographic characteristics, clinical history, treatment details, and bone health assessments were collected and analyzed.

Results

Forty-three patients were included, with a sex ratio of 0.34. The mean age was 71.8 ± 3.6 years. Horton's disease was associated in 4.7% of cases. All patients were treated with systemic glucocorticoids, with a mean dose of 17.14 ± 2.8 mg/day and a mean duration of 2.7 ± 0.5 years. Glucocorticoid-sparing strategies were implemented in 20.9% of cases. All patients received calcium and vitamin D supplementation. Glucocorticoid-induced osteoporosis was identified as a comorbidity in 20.9% of patients. The mean lumbar spine T-score was -3.2 ± 0.1, and the mean femoral T-score was -1.2 ± 0.22. Severe osteoporosis (T-score < -3) was observed in 13.9% of patients. In our study, osteoporosis was significantly associated with hypertension ($p = 0.002$). Additionally, lumbar spine T-scores were negatively correlated with the duration of systemic glucocorticoid therapy ($p = 0.02$, $r = -0.9$).

Conclusion

This study highlights a high prevalence of glucocorticoid-induced osteoporosis in patients with PMR, emphasizing the need for proactive management of bone health in this population. The duration of glucocorticoid therapy was strongly correlated with bone mineral density loss. These findings underscore the importance of regular bone density monitoring and the implementation of strategies to minimize glucocorticoid exposure, alongside adequate osteoporosis treatment.

P1172

CLINICAL AND EVOLUTIONARY PROFILE OF UNDIFFERENTIATED ARTHRITIS: WHEN GENDER MAKES A DIFFERENCE

O. Jomaa[1], O. Neifar[1], S. Abedallatif[1], M. Ardhaoui[1], R. Sarraj[1], M. Braham[1], M. Younes[1]

[1]Tahar Sfar Hospital, Rheumatology department, Mahdia, Tunisia

Introduction

Early diagnosis of inflammatory arthritis is crucial for optimizing management. However, some cases remain unclassifiable despite an in-depth investigation, referred to as undifferentiated arthritis (UA). This study aims to assess the characteristics and evolutionary profile of UA, with a focus on gender differences.

Patients and Methods

This was a retrospective descriptive study involving patients diagnosed with UA and followed in our rheumatology department over a 10-year period (2012–2022). Epidemiological, clinical, paraclinical, and evolutionary data were collected and compared between male and female patients.

Results

The study included 70 patients (53 women and 17 men) with a mean age of 53 ± 2.2 years (range: 19–84). The sex ratio was 0.32. The mean follow-up duration was 19.8 ± 3.7 months (range: 1–108).

In the female group (FG), the mean age at symptom onset was 41 ± [12–71] years. The primary clinical presentations were oligoarthritis (50.9%), polyarthritis (26.4%), and monoarthritis (22.6%). The average consultation delay was 836 ± 230 days (range: 2–7300). Extra-articular manifestations, including ocular (35.8%), cutaneous (9.4%), and renal (1.9%) involvement, were observed in 41.5% of cases. Laboratory findings revealed high inflammatory markers in 81.1%, anemia in 50.9%, positive rheumatoid factor in

7.5%, anti-citrullinated peptide antibodies in 5.7%, and antinuclear antibodies in 11.3%. X-ray abnormalities were reported in 18.9%. Evolution showed rheumatoid arthritis (RA) in 13.2% of cases and spondyloarthritis in 1.9%, while 58.5% remained undifferentiated. In the male group (MG), the mean age at symptom onset was 51 ± 4.7 years [12–71]. Monoarthritis was the most frequent presentation (41.2%), followed by oligoarthritis (35.3%) and polyarthritis (23.5%). The mean consultation delay was shorter at 225 ± 107 days (range: 1–3650). Extra-articular manifestations, including ocular (11.8%) and cutaneous (5.9%) involvement, were observed in 17.6% of cases. High inflammatory markers were present in 88.2%, anemia in 29.4%, and positive autoantibodies (rheumatoid factor, anti-citrullinated peptide antibodies, and antinuclear antibodies) in 11.8%. X-ray abnormalities were present in 17.6%. Evolution revealed RA in 5.9%, spondyloarthritis in 5.9%, and other connective tissue diseases in 11.8%, while 35.3% remained undifferentiated.

Comparative analysis showed that men had a shorter consultation delay (p = 0.037) and a higher frequency of evolution into connective tissue diseases (p = 0.049) compared to women. No other statistically significant differences were noted between the groups.

Conclusion

This study demonstrated that women with UA were characterized by oligoarticular onset and frequent extra-articular manifestations, while men more often presented with monoarthritis, shorter consultation delays, and a tendency to evolve into connective tissue diseases. These findings highlight the importance of considering gender in the management of UA. Further studies with larger cohorts are warranted to confirm these results.

P1173

THE IMPORTANCE OF THE SALT TRANSPORT ASSESSMENT ANALYSIS IN THE MANAGEMENT PATIENTS WITH METABOLIC DISORDERS OF BONE TISSUE AND NEPHROLITHIASIS

O. Nikitin[1], O. Nishkumay[1], A. Korytskyi[1], I. Kordubailo[2], M. Chan K.S.[3], M. Wong B.F.[3]

[1]O.O. Bogomolets National Medical University, Kyiv, Ukraine, [2]Kyiv Regional Clinical Hospital, Kyiv, Ukraine, [3]European Wellness Academy, Edenkoben, Germany

Resume

Kidney stone disease (KSD) is a polyetiological disease associated with a metabolic disorder accompanied by the formation of stones in the urinary tract. Many factors affect the cause of stone formation. It depends on the peculiarities of climatic, socio-economic conditions, food and drinking regime, heredity, concomitant diseases, and taking medicines. More and more recently, in modern literature, there has been a hypothesis regarding the association of KSD with metabolic diseases of bone tissue. Possible reasons for the relationship are increased crystalluria in the combined course of these diseases, especially associated with calcium metabolism in connection with osteopenia or osteoporosis.

The aim of the study was to evaluate bone mineral density (BMD) and salt transport analysis in patients with and without urolithiasis.

Materials and methods.

Assessment of the BMD and TBS was carried out on the basis of the Ukrainian Osteoporosis Center of the State University "Institute of Gerontology named after D. F. Chebotareva of the National Academy of Sciences of Ukraine", Kyiv, Ukraine (chief Prof. N.V. Grygorieva). To assess crystalluria qualitatively, a study of 24h-salt transport was conducted.

The results.

The study included 80 patients, 15 men (18.8%) and 65 women (81.3%). Patients were divided depending on the presence of KSD. The I group included 32 participants without KSD (women — 31 (96.9%), men — 1 (3.1%), median age 63.2 [58.8-67.4] years. The II group included 48 patients with KSD (women — 34 (70.8%)), men – 14 (29.2%), average age 55.5 years [51.5-62.5]).

When dividing the groups depending on the presence of KSD, it was established that a normal BMD in the 1st group was established in 10 patients out of 32 (31.2%), among them 9 women (28.1%) and 1 man (3.1%). BMD abnormalities within osteopenia were found in 13 patients (40.7%), all were women. Osteoporosis was diagnosed in 9 patients (28.1%), all were women.

In the II group with established KSD, normal BMD was observed in 11 patients out of 48 (22.9%), among them 4 women (8.3%) and 7 men (14.6%). BMD abnormalities within osteopenia were found in 16 patients (33.3%), among them 12 women (25%) and 4 men (8.3%). Osteoporosis was diagnosed in 21 patients (43.8%), 18 women (37.5%) and 3 men (6.25%).

During the comparative analysis of X-ray densitometry, it was established that there was no difference between BMD indicators at the level of the lumbar spine, the right femoral neck, the left femoral neck, and the ultra distal part of the forearm bones. However, the TBS bone quality index was significantly lower in women with KSD ($p<0.05$).

During the analysis of salt transport, it was established that in group I, oxaluria was established in 2 patients (6.25%), calciuria in 3 (9.3%), phosphaturia in 2 (6.25%), increased excretion of uric acid in 2 patients (6.25%). In the II group, a significant percentage of oxaluria was determined - 27 cases (56.3%), calciuria was observed in 5 cases (10.41%), as well as phosphaturia. In patients with KSD, the level of oxalate excretion probably exceeded both the indicators of the approximate reference norm and the indicators of patients without nephrolithiasis ($p<0.05$).

Patients with osteopenia were recommended to take calcium citrate (2400 mg), magnesium (25 mg), zinc (3.75 mg), vitamin K 2 (50 μg), and vitamin D (1000 IU). In patients with osteopenia and calciuria, an increase in calciuria was revealed after 1 month. Taking into account the recommendations of the European Association of Urologists 2023, the intake of calcium preparations was stopped and indapamide 2.5 mg was prescribed. After 1 and 6 months, repeated analysis of salt transport showed the normalization of indicators and the absence of negative dynamics of BMD. Taking a combined preparation of calcium, magnesium, zinc, vitamin K2, and vitamin D in patients with oxaluria normalized both crystalluria and BMD.

Conclusions. The obtained data indicate the need for ultrasound examination of kidneys and 24-hour salt transport results while checking BMD in patients at risk of osteoporosis to diagnose nephrolithiasis early and correct further management of patients with crystalluria.

Key words: nephrolithiasis, osteoporosis, calciuria, oxaluria, Trabecular Bone Score.

OSTEOCALCIN LEVELS IN ADOLESCENTS WITH IDIOPATHIC SCOLIOSIS, DEPENDING ON THE DEGREE OF SPINAL CURVATION

O. P. Galkina[1], V. B. Kaliberdenko[1], E. R. Kulieva[1], N. G. Nikolashina[1], S. Kulanthaivel[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: Idiopathic scoliosis (IS) has traditionally occupied high ranking places in the structure of diseases of the skeletal system for several decades. The characteristic feature of IS is progression of disese, especially in adolescents. It is possible to objectively assess the state of bone tissue in this contingent by using bone metabolism indicators. Osteocalcin (OC) is a vitamin K-independent protein, an indicative indicator of bone tissue synthesis. In a previous study, we found a decrease in the concentration of OK in the group of patients with IS without detailing the indicator depending on the degree of spinal deformation.
Methods: The 152 patients with IS aged 15.26±0.04 years (62 boys and 90 girls) were examined. In accordance with the clinical and radiological classification of IS, the following were identified: impaired posture (curvature angle of the spinal axis - up to 5 °) - 44 people, grade I IS (curvature 5-10 °) - 69 people, grade II IS (curvature 11-30 °) - 25 people, grade III IS (curvature 31-61 °) - 14 people. The control group included 20 practically healthy peers. The quantitative content of OK in the blood serum was determined by the method of solid-phase enzyme immunoassay using the N-MID Osteocalcin test system (Nordic Bioscience Diagnostics A/S, Canada).
Results: Depending on the degree of IS, the OK level in the group of adolescents sharply decreased in comparison with the age norm (93.4±14.1 ng/ml) and with the CG (96.66±2.17 ng/ml, $p<0.001$). The indicator was: with posture disorders - 81.41±0.98 ng/ml, scoliosis of the 1st degree - 77.34±0.98 ng/ml, scoliosis of the 2nd degree - 70.84±0.82 ng/ml, scoliosis of the 3rd degree - 66.41±0.69 ng/ml. When comparing the indicators by gender, taking into account the degree of curvature of the spine, no reliable differences were found ($p>0.05$).
Conclusion: Thus, adolescents suffering from IS, a pronounced dynamics of a decrease in the concentration of OC with an increase in the degree of curvature of the spine is determined. This result allows us to state a rapid slowdown in the osteosynthesis process proportional to the progression of IS. The primary task remains early diagnosis of IS and timely comprehensive treatment and preventive measures aimed at normalizing bone metabolism processes in a young organism.

P1175

THE EFFICIENCY OF SANATORIUM-RESORT TREATMENT IN ADOLESCENTS WITH SCOLIOSIS ACCORDING TO OSTEODENSITOMETRY

O. P. Galkina[1], V. B. Kaliberdenko[1], E. R. Kulieva[1], N. G. Nikolashina[1], V. R. Yas[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Ege University, Izmir, Turkiye

Objective: Rehabilitation in childhood and adolescence is a key stage in the formation of a healthy generation. Effective and low-cost measures include the stay of sick children in sanatorium-resort conditions. The high prevalence of musculoskeletal diseases among children, namely postural disorders and idiopathic scoliosis, dictates the need for increased attention to this contingent.
Methods: A total of 32 adolescents near 15-16 years old were observed at the rehabilitation stage in the spa conditions of Yevpatoriya. The participants were stratified into 4 groups according to diseases: with posture disorders (13), with scoliosis grade I (12), grade II (5) and with III (2). Spa treatment included: climatotherapy and balneotherapy, mud therapy, massage, calcium-containing diet (up to 1500 mg per day). The structural and functional state of bone tissue was determined using ultrasound densitometry on the calcaneus (osteodensitometer "Achilles +", Lunar-General Electric Medical Systems, USA). The examination was carried out upon admission to the sanatorium (1 day) and after 21 days.
Results: Before the start of the spa treatment, osteopenia and osteoporosis were registered in 16 people (50%). After the treatment, no signs of osteopenia were registered in 1 person (3.22%). The sigmoid deviation (SD) decreased in the group as a whole from -1.3 to -1.07 (by 17.69%), with posture disorders - from -0.33 to -0.07 (by 78.79%), with scoliosis of the 1st degree - from -1.76 to -1.52 (by 13.64%), with scoliosis of the 2nd degree - from -2.16 to -2 (by 7.41%), with scoliosis of the 3rd degree - from -2.77 to -2.62 (by 5.42%).
Conclusion: The standard spa treatment in adolescents with posture disorders and scoliosis contributes to the positive dynamics of changes in the skeletal system. With an increase in the degree of spinal deformation, changes in densitometry indicators are less significant.

P1176

THE FEATURES OF DENTAL HISTORY IN PATIENTS WITH JUVENILE RHEUMATOID ARTHRITIS

O. P. Galkina[1], V. B. Kaliberdenko[1], E. R. Kulieva[1], V. R. Yas[2], N. G. Nikolashina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Ege University, Izmir, Turkiye

Objective: In recent years, the incidence of juvenile rheumatoid arthritis (JRA) has increased worldwide. In this disease, various organs and systems are involved in the pathological process, including those in the maxillofacial region. In particular, the tem-

poromandibular joints, salivary glands, teeth, and periodontal tissues may be involved in the pathological process. The aim of our study was to investigate the features of the anamnesis data of children and adolescents with pathology of the dental system, suffering from JRA.

Methods: We collected anamnestic data from 307 children and adolescents aged 5-16 years (mean age - 11.08 ± 3.11 years), who were undergoing spa treatment at the State Institution "Children's Specialized Clinical Sanatorium "Zdravnitsa" in Yevpatoria with a diagnosis of JRA. The diagnosis of somatic disease was established by specialized doctors. The examination of patients was carried out in a dental office according to the standard method.

Results: Among the examined contingent, 24 (7.82%) people did not present complaints from the dental system. The presence of destroyed teeth was noted by 204 (66.45%) patients. Periodically occurring dry lips were found in 178 (57.98%) patients. Dry mouth (in the morning, after physical activity) bothered 127 (41.37%) people. Periodic pain and discomfort in the temporomandibular joint area was noted by 38 (12.38%) people. 98 (34.39%) children complained of periodic bleeding gums when brushing their teeth. During the external examination of the maxillofacial area of patients with JRA, we noted a disproportion of the lower third of the face (V-shaped narrowed or pointed chin, in some cases - protruding angles of the lower jaw, a large nose - "bird face") in 66.45% of cases (204 people) - a typical sign characteristic of this somatic pathology.

Conclusion: The studies have shown that in patients with JRA, in most cases, habitus has certain signs characteristic of rheumatoid arthritis. Dry mouth may indicate reactivity of the salivary glands. A possible reaction from the temporomandibular joint indicates polyarticular reactivity of the body. Thus, the obtained data are a prognostic sign of the development of JRA in a child and can be used by a pediatrician at the stage of Diagnosis praecox.

P1177

X-RAY CHARACTERISTICS OF PERIODONTAL BONE TISSUE IN ADOLESCENTS WITH GENERALIZED PERIODONTITIS, SUFFERING FROM IDIORPTIC SCOLIOSIS

O. P. Galkina[1], V. B. Kaliberdenko[1], E. R. Kulieva[1], V. R. Yas[2], M. G. Nikolashin[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Ege University, Izmir, Turkiye

Objective: According to published WHO studies, 100% of children at the age of 14 suffer from gingivitis. In recent years, according to literary data, the prevalence of generalized periodontitis (GP) also increases in adolescence. During the same age period, progression of idiopathic scoliosis (IS) is noted – 4-5 times – one of the most common diseases of the musculoskeletal system. The unity of metabolic processes occurring both in the bone tissue (CT) of the spine and in CT of the alveolar processes is confirmed. In clinical dental practice, objective X-ray diagnostics is the most accessible and accessible method for analyzing the CT state of the alveolar processes of the jaws.

Methods: We analyzed 60 orthopantomograms of patients with GP of the initial – 1st degree (classification of periodontal diseases, N. F. Danilevsky, 1994), suffering from postural disorder (PD) (22 images – 36.67%) and idiopathic scoliosis of the 1st degree (38 images – 63.33%).

Results: The analysis of orthopantomograms revealed changes diagnosed in GP of the initial – 1st degree. Signs of osteoporosis, widening of the periodontal gap and unclear contours of the compact plate were detected sporadically in 17 (77.28%) patients with OI and grade I scoliosis in 23 (60.53%) patients. Signs of osteoporosis of a diffuse nature and poor contouring of the compact plate were detected in 5 (22.72%) patients with OI and in 10 (26.32%) patients with grade I scoliosis. Osteoporosis phenomena and destruction of the cortical plate were detected in 5 (13.15%) patients with grade I scoliosis.

Conclusion: The conducted studies have shown that with an increase in the degree of spinal curvature in patients with initial – grade I GP, the frequency of recording more pronounced and profound changes in CT of the alveolar processes on orthopantomograms increases, which must be taken into account when drawing up treatment regimens and preventing periodontitis.

P1178

CALCIUM-DEPENDENT MECHANISMS OF REPARATIVE PROCESSES IN ADOLESCENTS SUFFERING FROM BRONCHIAL ASTHMA AND GENERALIZED PERIODONTITIS

O. Y. Poleshchuk[1], K. N. Kaladze[1], O. P. Galkina[1], J. A. Dovbnya[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: One of the leading places in the occurrence and implementation of pathogenetic mechanisms is given to calcium homeostasis. It is necessary to deeply study the biochemical, physiological and physicochemical patterns of calcium metabolism. In bronchial asthma (BA), calcium is involved in the processes of induction and release of mediators of allergic reactions, bronchospasm, functioning of glands producing bronchial secretions. Complex and to date not fully understood mechanism of calcium transport through the cell membrane. Treatment of generalized periodontitis (GP) is a complex and lengthy procedure, GP. Measures for the treatment and correction of GP are most effective in adolescence - the period of formation of the body, when the complete formation of periodontal tissues is not yet complete. All of the above has determined the interest in studying individual parameters of calcium homeostasis in the context of reparative processes of GP with BA.

Methods: 70 adolescents aged 15-16 years (28 boys and 42 girls) with GP and persistent mild to moderate BA in the remission phase are observed. They formed the main group (MG). The comparison group (CG) - 25 peers with severe BA without GP. The control group (CG) - 20 practically healthy peers. Calcium is one of the most important minerals for humans. The level of calcium in urine depends on its concentration in the blood and on kidney

function. Biochemical analysis of urine for calcium was done by the Sulkovich test.

Results: The calcium content in biological environments in MG patients blood before treatment 2.43±0.04, after treatment 2.51±0.06 mmol / l. Saliva before treatment 1.36±0.04, after treatment 1.38±0.05 mmol/l. In urine in GS up to 3.49±0.23, after 5.16±0.20 mmol/l.

Conclusion: The results of the study of individual indicators of calcium homeostasis in children showed that the level of calcium in the blood and saliva does not change. Studies have shown a more significant increase in the concentration of calcium in the urine at the end of treatment was observed in children with severe persistent bronchial asthma and GP.

P1179

PREVALENCE OF DENTAL CARIES IN PATIENTS WITH BRONCHIAL ASTHMA

O. Y. Poleshchuk[1], K. N. Kaladze[1], O. P. Galkina[1], J. A. Dovbnya[1], K. K. Kaladze[1], S. Kulanthaivel[2], S. A. Khamidova[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India, [3]Tashkent State Pedagogic Univ. named after Nizami, Tashkent, Uzbekistan

Objective: Research by scientists has shown that one of the factors in the development of caries is somatic pathology. It is known that the chronic course of any somatic pathology, in particular bronchial asthma (BA), is accompanied by a deterioration in the complex-organ capabilities of the child and the suppression of non-specific resistance of the body, including organs and tissues of the oral cavity. The results of clinical studies have shown that in children with BA, the prevalence and intensity of caries is higher in comparison with practically healthy children. It has been proven that the severity and duration of the disease affects the condition of hard dental tissues in children with BA. Among the causes that aggravate the condition of the oral organs, medications are distinguished. Inhaled glucocorticoids can cause changes in oral fluid parameters (reduce the rate of salivation, increase viscosity and decrease pH of oral fluid, change in local immunity parameters). They are prescribed to patients with bronchial asthma for long periods and almost constantly.

Methods: The study included 82 patients suffering from persistent bronchial asthma of moderate and mild severity, aged 7 to 12 years - the main group (MG). The control group (CG) consisted of 20 somatically healthy children and adolescents matched for age and gender.

Results: It was found that the prevalence of caries in patients with bronchial asthma was 93%. This is 49.84% higher than in the CG (43.16%) ($p < 0.001$). The highest prevalence and intensity of dental caries is observed in children with persistent moderate bronchial asthma – 91.1% and 1.8±0.7 ($p<0.05$), with mild asthma 85.4% and 1.04±0.02 ($p<0.05$), respectively.

Conclusion: Considering the significance level of the $p<0.05$ criterion, it should be concluded that there is a statistically significant difference between the arithmetic means of caries intensity in children with persistent moderate and mild bronchial asthma. The high prevalence of caries in patients with bronchial asthma compared to practically healthy children and adolescents indicates a significant role of bronchial asthma in the pathogenesis of caries development. Considering the progressive course of bronchial asthma, patients need systematic preventive measures of exogenous and endogenous nature. This issue is of interest for further study.

P1180

CLINICAL AND IMMUNOLOGIC SIGNIFICANCE OF FIBRONECTIN PARAMETERS IN PATIENTS WITH RHEUMATIC DISEASES

O. Rusanova[1], O. Emelianova[1], A. Trofimenko[1], S. Spicina[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Federal State Budgetary Educational Institution of Higher Education «Volgograd State Medical University», Volgograd, Russia

Due to the variety of properties of fibronectin (FN), the main of which are opsonizing, adhesive and chemotactic, its role in the pathogenesis of autoimmune diseases becomes obvious. During the inflammatory process the increased demand for opsonins, and first of all for FN, is compensated by its mobilization from the vascular wall, which leads to permeability disturbance and may be one of the key links in the pathogenesis of vasculitis. The increase in plasma FN concentration in systemic lupus erythematosus (SLE) and overlap syndrome is due to its hyperproduction by tissue macrophages and fibroblasts. In systemic scleroderma (SSD) the amount of bioactive FN (having unoccupied collagen domains) is reduced in patients with the III degree of disease activity, which reflects the depletion of opsonic activity of FN binding immune complexes and tissue derivatives. Its accumulation at the dermoepidermal border was also found, explained by local synthesis of FN by fibroblasts. A number of studies have revealed a correlation between the level of bioactive FN in the blood plasma of patients with rheumatoid arthritis (RA) and the degree of activity of the pathological process.

Objective: to study the content of AT to FN in blood sera of patients with RA, SLE and SSD by solid-phase enzyme-linked immunosorbent assay (ELISA) using immobilized granular antigenic preparations IGAP.)

Materials and Methods. Serum of 30 practically healthy individuals, 75 RA patients, 40 SLE patients and 20 SSD patients was analyzed. Antibodies to FN were determined in ELISA-test (classical method) and in ELISA-test with the use of magnetosorbents (modified by Gontar I.P. et al., 2002). The obtained results were expressed in units of optical density (e.o.p.).

Results. In the study of blood sera of healthy individuals the level of AT to FN was 0.03±0.01 e.o.p. Elevated levels of AT to FN in ELISA-test were revealed in 14 (17,6%) RA patients, 16 (40%) SLE patients and 6 (30%) SSD patients. In RA, the severity of antibodies to FN depended on the presence of extra-articular manifestations ($p<0.02$), and in 79% of cases increased levels of AT to FN

were found in patients with RPE and CNS lesions. In SLE patients, the level of AT to FN significantly depended on the activity of the pathologic process (p<0.02). In the presence of skin manifestations and when joints were involved in the pathologic process (arthritis, arthralgia), the percentage of detection of AT to FN in SLE increased to 70 and 72%, respectively. Heart (p<0.05), lung and nervous system (p<0.001) damage in SCD was most often accompanied by an increase in the level of AT to FN.
Conclusions: Thus, monitoring of AT to FN by MS due to the high sensitivity of the method and the possibility of detecting specific antibodies in the nanogram range can be used to predict the clinical variant course.

P1181

DIAGNOSTIC FEATURES IN SLE PATIENTS WITH THYROID DYSFUNCTION

O. Rusanova[1], A. Trofimenko[1], O. Emelianova[1], S. Spicina[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Federal State Budgetary Educational Institution of Higher Education «Volgograd State Medical University», Volgograd, Russia

The association of systemic lupus erythematosus (SLE) and autoimmunity is now well established, including the fact that both diseases are associated with HLA-DR3. In a recent study of 300 patients with SLE, 5.7% were found to have autoimmune hypothyroidism, 1.7% had Graves' disease, and 14% carried antithyroid antibodies. Screening evaluation of thyroid function in patients with SLE is well justified.
Objective. To evaluate the clinical and immunologic status of patients with systemic lupus erythematosus with thyroid pathology.
Materials and Methods. 70 patients with systemic lupus erythematosus were examined. In the studied group high (III) degree of pathologic process activity was observed in 9.3% of patients, average (II) - in 56.0%, low (I) - in 34.7% of patients. The average index of SLICC/ACR DI damage index in the examined patients amounted to 2.39±0.16 points. Skin manifestations (56.7%), joint lesions (in 59.7%), kidney (in 69.3%), lung (56.9%), blood (74.2%), constitutional disorders (61.1%), and Raynaud's syndrome (65.3%) were diagnosed. Almost one third of patients had antiphospholipid syndrome (25.6%). The patients were tested for TTG, T4 and TK levels using commercial RIA kits (AMERLEX-MAB FT) ELISA kits.
Results and Discussion. In the examined patients with SLE, thyroid changes were detected in one third of patients 33.5% (p=0.0001), which was significantly higher than the general population value. Autoimmune thyroiditis was found in 201%; 17.2% of patients were diagnosed with nodular goiter of the 1st and 2nd degree; diffuse goiter - 3.5%, mixed goiter - 7%. Thus, the dominant thyroid pathology in SLE was expectedly autoimmune thyroiditis. From the functional point of view, SLE patients with thyroid pathology had predominantly reduced (59.3%) and, less frequently, normal thyroid function (40.1%). Hypothyroidism was more often subclinical (24.2%) and mild (18.2%), and less often moderate (15.2%).
Conclusions. Thus, all patients with systemic lupus erythematosus need clinical evaluation of thyroid lesions with mandatory determination of thyroid hormones, antithyroid antibodies, and ultrasound parameters of the organ for timely detection of thyroid pathology, due to the latency of the course of this pathology, as well as in the dynamics.

P1182

THE EFFICACY OF THE TREATMENT WITH ROMOSOSUMAB IN COMMON POPULATION

O. Ruzickova[1], M. Sokalska[1], J. Sindelarova[1]

[1]Institute of Research in Revmatology, Prague 2, Czechia

Background: Osteoporosis is underdiagnosed and undertreated. 200 millions women suffer with osteoporosis worldwide, less than 1 out of 5 is diagnosed, less than 1 of 3 will receive treatment after a fracture[3]. The risk of the fractures is not linear over time. The relative risk of fracture is highest immediately after the first fracture. Approximately 41% of subsequent fractures in women and 52% in men occur within 2 years after the first fracture. Recent fractures (e.g. within the last 1-2 years) are a stronger risk factor for subsequent fractures than previous fractures (e.g. a fracture several years ago). Patients are at immediate risk of subsequent fractures at 1-2 years after the initial fracture. The risk of another fracture increases with each new fracture. The risk of fractures after multiple fractures is higher than in patients with a single fracture. The greater the number of fractures, the greater the risk of subsequent fractures is. The risk of fractures gradually increases with age, but certain events (initiation of antidepressant therapy, the first fracture,..) cause an increase in risk and can thus worsen the risk trajectory.
1 year after proximal femoral fracture 40% of patients are unable to walk without support, 80% of patients are limited in normal activities (driving, shopping)
Mortality within 12 months after fracture of proximal humerus is 10%, after fracture of thoracic or lumbar vertebrae is 14%, after fracture of proximal femur is 31%.
Treatment started immediately after a fracture can prevent higher number of new fractures compared to treatment given later.
Romososumab is drug of the choice in the treatment of the postmenopausal osteoporosis for the patients in the highest risk of fracture. Usually we have data from multicentric, randomized, double blind, placebo or active comparator controlled trials. The efficacy of the romososumab was performed on the study population, which fulfiled inclusion and exclusion criteria.
Objectives: To confirm effect of treatment with romososumab in common population
Methods: There are 18 patients treated with romososumab in our centre from October 2023 till December 2024. All of them met the indication reimbursement criteria of romosozumab (T-score -2.5 SD + osteoporotic fracture). They have not been diagnosed with MI and/or stroke. 3 of them have not been treated for more than 1 month, their results are not included.
Our patients underwent:

Entrance examination: medical history, physical examination, laboratory examination, DEXA, x-ray, education for self-administration
Checkups: baseline, weeks 4, 12, 24, 36, 52
Questions: question whether stroke, MI, IDLL, coronary angiography was performed since the last check-up?
Patients are required to receive the first 2 injections on site
Monitoring objectives: PINP, BetaCTX-I, OC, Ca, PTH in week 0, 2, 4, 12, 24, 36, 52
DXA before and 12 months after initiation of therapy
Side effects in week 0, 2, 4, 12, 24, 36, 52

Results:
Age: Average: 74.6
The oldest p: 82
The youngest p: 64

Comorbidities:

Postmenopausal only	6
+ rheumatoid arthritis +glucocorticoid therapy + biologic therapy	3
+ psoriatic arthritis	1
+ carcinoma in anamnesis	2
+ IBD	1
+ MDS	1
+ Morbus Parkinson	1

Fractures:
Vertebral fractures 45
Patients with vertebral fractures 12
Nonvertebral fractures 18
Patients with nonvertebral fractures 11
Previous treatment:

- treatment naive	8
- BP only	2
- Deno only	0
- BP + Deno	2
- combination	
- Calcitonin Salmon + BP + SR + Deno + Teri	1
- BP + SR + Deno + Teri	1
- BP + Raloxifen + Deno	1

Teriparatide in therapy 2

Entrance Densitometry in average:

Ls/T sc (SD)	-2,9
Ls/BMD (g/cm2)	0,570
Tot.fem T sc (SD)	-2,0
Tot.fem BMD (g/cm2)	0,752
Neck T sc (SD)	-2,3
Neck BMD (g/cm2)	0,710
Rad 33% T sc (SD)	-2,8
Rad 33% BMD (g/cm2)	0,629

Laboratory results:
Ca mmol/l (2,20-2,55)
P1NP ug/l (16,27-73,78)
Beta-CTX ug/l (1,152-0,858)
OC ug/l (5,4-59,1)
PTH pmol/l (0,69- 3,9)

Till this time we have not had new fractures during treatment, no clinical adverse events. The drug was well-tolerated. Transient hypocalcemia occurred in two patients without clinical consequences. Elevation of PTH occurred in most of our patients, it is only question we need to solve.

Conclusion: Elevation of PTH occurred in most of our patients and it is only question we need to solve. All patients are supplemented with calcium and vitamin D. There is a big difference from clinical trials.
We are looking forward to seeing the DEXA measurements after one year of treatment

Key words: postmenopausal osteoporosis, PINP, BetaCTX-I, OC, Ca, PTH, densitometry, romososumab

A CASE REPORT OF INVOLVEMENT OF CORONARY ARTERIES IN A 47-YEAR-OLD MAN WITH THROMBOANGIITIS OBLITERANS

O. Kuryata[1], O. Sirenko[1], M. Grechanyk[1]

[1]Dnipro state medical university, Dnipro, Ukraine

We present a case of a 47- years-old male smoker with complaints of chest pain, palpitations, sensation of coldness of toes and discoloration of digits in legs. The patient had a 29-year history of smoking 20 cigarettes a day. The patient had a Q-wave myocardial infarction of the posterior inferior and lateral wall of the left ventricle with transition to MI a year ago. According to the data of the performed coronary angiography, multiple, fusiform, partially thrombosed aneurysms and ectasias of the coronary vessels were detected. Previously the patient was treated according to guidelines for coronary artery disease. Given the occurrence of symptoms in the lower extremities and taking into account the

nature of coronary artery lesion, the patient was referred to a rheumatologist. Preliminary blood work-up was within the normal range. Serological tests for immunological markers and autoantibodies were normal. MRI data for the presence of induced ischemia were not obtained, no areas of hypoperfusion were detected. Arteriography of the vessels of the lower extremities excluded the presence of atherosclerosis. A biopsy of the inflammatory superficial veins of the lower extremities was performed, which showed changes characteristic of thromboangiitis obliterans. These clinical data led to a revision of the main diagnosis and a change in the treatment strategy. The presented clinical case demonstrates the need for clinical suspicion of systemic vasculitis, in particular thromboangiitis obliterans, in young people with a long history of smoking and signs of vascular damage to the lower extremities.

P1184

FRACTURE RISK ASSESSMENT, BODY MASS INDEX AND LEVEL BLOOD PRESSURE IN MILITARY SERVICEMEN WITH CHRONIC PAIN IN MUSCULOSKELETAL DISEASES

O. Kuryata[1], O. Sirenko[1], M. Grechanyk[1]

[1]Dnipro state medical university, Dnipro, Ukraine

Objective: The "FRAX®" tool is an algorithm created by the World Health Organization (WHO), in 2008, to predict the 10-year risk of hip and major osteoporotic fractures (spine, proximal humerus, hip and forearm). FRAX® algorithms express fracture risk as percentage (%) of hip and/or major osteoporotic fractures within a ten-year period based on the following variables: body mass index (BMI); history of previous fractures at classical osteoporotic fracture sites; family history of hip fracture; smoking; use of glucocorticoids; alcoholism diagnosis of and rheumatoid arthritis (RA). Musculoskeletal disorders are the leading cause of disability worldwide and represent a growing problem due to the ageing population. Risk factors of musculoskeletal disorders include: heavy physical work, smoking, high body mass index, high psychosocial work demands, and the presence of co-morbidities. Back pain, which has been reported to be the leading cause of disability in both high-income and developing countries, results in an increased fear of pain in the elderly population. Aim of our study was to evaluate the role of BMI in correlation with FRAX to predict fragility fractures in military servicemen with chronic pain in musculoskeletal diseases.

Methods: We studied 68 military servicemen with chronic pain in musculoskeletal diseases mean age 44,8±6,04 (group A) and 62 patients nonmilitary servicemen with chronic pain in musculoskeletal diseases mean age 44,6±4,8 (group B). Patients never treated with anti-osteoporotic drugs. The 10-y hip fracture risk was calculated with FRAX score and a value ≥2.5% signified an increased risk. Statistical significance was set at $p<0.05$.

Results: FRAX score in a group A was higher (6,78±4,1) than in group B (4,4±2,1) ($p<0,05$). The mean level of BMI: 30,4±4,2 kg/m2 in group A, 26,1±5,5 kg/m2 in a group B ($p<0,05$). According to FRAX score, value ≥2.5% was found in 63 patients (94%) in a group A and in 40 patients (64%) in a group B ($p<0,05$). There was correlation between the FRAX and BMI ($r=-0,42$; $p<0,05$), FRAX and fractures ($r=0,55$; $p<0,05$), FRAX and level diastolic blood pressure (BP) ($r=-0,41$; $p<0,05$) in a group A however in a group B such connection was not observed. The mean level systolic BP (124,4±9,4 mm Hg and 130,4±6,2 mm Hg, $p=0,50$) and diastolic BP changes did not significantly differ between the two groups (88,4±8,4 mm Hg and 86,8±6,2 mm Hg, $p=0,52$).

Conclusion: Risk of fracture is increased in military servicemen with chronic pain in musculoskeletal diseases. FRAX score in a group A was higher than in group B. There was correlation between FRAX score, BMI and level diastolic blood pressure in military servicemen with chronic pain in musculoskeletal diseases.

P1185

REGENERATIVE TECHNOLOGIES IN SURGICAL ORTHOPEDICS - EXPERIENCE OF MONOAXIAL FORM OF FIBROUS DYSPLASIA TREATMENT

A. Zyma[1], O. Skuratov[1], T. Kincha-Polishchuk[1], Y. Demyan[2], A. Cheverda[1], T. Skrypnychenko[1]

[1]SI "The Institute of Traumatology and Orthopedics" by NAMS of Ukraine, Kyiv, Ukraine, [2]Regional Children`s Hospital, Mukachevo, Ukraine, Mukachevo, Ukraine

Objective: To improve surgical treatment outcomes for recurrent pathological lesions in long bones of patients with fibrous dysplasia (FD) by incorporating regenerative technologies.

Materials and methods: 18 patients with one or more recurrent pathological lesions of the long bones with the monoaxial form of FD (humerus - 3, femur - 11, tibia - 4) were operated. They underwent intraosseous resection of pathological lesion with alloplasty and preventive synthesis and were divided into two groups.

Group I - 10 patients with multiple recurrence of the pathological FD lesions and multiple surgical interventions;

Group II - 8 patients with recurrent FD lesions and surgical intervention, in which the surgical technique was combined with the use of regenerative technologies. In group II, bone marrow punctate in a volume of 5 ml was used for patients under 10 years old; a preparation from concentrated bone marrow aspirate, made according to the standard technique from a punctate volume of 30-60 ml was used for patients over 10 years old.

We used clinical and radiological examination methods and surgical treatment. The average age of patients is 14 years. The observation period is 24-36 months.

Results and Discussion:
Analysis revealed limited efficacy of standard methods in Group I, with recurrence of pain, lesion reappearance, and graft lysis observed within 12–36 months. In Group II, no recurrence of pain or lesions was noted within 12–24 months. Preoperative lesion volumes averaged 18 cm^3 in both groups. Radiological studies in Group II showed accelerated remodeling and improved bone quality compared to Group I.
The average graft remodeling time in Group I was 16 months, while in Group II, it was significantly shorter 11.5 months. Complications, including recurrences in Group I, are likely due to the dominance of osteoresorption over bone formation in structurally deficient bone tissue. Improved remodeling in Group II is attributed to increased levels of osteogenic precursor cells and mesenchymal stem cells.
Conclusion: Incorporating bone marrow aspirate in intramedullary resections is essential for promoting robust bone regeneration and preventing recurrences in long bones affected by FD.

P1186

TIME TREND OF THE SCIENTIFIC PUBLICATIONS IN FIELD OF MACHINE LEARNING AND BONE FRACTURE DETECTION

O. Tabatabaei-Malazy[1], M. Golabchi[2], S. Mohammadhosseinzadeh Golabchi[1], B. Larijani[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Department of Energy (DENERG), Politechnico Di Torino, 10129 Torino, Torino, Italy, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Numerous recent studies have emphasized the role of artificial intelligence in the early detection of bone fractures. We conducted a bibliometric analysis of scientific publications in this field to identify time trend of the publications, productive countries and institutions, active researchers, key journals, and the most frequently indexed keywords.
Material and Methods: We carried out a comprehensive search in the Scopus web database up to 4 Oct 2024. After excluding unrelated papers, bibliometric metrics were analyzed using VOSviewer 1.6.20 and "analyze results" tool in Scopus.
Results: After an initial assessment of 2632 records, 264 studies were included in the final analysis. The earliest relevant study was published in 2006, followed by a steady increase in publications, peaking in 2024 (n=77, 29.2%). Original articles were the most common type of publications (n=195, 73.86%). The majority of studies were in the field of medicine (n=211, 79.9%). The US was the most productive country (n=77, 29.2%), followed by China (n=60, 22.7%), and South Korea (n=26, 9.8%). The main journal was "Journal of Bone and Mineral Research" (n=11, 4.2%), impact factor (IF): 5.1, followed by "European Journal of Radiology" (n=7, 2.7%), IF: 3.2. The total citation number was 2598. The most cited paper (214 citations) was titled "Handling limited datasets with neural networks in medical applications: A small-data approach", published in "Artificial Intelligence in Medicine" (IF: 6.1). The top two affiliations were from the US: "Harvard Medical School" (n=9, 3.4%) and "Flinders University" (n=8, 3.03%). Top author was "Doornberg, J.N." from the Netherlands. Out of the 587 keywords, 28 appeared at least 5 times, with the top five keywords being "machine learning", "artificial intelligence", "osteoporosis", "deep learning", and "fracture".
Conclusions: There is a growing trend in scholarly publications focusing on detection of fracture using machine learning. Our results highlight the strong position of the US and its institutions as the top-ranked country in terms of publications and researcher affiliations, and "Journal of Bone and Mineral Research" serving as a key journal for disseminating influential research.

P1187

A BIBLIOMETRIC ANALYSIS OF THE TOP 150 MOST-CITED ARTICLES ON THE FALLS IN POST-MENOPAUSE WOMEN

O. Tabatabaei-Malazy[1], S. Akbarpour[1], B. Larijani[2]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Numerous studies have shown that falls are a significant risk factor for bone fracture in post-menopausal women. We aimed in the current study to bibliometric analysis of the top 150 top-cited scientific publications on this topic. We want to identify subject area of these papers, the most productive countries, institutions, active researchers, main journals, and frequently indexed keywords.
Material and Methods: We performed a comprehensive search in the Scopus database up to 5 Oct 2024. After excluding unrelated papers, we selected the top 150 most-cited papers. Then, bibliometric metrics were analyzed using VOSviewer version 1.6.20 and the "analyze results" tool in Scopus.
Results: After an initial assessment of 1254 records, among 411 included studies was analyzed 150 top-cited studies. The earliest top-cited study was published in 2004, with 780 citations out of a total 13372 citation number (5.83%). This paper entitled "Physical activity and bone health" was an original study published in "Medicine and Science in Sports and Exercise", impact factor (IF): 4.029, and CiteScore 7.7. Research articles were the most common type of publications (n=102, 68.0%). The main subject area of the papers was medicine (n=145, 96.7%). The US was the most productive country (n=47, 31.33%), followed by the United Kingdom (n=21, 14.0%). The main journal was "Osteoporosis International" (n=14, 9.33%), IF: 3.59, followed by "Menopause" (n=13, 8.66%), IF: 3.36. The top three affiliations were "University of Jaén" (Spain), "Federal University of São Paulo" (Brazil), and

"MRC Lifecourse Epidemiology Unit" (United Kingdom), each contributing 5 studies (3.33%). Top author was "Cooper, C." from the United Kingdom. Of the 1463 indexed keywords, 226 appeared at least 5 times, with the top three being "female", "aged", and "bone density".
Conclusions: Based on our results, the US and the United Kingdom held strong positions as the top-ranked countries in terms of publications, with top-institutions in Spain, Brazil and the United Kingdom emerging as leading affiliations for researchers in the field. Moreover, "Osteoporosis International" was identified as the main journal for publishing high-impact research in this field.
Keywords: Fall, Post-menopause, Fracture, Bibliometric

P1188

ORAL HEALTH IN A NATIONWIDE STUDY OF OLDER ADULTS IN IRAN

Y. Azizpour[1], S. Akbarpour[1], O. Tabatabaei-Malazy[2]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Background: The global population is aging rapidly, and older individuals being particularly vulnerable to *oral health* problems. This study aims to assess the *oral health* status of older adults in *Iran*.
Methods: This cross-sectional study analyzed data from individuals aged 50 and older who participated in the 2021 STEPwise Approach to Non-communicable Disease Risk Factor Surveillance (STEPS) survey. The weighting procedure comprised steps: adjusting for non-response related to age groups affected by COVID-19, applying statistical formulas to mitigate bias from incomplete responses, weighting samples by age, sex, and residential area to ensure demographic representativeness, and presenting categorical data as percentages with confidence intervals (CIs).
Results: Out of 10,946 participants, 53.9% were female (95% CI: 52.8, 54.9), and 77.3% were urban residents (CI: 76.4, 78.1). The mean age was 62.0 years (Standard Error [SE]: 0.1). The prevalence of using oral hygiene devices (toothbrush, mouthwash, and dental floss) was higher among females (79.0%, CI: 77.8, 80.1) and urban residents (80%, CI: 79.1, 81.0) compared to males (72.5%, CI: 71.1, 73.8) and rural residents (62.2%, CI: 60.1, 64.2), respectively ($p < 0.001$). Overall, 10.6% of participants reported gum bleeding after eating, brushing, or flossing (CI: 10.0, 11.3), with higher prevalence in females (12.4%, CI: 11.5, 13.4), compared to males (8.5%, CI: 7.7, 9.4), and in urban areas (11.2%, CI: 10.5, 12.0) compared to rural areas (8.5%, CI: 7.4, 9.8) ($p < 0.001$). The prevalence of toothache or oral pain was 17.8% (CI: 17.1, 18.7), with females experiencing more pain than males. The prevalence of complete toothlessness and denture use was 29.5% (CI: 28.5, 30.4), while 6.5% (CI: 6.0, 7.0) of participants were completely toothless without using dentures, with rural residents being more affected by complete toothlessness than urban residents.
Conclusion: Oral health among older adults in Iran reveals notable sex and regional disparities, with urban residents and females showing better oral hygiene practices. Despite high usage of oral hygiene devices, many individuals experience gum bleeding, tooth pain, and toothlessness, highlighting the need for targeted interventions, especially in rural areas.

P1189

CLINICAL CHARACTERISTICS OF SYSTEMIC LUPUS ERITEMATOUSUS ASSOCIATED WITH ANTIBODY DYNAMICS TO THYROXINE AND TRIODOTHYRONINE

O. V. Paramonova[1], E. G. Korenskaya[1], L. N. Shilova[1]

[1]Volgograd State Medical University, Volgograd,, Russia

Systemic lupus erythematosus (SLE) is a systemic disease characterized by multiple organ pathology. One of the systems affected by SLE is the endocrine, and in particular the thyroid gland. Since SLE is a polysystemic autoimmune disease in which any target organ can be affected, some authors hypothesize that combined autothyroid pathology may be a consequence of the antithyroid activity of any group of antibodies produced in SLE. It is possible that autothyroid pathology is the result of immune damage to the thyroid gland in SLE, accompanied by the deposition of immune complexes. The information available in the literature on the study of autoantibodies to thyroid hormones thyroxine and triiodothyronine (T3 and T4) in SLE is scattered and not systematized. It should be noted that the pathological effect of such antibodies has not been fully determined. In addition, thyroid pathology, in turn, can cause symptoms similar to those of SLE, since both of these diseases mainly affect women in the same age groups.
The aim of the study was to analyze the clinical and laboratory manifestations of thyroxine in accordance with the presence or absence of increased amounts of antibodies to the thyroid hormones thyroxine (T4) and triodothyronine (T3). 65 patients with SLE were examined. The average age of the patients was 52.2±5.1 years. The average duration of diseases was 3.82±3.21 years. Antibodies to thyroxine and triiodothyronine were determined by enzyme immunoassay during antigen fixation in magnetically controlled sorbents using the Gontar method, 2001.
The data was processed using the STATISTICA software package FOR WINDOWS.
In the group of patients representing the interests of people (37 people), it was revealed that the most common clinical manifestations were: skin lesions - 28 (75.7%), joints - 33 (89.1%), cardiovascular system - 34 (91.9%), nervous system - 12 (32.4%), eyes-11 (29.7%). The presence of vasculitis and polyserositis was noted in 11 people (29.7%), anemia - in 10 (27.0%), leukopenia - in 12 (32.4%), Raynaud's syndrome - in 16 (43.2%). ANF was detected in 19 (51.3%), antibodies to DNA - in 37 (89.1%) patients. However, a statistically significant difference with the group of patients with negative antibody activity ($p<0.05$) was noted only in the presence of lesions of the skin, blood vessels, joints and the cardiovascular system. In addition, kidney damage prevailed

(30% versus 27%).
Thus, a significant increase in the concentration of antibodies to thyroid hormones is revealed in patients with skin manifestations of SLE, joint syndrome and high cardiovascular risk. The data obtained make it possible to recommend the study of antibodies to T3 and T4 to all patients with damage to the cardiovascular system on the background of SLE, in order to exclude/confirm thyroid pathology.

P1190

DENTAL HEALTH OF ADOLESCENTS WITH IDIOPATHIC SCOLIOSIS

O. P. Galkina[1], V. B. Kaliberdenko[1], J. A. Dovbnya[1], O. Y. Poleshchuk[1], E. R. Kulieva[1], N. G. Nikolashina[1], V. R. Yas[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Ege University, Izmir, Turkiye

Objective: In recent decades, there has been a trend towards an increase in the diagnosis of idiopathic scoliosis (IS). The prevalence of the disease in certain regions and different age groups is recorded at up to 40% of cases. Given the commonality of metabolic processes in the skeletal system and in the dental system in patients with IS, these pathologies are now considered as comorbid conditions.
Methods: The study involved 57 adolescent children (15-16 years old, average age 15.28±0.03 years) diagnosed with grade I IS (curvature angle 5-10°). Dental status and dental health indicators were recorded.
Results: The study revealed: soft tissue attachment anomalies (frenae of the lips and tongue) – 56.14% (n=32), dentoalveolar anomalies – 82.46% (n=47), dental caries – 87.72% (n=50), caries intensity (CFI) – 4.41±0.2, gingivitis (excluding symptomatic gingivitis) – 38.6% (n=22), periodontitis – 26.32% (n=15). The oral hygiene level according to Green-Vermillion was 1.69±0.06 points. Indicators characterizing the condition of periodontal tissues: prevalence and intensity of gingival inflammation (PMA index modified by C. Parma, 1960) – 26.6±0.82%, index of bleeding of gingival papillae – 1.16±0.05 points, combined periodontal index (PI, Russel, 1956) – 0.94±0.03 points, CPI index (determination of the volume of treatment) – 1.17±0.04 points.
Conclusion: The patients with periodontal disease in adolescence have a high prevalence of dental pathology in comparison with healthy peers. The level of oral hygiene in this contingent is defined as "satisfactory". The prevalence and intensity of caries are noted at the level of "average". This exceeds the standard values of indicators for this age.

P1191

NON-DRUG METHODS OF TREATMENT AND PREVENTION OF INITIAL DENTAL CARIES IN CHILDREN

O. Y. Poleshchuk[1], K. N. Kaladze[1], K. K. Kaladze[1], S. A. Khamidova[2], S. Kulanthaivel[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Tashkent State Pedagogic Univ. named after Nizami, Tashkent, Uzbekistan, [3]Naarayani Multispeciality Hospital, Erode, India

Objective: The problem of dental caries, despite the success achieved in reducing its prevalence and intensity throughout the world, continues to occupy a leading place among other dental diseases. Numerous works of scientists are devoted to early diagnosis, prevention and rational treatment of childhood caries. Currently, non-drug methods of treatment and prevention of caries are of considerable interest. Liquid extract of Saki therapeutic mud is produced under the name "Biol". The preparation contains a balanced complex of mineral salts present in the healing mud, trace elements, active organic substances and biogenic stimulants in high concentration. The aim of the study was to increase the effectiveness of dental caries prevention in children using natural factors.
Methods: A survey, dynamic observation and preventive measures were carried out in 235 children aged 12 in the industrial region. The Crimean Titan enterprise in the city of Armyansk is the largest manufacturer of titanium dioxide in Eastern Europe. In addition to titanium dioxide pigment, the enterprise produces red iron oxide pigment, mineral fertilizers, sulfuric acid, aluminum sulfate, liquid sodium glass, iron sulfate. And recreational - the city of Evpatoria. The intensity and prevalence of caries were determined. The effectiveness of preventive measures was assessed using the caries reduction index.
Results: A high prevalence of caries was revealed in children living in the industrial zone of Armyansk: 84%, in the recreational region 63%, respectively. Significant differences between the groups were also observed in caries intensity indicators (KPU, respectively, 3.9 ± 0.2 and 3.0 ± 0.3 ($p < 0.05$)). "Biol" was diluted in a ratio of 1:5, kept in the oral cavity for 2 minutes 2 times a day after brushing teeth. The course included 20 procedures - daily. The clinical effects of the proposed complex are due to an increase in the mineralizing function of oral fluid, the activity of antimicrobial protection and the antioxidant system of the oral cavity. Thus, the protective effect of the therapeutic and prophylactic complex was cumulative, as a result of which the reduction in dental caries by the increase in KPU over 2 years was 51.9%.
Conclusion: The study data indicate the need for measures that will help reduce the growth of caries and generally improve the dental health of the population. As a result of the treatment, a decrease in the growth and reproduction of opportunistic microflora was noted in the oral cavity of the observed children. Clinical effectiveness is confirmed by the dynamics of clinical data, including caries reduction indicators.

P1192

ASSESSMENT OF SARCOPENIC OBESITY BASED ON HANDGRIP STRENGTH AND SARC-F AND RELATED FACTORS IN MIDDLE-AGED AND OLDER INDIVIDUALS WITH DIABETES

O. Yilmaz[1], C. Idiz[2], C. Kilic[2], S. Gurkas[2], P. Kucukdagli[3], B. Ozulu Turkmen[3], H. Usta Atmaca[1], G. Bahat[2], I. Satman[2], M. A. Karan[2]

[1]Istanbul Training and Research Hospital, Istanbul, Turkiye, [2]Istanbul Medical Faculty, Istanbul, Turkiye, [3]Sisli Etfal Training and Research Hospital, Istanbul, Turkiye

Background: The increasing prevalence of diabetes in aging populations has increased the clinical significance of sarcopenic obesity (SO), a condition characterized by the coexistence of sarcopenia and obesity. This study aims to assess the prevalence of SO using handgrip strength (HGS) and the SARC-F questionnaire in patients with diabetes and explore associated factors.
Methods: We conducted this cross-sectional study on 276 patients with diabetes aged ≥50 years at a tertiary care diabetes outpatient clinic between October 2019 and March 2020. HGS and SARC-F participants were evaluated to identify sarcopenia and body mass index (BMI) for obesity. Clinical and demographic data, including frailty (FRAIL questionnaire), functional status (Katz and Lawton scales), nutritional status (MNA-SF), and depressive mood (GDS-SF) were also recorded.
Results: Men had higher HGS, while women had higher BMI and obesity prevalence. Sarcopenic obesity, identified in 7.4% of participants using the SARC-F questionnaire, was associated with significantly lower HGS, poorer nutritional status, functional decline, higher fall rates, and worse quality of life. Multivariate analysis revealed falls and EQ5-D scores as significant predictors of SARC-F-defined sarcopenic obesity. HGS-based sarcopenic obesity was linked to older age, lower HGS, worse IADL and EQ5-D scores, hypertension, and polypharmacy. HbA1c, hypertension, and EQ5-D scores emerged as significant predictors in logistic regression.
Conclusion: SO significantly impacts functionality, health outcomes, and quality of life. Identifying risk factors such as falls, hypertension, and poor quality of life can guide targeted interventions. Early recognition and management are crucial to mitigate its adverse effects.

P1193

ASSESSING THE APPLICABILITY OF THE MINI SARCOPENIA RISK ASSESSMENT QUESTIONNAIRE IN TURKISH OLDER ADULT POPULATION: A VALIDATION STUDY

O. Yilmaz[1], C. Kilic[2], N. Seker[3], P. Kucukdagli[4], B. Ozulu Turkmen[4], S. Guven[2], M. A. Karan[2], G. Bahat[2]

[1]Istanbul Training and Research Hospital, Istanbul, Turkiye, [2]Istanbul Medical Faculty, Istanbul, Turkiye, [3]Ankara Universitesi, Ankara, Turkiye, [4]Sisli Etfal Training and Research Hospital, Istanbul, Turkiye

Objectives and Aim: This study aimed to validate the Mini Sarcopenia Risk Assessment(MSRA) Questionnaire in a Turkish older adult population. It aims to establish the applicability of MSRA, specifically its Turkish versions, MSRA-5 and MSRA-7, as effective pre-screening tools for sarcopenia.
Materials and Methods: This study included 267 older adults from geriatric outpatient clinics. The MSRA questionnaire, comprising the MSRA-7 and MSRA-5 variants, was adapted to Turkish following a rigorous translation and cultural tailoring process. The participants' sarcopenia risk was evaluated using these questionnaires, and the results were analyzed for reliability, sensitivity, and specificity. Age, Hand Grip Strength (HGS), Usual Gait Speed (UGS), Appendicular Lean Mass (ALM), Body Mass Index (BMI), and psychological scales. The diagnostic accuracies of the MSRA-7 and MSRA-5 questionnaires were evaluated against multiple sarcopenia benchmarks.
Results: Significant differences were observed between genders in age, HGS, UGS, ALM, BMI and psychological parameters (all $p < 0.05$). The prevalence of sarcopenia varied by diagnostic criteria, with the Turkish BMI cutoff indicating a 24.0 % prevalence compared to a 3.0% prevalence with the height-squared cutoff. Diagnostic accuracy of MSRA tools showed high sensitivity and Negative Predictive Value (NPV) across different standards, with the Turkish BMI and height-squared cutoffs exhibiting notable sensitivity (79.7% and 98.8% NPV respectively) and the FNIH criteria showing high sensitivity (89.2%) and NPV (90.6%).
Conclusion: The Turkish versions of the MSRA-5 and MSRA-7 were validated pre-screening instruments for sarcopenia in older adults in Turkey. They exhibit reliable metric properties and substantial congruence.

P1194

COMPARISON OF DIAGNOSTIC VALUE OF THE SARC-F AND ITS TWO MODIFIED VERSIONS (SARCF-EBM AND SARCF-CALF) IN OLDER ADULTS IN TURKIYE

O. Yilmaz[1], P. Kucukdagli[2], N. Seker[3], C. Kilic[4], B. Ozulu Turkmen[2], M. A. Karan[4], G. Bahat[4]

[1]Istanbul Training and Research Hospital, Istanbul, Turkiye, [2]Sisli Etfal Training and Research Hospital, Istanbul, Turkiye, [3]Ankara Universitesi, Ankara, Turkiye, [4]Istanbul Medical Faculty, Istanbul, Turkiye

Objective
This study aimed to assess the diagnostic value of the SARC-F with SARC-F EBM and SARC-CalF, in identifying sarcopenia among community-dwelling older adults.
Methods
This study included 468 participants aged ≥65 years, recruited from outpatient clinics. The diagnostic tools assessed were the SARC-F, SARC-F EBM(which incorporates BMI and age), and SARC-CalF(which includes calf circumference).
Results
For BMI-based sarcopenia, the SARC-F EBM demonstrated the highest sensitivity (40.0%, 95% CI: 31-49.5) and specificity (80.7%, 95% CI: 76.4-84.6), with an AUC of 0.674(95% CI: 0.617-0.732, p < 0.001). SARC-CalF had a lower sensitivity(17.1%, 95% CI: 10.8-25.1) but a higher specificity(87.1%, 95% CI: 83.3-90.2) and an AUC of 0.574(95% CI: 0.512-0.636, p < 0.001).
Conclusion
The SARC-F EBM demonstrated superior sensitivity and diagnostic accuracy compared to the original SARC-F and SARC-CalF for detecting sarcopenia in older adults.. SARC-CalF, while offering higher specificity, may require refinement for broader clinical use, particularly in male populations.

P1195

PREDICTIVE FACTORS FOR ASSESSING PHYSICAL PERFORMANCE AND FUNCTIONAL RECOVERY FOLLOWING FRAGILITY HIP FRACTURE SURGERY: A PROSPECTIVE COHORT STUDY

S. Luarngjindarat[1], O.-A. Phruetthiphat[2], P. Pinijprapa[2], T. Tutaworn[2], T. Songpatanasilp[2]

[1]Rajavithi Hospital, Bangkok, Thailand, [2]Phramongkutklao Hospital, Bangkok, Thailand

INTRODUCTION:
Fragility hip fracture is a significant burden, causing high morbidity and mortality. Furthermore, the presence of concurrent osteoporotic vertebral compression fractures (OVCFs) can worsen functional outcomes. However, the incidence of combined fractures and their associated factors for short-term and long-term functional outcomes remain largely unknown. This study aimed to identify the associated risk factors for functional outcomes in both the short and long term in patients with fragility hip fractures, both isolated and combined with OVCF.
MATERIALS & METHODS:
A prospective cohort study was conducted from April 2021 to June 2022. Inclusion criteria included patients aged 60 years and older diagnosed with femoral neck fractures or intertrochanteric fractures treated with either bipolar hemiarthroplasty or Proximal Femoral Nail Antirotation (PFNA) fixation. All participants were enrolled in the Fracture Liaison Service care program. The cohort comprised 56 patients (52.3%) in the isolated hip fracture group and 51 patients (47.6%) in the group with combined OVCF. Bone mineral density (BMD) was measured, along with vertebral fracture assessment to evaluate the incidence of combined OVCF at the time of admission. Physical performance was assessed at 2-week and 6-week follow-up using the Timed Up and Go test (TUG), and functional outcome was evaluated using the Harris Hip Score (HHS) at 6 and 12 months. Other risk factors were analyzed using univariate and multivariate regression methods.
RESULTS:
General demographic data showed no significant differences between the isolated hip fracture and combined OVCF groups, including age, gender, body mass index (BMI), comorbidities, ASA classification, nutritional status, fracture type, type of surgery, time to surgery, operative time, estimated blood loss, and length of hospital stay. Two-thirds of this elderly population (63.6%) exhibited vitamin D insufficiency, and a high prevalence of possible sarcopenia (74%) was observed, assessed by low hand grip strength.
BMD at the femoral neck was significantly lower in the combined OVCF group (0.61 ± 0.09 g/cm² vs. 0.66 ± 0.12 g/cm², P = 0.02), as was the T-score at the femoral neck (-2.65 ± 0.67 vs. -2.25 ± 0.88, P = 0.01). However, spinal BMD did not show a significant difference between groups, while trabecular bone score (TBS) was significantly lower in the OVCF group (1.29 ± 0.15 vs. 1.37 ± 0.11, P < 0.01), indicating poorer bone microarchitecture. Furthermore, hip fractures occurred sooner than expected in most patients with osteopenia (59.1%) compared to those with osteoporosis (29.5%).
Contrary to some previous studies, the combined OVCF group did not exhibit significant differences in TUG test scores or HHS compared to the isolated group. However, OVCF significantly affected long-term ambulatory gait aid dependence at 6 months (P = 0.009) and 12 months (P = 0.05).
Multivariable analysis identified several key factors negatively impacting 12-month HHS, including advanced age, longer length of hospitalization, delayed time-to-surgery (over 72 hours), and femoral neck T-score less than -2.5.
CONCLUSION:
While OVCF did not significantly affect early recovery or BMD, it negatively impacted long-term ambulatory status and was associated with poorer bone microarchitecture. Advanced age, delayed surgery, longer length of hospitalization, and femoral neck T-score < -2.5 were significant predictors of long-term outcomes, emphasizing the need for personalized post-operative care and further research.

P1196

ACCURACY OF ARTIFICIAL INTELLIGENCE FOR VERTEBRAL FRACTURE ASSESSMENT BY DXA SCAN

P. Sinlapavilawan[1], K. Homsapaya[2], O.-A. Phruetthiphat[3]

[1]Bangkok Hospital Muangraj, Ratchaburi, Thailand, [2]Kasetsart University, Sriracha, Thailand, [3]Phramongkutklao Hospital, Bangkok, Thailand

Background:
Established osteoporosis patients with hip fractures often remain underdiagnosed for osteoporotic vertebral compression fractures (OVCFs). Our hospital's standard of care for assessing hip fracture patients and coexisting OVCFs involves bone mineral density evaluation using dual-energy X-ray absorptiometry (DXA) scans and Vertebral Fracture Assessment (VFA) tools. YOLOv8 (You Only Look Once version 8), a powerful and efficient object detection model, has the potential to detect occult vertebral collapses, graded by the Genant classification, aiding in the early identification of OVCFs.
Purpose:
To design and validate a multi-stage deep learning system for the automated detection, localization, and classification of OVCFs from DXA scans and VFA tools in established osteoporotic patients.
Materials and Methods:
Data from 548 hip fracture patients who presented to our hospital from January 2018 to September 2024 were collected. DXA scan and VFA images of 344 patients were retrospectively evaluated. Spine specialists marked and classified fractures according to the Genant classification (0, 1, 2, 3), considering the upper and lower endplates and the posterior wall. Radiological diagnosis confirmed these classifications. YOLOv8 was employed for vertebral fracture detection. VFA results were categorized into two precision groups: bounding box-based (B) and mask-based (M). Model performance was evaluated using recall, F1-score, mean average precision (mAP50), and mean average precision across IoU (Intersection over Union) values from 50% to 90% (mAP50-95).
Results:
The mean age of the 548 patients (262 female, 286 male) was 79.82 years (SD 8.62 years). Among them, 138 had intertrochanteric fractures, 203 had femoral neck fractures, and 5 had multiple fractures. The DXA scan and VFA images of 344 patients were recruited (138 with intertrochanteric fractures and 203 with femoral neck fractures). Bounding Box-Based Metrics (B) composed of Precision: 0.6635 (66.35% of predictions were correct), Recall: 0.8803 (88.03% of fractures were detected), F1-Score: 0.7567 (average of Precision and Recall), mAP50: 0.9609 (excellent performance in detecting positions at an IoU of 50%), and mAP50-95: 0.6881 (lower accuracy at higher IoU thresholds). Additionally, Mask-Based Metrics (M) composed of Precision: 0.5827 (lower precision compared to bounding box-based metrics), Recall: 0.8399 (83.99% of collapsed areas were detected), F1-Score: 0.6880, mAP50: 0.8937 (good performance), and mAP50-95: 0.5245 (lower accuracy at higher IoU thresholds). The final image shows an overlap of 90% between G1 and 81% between G2.
Conclusion:
The artificial intelligence model can accurately and automatically detect and classify OVCFs in established osteoporotic patients using DXA scans and VFA tools, according to the Genant classification. While the bounding box-based metrics outperformed the mask-based metrics, both demonstrated strong potential for clinical applications.

P1197

DISTRIBUTION AND GENDER-SPECIFIC DIFFERENCES OF CORONAL PLANE ALIGNMENT OF HEALTHY KNEE

O.-A. Phruetthiphat[1], P. Pinijprapa[1], C. Uthaicharatratsame[2]

[1]Phramongkutklao Hospital, Bangkok, Thailand, [2]Nopparat Rajathanee Hospital, Bangkok, Thailand

Background: Understanding optimal prosthesis alignment in TKA remains crucial despite ongoing debate. While current research focuses on osteoarthritic knees, a gap exists in characterizing healthy young adult knees in Asians. This study aims to fill this gap by identifying the distribution of coronal plane alignment of the knee (CPAK) phenotypes in this population, including potential gender variations and individual differences.
Methods: A total of 390 knees from 195 young adults aged 20 to 35 years without knee pain who underwent hip knee-ankle radiography were prospectively collected between February 2024 and March 2024. The average medial proximal tibial angle (MPTA), lateral distal femoral angle (LDFA), arithmetic hip knee ankle angle (aHKA), and joint line obliquity (JLO) were measured. The overall CPAK distribution was analyzed to assess gender variations and individual differences. On average, participants were 25.7 years old, 165.7 cm tall, and had a BMI of 23.6 kg/m². LDFA, MPTA, aHKA, and JLO averaged at 86.8°, 87.2°, 0.3°, and 174.0°, respectively.
Result: The participants' demographics are presented in Table 1. The mean age of all participants was 25.7 years. Their average height, body weight, and body mass index (BMI) were 165.7 centimeters (cm), 65.2 kg (kg), and 23.6 kg per square meter (kg/m2), respectively. The average LDFA, MPTA, aHKA, and JLO were 86.8°, 87.2°, 0.3°, and 174.0°, respectively. Knee alignments of all participants were categorized into 9 zones using the CPAK system as shown in Fig. 2. Overall, zone II was the most common (43.3%), with 19.5% and 14.1% in zones III and zone I, respectively, for both the men and women groups. When considering gender, the three most common zones in the men group (Fig. 3) were zone II, III, and I (45.7%, 23.4%, and 20.7%), while in the women group (Fig. 4), they were zone II, V, and III (41.1%, 18.3%, and 15.8%). Considering the individual patient's right and left knees, the specific most common zones differed slightly between sides (p = 0.507). In the right knee group, the most frequent zones were II, III, and V (42.6%, 21.5% and 13.8%), while the left knee group showed zones II, III, and I as the most common (44.1%, 17.4% and

16.9%). There were no differences between right and left knees in men (p = 0.321) and women (0.649). Additionally, comparing participants to their opposite knee (Table 3), there was comparable result (p = 0.895) within the same zone between men and women (56.4% and 55.4%, respectively). Additionally, a comparison of the overall CPAK distribution, CPAK with apex point distal (zone I-III), and CPAK zone V by gender was demonstrated in Table 4, there were significant differences in the overall CPAK distribution (p < 0.001), the CPAK with apex point distal (89.9% vs. 64.9%, p < 0.001), and CPAK zone V (5.9% vs. 18.3%, p < 0.001) between men and women.

Discussion and clinical application: Intra-individual participant similarity and variation in CPAK alignment is an important issue in current practices and considerations in preoperative planning for TKA. Hip and knee reconstruction surgeons typically rely on the alignment of the contralateral knee to inform potential CPAK zone determination for the affected knee undergoing TKA. However, data from this study suggests a significant discrepancy within individual participants. The concordance rate for CPAK type was only 56.4% for men and 55.4% for women. These findings necessitate a more comprehensive approach to preoperative planning for bone cuts during TKA. This approach should integrate three key factors, the CPAK alignment of the affected knee, the CPAK alignment of the contralateral knee, and the most prevalent CPAK type observed in the patient's geographical location. By considering all three factors, surgeons can make a more informed decision regarding bone cut placement during TKA.

Conclusion: This study examined CPAK distribution in young Asian adults without knee osteoarthritis and identified potential sex-based variations. The findings suggest a predominance of distally pointed CPAK (76.9%) and a possible benefit for slightly varus tibial cuts during TKA in this population for optimal joint alignment. Additionally, gender specific considerations should be incorporated into knee alignment assessments and treatment planning.

Table 1 The participants' demographics

Parameters (Mean ± SD)	All	Men	Women	*p*-value
N	195	94	101	
Age (years)	25.7 ± 2.9	25.5 ± 3.0	25.9 ± 2.8	0.119

Parhon National Institute of Endocrinology, Bucharest, Romania, [8]Department of Endocrinology, Carol Davila University of Medicine and Pharmacy & Department of Endocrinology, C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Introduction: Studies have reported the coexistence of papillary thyroid cancer(PTC) and primary hyperparathyroidism(PHPT) as an incidental finding while pathogenic connections are less understood. **Objective**. We aim to introduce such a case with particular involvement of bone status. **Method:** This is a case report. **Results:** A 73-year-old patient from an iodine-deficient area, known with PHTP due to a left parathyroid adenoma and left-sided PTC, underwent one-time left parathyroidectomy with a left thyroid lobe nodule removal, followed by redo total thyroidectomy and pathological confirmation of multifocal PTC is admitted for re-assessment amid paresthesia in lower limbs. She associates hypertension, NYHA class II heart failure, chronic obstructive pulmonary disease, asthma, obesity, type II diabetes mellitus, vitamin D deficiency, hyperuricemia, and cervical spondylosis with radiculopathy. The family history is significant for hypertension, diabetes mellitus, and psoriasis in the patient's sister and father. Laboratory investigations revealed total serum calcium=8.95mg/dL(Normal:8.4–10.2mg/dL), ionized calcium=4.05mg/dL (Normal:3.8–4.8mg/dL), phosphorus=3.61mg/dL(Normal:2.3–4.7mg/dL), magnesium=2.04 mg/dL(Normal: 1.6–2.55mg/dL), alkaline phosphatase=136U/L(Normal:35–129U/L), CrossLaps=0.62ng/mL(Normal:0.164–0.624ng/mL), osteocalcin=25.92ng/mL(Normal:14–46ng/mL), P1NP=107.5ng/mL(Normal:15–58ng/mL), PTH=56.5pg/mL(Normal:17.3–74.1pg/mL), 25-hydroxyvitamin D=19.4ng/mL(Normal:20–100ng/mL). Thyroid function tests showed TSH=1.18µUI/mL(Normal:0.5–4.5µUI/mL), free T4=16.72pmol/L(Normal:9–19pmol/L), anti-thyroglobulin antibodies=14.1UI/mL(Normal:0–115UI/mL), thyroglobulin=0.04ng/mL(Normal: 3.5–77ng/mL). Dual-energy X-ray absorptiometry(DXA) revealed osteopenia: lumbar spine BMD=0.987 g/cm², T-score=-2.1, Z-score=-2.3; femoral BMD=0.994 g/cm², T-score=-0.6, Z-score=0.2. TBS was 1.262 (partially degraded bone microarchitecture).

Conclusion: Accidental PTC detection during parathyroidectomy adds a supplementary fracture risk by suppressive levothyroxine therapy and long term DXA follow-up is required.

Acknowledgments: This is part of PhD research "Molecular and immunohistochemicalprofile of Radioiodine-Refractory Thyroid Cancers" (2024).

Parhon National Institute of Endocrinology, Bucharest, Romania, [7]Department of Endocrinology, C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Introduction: Serial check-up after prior thyroidectomy for thyroid cancer (TC) confirmation might allow an early detection of a primary hyperparathyroidism (PHPT) amid newly-identified hypercalcemia. **Objective:**we aimed to introduce such a case. **Method:** This is a clinical report. **Results:** A 78-year-old smoker female patient has a history of hypothyroidism secondary to total thyroidectomy performed for multinodular goitre, whereas a pathological confirmed of a papillary TC was done (and followed by levothyroxine suppressive therapy and radioiodine ablative therapy). During follow-up, she was identified with hypercalcemia and then a PHPT confirmation was done. She underwent a right superior parathyroidectomy with post-operatory normal PTH. Her medical history also includes ischemic stroke, atrial fibrillation, NYHA class III heart failure, and obesity. Currently, the lab findings included a low-normal calcium as total serum calcium=8.3mg/dL(Normal:8.4–10.2mg/dL), ionized calcium=3.8mg/dL (Normal:3.9–4.9mg/dL) and normal phosphorus=4.53mg/dL(Normal:2.3–4.5mg/dL), alkaline phosphatase=93U/L(Normal:38–105U/L), CrossLaps=0.25ng/mL(Normal:0.33–0.782ng/mL), osteocalcin=20.16ng/mL(Normal:15–46ng/mL), PTH=37.11pg/mL(Normal:15–65pg/mL), 25-hydroxyvitamin D=33.9ng/mL(Normal:20–100ng/mL). Thyroid panel showed function suppression and non-detectable levels of serum thyroglobulin. Dual-energy X-ray absorptiometry (DXA) revealed osteopenia: lumbar BMD=0.962 g/cm², T-score=-1.7, Z-score=-1.1; femoral BMD=0.915 g/cm², T-score=-0.9, Z-score=0.4; left forearm BMD=0.868 g/cm², T-score=-0.1 and Z-score=2.5. No fracture was detected at thoracic-lumbar spine X-Ray. Further vitamin D 2000 UI per day was recommended and serial bone health assessment. **Conclusion:** In this instance, smoking, age, levothyroxine suppression therapy and prior history of a parathyroid tumour might represent osteoporotic risk fractures; however, DXA showed osteopenia and a decision of postponing specific medication against osteoporosis was done since no prevalent fractures were detected.

CHALLENGES IN MANAGING OSTEOPOROSIS ON A MENOPAUSAL PATIENT WITH METASTATIC, RADIOIODINE-RESISTANT THYROID CARCINOMA ASSOCIATED WITH AN ADRENAL TUMOUR

A. Dumitrache[1], O.-C. Sima[2], M. Costachescu[3], C. Nistor[4]

[1]Department of Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [3]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy & Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [4]Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: Osteoporosis is a multifactorial condition with significant implications for patients with co-existing chronic diseases. Differentiated thyroid carcinoma (TC), particularly in its radioiodine-resistant form (RR), coupled with postmenopausal status, systemic malignancies, and advanced age, represents a high-risk constellation for accelerated bone loss. **Objective**:We aim to introduce such TC, highlighting the interplay of the comorbidities and osteoporosis. **Methods**:This is a case report. **Results**:A 69-year-old woman had a history of papillary TC treated with total thyroidectomy (2016) and radioiodine therapy (2017 - 100mCi, 2021 - 30 mCi, 2023 - 50mCi) with persistently elevated serum thyroglobulin (Tg), refractory to I^{-131} therapy (RR-TC). Imaging assessment revealed pulmonary and lymph node metastases and she is scheduled for tyrosine kinase inhibitors initiation. The patient's comorbidities include a unilateral adrenal tumour of 6 cm with possible (intermittent) autonomous cortisol secretion (the patient declined surgery), and an adrenal myelolipoma. Both menopausal status and TC management (complete thyroidectomy followed by radioiodine therapy, TSH suppression and oncologic medication) represent important risk factors for osteoporosis. Bone health assessment confirmed osteoporosis: (DXA)T-score of -0.8 at total hip, -2.0 at lumbar spine and -3.4 at third distal radius, BMD(g/sqcm) of 0.898, 0,942, respectively, 0,577. Whole body iodine scintigraphy excluded bone metastases. A suppressed TSH(<0.01μIU/mL;Normal:0.35-4.94) under levothyroxine suppression associated low 25-hydroxyvitamin D(16.4 ng/mL;Normal:20-100), and reduced bone turnover markers (P1NP=20.64ng/mL,Normal:20.25-76.31) and normal PTH(23.98pg/mL;Normal:17.3-74.1). The patient has a history of fragility fractures, including a vertebral compression fracture. Zoledronate (4 mg/year) was started alongside calcium (800 mg/day) and vitamin D supplementation (2,000 IU/day). The patient remained under close monitoring to balance the thyroid issues

and skeletal health.**Conclusion:**This case underscores the critical need for a multidisciplinary approach in managing osteoporosis in patients with systemic malignancies, including RR-TC associated with a potential intermittent source of endogenous (mild) cortisol production. Comprehensive strategies, including early diagnosis, targeted osteoporosis treatment, and individualized endocrine-oncologic planning are essential to improve outcomes in high-risk patients.

SERUM IRISIN LEVELS IN RELATIONSHIP WITH MINERAL METABOLISM ASSAYS: A CROSS-SECTIONAL ANALYSIS (PROJECT IRI-OP-OB)

L. Suveica[1], D. Manda[2], V. Cumpata[1], S. V. Schipor[2], M.-M. Vovc[1], O.-C. Sima[2], A. Popescu[1], D. Galea-Abdusa[1], M. Carsote[2]

[1]"Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova, [2]"C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Introduction. Irisin, a new player in the field of bone-metabolic connection acts as a muscle-derivate hormone which is prone to bone forming activity via multiple mechanisms (some of them are still incompletely known so far). Only a few studies address the blood assessment of the circulating levels until present time.
Objective. We aim to analyze the serum irisin profile amid blood assays in menopausal women.
Methods. This was a cross-sectional prospective, bi-centric pilot study. Inclusion criteria were 40 menopausal women (aged over 50) who did not have a prior exposure to specific medication against osteoporosis and signed the informed consent. Exclusion criteria were subjects with active cancers and/or endocrine tumors, and end stage kidney disease. The mineral metabolism was assessed according to three stratum: blood minerals (total calcium and phosphorus), bone hormones [25-hydroxyvitamin D (25OHD) and parathormone (PTH)], and serum bone turnover markers: of formation (P1NP, alkaline phosphatase, and osteocalcin) and of resorption (CrossLaps). Irisine kit was based on ELISA assays. Pearson correlation coefficient was calculated (statistical significance at $p<0.05$). Ethical consent was obtained from both centers (number 32/30.9.24, respectively, 97/20.11.24).
Results. Irisine statistically significant correlated with osteocalcin ($r=-0.338$, $p=0.01$), including after adjustment for body mass index and showed a tendency to correlate with serum phosphate ($r=-0.257$, $p=0.07$), and it did not correlate ($p>0.05$) with patients' age, 25OHD, P1NP, CrossLaps, alkaline phosphatase, and calcemic level.
Conclusion. We emphasize that irisin is one of the key regulatory factors in metabolic-bone interplay and further research might place irisin blood assays amid the panel of fracture risk and bone turnover status evaluation in certain population subgroups. Based on these preliminary data, irisin is associated with blood levels of osteocalcin which is known to connect the metabolism with the bone regulation.
Acknowledgment. This research is part of the project IRI-OP-OB ("Crossroad of metabolism and bone: the impact of irisin, bone turnover and inflammatory markers in patients with menopausal osteoporosis and obesity"): PN-IV-P8-8.3-ROMD-2023-0262.

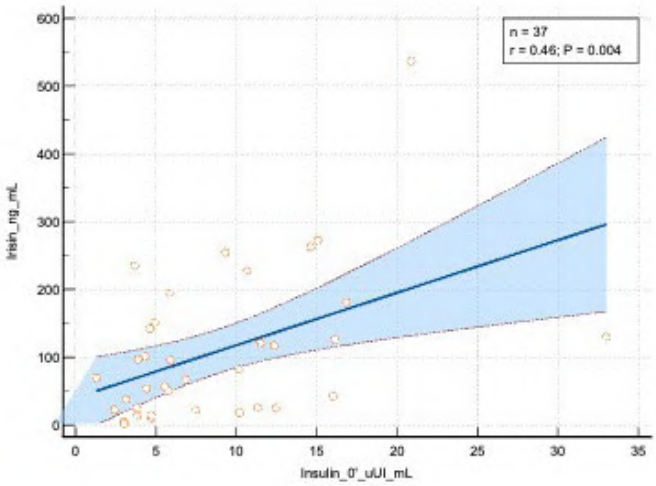
BLOOD IRISIN ASSAYS AND GLUCOSE METABOLISM EVALUATION IN MENOPAUSAL SUBJECTS (PROJECT IRI-OP-OB)

D. Manda[1], L. Suveica[2], O.-C. Sima[1], V. Cumpata[2], S. V. Schipor[1], D. Galea-Abdusa[2], M.-M. Vovc[2], A. Popescu[2], M. Carsote[1]

[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania, [2]Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova

Background: Irisin, muscle product amid cold exposure and physical exercise, seems to be associated with higher bone formation level and insulin sensitivity, particularly, in females. Approximately 70% of circulating levels represent the muscle product, while the rest is secreted by the subcutaneous and visceral adipose tissues. The current clinical studies are limited with respect to circulating irisin and its daily practical applications.
Objective: to evaluate irisin and compare it with glucose profile.
Methods: The study design was a bi-centric, cross-sectional analysis; the assays were performed in 37 menopausal women. We included subjects aged between 50 and 70 years, those who lacked a prior diagnosis of osteoporosis and/or (type 1 or secondary) diabetes and had no prior/current exposure to insulin, GLP-1 agonists or estrogen replacement. We excluded males, individuals with active malignancies (regardless of the applied multimodal management) and those with kidney failure. The study was approved by the Ethical Boards from both centers (32/30.09.2024-Bucharest, 97/20.11.2024-Chisinau) and each patient signed the informed consent. Irisine (ELISA, MyBioSource,ng/mL) was tested a jeun, as well as fasting blood glucose (photomethry,Abbott,mg/dL) and insulin (CLIA,Beckman Coulter,µUI/mL). Correlations were calculated with a cut-off significance at $p<0.05$.
Results:Mean irisin was of 120.958+/-115.823 ng/mL (ranges: 2.07 to 536.93 ng/mL, median of 95.7, with no correlation with the subjects' age). The serum irisin statistically significant correlated with fasting insulin in terms of a positive medium Pearson correlation as shown by $r=0.46$;$p=0.004$, but not with fasting glucose ($r=0.083$,$p=0.8$) Moreover, irisin positively correlated with insulin resistance index (HOMA-IR): $r=0.313$,$p=0.004$ as well as A1c glycated hemoglobin: $r=0.373$,$p=0.008$. Of note, the impairment of glucose profile might be reflected by the levels of serum triglycerides, too, but we did not find a correlation with irisin values ($r=0.129$,$p=0.3$).



Conclusion: These findings in small cohort size are encouraging to further expand the search of testing whether irisin assay might act as marker of metabolism status, including insulin resistance, as reflected by the positive correlation with basal insulin, HOMA-IR, and A1c glycated hemoglobin.

Acknowledgment:This research is part of the project IRI-OP-OB ("Crossroad of metabolism and bone: the impact of irisin, bone turnover and inflammatory markers in patients with menopausal osteoporosis and obesity"): PN-IV-P8-8.3-ROMD-2023-0262.

OSTEOPENIA IN A PATIENT WIHT SYSTEMIC LUPUS ERYTHEMATOSUS, HYPOTHYROIDISM AND CHRONIC C HEPATITIS COMPLICATED WITH PULMONARY HYPERTENSION

O. P. Ionescu[1], B.-A. Sandulescu[2], O.-C. Sima[3], C. Nistor[4], M. Costachescu[4], M.-L. Ciobica[2]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy & Department of Internal Medicine I and Rheumatology, "Dr. Carol Davila" Central Military University Emergency Hospital, Bucharest, Romania, [2]Department of Internal Medicine I and Rheumatology, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Internal Medicine and Gastroenterology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [3]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Thoracic Surgery, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background. Bone ailments represents a part of an otherwise complicated panel in systemic lupus erythematosus(SLE). **Objective.** We aimed to introduce a SLE case complicated with low BMD (bone mineral density) and pulmonary hypertension (PH), a rare SLE condition defined by mean pulmonary artery pressure over 20mmHg determined by right heart catheterization(RHC). **Methods.**This was a case report. **Results**. A 72-year-old female with a history of total thyroidectomy for Graves' disease, chronic hepatitis C virus infection and anemia was admitted for weight loss, joint pain, weariness, shortness of breath during moderate exercise, and lower limb swelling. Laboratory tests showed increased inflammation markers:C-reactive protein=30.96mg/L(Normal<5) with leukopenia. She had positive antinuclear antibodies R=5.7, intensely positive anti-double-stranded DNA>200U/mL(Normal<15), and reduced serum total calcium=8.61mg/dL(Normal:8.80-10.6) and 25-hydroxyvitamin D=22.7ng/mL(Normal>30). Cardiac biomarkers showed increased NTproBNP=580pg/mL(Normal<125), with high D-dimers=981ng/mL(Normal<250). SLE was confirmed. Echocardiography revealed minimal left ventricle hypertrophy, mitral and tricuspid valve regurgitation, bi-atrial enlargement, and a high probability of PH. Her symptoms and test results improved after being treated with corticosteroids, loop diuretics, aldosterone antagonists and direct oral anticoagulants that continued with daily 400mg of hydroxychloroquine. Moreover, DXA showed osteopenia: lumbar BMD of 0.932 g/cm^2, T-score -2.1, Z-score -0.7; femoral neck BMD 0.742 g/cm^2, T-score -2.0, Z-score -0.5, total hip BMD 0.713 g/cm^2, T-score -2.4, Z-score -1.1, and reduced TBS=1.291. Additionally, a coronary calcium computed tomography showed an elevated calcium score of 112 AU(reference range:101-400 for moderate evidence of heart disease due to substantial atheromatous infiltration of the proximal left circumflex artery, left anterior descending artery(I-II segments) and right coronary artery(segment II). The patient continued with 2000 U/day cholecalciferol.

Conclusion. This was an unusual case who presented to the rheumatology department with conventional symptoms, but who was actually concealing complex autoimmune illnesses that can have catastrophic and unpredictable effects on the cardiac, respiratory, and even musculoskeletal function. The evaluation of the bone health amid such a complex panel should be performed, as well, at the moment when the clinical status allows it, since factors such as chronic hypoxia, and inflammation, certain thyroid conditions, or chronic glucocorticoids exposure might contribute to the overall increased fracture risk.

P1204

PERSONALIZED STRATEGY AMID SEQUENTIAL THERAPY FOR MENOPAUSAL OSTEOPOROSIS AND PRIOR MULTIMODAL INTERVENTION FOR BREAST CANCER

O.-C. Sima[1], A. M. Ghemigian[2], D. E. Rentea[3], M. Costachescu[4]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania

Objective: Patients under anti-osteoporotic treatment should be thoroughly evaluated to ensure compliance to the adequate sequence of medication, especially for individuals with long-history

of osteoporosis. We aim to introduce such case. **Method:** case presentation. **Results:** A 73-year-old female has a history of type 2 diabetes and breast carcinoma since the age of 46 (for which she underwent chemotherapy, right mastectomy and 4 years of tamoxifen; at age 48 she also had total hysterectomy with bilateral adnexectomy). At age of 51, the patient was diagnosed with osteoporosis and started ibandronate intravenous (3 mg/3 months). She was poorly compliant for more than one decade, and then Dual-Energy X-Ray Absorptiometry (DXA) showed bone loss [lumbar BMD=0.763g/sqcm,T-score=-2.6; femoral neck BMD=0.654g/sqcm,T-score=-2.3; total hip BMD=0.687g/sqcm,T-score=-2.4]. Denosumab (60 mg twice yearly) was recommended and then self-decided to be stopped 2 years later, whereas DXA was stationary [lumbar BMD=0.907g/sqcm,T-score=-2.3; femoral neck BMD=0.751g/sqcm,T-score=-2.1; total hip BMD=0.680g/sqcm,T-score=-2.6]. Currently, after another 3 years without anti-osteoporotic treatment, while the patient remained fracture-free, DXA-BMD decreased [lumbar BMD=0.810g/sqcm,T-score=-3.3; femoral neck BMD=0.629g/sqcm,T-score=-2.9; total hip BMD=0.637g/sqcm,T-score=-3.0]. Increased bone turnover was confirmed by elevated bone formation markers [osteocalcin=51.03ng/mL(normal:15-46) and P1NP=113.8 ng/mL(14.28-58.92)] and resorption [CrossLaps=1.16ng/mL(0.33-0.782)]. Low TBS of 1.228 confirmed partially degraded microarchitecture. Zoledronate (5 mg/year) was administrated (plus cholecalciferol 2000IU/day). **Conclusion:** Zoledronate might represent an option in poorly compliant patients since it might experience a good outcome in fracture risk reduction upon a single injection from 12 to 36 months, particularly, with additional benefits for breast cancer outcome.

LIFE-LONG CONSEQUENCE OF LATE DIAGNOSIS AMID MOSAIC TURNER SYNDROME AND OSTEOPOROSIS

O.-C. Sima[1], M. Costachescu[2], E. Petrova[3], G. Voicu[4], A. Dumitrascu[5], A. M. Ghemigian[3]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [3]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Nuclear Medicine, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Patients with Turner syndrome (TS) are at risk of osteoporosis at young age due to hypogonadism (especially in the absence of hormonal replacement) and other co-morbidities such as celiac disease, vitamin D deficiency, etc. We aim to introduce a patient with mosaic TS firstly diagnosed in her fourth decade of life complicated with osteoporosis. **Method:** case report. **Results:** A 35-year-old female with short stature (-6.28SD) and hypoacusis had spontaneous menarche at 14, 2 spontaneous pregnancies (healthy new-borns) followed by secondary amenorrhea at 23 (no oestrogens or growth hormone therapy). Currently, premature ovarian insufficiency (elevated FSH=84.77mIU/mL), and autoimmune thyroid disease with high-normal TSH are confirmed. Mineral metabolism assays showed normal total serum calcium [9.51mg/dL (normal:8.4-10.3)]; low-normal 25-hydroxyvitamin D [24.3ng/mL (normal>30)]. Increased bone turnover markers [osteocalcin of 64.22ng/mL (normal:11-43), alkaline phosphatase of 116U/L (normal:35-104), P1NP of 118.5ng/mL(normal:15.13-58.59) and CrossLaps of 0.95ng/mL (normal: 0.162-0.487)] and normal parathormone [49.51pg/mL (normal:17.3-74.1)] were identified. Dual-Energy X-Ray Absorptiometry (DXA) confirmed low BMD (bone mineral density) for age for her age: lumbar BMD of 0.921g/sqcm, Z-score of -1.1, femoral neck BMD of 0.569g/sqcm, Z-score of -2.5 and total hip BMD of 0.592g/sqcm, Z-score of -2.5. Cytogenetic analysis showed mosaic karyotype 45,X[31]/46,XX[9], diagnosing 46,XX mosaic TS. Oestrogen-progestative replacement therapy and cholecalciferol 2000IU/day and levothyroxine 50µg/day were started. **Conclusion:** Due to the milder phenotype in mosaic TS, the adequate diagnosis and therapy may be delayed, including a potential impact on fracture risk, life-long surveillance being mandatory especially in poorly compliant individuals.

CHALLENGES IN THE MANAGEMENT OF SEVERE MENOPAUSAL OSTEOPOROSIS AMID AROMATASE INHIBITOR THERAPY: IS THERE AN INTERFERENCE OF THE COVID-19 PANDEMIC YEARS INTO ADHERENCE TO MEDICATION?

O.-C. Sima[1], A. M. Ghemigian[2], A. Dumitrascu[3], D. Terzea[4], D. Ioachim[4], G. Voicu[5], M. Costachescu[6]

[1]PhD Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Pathology and Immunohistochemistry, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Nuclear Medicine, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [6]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania

Objective: The management of osteoporosis requires a long-term strategy tailored to the patient's individual risk factors, treatment response, and tolerance/adherence to medication. We aim to introduce a senior patient with multiple comorbidities, interruptions in therapy, and breast cancer treatment with aromatase inhibitors. **Method:** case report. **Results:** This was a 90-year-old female patient admitted for bone status assessment. She entered menopause at 50 years old, was diagnosed with osteoporosis at 73 and started bisphosphonates. After 4 years, DXA improved [lumbar bone mineral density(BMD)=0.937g/sqcm, T-score=-2.0; femoral neck BMD=0.837g/sqcm, T-score=-1.4; total hip BMD=0.837, T-score=-1.4]. She had a 3-year drug holiday and then suffered multiple thoracic and lumbar vertebral fractures, thus teriparatide was recommended and stopped after 3 months due to persistent nausea and aggravated depression, thus zoledronate 5 mg/year was administered for 2 years. During COVID-19 pandemic restrictions, she stopped anti-osteoporotic treatment for 3 years. Meanwhile she underwent excision of a left breast invasive carcinoma and started aromatase inhibitor therapy. Currently, after 1 year of letrozole and 3 years without anti-osteoporotic medication, DXA-BMD decreased [lumbar BMD=1.275g/sqcm, T-score=-2.3; femoral neck BMD=0.644g/sqcm, T-score=-2.8; total hip BMD=0.729g/sqcm, T-score=-2.3]. Bone formation markers were normal [osteocalcin=21.76ng/mL(normal:15-46), P1NP=40.7ng/mL(normal:15.13-58.59)] and resorption [CrossLaps= 0.33ng/mL(normal:0.33-0.782)] without incidental fractures. Zoledronate 5 mg/year was administered, with annual follow-up. **Conclusion:** This case emphasizes the need for continuous surveillance of patients with a complex history of anti-osteoporotic treatment and adjustment of therapeutic approach based on each individual's case regarding fracture risk, co-existing diseases and drug options.

INTERPLAY OF THE THYROID AND ADRENAL COMORBIDITIES IN ALTERING THE BONE PROFILE AMID MENOPAUSE

O.-C. Sima[1], M. Costachescu[2], G. Voicu[3], D. Terzea[4], A. M. Ghemigian[5], A. Dumitrascu[6], A. Goldstein[3]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [3]Department of Nuclear Medicine, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Pathology and Immunohistochemistry, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [6]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Multiple osteoporotic risk factors may be co-present in menopause, including Thyroid Stimulating Hormone (TSH) suppressive therapy (TSH-ST) and excessive endogenous cortisol production. We aim to introduce such patient. **Method:** case report. **Results:** A 59-year-old female had a total thyroidectomy 5 years prior for papillary thyroid carcinoma, followed by 100 mCi radioiodine therapy and TSH-ST. She associates obesity, hypertension, impaired glucose tolerance and dyslipidaemia. Thyroid panel confirmed TSH-ST [TSH<0.1mIU/mL(target≤0.1), thyroglobulin=0.06ng/mL(normal:3.5-77) and negative anti-thyroglobulin antibodies]. Due to non-specific bone pain, investigations led to the detection of a left femur bone tumour of 2 cm with benign imaging features at computed tomography (CT). The patient declined biopsy. CT also showed bilateral adrenal tumours of 4.73 cm maximum diameter on the right and negative densities on native CT (adenoma). Basal ACTH was suppressed [2.7pg/mL(normal:7.2-63.3)] and plasma-morning-cortisol after 1-mg-dexamethasone suppression test confirmed mild autonomous cortisol secretion (MACS) [13.9mg/dL(normal:<1.8)]. Bone formation was suppressed [osteocalcin of 11.67ng/mL(normal:15-46)] with normal bone resorption. Dual-Energy X-Ray Absorptiometry (DXA) was normal: lumbar BMD (bone mineral density (BMD)=1.200g/sqcm, T-score=0.0, Z-score=0.0, femoral neck BMD=1.013g/

sqcm, T-score=0.3, Z-score=0.5, total hip BMD=1.098g/sqcm, T-score=0.8, Z-score=0.8. Bone microarchitecture was normal (trabecular bone score of 1.388). Right adrenalectomy was postponed by the patient. Surveillance of metabolic and bone status is mandatory. **Conclusion:** While DXA-BMD and TBS were normal in a pre-diabetic, menopausal female with obesity and reduced bone formation, TSH-ST and MACS are prone for an elevated fracture risk. The co-presence of a benign bone tumour might be incidental.

Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [5]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [6]Department of Nuclear Medicine, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Accelerated weight loss and low body mass index (BMI) is associated with higher bone mineral density(BMD) loss and fracture risk. We aim to introduce such patient. **Method:** case report. **Results:** This was a 72-year-old female admitted for non-specific bone pain. She had 26 years since menopause and decreased BMI of 16kg/sqm, a history of chronic viral hepatitis C treated with interferon and ribavirin for 12 years and chronic autoimmune hypothyroidism. Family history included mother with osteoporosis and femoral neck fracture. Adequate substitution [TSH =3.44mIU/mL(normal: 0.35-4.94)] was confirmed [under levothyroxine 50mg/day] and high anti-thyroperoxidase antibodies[182IU/mL(normal:0-5.61)]. Total serum calcium, phosphorus, 25-hydroxyvitamin D and parathormone were normal. Bone formation marker osteocalcin was 31.78ng/mL(normal:15-46), alkaline phosphatase was 63IU/L(normal:40-150), P1NP was 75.23ng/mL(normal:20.25-76.31) and bone resorption marker CrossLaps was 0.619ng/mL(normal:0.33-0.782). Malabsorption tests (including celiac disease and upper endoscopy) were negative. Dual-Energy X-Ray Absorptiometry (DXA) revealed osteoporosis: lumbar BMD=0.722g/sqcm,T-score=-3.7, Z-score=-1.3; femoral neck BMD=0.685g/sqcm,T-score= -2.5,Z-score= -0.3; total hip BMD=0.671g/sqcm,T-score=-2.7,Z-score=-0.8 Microarchitecture was partially degraded [Trabecular Bone Score (TBS) of 1.233]. She had no prevalent fracture on thoracic-lumbar spine X-Ray. 10-year fracture risk assessment for major osteoporotic fractures was of 13%, respectively, hip fracture of 7.3%, adjusted for TBS of 14%, and 7.5%. The patient declined injectable agents against osteoporosis; hence, risedronate (35 mg/week) was started, in addition to vitamin D supplementation (1000IU of cholecalciferol/day). **Conclusion:** A tailored recommendation of anti-osteoporotic medication should be made according to every patient's individual profile, including taking into consideration the T-score profile, identified risk factors, and compliance.

GLUCOCORTICOID-ASSOCIATED BONE LOSS AND MENOPAUSAL OSTEOPOROSIS: TAILORED STRATEGY FOR BISPHOSPHONATES DRUG HOLIDAY

O.-C. Sima[1], D. E. Rentea[2], M. Costachescu[3], A. Dumitrascu[4], A. M. Ghemigian[5]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [3]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [4]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [5]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Chronic glucocorticoid use is associated with a decrease of bone mineral density (BMD) and increase fracture risk,

especially in menopausal status. We aim to introduce such case. **Method:** case report. **Results:** A 75-year-old female followed a 6-year regime of oral bisphosphonates for severe osteoporosis (complicated with mild lumbar fractures) with Dual-Energy X-Ray Absorptiometry (DXA) showing improved BMD [lumbar BMD=0.921 g/sqcm, T-score=-2.2; femoral neck BMD=0.799 g/sqcm, T-score=-1.7; and total hip BMD=0.799 g/sqcm, T-score=-1.7]. She was then recommended drug holiday. After a period of 5-year drug holiday, she started metilprednisolone (a maximum dose of 32 mg/day) for the past 4 months because of diffuse interstitial lung disease. Currently, total serum calcium, 25-hydroxyvitamin D and parathormone were normal. She had reduced bone formation markers [osteocalcin and alkaline phosphatase of 8.58ng/mL (normal:15-46), respectively, 22.7IU/L (normal:35-104)], and normal P1NP [34.19ng/mL (normal:20.25-76.31)], and bone resorption marker CrossLaps [0.51ng/mL (0.33-0.782)]. A DXA reassessment showed BMD decreased [lumbar BMD of 0.869g/sqcm, T-score of -2.6; femoral neck BMD of 0.708g/sqcm, T-score of -2.4; and total hip BMD of 0.739g/sqcm, T-score of -2.1]. Screening thoracic-lumbar spine X-Ray did not confirm any incidental fractures. Noting the newly onset of the glucocorticoids exposure, despite stationary suppression of some bone turnover markers (BTM), a drug re-initiation was done [intravenous zoledronate 5mg/year] plus cholecalciferol 2000 IU/day. **Conclusion:** The decision of stopping the drug holiday should take into consideration a multimodal panel, including glucocorticoid therapy exposure, prior fractures, and the landscape of blood BTMs.

VITAMIN D DEFICIENCY AND BREAST HEMATOMA MASKING A MACROPROLACTINEMIA AND MICROPROLACTINOMA IN A YOUNG ADULT WITH LONG-TERM SECONDARY AMENORRHEA

O.-C. Sima[1], M. Costachescu[2], A. Dumitrascu[3], E. Petrova[4]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [3]Department of Radiology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania, [4]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Hyperprolactinemia might imply various etiologies and extensive investigations are sometimes required in order to avoid complications, including osteoporosis. We introduce a patient with hyperprolactinemia that was initially considered caused by a breast hematoma. **Method:** case report. **Results:**A 37-year-old female was admitted for the evaluation of secondary amenorrhea for several years. She recently suffered a chest-wall trauma 10 months prior (car accident), and breast magnetic resonance imaging confirmed a local hematoma. Elevated prolactin [145ng/mL(normal:4.79-23.31)] was found 6 months after trauma. On admission, she had high prolactin [125.6ng/mL(normal:3.34-26.72)], and inappropriately normal FSH [3.29mIU/mL(normal:1.79-5.12)] in amenorrhea. Post-PEG (polyethylene-glycol) precipitation prolactin (110.66ng/mL) confirmed macroprolactinemia and tumour-related prolactin. Pituitary computed tomography showed a hypodense left micro-nodule of 0.33/0.29cm. Mineral metabolism displayed normal calcemic profile, and parathormone, but vitamin D deficiency [5 ng/mL(normal>30)]. Bone turnover markers were normal. Cabergoline [progressively increased doses until 1mg/week) was started with hormonal and imaging follow-up. Vitamin D supplementation was initiated (2000 UI/day cholecalciferol followed by 1000 UI/day after 3 months). No apparent cause of vitamin D was identified. **Conclusion:** Hyperprolactinemia causing low estrogen and amenorrhea may impact the bone health. Thus, it is mandatory to determine the cause and establish an early management. PEG precipitation and imaging techniques are useful tools for selecting the patients that require prolactinoma protocols. Whether Dual-Energy X-Ray Absorptiometry should be performed in a young subject with long-term untreated secondary amenorrhea represents a personalized decision, and, in this instance, the investigation was declined by the patient.

P1211

THE CONSEQUENCES OF ACROMEGALY AND PREMATURE OVARIAN FAILURE ON BONE HEALTH AND CHALLENGES OF ASSOCIATED MANAGEMENT

O.-C. Sima[1], M. Costachescu[2], A. M. Ghemigian[3]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Department of Radiology and Medical Imaging, "Fundeni" Clinical Institute, Bucharest, Romania, [3]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania & Department of Endocrinology, „C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Objective: Acromegaly is associated with deteriorated bone microarchitecture and increased fracture risk, particularly vertebral fractures. Co-existing hypogonadism or diabetes increases the risk factor. We aim to introduce a female with acromegaly and hypogonadism complicated with osteoporosis. **Method:** case report. **Results:** This was a 50-year-old subject was diagnosed with pituitary meso-adenoma-related acromegaly at 31; she underwent trans-sphenoidal hypophysectomy followed by lanreotide PR for 1 year, achieving remission. After 9 years, recurrence was detected in terms of high insulin-like growth factor [IGF1=290ng/mL(normal:73-263)] and growth hormone (GH). Long-acting octreotide 20 mg/month and cabergoline 1 mg/week was started. At 42, she developed secondary amenorrhea (elevated FSH=75.67mIU/mL), confirming premature menopause/ovarian failure. Estro-progestative replacement was offered, but stopped after a few months because of severe headache. Mineral metabolism evaluation showed normal total serum calcium=9.7mg/dL (normal:8.4-10.3), and parathormone=33.55pg/mL(normal:15-65), and a mild vitamin D deficiency [25-hydroxyvitamin D=21.4ng/mL(normal>30)]. Bone formation markers were within normal range [osteocalcin=32.61ng/mL(normal:15-46), alkaline phosphatase=67.7IU/L(normal:35-104) and P1NP=75.5ng/mL(20.25-76.31)], as well as resorption marker CrossLaps=0.55ng/mL(normal:0.33-0.782). Dual-Energy X-Ray Absorptiometry confirmed abnormal results [lumbar bone mineral density (BMD)=0.888g/sqcm, T-score=-2.5, Z-score=-1.7, femoral neck BMD=0.773g/sqcm, T-score=-1.7, Z-score=-0.9, total hip BMD=0.770g/sqcm, T-score=-1.4, Z-score=-1.4. with partially degraded microarchitecture(TBS=1.335). She continued octreotide 20mg/month and cabergoline 0.5mg/week and initiate anti-resorptive treatment with risedronate (35mg/week) and vitamin D supplementation. **Conclusion**: Acromegaly and premature ovarian insufficiency/menopause (in individuals who are not estrogens candidates) act synergistically to alter bone quality and quantity. Long-term surveillance is mandatory since controlling GH and IGF1 excess might not be tidily reflected in the BMD normalization.

THE ROAD FROM IV TO SC INFLIXIMAB AND ITS IMPACT ON MUSCULOSKELETAL AND SKIN MANIFESTATIONS IN SYSTEMIC RHEUMATIC DISEASES

P. Athanassiou[1], L. Athanassiou[2], N. Koukosias[1], M. Mavroudi[1], C. Chatzigeorgiou[1], S. Mitsoulis[1], N. Sarianidou[1], I. Sanidis[1], C. Kalinou[3], I. Kostoglou-Athanassiou[4]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece, [2]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece, [3]Dermatology Unit, St. Paul's Hospital, Thessaloniki, Greece, [4]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Background: The management of autoimmune rheumatic diseases is under continuous research and evolution. New therapeutic developments enter and cover the remaining open space. Biological agents, in particular anti-TNFα agents led the road of therapeutic developments. The anti-TNF agent infliximab was the first anti-TNF agent to be applied in the treatment of rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA). Thereafter, major developments followed, however infliximab remains one of the most successful biological agents.
Objectives: The aim of the study was to describe the successful application of infliximab in SC administration in patients with RA, AS and PsA.
Methods: In a group of 40 patients, 31 female and 9 male, with RA aged 32-82 years the biological agent infliximab was administered. In a subgroup of 20 RA patients infliximab was initially administered as an induction treatment IV at times 0, 2 and 6 weeks, thereafter as a maintenance regimen 120 mg SC every 2 weeks. In a subgroup of 20 patients with RA infliximab was administered as an induction treatment at a dose of 120 mg SC every week for 5 weeks, thereafter as a maintenance regimen 120 mg SC every 2 weeks. In all patients methotrexate was administered SC at a dose 20 mg/wk. In all RA patients CRP, ESR and DAS28 were measured before treatment and 3 and 6 months later. In 20 patients, 6 female and 14 male, with AS infliximab was administered as an induction treatment IV at a dose of 5mg/kg at times 0, 2 and 6 weeks thereafter every 2 weeks at a dose of 120 mg SC. In AS patients ESR, CRP and BASDAI were measured before treatment, 3 and 6 weeks later. In 20 patients with PsA, 12 female and 8 male, infliximab was administered as an induction treatment at a dose of 5mg/kg IV at times 0, 2 and 6 weeks, thereafter as a maintenance regimen of 120 mg SC every 2 weeks. In PsA patients

methotrexate was administered at a dose of 20mg/wk SC. In PsA patients ESR, CRP and DAPSA were evaluated before treatment, 3 and 6 months later.
Results: In all RA patients a significant improvement in laboratory indices and DAS28 was observed (p<0.001). No significant difference in improvement was noted between the 2 subgroups of RA patients, i.e. the groups with IV and SC induction regimens. In AS patients laboratory indices and BASDAI improved significantly (p<0.001). In PsA patients laboratory indices and DAPSA improved significantly (p<0.001). In all groups musculoskeletal manifestations improved significantly, while in PsA patients skin manifestations improved significantly.
Conclusion: The majority of RA, AS and PsA patients described herein were managed successfully by infliximab in SC administration. The outcome was complete disease remission. It appears that the biological agent infliximab, the first anti-TNFα agent introduced, continues to be a gold standard in the treatment of RA and spondylarthritis.

PROTECTING PATIENTS WITH SYSTEMIC RHEUMATIC DISEASES AND MUSCULOSKELETAL MANIFESTATIONS FROM HERPES ZOSTER

P. Athanassiou[1], L. Athanassiou[2], I. Kostoglou-Athanassiou[3], N. Sarianidou[1], I. Sanidis[1], M. Mela[1], G. Kaiafa[4], C. Savopoulos[4]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece, [2]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece, [3]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece, [4]First Department of Propaedeutic Medicine, AHEPA University General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Patients with systemic rheumatic diseases present with various musculoskeletal manifestations. Therapeutic management of systemic rheumatic diseases and the respective musculoskeletal manifestations requires the administration of immune modulating agents which may lead to immunosuppression. Infectious diseases may appear such as herpes zoster. In immunocompromised patients herpes zoster may have severe manifestations, including severe or generalized rash, ocular involvement and postherpetic neuralgia. Vaccination against herpes zoster before the administration of immune modulating agents may prevent herpes zoster. A live attenuated vaccine against herpes zoster was developed and was used for some years. However, it was fraught with side effects. Therefore, a recombinant vaccine was developed.
Objectives: Systemic rheumatic diseases are characterized by immune dysregulation. The diseases require the administration of immune modulating agents. Therefore, vaccination against herpes zoster is required before the initiation of immune modulation. The aim was to describe a group of patients with systemic rheumatic diseases and musculoskeletal manifestations who were vaccinated against herpes zoster using the novel recombinant vaccine.
Methods: A group of 80 patients with systemic rheumatic diseases, 40 with rheumatoid arthritis (RA), 15 with ankylosing spondylitis (AS), 15 with psoriatic arthritis (PsA) and 10 with systemic lupus erythematosus (SLE) were vaccinated against herpes zoster with the novel recombinant vaccine before the administration of immune modulating agents. Vaccination was performed in 2 doses.
Results: Vaccination against herpes zoster with the recombinant vaccine was performed in a group patients with systemic rheumatic diseases before the administration of immune modulating agents. Vaccination was not found to have any adverse effects. Only one patient, a female patient with RA developed fever and two patients developed local pain in the site of the performed vaccination which improved a few hours later.
Conclusions: Vaccination against herpes zoster is necessary in systemic rheumatic diseases before the administration of immune modulating treatment. Vaccination with the novel recombinant vaccine was performed without any serious adverse events. Vaccination against herpes zoster using the recombinant vaccine seems to be safe and effective. Further studies are required to prove the necessity and efficacy of vaccination against herpes zoster with the novel recombinant vaccine in patients with systemic rheumatic diseases and musculoskeletal manifestations.

DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS WITH SEVERE MUSCULOSKELETAL MANIFESTATIONS AFTER SARS-COV-2 INFECTION

P. Athanassiou[1], G. Kaiafa[2], L. Athanassiou[3], C. Savopoulos[2], I. Kostoglou-Athanassiou[4], Y. Shoenfeld[5]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece, [2]First Department of Propaedeutic Medicine, AHEPA University General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece, [3]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece, [4]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece, [5]Reichman University, Herzilya, Israel

The SARS-CoV-2 virus is an autoimmune virus as it has been shown to induce autoimmunity. Systemic lupus erythematosus (SLE) may be related to various infectious agents. The aim was to describe the onset of SLE with severe musculoskeletal manifestations in a female patient after COVID-19 vaccine and COVID-19 infection.
A female patient, aged 47, had the first and the second dose of the vaccine against Covid-19. Two weeks later she developed a skin eruption affecting the face and the palmar surface of both hands and hair loss. Local treatment with corticosteroids was administered with improvement of the skin eruption. A few months later she developed diffuse musculoskeletal pain. Two years later she had a Covid-19 infection. A month after the infection she had diffuse musculoskeletal pain, arthritis of both knee joints, recurrence of the skin eruption and fatigue. Anti-dsDNA ab were posi-

tive, anti-Ro (+), anti-La (+) and anti-Sm (+). SLE was diagnosed. Hydroxychloroquine was administered without improvement. Azathioprine and belimumab were given without improvement. The patient responded with partial improvement to the administration of prednisolone 15 mg daily.
The case of a female patient is described who developed SLE after SARS-CoV-2 infection. It appears that the SARS-CoV-2 virus is an autoimmune virus and may cause systemic autoimmunity. In the case described herein a mild COVID-19 infection triggered the development of a systemic autoimmune disease with severe musculoskeletal manifestations which responded to the administration of corticosteroids. This case along with others in the literature is compatible with the potential of the SARS-CoV-2 virus to cause systemic autoimmunity.

P1216

COMPARATIVE ANALYSIS OF BONE MICROARCHITECTURE THROUGH 3D-X-RAY DENSITOMETRY BETWEEN WOMEN WITH TYPE 2 DIABETES AND HEALTHY CONTROLS

G.-A. Cruz-Priego[1], M.-A. Guagnelli[1], S. Ortiz-Santiago[1], P. Clark[1], R. Gómez-Díaz[2], L. Humbert[3]

[1]Hospital Infantil de México-Universidad Nacional Autónoma de México, Mexico City, Mexico, [2]Unidad Médica de Investigación en Epidemiología Clínica. Hospital de Especialidades, CMN Siglo XXI, Mexico City, Mexico, [3]3D-Shaper Medical, Spain, Spain

Objective: This study evaluates 3D-DXA parameters determining the cortical and trabecular compartments in patients with type 2 diabetes (T2D) compared to non-diabetic subjects, aiming to identify their determinants.
Material and methods: Patients with T2D were diagnosed according to ADA criteria. Anthropometric measurements were performed using WHO standards, and body mass index (BMI) was calculated using the Quetelet method. Bone densitometry (DXA) images were analyzed with 3D Shaper software, which assesses the cortical and trabecular structure of the femur in three dimensions from conventional DXA images. Volumetric bone mineral density (vBMD), bone mineral content (BMC), and volume in various regions of the femur, along with cortical thickness, were calculated. Data analysis was conducted using SPSS 27.0, with comparisons between T2D patients and controls using Student's t-test and ANCOVA, adjusting for age, sex, and BMI.
Results: A total of 125 subjects were recruited: 51 healthy controls and 74 T2D patients (70.3% women), with average ages of 53.9 and 53.6 years, respectively. The average disease duration in the T2D group was 11.4 years. Significant deficiencies in vitamin D levels were found, with 56% in the control group and 64% in the T2D group having levels below 20 ng/ml. No significant differences in aBMD were observed between groups. 3D-DXA analysis showed consistently lower volumetric bone mineral density (vBMD) in T2D patients compared to controls, with significant differences in the trochanter, femoral neck, and average cortical thickness. No significant correlation was found between HbA1c or disease duration and vitamin D levels, but a positive correlation was observed between waist circumference, BMI, and higher bone density in all regions.
Conclusions: This study highlights the potential of 3D-DXA for analyzing bone microarchitecture in T2D patients, revealing differences in cortical and trabecular bone not detectable with conventional aBMD measurements. Women with T2D exhibited lower bone parameters in the trochanter and femoral neck, consistent with research linking long-term T2D and poor glycemic control to compromised bone quality.

P1218

NEOADJUVANT AND ADJUVANT THERAPY FOR TRIPLE-NEGATIVE BREAST CANCER: OPTIMIZING TREATMENT OUTCOMES

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: This study investigates the efficacy of neoadjuvant and adjuvant therapies in triple-negative breast cancer (TNBC) with a focus on improving clinical outcomes and survival rates.
Methods: We conducted a multicenter, randomized controlled trial to evaluate the combination of chemotherapy, immunotherapy, and targeted therapy in TNBC patients. Biomarkers of response and recurrence were monitored using next-generation sequencing and liquid biopsy.
Results: Preliminary findings show a 30% improvement in overall survival (OS) in patients receiving combination therapies versus standard chemotherapy alone. The identification of specific biomarkers correlated with therapeutic efficacy further supports a personalized treatment approach.
Conclusion: Combining novel therapies in the neoadjuvant and adjuvant settings significantly enhances outcomes in TNBC, highlighting the importance of personalized treatment strategies in high-risk populations.

P1219

IMMUNOTHERAPY AND PRECISION MEDICINE IN HER2-POSITIVE BREAST CANCER: A NEW ERA OF TARGETED THERAPIES

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: This study explores the role of immunotherapy in HER2-positive breast cancer, alongside the integration of precision medicine for individualized treatment regimens.
Methods: We performed a retrospective cohort study analyzing patient outcomes from HER2-positive breast cancer trials combining immunotherapy agents such as trastuzumab deruxtecan with targeted therapies. Genomic profiling was conducted to identify potential biomarkers predictive of treatment response.
Results: Our data suggests that the combination of immunotherapy with precision-targeted therapy provides significant improvement in progression-free survival (PFS) and OS, especially in pa-

tients with mutations in the PI3K/AKT pathway.
Conclusion: Precision medicine combined with immunotherapy represents a promising frontier in the management of HER2-positive breast cancer, offering tailored treatment that improves patient outcomes.

P1220

ARTIFICIAL INTELLIGENCE IN CANCER CARE: LEVERAGING MACHINE LEARNING FOR EARLY DETECTION AND TREATMENT OPTIMIZATION

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: This research investigates the role of artificial intelligence (AI) and machine learning (ML) in enhancing early detection and optimizing treatment for various cancers.
Methods: We developed an AI-driven model that integrates clinical, genomic, and imaging data to predict cancer risk, detect early-stage tumors, and recommend personalized treatment protocols. The model was trained using a dataset of 10,000 patient records across multiple cancer types.
Results: The AI model demonstrated a 25% increase in early detection rates, particularly in colorectal and lung cancers, and significantly improved treatment recommendation accuracy.
Conclusion: AI and ML can revolutionize cancer care by providing real-time, data-driven insights for early detection and treatment optimization, thereby improving patient outcomes and survival rates.

P1221

PD1/PD-L1 INHIBITORS IN LUNG CANCER: MECHANISMS OF RESISTANCE AND OVERCOMING THERAPEUTIC LIMITATIONS

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: This study investigates the mechanisms of resistance to PD1/PD-L1 inhibitors in lung cancer and explores strategies to overcome these limitations.
Methods: A cohort of non-small cell lung cancer (NSCLC) patients undergoing PD1/PD-L1 inhibitor therapy was analyzed for resistance markers through tissue biopsy and liquid biopsy. We tested combination therapies with chemotherapy and alternative checkpoint inhibitors.
Results: Resistance to PD1/PD-L1 inhibitors was associated with mutations in the tumor microenvironment and loss of T-cell function. Combination therapy with chemotherapy and dual checkpoint blockade improved patient response rates by 35%.
Conclusion: Targeting resistance mechanisms through combination therapies can enhance the efficacy of PD1/PD-L1 inhibitors in NSCLC, offering new therapeutic avenues for patients who fail first-line immunotherapy.

P1222

CAR-T CELL THERAPY IN HEMATOLOGIC MALIGNANCIES: ADVANCES IN PERSONALIZED IMMUNOTHERAPY

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: To evaluate the potential of CAR-T cell therapy in personalized treatment for hematologic malignancies, including leukemia and lymphoma.
Methods: This phase II clinical trial involved 120 patients with B-cell malignancies who underwent CAR-T cell therapy tailored based on their tumor antigen profile. We analyzed treatment efficacy, safety, and long-term survival outcomes.
Results: CAR-T therapy showed a 60% complete remission rate in relapsed/refractory patients, with minimal adverse events. Personalized modifications to the CAR construct improved patient responses by enhancing T-cell persistence.
Conclusion: Personalized CAR-T cell therapy offers a promising and effective approach for treating hematologic malignancies, with improved patient outcomes and reduced side effects.

P1223

GLOBAL HEALTH DISPARITIES IN CANCER CARE: ADDRESSING GAPS IN ACCESS, EQUITY, AND OUTCOMES

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: To identify and address global disparities in cancer care, focusing on access to treatment, outcomes, and healthcare infrastructure in low-resource settings.
Methods: This global study surveyed 50 low- and middle-income countries, collecting data on healthcare access, treatment outcomes, and the burden of cancer. We analyzed the impact of telemedicine, mobile health, and international partnerships in improving care delivery.
Results: The study revealed that disparities in cancer care access significantly impacted patient survival rates. Telemedicine interventions led to a 40% increase in diagnosis and treatment adherence in remote areas.
Conclusion: Global strategies that include telemedicine, international collaborations, and infrastructure development can significantly reduce disparities in cancer care and improve patient outcomes in underserved regions.

P1224

NEXT-GENERATION MOLECULARLY TARGETED THERAPIES IN COLORECTAL CANCER: PRECISION MEDICINE APPROACHES

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: This research explores the role of next-generation molecularly targeted therapies in colorectal cancer (CRC), with a focus on precision medicine.
Methods: A cohort of 250 CRC patients underwent molecular profiling to identify novel biomarkers associated with treatment response. We tested targeted therapies against mutations in the KRAS, BRAF, and EGFR pathways.
Results: The use of targeted therapies based on molecular profiling resulted in a 50% improvement in response rates for patients with BRAF-mutated CRC. The identification of novel biomarkers in the tumor microenvironment further enhanced treatment personalization.
Conclusion: Precision medicine approaches, incorporating advanced molecular diagnostics, can significantly improve the efficacy of targeted therapies in CRC, offering more effective treatment options for patients.

P1225

RADIOPHARMACEUTICALS IN ONCOLOGY: REVOLUTIONIZING TARGETED CANCER THERAPY WITH PRECISION RADIATION

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: To evaluate the role of radiopharmaceuticals in providing targeted radiation therapy for various cancers, with an emphasis on personalized treatment.
Methods: This study examined the use of novel radiopharmaceutical agents in prostate cancer, neuroendocrine tumors, and thyroid cancer. We assessed efficacy, toxicity, and tumor response using PET scans and patient outcomes over 12 months.
Results: Radiopharmaceuticals demonstrated a high degree of specificity in targeting tumor cells, resulting in a 40% increase in tumor shrinkage without significant off-target effects.
Conclusion: Radiopharmaceuticals are poised to revolutionize cancer treatment by offering highly targeted therapies with reduced toxicity, improving both treatment efficacy and patient quality of life.

P1226

SYMPTOM MANAGEMENT IN PEDIATRIC CANCER: INNOVATIVE APPROACHES TO PALLIATIVE CARE AND QUALITY OF LIFE

P. Damodaran[1]

[1]Medicine , Acs medical college and hospital, Chennai, India

Objective: To explore novel approaches in symptom management and palliative care for pediatric cancer patients, emphasizing quality of life and family-centered care.
Methods: A multi-center study focused on pediatric patients with advanced cancer was conducted, assessing pain management, psychological support, and family involvement. Innovative palliative care models were implemented, including integrative medicine and home-based care options.
Results: The implementation of innovative palliative care strategies resulted in a 50% reduction in symptom burden and a 25% increase in overall family satisfaction with care.
Conclusion: Enhanced symptom management and palliative care strategies are essential for improving the quality of life in pediatric cancer patients, with a family-centered approach offering significant benefits in both clinical and emotional outcomes.

P1227

FUNCTIONAL OUTCOMES OF PATIENTS WITH OSGOOD-SCHLATTER DISEASE TREATED WITH OPEN REDUCTION AND SCREW FIXATION OF THE TIBIAL TUBERCLE: A AMBIDIRECTIONAL COHORT STUDY

P. Evangelista[1], T. J. Arellano[1]

[1]Jose B. Lingad Memorial General Hospital, SAN FERNANDO, Philippines

Background: Osgood-Schlatter disease (OSD) is a common cause of anterior knee pain in adolescents, often resolving with conservative management. However, some cases are refractory and require surgical intervention. Open reduction and screw fixation of the tibial tubercle have been utilized to address persistent pain and instability, but data on long-term functional outcomes remain limited.
Objective: This study aims to evaluate the functional outcomes of patients with OSD who underwent open reduction and screw fixation of the tibial tubercle. Specifically, we assess postoperative pain, knee function, range of motion (ROM), surgical complications, return to sports, and overall quality of life.
Methods: This ambidirectional cohort study includes patients diagnosed with OSD who underwent surgical fixation at Jose B. Lingad Memorial General Hospital. Preoperative and postoperative assessments include pain levels (Visual Analog Scale), knee function (Kujala Anterior Knee Pain Scale and Knee Injury and Osteoarthritis Outcome Score), ROM, and quality of life (SF-36). Patients were followed up at 6 weeks, 3 months, 6 months, 12 months, and annually thereafter. Descriptive statistics, paired

t-tests, chi-square tests, and regression models were used for data analysis.
Results: The study aims to provide comprehensive data on the efficacy and safety of surgical intervention for OSD. Preliminary findings suggest significant improvement in knee function and pain reduction postoperatively, with minimal complications. Further analysis will determine predictors of optimal recovery and long-term patient satisfaction.
Conclusion: This study provides valuable insights into the role of surgical fixation in managing refractory OSD. By evaluating functional outcomes and recovery patterns, we aim to contribute to the optimization of treatment strategies for adolescent patients suffering from persistent OSD symptoms.

P1228

THE ADDED VALUE OF DISTAL RADIUS BONE MINERAL DENSITY FOR THE DIAGNOSIS OF OSTEOPOROSIS IN PATIENTS WITH A HISTORY OF FRAGILITY FRACTURE

P. Heidari[1], A. Mirzaei[2], P. Tabrizian[1], M. Zabihiyeganeh[1]

[1]Bone and joint reconstruction research center, Department of orthopedics, School of medicine, Iran University of Medical Sciences, Tehran, Iran, Tehran , Iran, [2]Department of Orthopedic Surgery, University of Minnesota Minneapolis, Minnesota, USA, Minnesota , United States

Background: Preventing osteoporotic fragility fractures is a critical health priority, yet there is limited data on the utility of distal radius bone mineral density (BMD) for this purpose. This study aimed to evaluate the added value of distal radius BMD in osteoporosis diagnosis in patients with a history of fragility fractures.
Methods: In a retrospective analysis of prospectively collected data, 1205 who were enrolled in the Fracture Liaison Service of our institute were included in the analysis. The main outcome was the BMD classification of patients using a 3-region BMD (femoral neck, lumbar spine, and distal radius) compared to the conventional 2-region BMD (femoral neck and lumbar spine). The lowest T-score from any skeletal site was used to classify patients into normal, osteopenia, or osteoporosis categories.
Results: Using a 2-region BMD, normal, osteopenia, and osteoporosis were identified in 11.1%, 42.7%, and 46.2% of patients, respectively. After adding distal radius BMD, normal, osteopenia and osteoporosis were detected in 5.6%, 32.9%, and 61.6% of patients, respectively. Two-region and 3-region BMD were discordant in 185 patients. A significant moderate correlation was observed between the distal radius and lumbar spine T-scores (r=0.470, P<0.001). No significant correlation was observed between the distal radius and femoral neck T-scores (r=-0.020, P=0.48).
Conclusion: The addition of distal radius densitometry to the conventional BMD regions can result in earlier diagnosis and treatment initiation in patients with a high risk of fragility fracture.
Keywords: Bone mineral density, distal radius, fragility fracture

P1229

EFFECT OF PARATHYROIDECTOMY ON BONE TURNOVER MARKERS AND BMD OF SYMPTOMATIC AND ASYMPTOMATIC PATIENTS WITH PRIMARY HYPERPARATHYROIDISM: PROSPECTIVE FOLLOW UP STUDY FROM A TERTIARY CARE CENTRE IN NORTH INDIA

P. Kaur[1], D. Hegde[1], S. Mishra[1], D. Sarin[1], D. Gautam[1], A. Mithal[1]

[1]Medanta The Medicity, Gurugram, India

Objective: To study the effect of parathyroidectomy on Bone mineral density (BMD) and serum collagen C-telopeptide (CTx) in symptomatic and asymptomatic patients with primary hyperparathyroidism(PHPT).
Methods: Prospective follow-up study conducted at a tertiary care centre in North India. Consecutive patients with PHPT undergoing parathyroidectomy were included in the study. All biochemical parameters, serum CTx and BMD at hip, forearm and lumbar spine (with DXA scan, GE Lunar) were evaluated at baseline and again at 3 months post parathyroidectomy. Study was approved by institutional ethics committee.
Results: Total of 84 patients underwent parathyroidectomy. Following exclusion of 6 patients, 78 (M = 31, F= 47) were included in the final analysis. Mean±SD age was 50.36 ± 14.83 years. 34 patients (43.5%) were asymptomatic. Mean serum phosphorus level was significantly lower and mean serum PTH level was significantly higher among symptomatic patients as compared with asymptomatic group. There was no statistically significant difference between 2 groups in other parameters. Post surgery, Significant decline in S.CTx levels was seen in both symptomatic and asymptomatic groups. In total study participants, there was a 64% decrease in serum CTx levels post-surgery (320.1 ± 293.8 pg/ml) compared to pre-surgery levels (889.3 ± 508.3 pg/ml). Similarly, serum calcium, iPTH, and urine calcium-creatinine ratio were significantly lower at 3 months post-surgery as compared to pre-surgery level. The proportion of osteoporosis and osteopenia at baseline among study participants were 50% and 37.14% respectively. There was a significant gain in lumbar spine BMD (5.1%) and left femur BMD (5.8%) post-surgery, however, there was no significant change in forearm BMD. Symptomatic PHPT patients showed greater BMD gains at lumbar spine compared to asymptomatic patients (6.12% vs 3.03 %, p<0.05).
Conclusions: A significant decline in Serum CTx levels and gain in BMD at lumbar spine was seen as early as 3 months post parathyroidectomy in both symptomatic and asymptomatic PHPT patients with significantly greater gain in lumbar spine BMD in symptomatic group.

P1230

BREAKTHROUGH ROBOTIC-ASSISTED INTERVENTIONS FOR OSTEOPOROTIC VERTEBRAL FRACTURE MANAGEMENT

P. Khashayar[1], A. Noshin[2], A. Khan[2], P. Khashayar[3]

[1]School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom, [2]University of Minnesota/Department of Computer Science, Duluth, United States, [3]University of Minesota/International Institute for Biosensing, Minneapolis, United States

Osteoporotic spinal (OSF) and vertebral compression fracture (OVCF) are common complications occurring during everyday routines, such as reaching, twisting, coughing, and sneezing. They are closely linked to advancing age and may cause long-term disabilities and progressive deformities, exerting a tremendous burden on society. Their treatment can be conservative or surgical. Recently robotic-assisted techniques have shown promising results in improving the outcome of such interventions.

A systematic review in PubMed using keywords including ('robot assisted' or robotic or 'programmable robot') and (fracture or 'fragility fracture' or 'osteoporosis' or 'bone loss' or 'vertebral fracture') and (('spinal surgery' or vertebroplasty) or (exoskeleton or orthoses or brace)) illustrated a picture of recent advancements in the field.

Multiple studies indicated that robot-assisted minimally invasive surgery (R-MIS), as well as percutaneous-vertebroplasty (R-PVP) and kyphoplasty (R-PKP) can substantially decrease OSF/OVCF complications, especially in complex fractures. All offer advantages such as higher accuracy, better dexterity, enhanced visualization of the fracture site, shorter operation times, minimized radiation exposure for the surgeon, and a more effective learning curve for medical professionals caring for osteoporosis patients. Improved screw placement is recognized as a critical factor determining success of the surgical procedure.

Exoskeletons are robots, designed to support their fragile bones during and after surgery, to help patients move and recover. They improve the precision of surgical procedures, provide passive assistance and actively enhance human movements during rehabilitation. Flexible, versatile spinal exoskeletons are shown to overcome the weaknesses and complications commonly connected with traditional braces, improving efficiency, while providing more intensive patient training, better quantitative feedback, and eventually improved overall functional outcomes.

It was also shown that coupling radiomics and biomechanical modeling with either robotic-assisted surgery or the design of cutting-edge robotic exoskeleton technologies exhibits superiority regarding restoration of vertebrae and melioration of functional outcomes by providing personalized details of affected vertebrae.

P1231

AI-ENABLED BONE RADIOMICS, A MORE EFFICIENT TOOL FOR OSTEOPOROSIS/FRACTURE SCREENING

P. Khashayar[1], A. Khan[2], B. Larijani[3], P. Khashayar[4]

[1]University of Hertfordshire/School of Life and Medical Sciences, Hatfield, United Kingdom, [2]University of Minnesota Duluth, Department of Computer Science, Duluth, United States, [3]Tehran University of Medical Sciences, Endocrinology and Metabolism Clinical Sciences Institute, Endocrinology and Metabolism Research Center, Tehran, Iran, [4]University of Minnesota, International Institute for Biosensing, Minneapolis, United States

Radiomics, a rapidly evolving field in medical imaging, is commonly used in the context of clinical oncology; several studies, however, have shown its potential for bone health assessment. To study its efficacy, a systematic search in PubMed using keywords including (osteoporosis, bone mineral/density/mass/loss, fragility/osteoporotic fracture) AND (radiomic(s)) was performed. The search identified 90 articles, 60 of which were relevant.

These studies revealed the radiomics-based approaches extract a large number of textural features from medical images (radiography (digital or conventional), dual-energy x-ray absorptiometry (DXA), computed tomography (CT), and magnetic resonance imaging (MRI)) using data-characterization algorithms. As a result, they offer advantages such as potential for opportunistic screening using existing imaging studies and the ability to capture complex patterns and biometric data of bone microarchitecture, determining bone modifications related to subjects' sex and age. Compared with current diagnostic techniques (DXA and bone turnover markers), these quantitative approaches are shown to have improved diagnostic accuracy.

Incorporating the radiomics score and clinical risk factors (for instance through FRAX), known as a clinical-radiomic model, was also shown to improve fragility fractures prediction considerably. In another approach the image-derived features were combined with various machine learning algorithms, aiming to build more accurate diagnostic, prognostic, and predictive models. Deep radiomics models, benefiting from deep learning algorithms, were shown to have the highest diagnostic performance for both osteoporosis and fracture screening.

It could be concluded that the use of bone radiomic signature in low-dose routine CT can be the future of precision medicine for osteoporosis management. The implementation of such methods into the clinical workflow can be used as an adjunct for opportunistic screening for osteoporosis and fragility fracture with higher accuracy. Our plan is to couple the resulted signature with novel robotic solutions to provide personalized care and revolutionize fracture management and improve recovery in these patients.

P1232

ENHANCING SURGICAL OUTCOMES WITH ROBOTIC-ASSISTED KNEE SURGERY IN OSTEOPOROTIC PATIENTS

A. Noshin[1], P. Khashayar[2], A. Khan[1], P. Khashayar[3]

[1]University of Minnesota/Department of Computer Science, Duluth, United States, [2]School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom, [3]University of Minesota/International Institute for Biosensing, Minneapolis, United States

Patients undergoing knee replacement often have concurrent osteoporosis, resulting in postoperative complications such as periprosthetic fractures. This is mainly because reduced bone mass can impair osseointegration of the implant, raising the risk of aseptic loosening. It also renders the structures more vulnerable to prosthesis misalignment, leading to abnormal stress and strain.

The ongoing transformation in robotic-assisted knee replacement surgeries has shown benefits such as minimal invasion, higher precision, accuracy, and surgeon control, and reduced recovery time.

We conducted a systematic search in Google Scholar and PubMed utilizing keywords i.e 'Osteoporosis,' 'Robotic Surgery,' 'Total Knee Arthroplasty (TKA),' 'Robot-Assisted Surgery,' and 'fracture,' while restricting the results to FDA-approved methods, to identify the optimal options in osteoporotic patients.

According to the literature, i) Teleoperated, ii) Autonomous, and iii) Semi-autonomous Robotic Systems can be used for this purpose.

Teleoperated Systems like da Vinci Surgical Systems have showcased versatility in soft tissue surgery, with limited applications in rigid bone knee surgeries.

The ROBODOC, a pioneering Autonomous Robotic system, offers accurate placement of bone implants compared to conventional methods. It competed with CASPER, which was discontinued due to an increased rate of postoperative complications.

Semi-autonomous Robotic Systems (MAKO, ACROBAT, and NAVIO) have gained traction by allowing greater control. ACROBAT system, designed for unicompartmental knee arthroplasty, enables high-precision bone cutting. Underlying osteoporosis, however, worsens abnormal stress and strain distributions during this surgery, increasing the risk of postoperative osteoarthritis progression. NAVIO uses a probe to map out the knee anatomy during surgery, providing higher precision. MAKO is an image-based robotic system that allows real-time implantation and alignment adjustments. This can help with real-time tracking, positioning, and alignment of the prosthesis during surgery, lowering the stress rate on the joint. It, therefore, seems to be the method of choice in reducing the risk of future osteoporosis-related complications in TKA.

P1233

PREDICTING OF RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS

P. Kovalenko[1], I. Dydykina[1], A. Smirnov[1], M. Diatroptov[1], S. Glukhova[1]

[1]V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia

The aim: to find the predictors of erosion score dynamics reflecting progression in patients with rheumatoid arthritis with long-term follow-up.

Materials and methods: 151 women with rheumatoid arthritis (RA) (ACR 1987, EULAR/ACR 2010) were included in an open-label, prospective, cohort study, the average age was 63.6 ± 9.2 years, RA duration at baseline 14.3 ± 9.8, who underwent an outpatient or inpatient examination in 2010-2014 (follow-up duration was 9.7 ± 1.7 years). At baseline and in dynamics there were performed a generally accepted clinical examination, X-ray of hands and feet in direct projection (with Sharp/Van der Heide assessment), DEXA of L1-L4, hip neck and total hip; immunological analysis of ACCP (cyclic citrullinated peptide antibodies), RF (rheumatoid factor), CRP (C-reactive protein), IL-6 (Interleukin 6), MMP-3 (Matrix metalloproteinase-3) as well as osteoimmunological markers (osteocalcin, osteoprotegerin, RANKL (Receptor activator of NF-κB ligand), CTX-1 (C-telopeptide of crosslinked collagen type I), BAP (Bone alkaline phosphatase)) were determined.

Results: During the period the group showed a significant ($p < 0.0001$) increase in erosion count: 10.5 [1.0; 38.0] vs 16.0 [3.0; 55.0] Me [25%; 75%]. An increase in erosion count was observed in 64 patients, while stabilization of this indicator was observed in 59 people. When comparing these groups of patients (with increase (group 1) or stabilization of erosion count (group 2) over the study period), it was found that in group 1 patients were significantly more often positive for the RF and ACCP: 51 (80%) vs 29 (49%) ($p = 0.008$) and 50 (78%) vs 36 (61%) ($p = 0.03$), respectively. The ACCP level in dynamics in group 1 was higher than in group 2: 186.1 [17.5; 300.0] vs 33.9 [7.1; 160.8] ($p = 0.02$). Also at baseline, patients in group 1 had higher levels of MMP-3 and IL-6 than in group 2: 55.5 [19.8; 119.5] vs 23.8 [12.9; 67.2] ng/mL ($p = 0.01$) - for MMP-3 and 7.4 [2.6; 21,3] vs 6,1 [0,4; 10.1] pg/mL ($p = 0.02$) - for IL-6. The delta (Δ, %) of BMD in hip neck and total hip was lower ($p<0.05$) in group 1 (M: -11.5 vs -5.2 and -9.0 vs -2.1) as well as BMD of hip neck and total hip was lower in group 1, than in group 2 ($p<0.05$). Correlation analysis also revealed a valid association between delta of erosion count and studied parameters. The discriminant analysis revealed the following variables: MMP-3 and IL-6 levels at baseline, RF level in dynamics, ΔBMD and BMD in dynamics of hip neck – that formed the formula for predicting the high risk of radiological progression in a patient with RA. The area under the ROC curve (AUC) is 0.777, 95% CI (0.674-0.881), sensitivity - 62%, specificity - 73%.

Conclusions: The analysis of the results of long-term observation of patients with RA showed that higher levels of MMP-3 and IL-6 at baseline, RF level in dynamics, lower ΔBMD and BMD in dynamics of hip neck are associated with an increase in erosion count.

P1234

DETERMINATION OF THE ROLE OF IL-6R GENOTYPE IN THE DEVELOPMENT OF LOCAL BONE LOSS IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Kovalenko[1], I. Dydykina[1], A. Smirnov[1], I. Guseva[1], M. Diatroptov[1], S. Glukhova[1]

[1]V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia

The aim: to evaluate whether functional single nucleotide polymorphism (SNP) rs2228145 in the IL-6 receptor (IL6R) gene could predict a local bone loss in patients with RA.
Materials and methods: 151 women with rheumatoid arthritis (RA) (ACR 1987, EULAR/ACR 2010) were included in an open-label, prospective, cohort study, the average age was 63.6 ± 9.2 years, RA duration at baseline 14.3 ± 9.8, who underwent an outpatient or inpatient examination in 2010-2014 (follow-up duration was 9.7 ± 1.7 years). At baseline and in dynamics there were performed a generally accepted clinical examination, X-ray of hands and feet in direct projection (with Sharp/Van der Heide assessment); immunological analysis of ACCP (cyclic citrullinated peptide antibodies), RF (rheumatoid factor), CRP (C-reactive protein), IL-6 (Interleukin 6), MMP-3 (matrix metalloproteinase-3) as well as osteoimmunological markers (osteocalcin, osteoprotegerin, RANKL (receptor activator of NF-κB ligand), CTX-1 (C-telopeptide of crosslinked collagen type I), BAP (bone alkaline phosphatase)) were determined. Genomic DNA was automatically extracted from peripheral whole-blood samples of 141 patients. SNP rs2228145 (Asp358Ala) were analyzed by real-time PCR.
Results: As expected from the allele frequency population-based studies (European population), we found that the wild-type (A) was more frequent than the mutated allele (C) of the SNP rs2228145: A/A (38,3%), A/C (47,5%), C/C (14,2%). At baseline and in dynamics the AA carriers for rs2228145 had 1 X-ray stage of RA more often than patients carrying the C allele (AC+CC): 13% vs 3% (p=0.03) and 9% vs 0% (p=0.016) respectively. In dynamics the C allele carriers more often had stage 3-4 than those with the AA genotype (p=0.01). An erosion count at baseline and in dynamics was significantly greater in patients carrying the C allele (AC+CC) than AA: 16,0 [2,0; 47,5] vs 5,0 [0; 19,5] (p=0.01) and 27,0 [5,25; 62,0] vs 12,0 [2,0; 42,5] (p=0.04) respectively. Also, it was found that the RANKL level above normal in dynamics was more often in CC carriers than in patients carrying the A allele (AA+AC): 30% vs 7% (p=0.01). As for the other immunological and osteoimmunological markers studied, no statistically significant associations were found.
Conclusions: In this study, we found an association between rs2228145 and the radiological progression (the development of local bone loss) in patients with RA. Our results suggest that patients carrying CC genotype and minor (mutated) C allele present greater local bone loss, which is expressed in X-ray stage, erosion count and indirectly in RANKL level.

P1235

VERTEBRAL AND PERIPHERAL BONE FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS (BASED ON LONG-TERM FOLLOW-UP DATA)

P. Kovalenko[1], I. Dydykina[1], A. Smirnov[1], S. Glukhova[1]

[1]V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: In rheumatoid arthritis (RA) fractures occur on average 2-3 times more often than in the population. Information on the frequency of vertebral fractures in RA is contradictory and depends on the method by which they were determined.
Aim: To determine the incidence of vertebral fractures and peripheral bones in patients with RA with long-term prospective observation.
Materials and methods: A prospective multi-year cohort non-interventional study included 120 women with RA (mean age at inclusion 54.3 ± 8.9 years), the duration of follow-up was 9.5 ± 1.9 years. Initially and in dynamics, a clinical and X-ray examination were performed (X-ray morphometry of the spine according to the Genant method, X-ray absorptiometry of the lumbar spine (L1-L4) and femoral neck (FN)).
Results: During the follow-up period, 104 low-energy fractures occurred in 64 (53%) patients: 69 (66%) vertebral fractures and 35 (34%) peripheral fractures. Two or more fractures occurred in 25 (39%) patients. In 30 (25%) patients 52 fractures occurred again. Among peripheral fractures the most frequent localization was fractures of the distal forearm and lower leg bones. Patients who suffered fractures during the follow-up period were more likely to have fractures before entering the study; had an initially longer duration of RA (Me 14,0 vs 10,0 p=0.001); an average daily dose, cumulative dose – at baseline and in dynamics (p<0.05) and duration of GC administration (Me 133 vs 43, p=0.008) and lower bone mineral density in L1-L4 and hip at baseline and in dynamics (p<0.05). There was no effect of RA activity (DAS-28), RF or ACCP positivity on fractures. The diagnosis of osteoporosis (OP) was established in 83 (69%) patients at baseline and in 95 (79%) in dynamics. All patients with OP were recommended anti-osteoporotic treatment (bisphosphonates or denosumab). 94% of patients stated that they followed the recommendations for the treatment of OP, among which 36% of patients received treatment for more than 3 years continuously. The rest took anti-osteoporotic drugs in intermittent courses with the whole mean duration of anti-OP therapy during follow-up for 43 months (3.5 years).
Conclusions: More than a half of the patients had low-energy fractures during the observational period, among which fractures of the vertebrae, distal forearm and lower leg bones predominated; there was a high frequency of repeated fractures. Analysis of risk factors showed that a long duration of RA, an average daily/cumulative dose and duration of GC administration, a history of low-energy fractures, and low BMD are associated with the occurrence of fractures in patients with RA. The adherence to anti-OP therapy was estimated to be low.

P1236

NEW INSIGHTS INTO OSTEOGENESIS IMPERFECTA: IDENTIFICATION OF NOVEL GLYCINE-SUBSTITUTING MUTATIONS

P. Marozik[1], E. Rudenka[2], P. Kavaleuskaya[3], K. Kobets[1], A. Pachkaila[4]

[1]Institute of Genetics and Cytology of the National Academy of Sciences of Belarus, Minsk, Belarus, [2]Belarusian State Medical University, Minsk, Belarus, [3]International Sakharov Environmental Institute of the Belarusian State University, Minsk, Belarus, [4]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

Objective: The study aims to explore the genetic and clinical features of patients diagnosed with *osteogenesis imperfecta* (OI), with a focus on identifying novel missense mutations affecting glycine residues in collagen-coding genes. These findings are intended to advance the understanding of OI pathogenesis and improve diagnostic and therapeutic strategies.
Material and Methods: A cohort of 92 Belarusian patients diagnosed with OI was recruited, including 55 children and 37 adults. Comprehensive clinical assessments were performed, including anamnesis, physical examinations, laboratory tests, molecular genetic analyses, and dual-energy X-ray absorptiometry (DXA). The sequencing methodology was based on a custom AmpliSeq research panel, optimized for the Illumina MiSeq platform. Variant filtering for pathogenicity followed ACMG guidelines and was supported by bioinformatics tools ANNOVAR, SIFT, and PolyPhen-2.
Results: The analysis identified 87 pathogenic or likely pathogenic variants, including 24 novel missense mutations affecting glycine residues in *COL1A1* and *COL1A2*. Among these, key mutations such as p.Gly238Val, p.Gly325Asp, and p.Gly493Cys in *COL1A1*, as well as p.Gly221Ser, p.Gly565Val, and p.Gly717Ala in *COL1A2*, were found to disrupt the triple-helical domain, leading to severe clinical phenotypes (Figure).

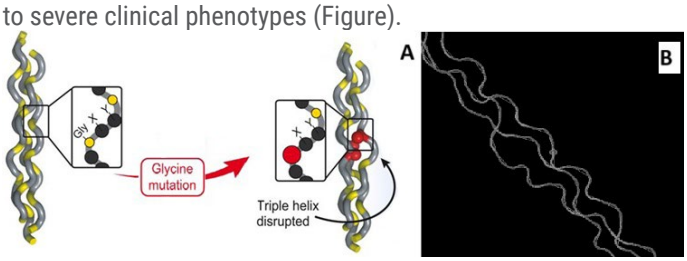

Figure. A. Schematic representation of a missense mutation of glycine in the triple helix of collagen, leading to a change in its structure and function. B. Novel mutation c.G662A of the COL1A1 gene, affecting the protein structure through the amino acid substitution p.G221D (PolyPhen 2, the position of SNV is indicated by a circle)
The revealed mutations were associated with frequent fractures, significant skeletal deformities, and extra-skeletal manifestations such as hearing loss and dentinogenesis imperfecta. Functional annotation confirmed their impact on collagen stability.
Conclusion: This study underscores the critical role of glycine residues in collagen stability and their impact on the clinical severity of OI. The identification of 24 novel glycine-substituting missense mutations expands the mutational spectrum of *COL1A1* and *COL1A2* and highlights their diagnostic relevance. These findings emphasize the importance of genetic testing in OI care.

P1237

HANDGRIP STRENGTH AND BONE HEALTH IN YOUNG CHILDREN: A POPULATION-BASED PROSPECTIVE BIRTH COHORT STUDY

P. N. Che[1], M. Breslin[1], M. Thompson[1], B. Fraser[1], N. C. Harvey[2], R. J. Moon[2], L. Scheepers[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]MRC Lifecourse Epidemilogy Centre, University of Southampton, Southampton General Hospital, Southampton, United Kingdom

Objective: Higher levels of grip strength have been associated with greater bone health, but evidence is mostly in adolescence and early adulthood and often cross-sectional, so we aimed to evaluate the longitudinal relationship between grip strength and bone health in young children.
Materials and Methods: This study analysed data from the Southampton Women's Survey, a population-based prospective birth cohort in the UK initiated in 1998. Handgrip strength (kg) was measured using a Jamar handgrip dynamometer and averaged over three attempts for each hand and a total body less head area-adjusted bone mineral content (aBMC) was assessed using dual-energy X-ray absorptiometry (DXA) at ages 4 (n = 990), 6 (n = 443), and 8 years (n = 972). Associations were examined using linear mixed-effects models for aBMC with an interaction term for grip strength (measured longitudinally) and age, and adjusted for sex, birthweight, and socio-economic status.
Results: Grip strength had a positive association with aBMC at baseline (4 years of age) such that those with 1kg higher grip strength had 2.6 g greater aBMC (CI (0.9, 4.3)). Additionally, higher grip strength was associated with a higher rate of growth of aBMC over time (interaction term 0.5 g, *p-value* < 0.001). That is, for every 1kg greater grip strength at any timepoint, the rate of growth of aBMC per year at that time was increased by 0.5 g/year. For example, those with grip strength at the 25th percentile had an increase of aBMC of 62.2 g/year, while those with grip strength at the 75th percentile had an increase of 65.5 g/year.
Conclusion: Grip strength was positively associated with baseline bone health and its growth throughout childhood across the follow-up period of this study, contributing to growing evidence supporting the potential benefits of muscle strength for bone health in childhood.

P1238

THE GUT MICROBIOME IN EARLY LIFE AND BONE HEALTH AT 6 YEARS: FINDINGS FROM A DANISH BIRTH COHORT STUDY

P. N. Che[1], J. Jiang[2], M. Breslin[1], M. Thompson[1], J. Stokholm[2], L. Scheepers[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]Copenhagen Prospective Studies on Asthma in Childhood (COPSAC), Copenhagen, Denmark

Objective: The gut microbiome is associated with bone health in animals and adult humans, but longitudinal evidence in childhood is lacking, so we aimed to investigate the association between the gut microbiome and later bone health in childhood.
Materials and Methods: We used data from the Copenhagen Prospective Studies on Asthma in Childhood$_{2010}$ study, an ongoing population-based mother-child cohort study in Denmark. Infant gut microbiome was measured at 1-week (n = 445), 1-month (n = 492), 1 (n = 509), 4 (n = 350), and 6-years (n = 327) by 16S rRNA sequencing (V4 region). Total body less head (TBLH) bone mineral density (BMD) and area-adjusted bone mineral content (aBMC) were measured by dual-energy x-ray absorptiometry (DXA) at age six. Gut microbiome characteristics were assessed based on α-diversity (within-sample) and relative abundance, by multiple linear regression and β-diversity (between-sample) by permutational multivariate analysis of variance. Differential abundance was assessed by stratifying bone outcomes into tertiles.
Results: Higher α-diversity at 1 year was associated with lower BMD (β = -1.8x10^{-3} CI [-3.4x10^{-3}, -1.5x10^{-4}]) and at 4 years to lower BMD (β = -1.4x10^{-3} CI [2.7x10^{-3}, -7.7x10^{-5}]) and aBMC (β = -1.8 CI [-3.2, -0.4]). β-diversity at 6 years was associated with BMD (F = 1.9, *p* = 0.026). No associations with α/β-diversity were observed for other ages. After adjustment for multiple testing, *Escherichia-Shigella* in 1-month olds was 1.7-fold more abundant for children in the low compared to high BMD tertile (Log Fold Change = -1.7; *adjusted p-value* = 0.038). Additionally, for every unit increase in *Sutterella* abundance in 1-year-olds, aBMC was 2.2 g lower (CI [-3.4, -1.0]). No other taxa were significantly associated with bone health outcomes at age six.
Conclusion: While we observed some associations, our study does not suggest the early life gut microbiome to be a major contributor to bone health at age six.

P1239

DIFFERENT MUSCLE STRENGTH AND QUALITY ADAPTATIONS AFTER 12 WEEKS OF HIGH INTENSITY INTERVAL TRAINING COMBINED WITH CITRULLINE SUPPLEMENTATION IN MALE AND FEMALE OBESE OLDER ADULTS

P. Noirez[1], L. Youssef[2], V. Marcangeli[3], A. Morais[4], P. Gaudreau[2], G. Gouspillou[3], M. Aubertin-Leheudre[3]

[1]Université Reims Champagne-Ardenne, Reims, France, [2]Université de Montréal, Montréal, Canada, [3]Université du Québec à Montréal, Montréal, Canada, [4]McGill University, Montréal, Canada

Introduction: Normal aging is associated with decreased muscle mass and strength (S) and increased fat mass that affect health. Among effective strategies to prevent this phenomenon, physical activity and nutritional interventions are widely known, especially in older adults (OA). In our previous research (PMID:35257499), a 12-week High-Intensity Interval Training (HIIT) combined with citrulline (CIT) supplementation enhance the health status of obese OA. However, it remains unclear if these health benefits are sex-dependent. We aim to assess sex differences in muscle and biological adaptations following a 12-week intervention combining HIIT with CIT in obese OA.
Methods: A 12-week HIIT intervention (3 times/week) was realized by eighty-one obese OA, combined with either a citrulline [HIIT-CIT: n=45 (men=20, women=25)] or a placebo [HIIT-PLA: n=36 (men=18, women=18)] supplementation. Body composition (DXA/QPCT), absolute muscle S (AMS) and muscle quality (AMS relative to body mass or specific lean mass) were compared pre (T0) and post (T12) intervention (3-way-anova with repeated measures).
Results: We observed sex-divergent health adaptations following the intervention. In women, handgrip (HG) S decreased (-12%, p<0.01) whereas in men it increased (+43%, p<0.001). Relative HGS to body mass still increased (+34%, p<001) in men but was not affected in women. There was no effect in relative HGS to arm lean mass. HIIT-CIT women exhibited a higher increase (+15%, p<0.001) in leg extension S (N; HIIT-CIT: T0=277±64 - T12=320±70 vs. HIIT-PLA: T0=272±62 - T12=270±55; p<0.05) than HIIT-CIT men (+11%, p<0.05). The same result was observed in leg extension S relative to body weight. but only HIIT-CIT women exhibited a higher significant increase in leg extension S relative to leg lean mass (N.kg^{-1}; HIIT-CIT: T0=9.4±2.2 - T12=10.6±1.9 vs. HIIT-PLA: T0=9.6±2.0 - T12=9.6±1.7; p<0.05).
Conclusion: Although previous research has concluded that HIIT-CIT is beneficial for obese OA, it appears that women and men don't adapt in the same way. This raises the question of how to consider strength to determine sarcopenia and sarcopenic obesity: should we use absolute strength or muscle quality? These findings underscore the importance of assessing sex differences in adaptations to address specific recommendations.

P1240

5-YEAR RISK FRACTURE ASSESSMENT IN PATIENTS AFFECTED BY MASTOCYTOSIS BY THE USE OF REMS TECHNOLOGY

P. Pisani[1], E. Casciaro*[1], F. R. Contaldo*[2], F. Conversano*[1], M. Di Paola*[1], R. Franchini*[1], F. A. Lombardi*[1], A. C. Stetco*[2], C. Stomaci*[2], S. Casciaro[1]

[1]National Research Council, Institute of Clinical Physiology, Lecce, Italy, [2]University of Salento, Department of Biological and Environmental Sciences and Technologies, Lecce, Italy

*Equal contributors listed in alphabetic order

Objective(s): One of the most common manifestations of mastocytosis is bone structure deterioration, which is often linked to either neoplastic mast cell infiltration or, more likely, the local release of mediators like histamine.[1] According to literature, around 70% of individuals [2] with mastocytosis experience bone damage, with high incidence of fractures.[3] As a result, these patients require regular monitoring of bone mineral density (BMD) and timely treatments. Given the elevated risk of bone-related issues in mastocytosis, early detection of osteoporosis is crucial. This study aims to explore the relationship between mastocytosis and bone health by using REMS technology to assess the imminent fracture risk in mastocytosis patients (MPs).

Material and Methods: The imminent five year Fracture risk has been assessed by combining the REMS T-score with the REMS Fragility Score. Specifically, seven distinct risk categories are established, ranging from the lowest (R1) to the highest (R7).

Results: Femoral REMS-BMD and Fragility score measurements were performed on 47 MPs, aged 40 to 89, with an average BMI of 25 kg/m^2. As expected, they were classified into the high-risk categories R5-R7, indicating a higher probability of experiencing a fragility fracture at a major skeletal site within the next five years.

Conclusion(s): The integration of REMS technology into routine clinical practice for MPs can play a pivotal role in proactively managing bone health. By early identifying individuals at higher risk of fractures, timely interventions can be implemented to prevent fractures and improve the overall quality of life for these patients.

DETERMINANTS OF ANTI-OSTEOPOROSIS MEDICATION PRESCRIPTION BY ORTHOPEDIC SURGEONS FOLLOWING HIP FRACTURE IN THAILAND

P. Piyaprapaphan[1], P. Chotiyarnwong[1], N. Gerdsri[2], W. Wannamakok[3], E. Vanitcharoenkul[1]

[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]College of Management, Mahidol University, Bangkok, Thailand, [3]Faculty of Agro-Industry, Chiang Mai University, Chiang Mai, Thailand

Objective: To identify the factors influencing orthopedic surgeons' decisions to prescribe anti-osteoporosis medication (AOM) following hip fractures in Thailand.

Materials and Methods: We conducted a cross-sectional study among orthopedic surgeons who treat hip fractures. Using a model integrating the Technology Acceptance Model and the Theory of Planned Behavior, an online self-administered questionnaire was designed to assess perceived usefulness, perceived ease of use, perceived behavioral control, subjective norms, attitudes toward use, self-efficacy, and the intention to prescribe AOM after hip fractures. The questionnaire was validated by osteoporosis specialists and distributed purposively. Using Krejcie and Morgan's formula, the required sample size was 250. Data were analyzed using structural equation modeling (SEM) with a significance level set at p-value<0.05.

Results: A total of 262 surgeons from all parts of Thailand participated. SEM revealed that attitude toward use (β=0.617, p<0.01) and self-efficacy (β=0.201, p<0.01) were significant predictors of the intention to prescribe AOM. Perceived usefulness and subjective norms not only directly influenced attitudes toward use (β=0.427 and 0.232, p<0.01), they also indirectly predicted the intention to prescribe (β=0.263 and 0.143, p<0.01). However, perceived ease of use and perceived behavioral control did not have significant effects on AOM prescription.

Conclusions: This is the first study incorporating behavioral science to offer new insights into factors influencing AOM prescription. In addition to recognizing AOM's benefits in reducing fractures, surgeons' confidence in prescribing and social influences significantly impact prescribing decisions. Strategies should focus on highlighting AOM's practical advantages, strengthening surgeons' prescribing confidence, and leveraging external incentives—such as institutional guidelines, reimbursement programs, and regulatory support—to promote AOM prescription.

P1243

RELATIONSHIP BETWEEN OSTEOPOROSIS AND FRAILTY IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

P. S. Bücük[1], A. Kılavuz[1], K. Aksu[1]

[1]Ege University, Izmir, Turkiye

OBJECTIVE

Osteoporosis and frailty are two conditions commonly seen in the elderly. This study aims to evaluate the relationship between osteoporosis and frailty in elderly patients with rheumatoid arthritis (RA).

MATERIAL AND METHODS

Ninety-nine RA patients aged 65 years and older, without active arthritis and with low DAS28 levels, were included in this cross-sectional study. Osteoporosis was diagnosed using DEXA (T-score ≤-2.5). Sociodemographic characteristics, frailty status (assessed via the KIHON checklist), and nutritional status (assessed via MNA-SF) were recorded. Body mass index (BMI) categories were defined as <25 (underweight), 25–30 (normal), and >30 (overweight/obese). Logistic regression analysis was performed to identify independent predictors of osteoporosis.

RESULTS

The mean age of participants was 72.4 ± 6.7 years, and 83.8% were female. Osteoporosis prevalence was 54.5%. Education level, frailty status, and BMI categories were significantly associated with osteoporosis (respectively, p <0.001, p = 0.042 and p = 0.034). Lower education level and frailty were at higher risk for osteoporosis (OR = 4.689, 95% CI: 1.358–16.189, p = 0.015). Additionally, a BMI <25 was associated with a higher risk of osteoporosis (OR = 4.149, 95% CI: 0.954–18.039, p = 0.058).

CONCLUSIONS

This study highlights the importance of education level, frailty, and BMI as significant factors associated with osteoporosis in elderly patients with RA. In particular, studies investigating the relationship between osteoporosis and frailty in RA patients aged 65 years and older are very limited in the literature. This ongoing study aims to contribute significantly to addressing this gap and enhancing understanding of osteoporosis in this vulnerable population.

P1244

PREVALENCE AND RISK FACTORS FOR OSTEOPOROSIS IN RHEUMATOID ARTHRITIS - INSIGHTS FROM EMERGING REMS TECHNOLOGY

P. Santos-Moreno[1], M. C. Martínez-Ayala[2], J. V. Villamarín-Rojas[2], P. Rodríguez-Linares[2], L. Villarreal-Peralta[2], N. Gutiérrez-Gaitán[2], F. Rodriguez-Florido[2], A. Díaz-Alba[3], Y. Bonilla-Pérez[3], A. Medina-Orjuela[4]

[1]Biomab - Center for rheumatoid arthritis. Rheumatology, Bogotá, Colombia, [2]Biomab - Center for rheumatoid arthritis. Research department, Bogotá, Colombia, [3]Biomab - Center for rheumatoid arthritis. Administrative department, Bogotá, Colombia, [4]Hospital San José. Endocrinology, Bogotá, Colombia

Objective: Rheumatoid Arthritis (RA) is a chronic autoimmune/inflammatory disease associated with increased osteoporosis (OP) risk, driven by chronic inflammation, glucocorticoid use, and disease-related factors. Radiofrequency Echographic Multi Spectrometry (REMS) is an emerging ultrasound-based, non-ionizing technology for assessing bone mineral density (BMD) and fracture risk, offering a radiation-free alternative to dual-energy X-ray absorptiometry (DXA). The aim was to determine the prevalence and risk factors for OP using REMS in RA patients.

Materials/Methods: A cross-sectional study in a cohort of RA patients. Demographic and clinical data from medical records were included. BMD was evaluated using REMS in the spine and hip, considering factors such as age, sex, disease duration, and glucocorticoid treatment. Logistic regression analysis identified factors associated with OP.

Results: Were included 1,601 RA patients, 78.8% diagnosed with OP. Patients with OP were older (mean: 72.07, SD: 8.36 vs. 63.64, SD: 9.27; p < 0.001), and predominantly female (93.8% vs. 81.6%; p < 0.001). Disease duration was longer in the OP group (mean: 16.85 years, SD: 11.85 vs. 13.09 years, SD: 10.02; p < 0.001). Hypertension (HT) and cardiovascular disease (CVD) were more common in OP patients (HT: 41.6% vs. 30.0%; p < 0.001; CVD: 43.0% vs. 30.5%; p < 0.001). Independent risk factors for OP included age (OR: 1.10, 95% CI: 1.08–1.12; p < 0.001) and female sex (OR: 0.30, 95% CI: 0.20–0.41; p < 0.001). While disease duration, HT, and CVD were significant in univariate analysis, they did not retain significance in the multivariate model. No correlation with glucocorticoid use or RA disease activity.

Conclusions: The prevalence of OP in RA patients is very high, highlighting the need for continuous BMD monitoring. REMS technology represents an emerging, effective, and accessible alternative for OP diagnosis/monitoring in this population without radiation exposure.

P1245

PREVALENCE AND RISK FACTORS FOR OSTEOPOROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS - INSIGHTS FROM EMERGING REMS TECHNOLOGY

P. Santos-Moreno[1], M. C. Martínez-Ayala[2], J. V. Villamarín-Rojas[2], P. Rodríguez-Linares[2], L. Villarreal-Peralta[2], N. Gutiérrez-Gaitán[2], F. Rodriguez-Florido[2], A. Díaz-Alba[3], Y. Bonilla-Pérez[3], A. Medina-Orjuela[4]

[1]Biomab - Center for rheumatoid arthritis. Rheumatology, Bogotá, Colombia, [2]Biomab - Center for rheumatoid arthritis. Research department, Bogotá, Colombia, [3]Biomab - Center for rheumatoid arthritis. Administrative department, Bogotá, Colombia, [4]Hospital San José. Endocrinology, Bogotá, Colombia

Objective: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease associated with increased osteoporosis (OP) risk, driven by chronic inflammation, glucocorticoid use, and disease-related factors. Radiofrequency Echographic Multi Spectrometry (REMS) is an emerging ultrasound-based, non-ionizing technology for assessing bone mineral density (BMD) and fracture risk, offering a radiation-free alternative to dual-energy X-ray absorptiometry (DXA). The aim was to determine the prevalence and risk factors for OP using REMS in SLE patients.
Materials/Methods: A cross-sectional study was conducted in a cohort of 385 SLE patients. Demographic and clinical data were retrieved from medical records, including age, sex, treatment modality (biological vs. conventional therapy), and glucocorticoid use. BMD was assessed using REMS at the lumbar spine and hip, stratifying patients into normal BMD, osteopenia, osteoporosis, and severe osteoporosis. Logistic regression analysis identified factors associated with OP.
Results: The study included 385 SLE patients; they were predominantly female (85.7%). The prevalence of OP was 41.3%, mainly associated with older age (OR 1.14, 95% CI 1.10–1.17, $p < 0.001$) and female sex (OR 2.29, 95% CI 1.23–4.49, $p = 0.015$). No statistically significant association was observed with glucocorticoid use (OR 1.30, 95% CI 0.85–2.01, $p = 0.230$) or therapy type (OR 1.53, 95% CI 0.72–3.47, $p = 0.289$). No correlation with another sociodemographic or clinical factors.
Conclusion: The prevalence of OP in SLE patients is high, especially among older women. REMS offers a safe, portable, and radiation-free alternative for OP diagnosis and monitoring. These features make REMS a valuable tool for optimizing osteoporosis management in SLE patients, particularly in resource-limited settings, and for those with limited mobility.

P1247

SERUM VITAMIN D DEFICIENCY AND ASSOCIATED FACTORS IN PATIENTS WITH ACUTE AND CHRONIC LOW BACK PAIN AT TAM ANH GENERAL HOSPITAL : A CROSS-SECTIONAL DESCRIPTIVE STUDY

P. T. Pham[1], H. H. Dang[1], L. T. K. Nguyen[1]

[1]Rheumatology Department, Tam Anh General Hospital, Hanoi, Vietnam

Introduction: Low back pain (LBP) is a worldwide medical problem. Vitamin D deficiency has been pinpointed to be involved in many chronic disorders. Low back pain (LBP) is a common medical problem worldwide, and vitamin D deficiency has been pinpointed to be involved in many chronic disorders. However, the serum Vitamin D levels in patients with acute and chronic low back pain in Vietnam remain understudied.
Objective: The aim of this study is to describe the situation of Vitamin D deficiency and evaluate the association between serum concentration of 25-hydroxyvitamin D3 and symptoms of adults in Hanoi, Vietnam, suffering from chronic or acute low back pain.
Material and Methods: This prospective observational study used data from the Rheumatology Department, Tam Anh General Hospital in Hanoi. Database on 220 patients diagnosed with chronic or acute low-back pain between January 1, 2023, and January 1, 2024.
Results: **1.** The average serum concentration of 25-hydroxyvitamin D3 of 220 patients was **31,57 ± 16,94** ng/ml. The Vitamin D deficiency ratio of low back pain patients was **54,09%. 2.** There are significant differences between the level of serum Vitamin D with factors: VAS score, smoking, and bone mineral density.
Conclusions: The Vitamin D deficiency rate of low back pain patients was **54,09%** and related to VAS score, smoking, and bone mineral density
Keywords: Vitamin D deficiency, Chronic, and Acute low back pain.

P1248

PREDICTION OF BONE FRACTURE PROBABILITY BY FRAX MODEL IN CHRONIC KYDNEY DISEASE PATIENTS NOT YET ON DIALYSIS IN BACH MAI HOSPITAL : A RETROSPECTIVE STUDY

P. T. Pham[1], D. V. Hoang[2], T. G. do[3]

[1]Rheumatology Department, Tam Anh General Hospital, Hanoi, Vietnam, [2]Hai Phong International Hospital, Hai Phong, Vietnam, [3]Bach Mai Hospital, Hanoi Medical University, Hanoi, Vietnam

Introduction: Fractures caused by osteoporosis have become a major issue in the healthcare community, especially in Chronic Kidney Disease (CKD). The FRAX model (Fracture Risk Assessment in next 10 years) developed by the World Health Organization (WHO), is being widely used in many countries.
Objective: Describe the bone mineral density (BMD) and the fracture risk by the FRAX model of CKD Patients not yet on dialysis in

Bach Mai Hospital, Hanoi, Vietnam

Material and Methods: A retrospective descriptive study included CKD Patients (Diagnostic criteria by KDIGO – Kidney Disease Improving Global Outcomes) who had not been on dialysis in 2 years from 2018 to 2020. Data collection was performed using a database from GE Lunar Hologic bone densitometry equipment in Bach Mai Hospital, and fracture risk was calculated using the FRAX model. Statistical analysis was performed using SPSS software version 2.0.

Results: Sixty-five CKD patients were included (34 females, 31 males). The average age was 52 years [40-85 years], and the mean body mass index was 21.6, diagnosed CKD (40% of grade IV, 35.4% of Grade V, and other grades). The average bone mineral density (BMD) was 0,884 ± 0,2 g/cm2 in the spine and 0,721 ± 0,1 g/cm2 in the total femur. The osteoporosis ratio of this group is 24.6%. A statistically significant osteoporosis ratio with the ages above 60 and increasing PTH serum ($p< 0.05$). The average FRAX was 3,17 % for the probability of major fracture and 1,11 % for hip fracture. The 10,8% of this patient group had high risk of the next 10 years hip fracture, according to the FRAX model (FRAX hip ≥3%)

Conclusions: 24.6% of CKD patients not yet on dialysis were diagnosed with osteoporosis, and 10.8% were at high risk of hip fracture within the next 10 years based on the FRAX model.

Keywords: *Osteoporosis, FRAX, chronic kidney disease*

EXPERIENCE WITH TREATMENT OF SEVERE OSTEOPOROSIS WITH ROMOSOZUMAB IN SLOVAKIA

P. Vanuga[1], H. Urbankova[1], M. Kuzma[2], P. Jackuliak[2], J. Payer[2]

[1]National Institute of Endocrinology and Diabetology, Lubochna, Slovakia, [2]5th Department of Internal Medicine, Comenius University Faculty of Medicine, Bratislava, Slovakia

The treatment with romosozumab (ROMO) for patients with severe postmenopausal osteoporosis has been available in Slovakia since May 1, 2024. The first patient was educated at our facility NEDU Ľubochňa on May 2, 2024, and simultaneously received the first dose of ROMO. Experience with ROMO treatment in Slovakia is still modest, but indirect indicators of laboratory parameters are very encouraging. Patient satisfaction with the administered treatment is exceptionally good, with compliance nearly 100% due to the active management by the nursing staff.

Covered treatment with ROMO in Slovakia can be indicated for patients in two scenarios: a) severe postmenopausal osteoporosis in women (with a densitometrically determined T-score of less than -2.5 in the femoral neck, total hip area, or lumbar spine) and with multiple vertebral fractures (two or more fractures), where a vertebral fracture is defined as a reduction in the anterior height of the vertebral body by more than 20% compared to the normal height of the vertebral body; b) severe postmenopausal osteoporosis in women (with a densitometrically determined T-score of less than -2.5 in the femoral neck, total hip area, or lumbar spine) in whom previous anti-resorptive treatment has failed: 1. if they suffered an osteoporotic fracture after at least two years of anti-resorptive treatment, 2. if there was a significant decrease in bone density in the femoral neck (≥ 6%) after two years of anti-resorptive treatment. Covered treatment can only be indicated and prescribed in five selected osteocenters. Covered treatment is limited to one treatment cycle, which lasts a maximum of 12 months. A condition for covered treatment is its continuity and the simultaneous administration of an adequate amount of vitamin D and calcium, typically at a dose of 1000 mg, unless the patient has hypercalcemia.

P1250

NURSING GUIDELINE ON FRACTURE PREVENTION AND OSTEOPOROSIS CARE IN DUTCH COMMUNITY AND PRIMARY CARE: A WORLDWIDE FIRST

M. van Oostwaard[1], M. Tuut[2], A. De Haan[3], I. Ter Beek[4], E. Appelman[5], N. Appelman - Dijkstra[6], W. Beex - van den Broek[7], L. Maartens[8], O. van Eeden[9], I. Wiese[10], T. Zaal[10], P. van den Berg[11]

[1]Nurse practitioner FLS VieCuri Medical Center, Venlo, Netherlands, [2]Prova Guideline Methodologist, Varsseveld, Netherlands, [3]V&VN, Utrecht, Netherlands, [4]Nurse Specialist FLS ZGT, Almelo, Netherlands, [5]Nurse Specialist FLS Haga Medical Center, Den Haag, Netherlands, [6]Endocrinologist Leiden University Medical Center, Leiden, Netherlands, [7]Nurse Specialist Primary Care, Eindhoven, Netherlands, [8]General Practitioner, Eindhoven, Netherlands, [9]Teacher healthcare and Education Developer, Elst, Netherlands, [10]Patient Association, Haarlem, Netherlands, [11]Nurse practitioner FLS Reinier de Graaf Gasthuis, Delft, Netherlands

Aims

Fractures (especially in spine, hip and wrist) cause pain and might lead to disability and need for nursing care. In community and primary care settings, over 18,000 nurses and nurse practitioners care for patients with potentially increased fracture risk and osteoporosis in whom fractures can be prevented by timely risk identification and preventive measures. Therefore, a clear nursing clinical practice guideline (CPG) was developed to address fracture prevention in community and primary care.

Methods

Within a governmentally funded program, the Dutch Nursing Association (V&VN) assembled a guideline panel, with representatives from different nursing specialisms, nurse practitioners, general practice, internal medicine, and patient representatives. This panel was led by an independent guideline methodologist and presided by a process lead. As a starting point, this panel focused on topics deemed important in a national survey [1] among nursing professionals working in community and primary care. Furthermore, the guideline panel developed evidence-based recommendations (using the GRADE approach and according to AGREE-II) for nursing professionals, in line with existing national multidisciplinary guidelines [2,3]. The draft guideline was sent out for consultation and pilot implementation and was with minor ad-

justments authorized by all stakeholders.

Results

The pilot implementation showed that the CPG provided guidance in fracture prevention. The CPG includes recommendations for patients after a recent fracture, with increased fracture risk, and patients treated with glucocorticoids. The recommendations on preventive measures include risk assessment, education and counseling, exercise, nutrition and supplements, sleep, adherence and fall prevention. The CPG emphasizes analyzing patient`s preferences and restrictions regarding nutrition and exercise and addresses medication compliance in patients taking anti-osteoporosis medications.

Conclusions

Nurses and nurse practitioners in community and primary health care meet patients with increased fracture risk daily. They fulfill pivotal observational roles in early detection, prevention (of falls and fractures) and providing tailor-made guidance on nutrition, exercise and therapy compliance. This nursing guideline contributes to optimizing care for patients with increased risk of osteoporotic fractures, with the aim to prevent fractures and optimize quality of life. To our best knowledgeIn our opinion, this is the first community nursing guideline for Fracture Prevention and Osteoporosis worldwide aiming at primary as well as secondary fracture prevention in community care.

THE NERVE-BONE AXIS: MENDELIAN RANDOMIZATION IDENTIFIES A CAUSAL RELATIONSHIP BETWEEN HEART RATE VARIABILITY AND BONE MINERAL DENSITY

Q. Xiuqi[1], P. Qi[1]

[1]Beijing Hospital, Beijing, China

Background

Mounting evidence suggests a potential role for nerve-bone axis in the regulation of skeletal metabolism. Consequently, our study employed Mendelian randomization (MR) analysis to explore the influence of the autonomic nervous system (ANS) on bone mineral density (BMD).

Methods

We used heart rate variability (HRV) to represent ANS activity in the MR analysis. Initially, we employed a two-sample MR approach to evaluate the causal impact of HRV on BMD. Subsequently, we utilized an additional mediation analysis to assess the influence of circulating metabolites on the observed associations. Finally, we conducted reverse MR analyses to further explore these relationships. To ensure the reliability of our results, we also performed sensitivity analyses.

Results

Genetic liability to standard deviation of the normal-to-normal inter beat intervals (SDNN) (odds ratio [OR]=1.10, 95%CI=1.05~1.15, P<0.001), the root mean square of the successive differences of inter beat intervals (RMSSD) (OR=1.08, 95%CI=1.04~1.13, P<0.001) and peak-valley respiratory sinus arrhythmia or high frequency power (pvRSA/HF) (OR=1.06, 95%CI=1.03~1.09, P<0.001) were positively associated with BMD. And their associations were independent of circulating metabolites. The results of reverse MR analyses indicated no substantial reverse causal relationships. Furthermore, sensitivity analyses reinforced the validity of our causal interpretations.

Conclusion

In summary, the present research supports a genetic correlation between ANS and BMD, which reinforces the concept of nerve-bone axis. Notably, the unidirectional interplay between ANS function and BMD was found to be independent of circulating metabolites. Additional mechanistic and clinical investigations are required to corroborate our findings.

Keywords Heart rate variability, autonomic nervous system, bone mineral density, Mendelian randomization

P1252

THE GUT-NERVE-BONE AXIS: MENDELIAN RANDOMIZATION IDENTIFIES THE RELATIONSHIP BETWEEN GUT MICROBIOTA AND THE NERVE-BONE AXIS

Q. Xiuqi[1], P. Qi[1]

[1]Beijing Hospital, Beijing, China

Background

Mounting evidence suggests that the nerve-bone axis and gut-bone axis may act in the regulation of skeletal metabolism. Consequently, our study uses Mendelian randomization (MR) analysis to explore the existence of the gut-nerve-bone axis.

Methods

Genetic variants associated with gut microbiota were extracted from the MiBioGen consortium. Summary statistics for bone mineral density (BMD) were derived from a UK Biobank genome-wide association study dataset. We used heart rate variability (HRV) to represent the activity of autonomic nervous system (ANS) in the MR analysis. Initially, we employed a two-sample MR approach to evaluate the causal impact of gut microbiota on BMD. Subsequently, we used an additional mediation analysis to assess the effect of HRV on these associations, and sensitivity analysis was used to ensure the reliability of our results.

Results
Coprococcus 2 (β=0.03, 95% confidence interval, CI: 0.00 to 0.05, *P*=0.02), *Lachnospiraceae* NC2004 (β=0.01, 95%CI: 0.00 to 0.03, *P*<0.05), and another 11 genetically predicted taxa exhibited correlations with BMD. Among three types of HRV, pvRSA/HF and RMSSD were both associated with gut microbiota and BMD. The effect of *Lachnospiraceae* NC2004 on BMD occurs through RMSSD with a mediated proportion of 40.0% (95%CI: 21.1 to 58.9%, *P*=0.03) of the total effect. Sensitivity analyses reinforced the validity of our causal interpretations.
Conclusion
In summary, the present research supports a genetic correlation among gut microbiota, ANS, and BMD, which reinforces the concept of a gut-nerve-bone axis. Notably, the interplay between gut microbiota and BMD may be mediated by ANS. Additional mechanistic and clinical investigations are required to corroborate our findings.
Keywords Gut microbiota, autonomic nervous system, bone mineral density, heart rate variability, Mendelian randomization

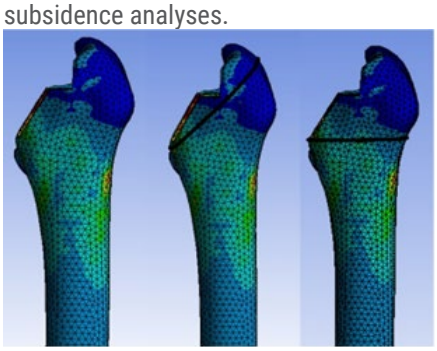
P1253

PROXIMAL FEMUR BIOMECHANICS: A COMPARATIVE STUDY OF PROPHYLAXIS WIRING AND NON-WIRING IN HIP ARTHROPLASTY

A. S. Sangroungrai[1], K. S. Sukhonthamarn[1], R. A. Apinyankul[1]

[1]Department of Orthopedics, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand

Objective
Intraoperative periprosthetic femur fracture presents a significant complication during total hip arthroplasty, demanding prompt recognition for optimal patient outcomes. This study aims to investigate proximal femur biomechanics and compare failure loads between prophylactic wiring and non-wiring techniques.
Material and Methods
Using Ansys, a finite element model was developed to assess biomechanical differences in the area and technique of wiring, identifying the strongest area and optimal wiring technique. Twenty fresh cadaveric femurs underwent standard preparation followed by cerclage wiring on the left femur. Biomechanical evaluations were conducted under axial loading on the femoral stem until catastrophic failure. Shapiro-Wilk test and independent t-tests were utilized for energy absorption, ultimate load, seeding load, and subsidence analyses.



Results
The wiring group exhibited higher absorption force before femoral stem failure (41.9±18.1 Nm) compared to the non-wiring group (41.0±19.1 Nm) (p=0.918). However, ultimate load and seeding load were lower in the wiring group (7.7±2.1 kN and 3.1±0.7 kN, respectively) than the non-wiring group (7.7±2.0, p=0.901), (3.4±1.4, p=0.589). Both groups demonstrated comparable subsidence distances: wiring group (7.7±2.6 mm) and non-wiring group (7.7±3.8 mm) (p=0.978).

Conclusion

The wiring group exhibited higher energy absorption before fracture occurrence, but no significant difference in ultimate load to fracture was observed. Additionally, comparable subsidence distances suggest no substantial advantage of wiring for prophylaxis. It's noted that wiring may deform proximal morphology, potentially altering stem load distribution to the proximal femur.

P1254

INFLUENCE OF VERTEBRAL EXCLUSION ON PRECISION ERROR AND LSC IN DXA STUDIES

R. Abdala[1], A. G. Mumbach[1], A. Benitez[1], S. Gomez[1], M. Sesta[1], M. B. Zanchetta[1]

[1]IDIM (Instituto de Diagnóstico e Investigaciones Metabólicas), Buenos Aires , Argentina

Introduction: Osteoporosis is a common bone disease marked by decreased bone mineral density (BMD) and quality, leading to a heightened risk of fragility fractures. Dual-energy X-ray absorptiometry (DXA) is considered the "gold standard" for diagnosing osteoporosis and is essential for monitoring treatment efficacy. The World Health Organization (WHO) established diagnostic criteria for osteoporosis using T-score thresholds in 1994, where the T-score reflects the patient's BMD in comparison to a young adult reference population. According to the International Society for Clinical Densitometry (ISCD), osteoporosis is diagnosed when the T-score is less than or equal to -2.5 in any evaluable region. In lumbar spine assessments, the ISCD recommends excluding vertebrae that are non-evaluable or differ significantly from adjacent vertebrae, requiring at least two vertebrae for an accurate diagnosis.

Given that DXA measures bone mass in g/cm² and is not entirely reproducible, it is crucial to calculate precision error and the Least Significant Change (LSC) for reliable assessments. The LSC must be determined for each region reported and for all possible combinations of vertebrae if exclusions are necessary. The objective of the study is to analyze the variations in precision error and LSC obtained through DXA across different vertebral combinations, thereby enhancing the understanding of how these factors impact osteoporosis diagnosis and management.

Materials and Methods: A prospective study was conducted at a reference center in Buenos Aires in April 2024 to evaluate precision and LSC. Following ISCD guidelines, the performance of technicians, DXA equipment, and biological variability were assessed. Two technicians evaluated 30 representative female participants, each scanned twice, resulting in 120 studies for analysis. The study adhered to the Helsinki Declaration principles, received local committee approval, and informed consent was obtained.

In the short-term precision study, bone mineral density (BMD) of the lumbar spine anteroposterior (LSAP) was measured using a GE Lunar Prodigy device. A total of 30 individuals were assessed by two technicians, ensuring a 95% confidence interval (CI), with all evaluations conducted on the same day and involving repositioning of patients. For each technician, 30 standard deviations (SD) and coefficients of variation (CV) were calculated, which were then squared and averaged. The square roots of the SD (RMS-SD) and CV (RMS-CV) multiplied by 100 were computed to express the precision error in both grams and percentage. Additionally, LSC was calculated in grams and percentage, also with a 95% CI, to evaluate the reliability of the measurements.

Results: The mean age of participants was 61.99 ± 13.37 years, with a weight of 66.88 ± 13.53 kg and height of 157.66 ± 6.25 cm. The study found that precision error increases with vertebral exclusions, leading to substantial variations in minimal significant change (Table 1). The L1-L4 region exhibited a lower minimal significant change, indicating it should not be used when reporting on two or three vertebrae, as misreporting could result in inappropriate therapeutic decisions .

	1 vertebra	2 vertebrae	3 vertebrae	4 vertebrae
BMD gr/cm²	1.036	1.055	1.056	1.050
RMS-SD g/cm²	0.019	0.012	0.009	0.007
RMS-CV %	1.71	1.09	0.80	0.62
LSC gr/cm²	0.053	0.034	0.025	0.018
LSC (%)	**4.7**	3.0	2.2	1.7

Conclusion: Measuring BMD from L1-L4 presents challenges; thus, the ISCD recommends excluding this region when necessary. Reports often exclude vertebrae without calculating the corresponding LSC for all combinations. This study emphasizes the necessity of determining precision error and LSC for all vertebral combinations, highlighting clinical differences and increased variability when fewer regions are analyzed. To our knowledge, no local data exist demonstrating these variations post-exclusion of regions of interest. This research aims to enhance the quality of densitometry studies and reports, ensuring their reliability.

P1255

THE STATUS AND TRENDS OF OSTEOPOROSIS RESEARCH IN THE WORLD: WITH EMPHASIZES ON THE HIGHLY-CITED PAPERS

R. Atlasi[1], S. M. Sajjadi-Jazi[1], B. Larijani[1], M. R. Mohajeri-Tehrani[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objectives: Many studies have been done on osteoporosis. So, this study provides an overview of researchers' efforts and knowledge gaps by analyzing the publications related to osteoporosis and shows much information such as the active organizations and authors, highly-cited papers, and topic trends of these studies.
Material and Methods: The search in the Web of Science (WOS) database was conducted until August 14, 2024, and all articles containing "osteoporosis" or "osteoporoses" in their keywords or titles were extracted and analyzed. Also, the Highly-Cited Papers (HCP) of the last ten years were extracted and visualized using WOS software and bibliometrix R-package 4.1.1.
Results: In total, 57,579 documents were retrieved. The most documents were articles (n=40,842), followed by meeting abstracts and reviews. The USA (n=11795) followed by China, England, Japan and Italy were the most productive countries. “University of California System” (n=1350) and then “Harvard University” (n=1065) had the most publications. “Cyrus Cooper” (n=469) from “University of Southampton” (UK) has been the most prolific author in this field, and “Osteoporosis International” (n=5627), “Journal of Bone and Mineral Research” (n=1991) and “Bone” (1543) published the most articles in this field. The results of the analysis of 187 HCP in osteoporosis also showed that “Cyrus Cooper” (n=15) had the most HCP. “University of Sheffield” (n=25) and “University of Southampton” (n=17) were the most productive organizations. “Osteoporosis International” (n=15) and “Journal of Bone and Mineral Research” (n=8) also published the most HCP. “Postmenopausal women” was the most frequented keyword and “oxidative stress” was the topic trend of the last ten years and in 2024. Two articles were also Hot-Papers, one was a guideline and one was a review of the global prevalence of osteoporosis.
Conclusion: Osteoporosis is a skeletal disorder that gradually reduces bone strength and exposes a person to the risk of sudden and unexpected fractures. Analysis of studies that have been conducted in this field showed that most authors and institutions with HCP were from the UK and “Osteoporosis International” has published the most articles in the field of osteoporosis in the world and also the most HCP.

P1256

KNOWLEDGE MAPPING OF GLOBAL PUBLICATIONS ON PITUITARY DWARFISM

S. M. Sajjadi-Jazi[1], B. Larijani[1], M. R. Mohajeri-Tehrani[1], R. Atlasi[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Background and purpose: Pituitary dwarfism is a form of dwarfism caused by complete or partial growth hormone deficiency. This research is purposed to analyze and map the scientific characteristics of studies conducted in this field from the beginning to the present and to identify the most active countries, organizations, and individuals, as well as the trend topics carried out in recent years.
Methods: All articles indexed in PubMed/Medline that had the MESH’s subject heading of "Pituitary dwarfism" and were published up to 2024 were extracted and analyzed. In total, 2616 documents were retrieved from 1946 to 2024, which were analyzed and visualized using the VOSviewer software and bibliometrix package on R software.
Results: The highest number of documents were produced in the year 2022 (n=84), then in 1972 (n=83) and 1970 (n=74). "The Journal of Clinical Endocrinology and Metabolism" published by far the most papers in this field (n=138). Then "Growth Hormone & IGF Research" (n=78) and "Journal of Pediatric Endocrinology & Metabolism" (n=60) published the most papers in this field, respectively. "K Shizume " with 46 documents from Japan and "R Salvatori" (n=43) from the USA were the most active authors. Also, the “Federal University of Sergipe” (n=238), “Peking Union Medical College Hospital “ (n=42) and the “University Of Palermo” (n=35) were the most active organizations. Among the countries, the USA (n=628), Italy (n=618), China (n=530), Brazil (n=354), and Japan (n=262) published the most documents. The topics "Histidine", "mannitol", and "human growth hormone/adverse effects" have been the most trending in the last two years.
Conclusion: The surge in scientific output in 2022 highlights enhanced improvements in diagnostic methods and treatment protocols for pituitary dwarfism. Also, understanding of the genetic and hormonal mechanisms underlying the condition, alongside advancements in imaging technologies like MRI, have improved the diagnosis and assessment of growth hormone deficiencies. Furthermore, the progress made during the past decades reflects the evolution of treatment approaches, particularly the development of more effective hormone replacement therapies. Together, these advancements have likely contributed to a decline in severe cases of pituitary dwarfism and associated complications.

P1257

ANALYSIS AND VISUALIZATION OF SYSTEMATIC REVIEWS ON METABOLIC BONE DISEASES

M. Pejman-Sani[1], S. Mohseni[1], R. Atlasi[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objectives: Metabolic bone diseases such as mucolipidoses, osteoporosis and rickets are diseases that affect the metabolic processes of bone tissue. In this research, we aimed to analysis of systematic reviews conducted in this field and visualize their characters to obtain an overview and find the gaps in this type of studies conducted in this field.

Material and Methods: We selected the "Metabolic Bone Diseases" in Medical Subject Headings (MESH) then searched PubMed to retrieve all published documents on this subject up to August 2024 and limited that to systematic review document type. The results were saved and then analyzed and visualized using the bibliometrix R-package 4.1.1.

Results: 1124 systematic reviews were retrieved, and published between 1997 and 2024. The largest number of articles was published in 2023 (n=127) and 2022 (n=105). The journals "Osteoporosis International" (n=168) and "The Cochrane Database of Systematic Reviews" (n=67) published the most articles and " Ann Cranney " (n=3) and " Peter Tugwell " (n=20) both from Canada were the most prolific authors in this field. The countries China (n=1797), USA (n=441), Canada (n=392), and Italy (n=376) had published the most documents respectively. Also, the "University of Toronto" (n= 67), "Sichuan University" (n= 50), "Kaohsiung Medical University" (n= 46), and "Tehran University of Medical Sciences" (n= 45) were the most prolific organizations. Among the topics, "bone diseases, metabolic", "network meta-analysis", and "diphosphonates/adverse effects" were the trend of the year 2023 and "bone density", "aged", "randomized controlled trials", "middle-aged", "risk factors", and "bone density/drug effects" were the most frequently used keywords.

Conclusion: "Metabolic Bone Diseases" was a trending topic last year in systematic reviews in this field. The most active countries and organizations in this field were from the Asian continent, mostly from China. And the most prolific authors were from Canada.

Keywords: Metabolic Bone Diseases, Visualization, Scientometric Analysis, Bibliometric Analysis, Systematic Reviews

RANDOMIZED CLINICAL TRIALS ON THE TREATMENT OF BONE CANCERS: ANALYSIS & VISUALIZATION

R. Atlasi[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objectives: Bone neoplasms are tumors or cancers located in bone tissue or specific bones. In this research, we purposed to review and analyze Randomized Controlled Trials (RCT) studies conducted in the field of treatment of this disease to identify the most relevant topics and the most active individuals and organizations in this field, and to present knowledge gaps to provide a roadmap for researchers in this field.

Material and Methods: The subject headings of "bone neoplasms" and "therapy" were extracted from the Mesh database and searched in PubMed. Then they were limited to the type of evidence that was RCT. 744 studies from 1972 to 2024 were retrieved and subjected to scientometric analysis using the R program.

Results: Analysis of these RCTs showed that most of these RCTs were produced in 2016 (n=34), 2015 (n=32), and 2014 (n=31) respectively. 4916 authors contributed to the production of these documents, of which only 20 were single-authored articles, and the rest were written in groups. The average number of authors in these articles was 9.55, and their international collaboration was 10.35. "Yvette M van der Linden" with 20 articles from the Netherlands has been the most prolific author in this field. Also, the "Journal of Clinical Oncology"(n=71), "Cancer"(n=41) and "European Journal of Cancer"(n=34) published the most RCT articles. Among the countries, The USA (n=92), Germany (n=49), and China (n=42) had the most RCT articles. The most important trending topics over the years have been "middle-aged", "aged", "adult ", "treatment outcome", "prospective studies", "adolescent", "survival rate", "double-blind method", and "combined modality therapy".

Conclusion: Since 2016, the number of RCT studies in this field has been declining, and given the importance of treating bone cancers, more studies are needed in this field. Analyzing these studies, from time to time, and finding characters of them can help to better conduct future studies and fill knowledge gaps.

Keywords: Randomized Controlled Trials, RCT, Bone Cancer, Therapy

P1259

ANALYSIS OF THE TOP 100 MOST-CITED PAPERS ON FRACTURE & CANCERS

R. Atlasi[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Background and purpose: Fracture and cancer are associated with each other, and studies have shown that the risk of fracture is two times higher in cancer survivors compared with individuals with no history of cancer, and injury may lead to finding cancer in the injured area. Therefore, this study aims to analysis the most cited articles published in this field to provide an overview of the most influential articles on this topic.

Methods: All articles that contained words related to the concepts of fracture and cancer in their titles or keywords were searched and retrieved through a search strategy designed in the Web of Science database in August 2024 (4405 articles). They were then sorted by number of citations to identify the top 100 most cited articles. Data were analyzed using the bibliometrix R-package to analyze and map the networks, topics and characteristics of these articles.

Results: Analysis of the top 100 most cited articles showed that these articles were published from 1991 to 2019, with the highest number of articles(n=9) published equally in 2002 and 2005. The most cited article was entitled “Risks and Benefits of Estrogen Plus Progestin in Healthy Postmenopausal Women: Principal …” by “Jacques E Rossouw” and his colleagues from the USA published in 2002 and in JAMA (n=11,897), followed by a paper by “Cosman F” in 2014 published in “Osteoporosis International” (n=2,091). “Cauley JA” published the most articles of these top 100 articles (n=6), and “University of California, San Francisco” (n=18) and "University of Toronto” (n=14) being the most prolific institutions. Also, the most active countries were the USA (n=320), UK (n=45), Canada (n=43), Germany(n=16), and Japan (n=15). The most frequently used keywords in these articles were “Breast Cancer”, “Hip Fracture”, “Bone Mineral Density”, “Postmenopausal Women”, and Risk, respectively.

Conclusion: Of the countries, the USA had the most cited articles in the world and the most cited articles. The topic of fractures was more frequently discussed in these articles related to women's cancers, including breast cancer. This could be due to the importance of hormonal issues in women's cancers and their impact on bone fractures.

Keywords: Fracture, Cancers, Scientometric Analysis, Most-Cited Papers

SCIENTIFIC OUTPUTS ON OSTEOARTHRITIS IN THE MIDDLE EASTERN COUNTRIES: A SCIENTOMETRIC ANALYSIS OF THE LAST TEN YEARS' ACTIVITIES

R. Atlasi[1], S. M. Sajjadi-Jazi[1], B. Larijani[1], M. R. Mohajeri-Tehrani[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Background and purpose: Osteoarthritis is a progressive, degenerative joint disease in the elderly but from biochemical changes and biomechanical stresses affecting articular cartilage. This study aims to scientometric analysis of the research conducted in Middle Eastern countries in this field and to determine the status of research in these countries.

Methods: All terms related to the concept of Osteoarthritis were extracted from the MESH database and the search strategy was conducted in the titles and keywords of articles indexed in the Scopus database from 2015 to 2025. The results were limited to Middle Eastern countries and the documents were analyzed using VOSviewer and CiteSpace software.

Results: In total, 4415 documents were extracted between 2015 and 2025, most of which were published in 2024 and were mostly, Article, Review, Letter, Book chapter, and Conference paper type. “International Orthopaedics” (n=60), “Archives of Bone and Joint Surgery” (n=55), and “BMC Musculoskeletal Disorders” (n=53) published the most articles in this field. Among the countries, Turkey (n=1517), Iran (n=1166), Saudi Arabia (n=646), and Egypt (n=633), had the most publications. Also, “Tehran University of Medical Sciences” (n=209), “Shahid Beheshti University of Medical Sciences” (n=204), “King Saud University” (n=189), “Cairo University” (n=181), and “Iran University of Medical Sciences” (n=177) were the most active organizations, respectively. “Jean-Yves Reginster” (n=63), “Cyrus Cooper” (n=51), and “Olivier Bruyère” (n=50), from Belgium and the UK, were the most prolific authors, collaborating with Saudi Arabia. The article, "Global, regional, and national incidence, prevalence, and years lived with disability for 328 diseases…", was the most cited article (n=5870). Among the topics and keywords, "Knee Osteoarthritis", "Controlled Study", "Major Clinical Study", "Follow Up", "Procedures", "Visual Analog Scale", and "Treatment Outcome" were the most used and noted.

Conclusion: Since 2018, the trend of scientific production in the Middle East in Osteoarthritis has been on an upward trend and has reached its peak in the last year. All Middle East countries were active in this field, but Turkey had the most publications. Most of the knowledge-producing organizations were related to Iran. The most prolific authors were from outside the Middle East, which collaborated with Saudi Arabia.

Keywords: Osteoarthritis, Middle East, Scientometric Analysis

ANALYSIS OF HIGHLY-CITED PAPERS & HOT PAPERS ON ARTHRITIS RHEUMATOID

R. Atlasi[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Background and purpose: Arthritis Rheumatoid is a chronic inflammatory and autoimmune disease that causes pain in the joints. This study aims to achieve up-to-date and effective knowledge by analyzing Highly-Cited Papers (HCP: Papers that have received more citations than their peers in the last ten years) and Hot Papers (HP: Papers that have been published in the last two years and have received a lot of citations in recent 2 months) in this field.

Methods: A search was conducted on the keywords of indexed documents in the Web of Science database up to 2025. Then, it was limited to HCP and HP. The papers were analyzed using scientometric software from various perspectives, and the active authors, organizations, and main and hot topics of recent years in this field were identified.

Results: In total, 561 HCP and 11 HP were retrieved between 2014-2024 and most of them were published in 2023, followed by 2021 and 2022. In HCP, each article had an average of 283.2 citations. Co-authors per document were 8.54 and international co-authorships were % 47.42. "Désirée van der Heijde" (n=15) from Netherlands and "Josef S Smolen" (n=14) from Austria were the most active authors. USA (n=851), UK (n=364), China (n=297) and Germany (n=192) had the most documents and among organizations, "Medical University of Vienna " (n=37) and "Harvard Medical School" (n=33) had the most HCP productions, respectively. The article "NF-κB signaling in inflammation." by Liu, T., et al had the highest number of citations (n=5663). The most frequented keywords were, "double-blind", "nf-kappa-b", "systemic-lupus-erythematosus", "efficacy", "collagen-induced arthritis", "dendritic cells", "in-vitro", "risk", "disease-activity", "expression", and "tumor-necrosis-factor". Analysis of 11 HP also showed that "Annals of The Rheumatic Diseases" (n=57) had published the most articles and the most active organization was, "Sichuan University (n= 4). Also, the HP topics are, "monoclonal-antibody", "systemic-lupus-erythematosus", "molecular-cloning ", "plasmacytoid dendritic cells", "risk", and "Alzheimer-disease.

Conclusion: The USA has published the most HCP and HP and most of these articles have been published in the last year. These are influential articles and reviewing them from time to time can provide up-to-date and useful information for awareness of effective research and for conducting future studies.

SCIENTOMETRIC ANALYSIS AND MAPPING OF THE CASE REPORTS CONDUCTED ON THE OSTEITIS DEFORMANS

R. Atlasi[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Background and purpose: Osteitis Deformans or Paget's disease of bone, is a very common chronic bone disorder characterized by excessive breakdown and regrowth in the affected bone. This study aims to analyze and visualize the characteristics of the case reports produced so far in this field and identify the topics of these documents.

Methods: All case reports in the field of Osteitis Deformans from the beginning to the end of 2024 were extracted by searching for this concept in the MESH database and limiting it to the case reports filter. The results were saved and analyzed using scientometric software such as R bibliometrix and CiteSpace, and knowledge visualization was performed.

Results: 1326 case reports were retrieved from 1955 to 2024, with 4287 authors contributing. Annual growth rate was % 2.86 and 167 authors were of single-authored documents. Co-Authors per Documents was 3.54 and the international co-authorships was % 0.7541. Most of these case reports were published in 1979 and in the last 5 years, most were published in 2022 with 10 articles. The journals "Clinical Nuclear Medicine" (n=66), "Skeletal Radiology" (n=40), And "Clinical Orthopaedics and Related Research" (n=30) published the most case reports in this field. USA, China, India, Italy, Spain, Germany, and Turkey had the most scientific production in this field, respectively. Also, "Peking Union Medical College Hospital" (n=20), "University of Auckland" (n=15), and "Mayo Clinic" (n=14) were the most active organizations. In addition, "Michael P Whyte" from the USA was the most prolific author of this type of document(n=14). Radiography, diagnosis differential, osteitis deformans/complications, radionuclide imaging, and tomography x-ray computed, were the most frequently used keywords.

Conclusion: The number of case reports in the field of Osteitis Deformans has decreased in recent decades compared to the 1970s. The USA and China have been the leaders in producing these documents, and topics related to diagnosis and medical imaging have been the most discussed topics in this type of study.

THE TOP 100 ARTICLES IN THE FIELD OF OSTEOPOROSIS AND TREATMENT: SCIENTOMETRIC AND CONTENT ANALYSIS

N. Rezaei[1], R. Naemi[2], H. Gerami[3], M. Sanjari[4], R. Atlasi[3]

[1]Department of Medical Library and Information Sciences. School of Paramedicine. Hamadan University of Medical Sciences. Hamadan. Iran, Hamedan, Iran, [2]Department of Health Information Management, School of Paramedical Sciences, Ardabil University of Medical Sciences, Ardabil, Iran, Ardabil, Iran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [4]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Background and purpose: Osteoporosis is a common disease and numerous studies have been conducted in the field of its treatment. This study aims to analyze the top 100 most-cited articles among all the documents published in this field and to identify their characteristics, topics, document type, journals, authors and organizations active in publishing these articles.
Methods: First, all articles in the field of treatment and osteoporosis that were indexed in the Web of Science database until August 2024 were extracted, and then the top one hundred articles in terms of the number of citations were identified and saved in the required formats for scientometric and content analysis.
Results: The results showed that these articles were published between 1993 and 2022, and most of them were published in 2016 (n=14) and then in 2020 (n=10). Most of these articles were published in the "Osteoporosis International" (n=11) then in "Archives of Osteoporosis" and "New England Journal of Medicine" both with 6 articles. "Cyrus Cooper" (n=13) and "John A. Kanis" (n=12) from the UK had the most articles on this topic. The USA and UK countries and organizations such as "The University of Sheffield" (n= 28), "University of California, San Francisco" (n=19) and "The University of Southampton" (n= 15) were also the most active and had the most cited articles, respectively. The article entitled "Osteoporosis Prevention, Diagnosis, and Therapy" published by "Anne Libanski" and et. al. in "JAMA-Journal of The American Medical Association" in 2001 (IF=63.5, Q1) had the most citations (n=3766) and with 150.64 citations per year. "bone-mineral density", "postmenopausal women", "hip fracture", "vertebral fractures", "zoledronic acid" were the most relevant keywords, respectively. Also, content analysis of these articles showed that most of these studies were review and systematic review types, followed by clinical trials and guidelines.
Conclusion: In producing the top 100 most cited and influential articles in the field of osteoporosis treatment, it is observed that authors and organizations from the UK have shown more activity over the years. Also, review studies in this area are important and have received more citations.

P1265

EB613 TABLET TREATMENT [ORAL PTH(1-34)] – DOES PK DRIVE BONE MODELING VERSUS BONE REMODELING?

G. Burshtein[1], C. Itin[1], H. Galitzer[1], A. Hoppe[1], C. Sternberg[2], A. Raskin[1], R. B. Wagman[3], M. Toledano[1], Y. Caraco[4]

[1]Entera Bio Ltd., Jerusalem, Israel, [2]CSC Ltd., Shoham, Israel, [3]SoCal PCH Ventures, San Bruno, United States, [4]Hadassah Clinical Research Center, Jerusalem, Israel

Objectives: EB613 is being developed as a first-in-class oral daily tablet treatment of PTH(1-34) for postmenopausal women with osteoporosis at increased risk for fracture. In a 6-month Phase 2 study (NCT04003467) in 161 postmenopausal women with low BMD or osteoporosis, EB613 showed dose-dependent increases in BMD at the lumbar spine, total hip, and femoral neck and a dual mechanism of increases in bone formation (PINP) and decreases in bone resorption (CTx). Here, we report Phase 1 data that assessed PK of the two EB613 doses, which will be advanced to Phase 3.
Materials and Methods: In a cross-over Phase 1 study (NCT05965167) in 15 healthy young male volunteers, EB613 (1.5 and 2.5 mg) and injectable PTH(1-34) (0.02 mg) were administered in a random sequence following an overnight fast. The PK profile of PTH(1-34) was assessed following the three treatments.
Results: EB613 1.5 and 2.5 mg dose levels were characterized, respectively, by a rapid increase in plasma PTH(1-34) (Tmax within 20 min), rapid elimination (T1/2 of 11.1 and 8.8 min) and generally dose-proportional increases of mean Cmax (270 vs 488 pg/ml) and mean AUClast (4,590 vs 7,590 pg/ml*min). The overall duration of exposure was substantially shorter than the PTH(1-34) injection (median Tlast 20, 30, and 75 min for EB613 1.5 mg, 2.5 mg, and injection, respectively) (Figure). EB613 was well tolerated: all AEs were mild or moderate, and there were no SAEs.
Conclusion: The PK profile of EB613 is characterized by a shorter systemic exposure vs the SC injections of PTH(1–34). While the AUC of maximal clinical EB613 dose (2.5 mg) is similar to that of the daily injection, Cmax is much closer to that of the reported once-weekly injection (0.056 mg). In contrast to the daily injection, EB613 and the reported weekly injection appear to have a dual anabolic and antiresorptive effect, maintaining bone formation while reducing bone resorption, a potentially ideal osteoanabolic treatment. Safety and efficacy of EB613 will be evaluated in the planned Phase 3 trial.

P1266

WHAT PATIENTS THINK ABOUT THE IMPACT OF DIET ON SPONDYLOARTHRITIS

R. Ben Tekaya[1], D. H. Khalifa[1], N. Elamri[1], R. Fakhfakh[1], H. Hachfi[1], K. H. Baccouch[1], E. Bouagina[1]

[1]University Hospital Farhat Hached, Rheumatology Department, Sousse, Tunisia, Sousse, Tunisia

Background:
Rheumatic patients often seek dietary solutions to alleviate their symptoms.
Objectives:
Our aim is to understand the ppatients eating habits and the beliefs underlying these practices.
Methods:
A cross-sectional descriptive study conducted in our rheumatology department recruited patients with axial spondyloarthritis (AS). The patients completed a questionnaire exploring their eating habits, diets followed (sugar-free, cow's milk-free, gluten-free, olive oil consumption, turmeric, fruits, green vegetables, red meat, fatty fish, nuts), and the perceived effects of diet on rheumatic symptoms (pain, fatigue). Analytical analyses assessed the association between eating habits or the impact of food on disease activity.
Results:
A total of 39 patients were included and analyzed, with an average age of 45 ± 10.4 years; 88.5% of patients with AS were receiving biologic therapy. The mean disease activity scores (BASDAI, BASFI, ASDAS (vs), and ASDAS (CRP)) were 3.5 ± 1.2, 3.9 ± 1.3, 2.7 ± 0.8, and 3 ± 0.7, respectively. Twenty-five percent of patients had followed or were following at least one specific diet. The most commonly followed diet was sugar-free (by 8 patients). Two patients were following a gluten-free diet. In our study, we did not find any patients following a cow's milk-free diet. Of all the diets followed, 50% were associated with a reduction in pain and 80% with an improvement in general condition. Only 22% of patients had adopted the diet based on a doctor's advice. Dairy products, red meat, and sugary foods were more often reported to increase pain, while green vegetables, fruits, fatty fish, and turmeric were more frequently reported to reduce pain. We compared the disease activity of patients following a diet with those not following a diet: BASDAI 2.5 ± 0.8 vs 4.2 ± 1.02 ($p < 0.001$); BASFI 3.2 ± 0.8 vs 4.4 ± 1.2 ($p = 0.01$); ASDAS (CRP) 2.2 ± 0.8 vs 3.01 ± 0.9 ($p = 0.02$). Health beliefs and lack of information were important determinants in adopting a diet or perceiving an effect on pain.
Conclusion:
Our study shows that following a sugar-free or gluten-free diet may have a beneficial effect on the activity of rheumatic diseases. This study provides insight into the determinants of eating practices and beliefs in the Tunisian population. It encourages the inclusion of diet in the management of rheumatic diseases and emphasizes the need to better educate our patients about the effects of diet.

P1267

JUVENILE IDEOPATHIC ARTHRITIS AS SEEN BY YOUNG PEDIATRICIANS: WHAT BELIEFS AND WHAT ISSUES?

R. Ben Tekaya[1], R. Fakhfakh[1], H. Hachfi[1], D. H. Khalifa[1], N. Elamri[1], K. H. Baccouch[1], E. Bouagina[1]

[1]University Hospital Farhat Hached, Rheumatology Department, Sousse, Tunisia, Sousse, Tunisia

Background:
Although juvenile idiopathic arthritis (JIA) is common in children, it remains poorly understood by many pediatricians. Objectives: This study aimed to assess their knowledge of the epidemiology, clinical features, and treatment of this disease.
Methods:
An online survey was created using Google Forms and sent via social media to pediatric residents. Thirteen questions were designed to assess beliefs and misconceptions about JIA. These were organized into three blocks of multiple-choice questions: "epidemiology" (4 questions), "clinical and laboratory manifestations" (6 questions), and "therapy" (3 questions).
Results:
A total of 43 pediatric residents responded to the survey, of whom 69.7% were women. Regarding age, 23.2% of respondents knew that oligoarticular JIA more commonly affects girls aged 2 to 4 years. Most of them thought that oligoarticular JIA was more frequent in adolescents (44.1%), and 32.5% considered that the disease was more common in boys, regardless of age. On the other hand, most participants knew that oligoarticular JIA was the most common form of JIA (76.7%) and that uveitis was more frequent in patients with positive ANA. The majority of the residents surveyed (65.1%) selected arthralgia as the most frequent symptom of oligoarticular JIA. Most respondents were aware of the recommendation for regular uveitis screening (81.3%) and the clinical features of inflammatory back pain (93%). More than half of the survey participants (60.4%) correctly indicated that inflammation markers could be either normal or elevated, while others thought they were generally elevated (20.9%) or that inflammation markers were elevated in polyarticular forms but not in oligoarthritis (18.6%). Sixty-nine percent of the doctors knew that NSAIDs do not alter the course of arthritis. Regarding biolog-

ic therapy, most respondents (71%) knew that these medications are used in patients whose disease is refractory to disease-modifying antirheumatic drugs such as methotrexate.
Conclusion:
This study highlighted significant gaps in the knowledge of young pediatricians regarding JIA, which could delay patient referral. In particular, one-third of respondents had misconceptions about biologic therapies.

P1268

WHAT IS THE IMPACT OF INTERMITTENT FASTING ON THE EVOLUTION OF RHEUMATOID ARTHRITIS UNDER BIOLOGICAL TREATMENT?

R. Ben Tekaya[1], R. Fakhfakh[1], H. Hachfi[1], D. H. Khalifa[1], N. Elamri[1], K. H. Baccouch[1], E. Bouagina[1]
[1]University Hospital Farhat Hached, Rheumatology Department, Sousse, Tunisia, Sousse, Tunisia

Background:
Several experimental studies have highlighted the role of intermittent fasting in immune responses that reduce inflammation. Various fasting protocols, supported by experimental studies, have recently gained popularity among the general public. Fasting leads to a reduction in oxidative stress and inflammation, enhances cellular protection, and increases resistance to harmful insults.
Objectives:
Our aim is to describe the rheumatoid arthritis activity during the fasting period (Ramadan).
Methods:
We conducted a cross-sectional study on patients with rheumatoid arthritis (RA) according to the 2010 ACR/EULAR criteria, treated with biologic therapy. RA activity was assessed two months before Ramadan (February 2024) and during the Ramadan fasting period in Tunisia (intermittent fasting) using clinical parameters, the Visual Analog Scale (VAS) of pain (10 cm), morning stiffness, nocturnal awakenings, number of painful joints (NPJ), and number of swollen joints (NSJ); biological parameters, including C-reactive protein (CRP); and disease activity scores, DAS28 (CRP) and DAS28 (ESR) for RA. Data analysis was performed using SPSS software.
Results:
We included 40 patients, with a mean age of 52 ± 7 years, and 92% were women. The average disease duration was 11.68 ± 8.81 years. RA was seropositive (RF and/or anti-CCP) in 77% of cases, erosive in 70%, and deforming in 45%. Coxitis was present in 25% of patients, including two with bilateral coxitis. Forty-five percent of patients had osteoporosis and were on treatment, and 22.5% had diffuse interstitial pneumonia. Thirty-five patients were on conventional disease-modifying antirheumatic drugs (DMARDs), with 80% on Methotrexate, 14% on Leflunomide, and 5% on Sulfasalazine. All patients were on biologic therapy, with 50% on Infliximab, 35% on Certolizumab, 5% on Adalimumab, 7.5% on Tocilizumab, and 2.5% on Rituximab. Eighty-five percent were on corticosteroids, and 13% were on non-steroidal anti-inflammatory drugs (NSAIDs). The following parameters were lower during the Ramadan month compared to the pre-Ramadan period: NPJ 3.8 vs 8.6 (p = 0.02); NSJ 2.1 vs 4.8 (p = 0.01); mean CRP 8.1 vs 24.6 (p = 0.001); mean DAS28 CRP 3.2 vs 4.25 (p = 0.01); mean DAS28 (ESR) 3.1 vs 3.9 (p = 0.05); pain VAS 5.2 vs 3.4 (p = 0.01). However, we found no statistically significant association between intermittent fasting and nocturnal awakenings or morning stiffness.
Conclusion:
Our study concluded that intermittent fasting was associated with reduced RA activity. Integrating intermittent fasting could promote optimal health and reduce the activity of certain chronic inflammatory diseases.

P1269

SHARED DECISION-MAKING IN IDEOPATHIC JUVENILE ARTHRITIS: THE PHYSICIAN'S PERSPECTIVE

R. Ben Tekaya[1], R. Fakhfakh[1], N. Elamri[1], D. H. Khalifa[1], H. Hachfi[1], K. H. Baccouch[1], E. Bouagina[1]

[1]University Hospital Farhat Hached, Rheumatology Department, Sousse, Tunisia, Sousse, Tunisia

Background:
Shared decision-making (SDM) has proven to be useful in managing chronic diseases. This study aims to evaluate the practice of SDM by physicians treating patients with juvenile idiopathic arthritis (JIA), as well as the obstacles they face, particularly when initiating biologic treatments.
Objectives:
The aim of this study was to evaluate the practice of SDM among physicians treating patients with JIA, and to identify the obstacles they encounter, particularly in the initiation of biologic treatments.
Methods:
A national online survey was conducted. The questions were designed by the authors to assess SDM and its associated obstacles, targeting pediatric and rheumatology residents. The survey was created using Google Forms and sent via social media platforms (Messenger, WhatsApp) to residents.
Results:
A total of 60 pediatric and rheumatology residents responded to the survey. Most of the respondents (70%) were women. Seventy-five percent of respondents indicated that SDM was their usual approach for decisions regarding biologic treatments. When asked about the importance of specific aspects of the SDM process, most physicians reported that discussing the advantages and disadvantages, as well as treatment options between the parents and the doctor, were very or extremely important factors. Additionally, 55% of physicians considered it extremely important for parents to provide information to the doctor, and 79% of physicians believed that the information provided by the doctor to the parents was extremely important. Most respondents felt that parental trust (87%) and emotional openness (70%) greatly facilitated SDM. When making decisions with adolescents, most respondents stated that the patient's trust (80%), emotional preparedness (60%), and willingness to engage in the discussion

(60%) could significantly help facilitate SDM. The obstacle most perceived as interfering with the SDM process was limitations related to social insurance (30%). Regarding obstacles to SDM with adolescents, 21% of respondents thought that the difficulty in accepting their own diagnosis interfered with SDM.
Conclusion:
Our results highlight the interest of physicians in a collaborative approach with families. While some obstacles, such as those related to health insurance constraints, are more difficult to overcome, others, such as those related to skills and tools, can be addressed to promote shared decision-making, particularly regarding biologic treatments.

P1270

SELF-ESTEEM: A MAJOR ISSUE IN RHEUMATOID ARTHRITIS

R. Ben Tekaya[1], R. Grassa[1], W. Tekaya[1], N. Ben Chekaya[1], M. Jguirim[1], S. Zrour[1], I. Bejia[1]

[1]University Hospital Fattouma Bourguiba, Rheumatology Department, Monastir, Tunisia, Monastir, Tunisia

Background:
The self-esteem of patients with chronic diseases is closely related to their health status and their perception of the disease. This study aims to explore how psychological well-being and social support influence self-esteem in individuals suffering from chronic inflammatory rheumatic diseases. Objectives:
The aim of this study was to explore how psychological well-being and social support influence self-esteem in individuals suffering from chronic inflammatory rheumatic diseases.
Methods:
This is an analytical cross-sectional study involving patients with chronic inflammatory rheumatic diseases (CIRDs) followed in a rheumatology department. Sociodemographic, clinical, paraclinical, and therapeutic data were collected. Each patient completed validated questionnaires: the MSPSS score assessing perceived social support (The Multidimensional Scale of Perceived Social Support), the Rosenberg Self-Esteem (RSE) score, and the HAD score evaluating anxiety and depression (Hospital Anxiety and Depression Scale). We used validated Arabic versions of these questionnaires.
Results:
A total of 82 patients participated: 58 women and 24 men, with an average age of 51.4 years [18-72 years]. Rheumatoid arthritis was seropositive in 71.9% of cases. The mean disease duration was 11.2 years [1-35 years], and disease activity was moderate to high in 60.9% of cases. The mean MSPSS score was 57.9 [14-82]. Social support levels were considered "low" in 9 patients (10.9%), "moderate" in 45 patients (54.8%), and "high" in 28 patients (34.1%). The mean RSE score was 25.6 [14-38]. Self-esteem levels ranged from "low" to "very low" in 34 patients (41.4%). Fourteen patients (17.1%) had suspected anxiety, and 28 patients (34.1%) had definite anxiety. Eight patients (9.7%) had suspected depression, and 39 patients (47.5%) had definite depression. A significant correlation was found between MSPSS and RSE scores ($r = 0.4$; $p < 0.001$). The RSE score was inversely correlated with the HAD-anxiety score ($r = -0.8$; $p < 0.001$) and the HAD-depression score ($r = -0.8$; $p < 0.05$).
Conclusion:
Our results show that strong social support is associated with better self-esteem and a reduction in anxiety and depression.

P1271

FACIAL SKIN LESIONS: A PSYCHOLOGICAL BURDEN FOR LUPUS PATIENTS

R. Ben Tekaya[1], R. Grassa[1], N. Ben Chekaya[1], W. Tekaya[1], M. Jguirim[1], S. Zrour[1], I. Bejia[1]

[1]University Hospital Fattouma Bourguiba, Rheumatology Department, Monastir, Tunisia, Monastir, Tunisia

Background:
Self-esteem and body image are key components of quality of life. Facial lesions associated with lupus can affect these dimensions.
Objectives:
Our study aims to assess the impact of these lesions on the self-esteem of patients with lupus.
Methods:
This is a descriptive cross-sectional study involving patients with systemic lupus erythematosus (SLE) followed in a rheumatology department. The included patients completed the Rosenberg Self-Esteem Scale (RSE) questionnaire. All data were collected with patient consent and analyzed using SPSS statistical software.
Results:
Forty-five patients meeting the 2019 ACR/EULAR classification criteria for systemic lupus erythematosus were included. There were 7 men and 38 women, with a female-to-male ratio of 5.4. The median age was 46 ± 4.2 years [19-66 years], and the average disease duration was 8.6 ± 7.2 years. Thirty-two (71.1%) patients had cutaneous manifestations. Twenty-one patients (46.67%) had a butterfly-shaped facial erythema, 7 patients (15.56%) had erythematous lesions on the forearms, and 2 women had mouth ulcers. Raynaud's phenomenon was observed in 3 patients (6.67%). Renal involvement was seen in 2 patients (4.4%). The mean Rosenberg Self-Esteem Scale score was 25.1 ± 2.1, reflecting low self-esteem. The Rosenberg Self-Esteem score was negatively correlated with cutaneous involvement ($r = -0.27$; $p = 0.04$). Low self-esteem levels were more strongly associated with facial symptoms, and there was no correlation between the RSE and gender, age, or renal manifestations.
Conclusion:
Patients' perception of their facial involvement in systemic lupus erythematosus is poor and can be considered an important component of their self-esteem. Effective interventions should be implemented during follow-up to improve body image function and satisfaction.

P1272

SPONDYLOARTHRITIS: A BARRIER TO WORK?

R. Ben Tekaya[1], R. Grassa[1], N. Ben Chekaya[1], M. Jguirim[1], S. Zrour[1], I. Bejia[1]

[1]University Hospital Fattouma Bourguiba, Rheumatology Department, Monastir, Tunisia, Monastir, Tunisia

Background:
Spondyloarthritis (SPA) significantly affects the quality of life and work productivity of patients.
Objectives:
This study aims to quantify this loss of productivity.
Methods:
Patients in this cross-sectional study were recruited from a rheumatology department. Sociodemographic, clinical, paraclinical, and therapeutic data were collected. Each patient completed validated questionnaires: the Rosenberg Self-Esteem Scale (RSE), the Work Productivity and Activity Impairment (WPAI) questionnaire, the Workplace Activity Limitations Scale (WALS), consisting of 12 items (total score ranging from 0 to 48), and the Hospital Anxiety and Depression Scale (HAD) to assess anxiety and depression.
Results:

A total of 55 patients were included, of whom 37 (56.3%) were employed. The patients had axial radiographic SPA in 41.8% of cases, psoriatic arthritis in 41.8% of cases, and 16.3% had SPA associated with inflammatory bowel disease (IBD). The average disease activity scores for BASDAI and BASFI were 3.5 ± 1.2 and 3.9 ± 1.3, respectively. Twelve patients were on biologic treatment with anti-TNF agents. The WPAI showed that the average number of work hours missed due to SPA was 10.2 ± 8 hours, with an average absenteeism rate of 17.5 ± 1.9%. The overall impairment of health-related activities was 30 ± 4.4%. The average WALS score was 18 ± 2.7. A significant negative correlation was found between the WALS score and disease activity ($r = -0.35$; $p = 0.02$). The average depression score was 7.98 ± 3.5, and the average anxiety score was 10.21 ± 5 [0-20], with 34.5% showing no anxiety, 20% showing doubtful anxiety, and 45.4% having definite anxiety. A significant association was found between disease activity and the WALS score, with increased disease activity and worsening health status significantly associated with greater impairment of productivity and professional activity. Our study showed a significant association between impaired productivity and anxiety-depressive disorders in our patients ($r = 0.16$; $p = 0.02$).
Conclusion:
Our study suggests that patients with SPA tend to experience a decrease in their work productivity, which is closely associated with anxiety-depressive disorders and impaired quality of life.

P1273

IMPACT OF ILLNESS COGNITION ON THE WELL-BEING OF WOMEN WITH AUTOIMMUNE DISEASES

R. Ben Tekaya[1], N. Ben Chekaya[1], R. Grassa[1], M. Jguirim[1], S. Zrour[1], I. Bejia[1]

[1]University Hospital Fattouma Bourguiba, Rheumatology Department, Monastir, Tunisia, Monastir, Tunisia

Background:
Chronic inflammatory rheumatic diseases (CIRD) have a significant impact on quality of life. This study aims to explore how disease perception and self-esteem influence the well-being of women of reproductive age with CIRD.
Objectives:
The aim of this study is to explore how disease perception and self-esteem influence the well-being of women of reproductive age suffering from chronic inflammatory rheumatic diseases (CIRD).
Methods:
An observational, cross-sectional, and descriptive study was conducted with women of reproductive age (18-50 years) suffering from rheumatic diseases in a rheumatology department. Three questionnaires were used: The Illness Cognition Questionnaire (ICQ), a 18-item questionnaire assessing three dimensions—helplessness, acceptance, and perceived benefits, each with a scoring range of 6 to 24; the WHOQOL-Bref, a 26-item quality of life scale ranging from 26 to 130 (higher scores indicate better quality of life); and the Rosenberg Self-Esteem Scale (RSE), a 10-item scale with scores ranging from 10 to 40 (higher scores indicate better self-esteem).
Results:
A total of 92 women with CIRD were included, with a mean age of 39.7 ± 5.017 years. The patients were diagnosed with rheumatoid arthritis (45.6%), psoriatic arthritis (21.7%), axial spondyloarthritis (16.3%), and systemic lupus erythematosus (16.3%). The average ICQ score was 48.7 ± 7.36, with the acceptance dimension score averaging 25.9 ± 11.2. The mean WHOQOL score was 87.53 ± 16.21, and the RSE score was 24.5 ± 3.8. A significant correlation was found between the perceived benefits of the disease and quality of life ($p < 0.001$, $r = 0.7$) and self-esteem ($p < 0.001$, $r = 0.51$). Helplessness was significantly correlated with quality of life ($p = 0.001$, $r = -0.42$) and self-esteem ($p < 0.001$, $r = -0.73$). Disease acceptance was significantly correlated with quality of life ($p = 0.02$, $r = 0.59$) and self-esteem ($p = 0.01$, $r = 0.42$). A significant correlation was found between disease acceptance and the number of years of education ($p = 0.03$, $r = 0.21$).
Conclusion:
Our results show that positive disease perception and good self-esteem are associated with better quality of life in women with CIRD.

3D PRINTING FOR ASSESSING BONE STRENGTH AND RIGIDITY IN PUNCHING SPORTS: A FOCUS ON TOMOGRAPHIC INDICATORS

L. Intelangelo[1], J. Bazan[1], G. Cointry[2], R. Capozza[2]

[1]Unidad de Investigación Musculoesquelética, CUADI, Universidad del Gran Rosario, Santa Fe, Argentina, Rosario, Argentina, [2]Centro de Estudios de Metabolismo Fosfocálcico, CEMFoC, Universidad Nacional de Rosario, Rosario, Santa Fe, Argentina, Rosario, Argentina

Introduction and Hypothesis. Punching sports like Muay Thai (MT) demand high skeletal strength and resilience. This study hypothesizes that bone strength index (BSI) and cortical density (CtD) are significantly higher in MT practitioners compared to non-practitioners and correlate strongly with bone strength and rigidity as measured through 3D-printed models.
Methodology. Third metacarpals were scanned using XCT 2000 tomography in two groups: control (C) and MT practitioners. Based on these scans, 3D bone models were printed in PLA (0.2 mm nozzle) and tested in three-point bending (5 mm/min displacement rate) to determine fracture load (Wf), flexural strength (Rf), and modulus (Ef). Peripheral quantitative computed tomography (pQCT) was used to measure CtD, cortical area (CtA), cortical content (CtC), moment of inertia (MI), and BSI (CtD × MI).
Results. ANOVA revealed significant group differences in Wf, Ef, Rf, and BSI ($0.01 < p < 0.05$). Regression analysis showed BSI as the best predictor of Wf ($R^2 = 0.82$ for MT; 0.92 for C), while CtD was strongly associated with Rf ($R^2 = 0.83$ for MT; 0.93 for C), both with $p < 0.01$.
Interpretation. BSI reflects both density and structural distribution, making it a strong predictor of Wf. CtD emphasizes cortical bone quality, strongly predicting Rf due to its dependence on material properties.
Practical application. BSI and CtD are essential for monitoring bone health and optimizing training programs. Impact exercises enhance BSI, while resistance training increases CtD. 3D printing provides a non-invasive method to study bone adaptation. Future advancements, such as hydroxyapatite composites, could further enhance these applications.
Conclusions. BSI and CtD enable precise evaluations of bone strength and rigidity, guiding performance-enhancing and injury-prevention strategies in punching sports. The integration of 3D printing represents an innovative and practical approach to non-invasive bone health assessment.

MUSCLE OXYGENATION CHARACTERISTICS OF HEALTHY AND SARCOPENIC FRAIL ELDERLY PEOPLE

R. Dadeliene[1], J. Kilaite[2], I. E. Jamontaite[1], A. Mastaviciute[1], E. Pranckeviciene[3], V. Gineviciene[1], A. Urnikyté[1], I. Ahmetov[4], V. Alekna[1]

[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [2]Clinic of Internal Diseases and Family Medicine, Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [3]Faculty of Medicine, Vilnius University and Faculty of Informatics, Vytautas Magnus University, Kaunas, Vilnius, Lithuania, [4]Faculty of Medicine, Vilnius University and Liverpool John Moores University, Liverpool, United Kingdom, Vilnius, Lithuania

Objective. To investigate muscle oxygenation responses during rest, exercise and passive recovery in healthy and sarcopenic frail elderly people.
Material and Methods. A total of 61 subjects, aged 78.89±7.44 years old, participated in this study. Participants were divided into groups: group I (n=50) - healthy persons and group II - persons with sarcopenia and frailty (n=11). The age, height, body mass, and body mass index (BMI) were homogenous in both groups. Sarcopenia was defined according to the criteria of the European Working Group on Sarcopenia in Older People in 2018 (EWGSOP2). Frailty status was determined using Fried's criteria. A near-infrared spectroscopy (NIRS) monitor was placed on the Vastus Lateralis muscle (10 cm above the proximal border of the patella). After warming up, participants performed an aerobic standard physical load on an ergometer for 6 minutes, with an intensity of 60 W and a revolution of bicycle 60. The oxygenation level of exercising muscle saturation (oxygenated haemoglobin - SmO_2, %) was recorded after 5 min of resting time in a sitting position, at the end of 6 min of aerobic physical load and every minute of passive recovery (5 min.) Heart rate (HR) responses were assessed with a telemetric HR monitor.
Results. The study showed that SmO_2 during the resting time significantly differed between the two groups (77.88±16.6 and 35.09±7.43 %), as well as, SmO_2 differed at the end of the standard physical load (68.06±19.75 and 26.00±11.14 %) and after 5 min recovery (77.55±16.18 and 46.09±11.21 %) ($p< 0.001$). However, the decrease in SmO_2 at the end of the standard exercise was similar in both groups 9-10%. The current results show that during recovery, SmO2 in a group with sarcopenia and frailty reached an 11% higher level than SmO_2 was before exercise.
Conclusions. Persons with sarcopenia and frailty have significantly lower muscle oxygenation at rest and the end of standard physical exertion. It can provide valuable insights as internal predictors of muscle metabolic changes. However, this area requires further research.
This project has received funding from the Research Council of Lithuania (LMTLT), agreement No S-MIP-22-36.
Keywords: sarcopenic frail, elderly people, muscle oxigenation.

P1276

PERIOPERATIVE BONE OPTIMIZATION IN ARTHROPLASTY, ¿HOW ARE WE IN MÉXICO TWO YEARS OF COMMUNITY OUTREACH?

R. E. Lopez-Cervantes[1], J. M. Gomez-Acevedo[2], L. G. Padilla-Rojas[2], D. E. Garin-Zertuche[2], F. Torres-Naranjo[3], R. M. Figueroa-Pardo[2], C. A. Alvarez-Rengiffo[4]

[1]Hospital de Especialidades San Francisco de Asis de Guadalajara, ZAPOPAN, Mexico, [2]SMIOT (Mexican Society of Orthopedics and Trauma Research), ZAPOPAN, Mexico, [3]AMMOM (Mexican Association of Bone and Mineral Metabolism), GUADALAJARA, Mexico, [4]FEMECOT (Mexican Federation of Orthopedics and Trauma Colleges), GUADALAJARA, Mexico

Background
In recent years, evidence has emerged that osteoporosis is a risk factor for arthroplasty complications. However, this has not affected the perioperative osteoporosis treatment rate.
In other countries, such as México, the osteoporosis treatment rate before arthroplasty was about 4%. (3)
Materials and methods
A group of seven national societies (FEMECOT, AMMOM, ACOMM, SCCOT, SECOT, SEFRAOS, SEIOMM.) developed a joint statement position on the diagnosis of osteoporosis and perioperative bone optimization in candidates for arthroplasty: "Perioperative Bone Optimization in Arthroplasty" "POBO." After that, FEMECOT´s Osteoporosis Committee and AMMOM started a community outreach in regional and national meetings.
To assess the impact of the diffusion, the research group of SMIOT (Mexican Society of Orthopedics and Trauma Research) launched a 12-question online questionnaire about POBO. The questionnaire was distributed through the Official FEMECOT e-mail twice (October and November 2024), and the results were analyzed in December 2024.
Conclusions.
We gathered 120 surveys, encompassing orthopedic surgeons from 26 out of 32 states. Of these, 36% were high-volume surgeons, and 97% were orthopedic surgeons with more than 5 years of experience.
Of the respondents, 71% say they change their surgical criteria if they find bad bone quality. However, we found that only 53% of the surgeons do a POBO. In their protocols, 64% include more than 3 Bone loss-related factors, 78% include DXA, 27% 25OHD, 11% FRAX, 5% Bone turnover markers, and 6% X-ray measures. Of the ones that don't perform any POBO, 46.4% are because they don't have the infrastructure in their settings.
A good thing is that the respondents say that if they found Bad bone quality during surgery, 82% initiated POBO or sent the patient to the osteoporosis specialist. After diagnosing osteoporosis, 83% will start pharmacological treatment.
This type of outreach can dramatically increase the number of patients diagnosed and treated during the perioperative period.
We must also prepare the health system to make these protocols actionable in all settings.

EVIDENCE-BASED JOINT STATEMENT POSITION OF PERIOPERATIVE BONE OPTIMIZATION IN THE ARTHROPLASTY CANDIDATE, FROM 7 NATIONAL SOCIETIES

R. E. Lopez-Cervantes[1], F. Torres-Naranjo[2], I. Etxebarria-Foronda[3], C. Ojeda-Thies[4], F. Linares-Restrepo[5], M. A. González-Reyes[6], J. R. Caeiro-Rey[7], D. E. Garin-Zertuche[1]

[1]FEMECOT (Mexican Federation of Orthopedics and Trauma Colleges), GUADALAJARA, Mexico, [2]AMMOM (Mexican Association of Bone and Mineral Metabolism), GUADALAJARA, Mexico, [3]SEFRAOS (Spanish Society of Osteoporotic Fractures), Vitoria-Gasteiz, Spain, [4]Spanish Society of Orthopedic Surgery and Traumatology (SECOT), Madrid, Spain, [5]Colombian Society of Osteoporosis and Mineral Metabolism (ACOMM), Bogota, Colombia, [6]Colombian Society of Orthopedic Surgery and Trauma (SCCOT), Bogota, Colombia, [7]Spanish Society of Bone Research and Mineral Metabolism. (SEIOMM), Madrid, Spain

Background
The prevalence of arthroplasty is increasing. Nearly two thirds of patients undergoing elective arthroplasty procedures have low bone mineral density (LBMD), among those, only 32.8% were receiving treatment at the time of surgery. (1)
In recent years, evidence that defines osteoporosis as a risk factor for arthroplasty complications has emerged. However, it has not affected the perioperative osteoporosis treatment rate. (2)
Bone quality is underestimated and undertreated prior to elective arthroplasty.(3)
Materials and methods
A group of 7 national societies (FEMECOT, AMMOM, ACOMM, SCCOT, SECOT, SEFRAOS, SEIOMM.) developed a joint statement position on the diagnosis of osteoporosis and perioperative bone optimization in candidates for arthroplasty. "Arthroplasty Bone Optimization"
A scoping review of the available literature was performed, followed by a systematic review and meta-analysis. Subsequently, a Delphi Modified method was used to gather the different positions.
Results and recommendations

Recommendation 1: Patients scheduled for elective arthroplasty should undergo a bone health assessment (BHA).
Experts' concordance: 100%
This assessment should evaluate risk factors and clinical signs of osteoporosis and low bone quality. Additionally, a bone mineral density (BMD) DXA scan should be performed for those with one or more risk factors for osteoporosis, meeting ISCD or regional indications for DXA testing.
Recommendation 2: If poor bone quality is observed during surgery and a bone health assessment has not been conducted promptly, a complete BHA, including a DXA scan, is imperative.
Experts' concordance:71.4%
Recommendation 3 In the arthroplasty candidate, If LBMD or osteoporosis are noticed, bone loss related factors should be corrected, and appropriate treatment for osteoporosis should be started before or right after arthroplasty.
Experts' concordance: 90.5%
The use of Anti-resorptive and bone anabolic agents have been shown to reduce periprosthetic bone loss, complications and non-septic revision rates after joint arthroplasty
Recommendation 4: In arthroplasty candidates, the diagnosis of osteoporosis or low bone mineral density (LBMD) should not delay the surgery.
Position 5: Monitoring axial and periprosthetic bone mineral density through DXA protocols can help identify bone loss in central and periprosthetic areas in patients with risk factors or osteoporosis.
Experts' concordance: 83.3%
CONCLUSIONS
Perioperative bone optimization is an approach that should be considered in all patients who are candidates for arthroplasty. We encourage the orthopedic surgeon and multidisciplinary team to diagnose and treat the arthroplasty candidate's bone by screening for bone-loss-related factors, diagnosing osteoporosis, and starting treatment. Following these recommendations could lower PPBL, complications, and aseptic revision rates after arthroplasty.

Objective: To compare the efficacy, safety, pharmacodynamics (PD), pharmacokinetics (PK), and immunogenicity of Bmab-1000 (a biosimilar to denosumab) and denosumab (Deno) in women with postmenopausal osteoporosis (PMO).
Material and Methods: Overall, 479 women (mean age, 66.6 years) with osteoporosis [with lumbar spine (L1-L4) absolute bone mineral density (LS-BMD) and T-score ≤−2.5-≥−4.0] were randomized 1:1 to 60 mg of Bmab-1000 (n=238) or Deno (n=241) subcutaneously. Part 1 (week 0-52) was double-blind and active-controlled, comparing Bmab-1000 to Deno (two doses on day 1 and week 26). In Part 2 (week 52-78), patients initially on Bmab-1000 continued Bmab-1000 at week 52; n=218. Patients initially randomized to Deno (n=208) were re-randomized to Bmab-1000 or Deno at week 52 (n=104 each). Part 1 evaluated the therapeutic and PD equivalence between Bmab-1000 and Deno using %change from baseline (%CfB) in LS-BMD at week 52 and area under the effect curve (AUEC) of serum C-terminal telopeptide of Type 1 collagen (sCTX) from baseline to 26 weeks. Part 2 monitored the safety of Bmab-1000 and Deno after transition from Deno to Bmab-1000 versus continuing Deno. Secondary analyses included additional efficacy, PK, safety, and immunogenicity parameters.
Results: Equivalence was demonstrated for the primary efficacy endpoint. The confidence intervals (CIs) for the difference in least square means (LSMs) in %CfB in LS-BMD at week 52 between Bmab-1000 and Deno were contained within the predefined margins (±1.45; LSM diff: 0.610, 95% CI: -0.095, 1.316). The sCTX AUEC up to 26 weeks for Bmab-1000 was similar to that observed following a single dose of Deno (geometric LSM ratio: 104.14; 95% CI: 97.76, 110.95). The secondary efficacy, PD, PK, safety, and immunogenicity results were comparable among all groups up to Week 78, including after transitioning to Bmab-1000 from Deno.
Conclusion: Bmab-1000 demonstrated equivalent efficacy and PD to Deno in women with PMO with similar safety, tolerability, and immunogenicity profiles. There was no effect of transition from Deno to Bmab-1000.

P1279

BONE MINERAL DENSITY IN FEMALE PATIENTS WITH HIP FRACTURES AND INFLUENCE OF PREVIOUS FRACTURES

R. F. Filipov[1], D. Stojanović[2], K. M. Marković[1], I. D. Dimitrijević[1], T. A. Šušulović Arsić[1], I. J. V. Jovanović Vasović[1]

[1]Institute for Treatment and Rehabilitation Niška Banja, Niš, Niš, Serbia, [2]University Clinical Center Nis, Niš, Serbia

Introduction: Osteoporotic fractures are often low-energy and occur spontaneously or when falling from a height while standing or sitting. The most common osteoporotic fractures are fractures of the wrist, spinal vertebrae and hip.
The aim of the study is to examine the bone density (BMD) in female patients with a hip fracture that occurred spontaneously or when falling from a height while standing or sitting, and to determine the existence of the influence of previous fractures on bone density values.
Material and methods: The study included 94 menopausal patients who were rehabilitated at the "Niška Banja" Institute in the period from January 1, 2023. until 31.12.2024. after operative or conservative treatment of hip fracture. All patients were in menopause, and the average age was 75.05+6.23 years. The control group was represented by 83 women, also in menopause, without fractures, average age 72.28+5.37 years. In all subjects, BMD was measured (spine and hip) using the DXA method on the Hologic device.
Results: The average value of BMD on the lumbar spine in the examined group was 0.740+0.12g/cm2, T-score -2.7+0.86, and in the control group 0.824+0.25g/cm2, T-score -1.92+0.93. On the hip in the examined group, the average value was 0.580+0.13g/cm2, T-score -2.9+0.97, and in the control group 0.655+0.23g/cm2, T-score -2.1+0.94. A highly statistically significant difference was obtained between the absolute values of BMD both at the lumbar spine in the tested and control groups ($p<0.001$) and at the hip ($p<0.001$). The difference was statistically significant between the cross-sectional T-score values at the lumbar spine and hip in the test and control groups. In the examined group (n=94), 21 patients had a previous fracture, in 15 cases on the forearm (fractura radii loco typico), in 4 on the lower leg, and in 3 cases on the second femur. Comparing the mean values of BMD between the group with one fracture (n=73) and the group that had a previous fracture (n=21), we found that the BMD in the lumbar spine and hip was lower in the group with a previous fracture, and the statistical significance present only for hip BMD ($p<0.05$).
Conclusion: The obtained results confirm the influence of bone density on the occurrence of hip fractures, and along with bone density, previous fractures represent an important risk factor for future fractures.
Key words: osteoporotic fractures, bone density, female patients.

FACTORS INFLUENCING SF-12 HEALTH-RELATED QUALITY OF LIFE SCORES IN ADULTS WITH OSTEOARTHRITIS

R. Grassa[1], Y. Ben Slama[1], N. Ben Chekaya[1], R. Bouazra[1], M. Ghali[1], M. Bekey[1], M. Jguirim[1], S. Zrour[1], I. Bejia[1]

[1]Department of Rheumatology, Fattouma Bourguiba University Hospital, Monastir, Tunisia

Introduction :
Osteoarthritis (OA) is a degenerative joint disease that significantly impacts an individual's quality of life. As it progresses, these symptoms can limit a person's ability to perform daily tasks . The quality of life of patients with osteoarthritis is altered not only by the physical discomfort but also by the psychological and social consequences .
Objectives :
The aim of the study was to predict the associated factors to a poor quality of life in patients with knee osteoarthritis and Osteoarthritis of the hand .
Methods :
This was a cross-sectional study including patients followed in the Rheumatology department for osteoarthritis. We used the short form SF-12 questionnaire to assess the quality of life. The statistical analysis was done by SPSS software.
Results :
Our study included 72 patients: 77,8% women and 22,2% men with a mean age of 68 ± 8.79 years [50-91]. Most common comorbidities were hypertension(59,7%) , diabetes (33,3%) , cardiac disorders (23,6%) , osteoporosis (27,8%) and rheumatoid arthritis (13,9%). The average BMI was 35.17 ± 5,21 [26- 39]. knee osteoarthritis was isolated in 61,1% , and associated to Osteoarthritis of the hand in 38,9% . The average mental quality of life score was 46,97 ± 18,15. The average physical quality of life score was 48,12 ± 14,17. Both were below the average health status. A positive correlation was found between the assessment of a poor physical (PCS) quality of life and young age(p=0,02) , female sex (p=0,03) ,presence of deformities (p=0,03) , and an advanced stage of Kellgren and Lawrence (p=0,02). A poor mental quality of life (MCS) was associated to comorbidities such as hypertension (p=0,04) , rheumatoid arthritis (p=0,04) and the presence of heberden nodes (p=0,03). Both physical and mental quality of life were more altered in patients with Osteoarthritis .
Conclusion :
A comprehensive approach of osteoarthritis and the associated factors to a poor quality of life is the key to manage and enhance those affected by this chronic disease .

TYPES OF ATTITUDES TO ILLNESS IN PATIENTS WITH SYSTEMIC SCLEROSIS

R. Grekhov[1], A. Alexandrov[2], V. Aleksandrov[2]

[1]Zborovski' Research Institute for clinical and experimental rheumatology, Volgograd state medical University, Volgograd, Russia, [2]Zborovski' Research Institute for clinical and rheumatology, Volgograd State Medical University, Volgograd, Russia

Aims: To study the peculiarities of attitude to their disease formation in patients with systemic sclerosis (SS).
Materials and methods: 54 patients with SS were examined. The questionnaire "Type of attitude to the disease", created in the laboratory of clinical psychology of the V.M. Bekhterev Research Institute based on clinical and psychological typology of attitude to the disease, proposed by A.E. Lichko, was used.
Results: Table 1 shows the distribution of the basic attitude to the disease depending on the activity of the pathological process.
Table 1. Distribution of the basic attitude to the disease in SS patients depending on the degree of activity

Attitude to the disease types	I degree activity (n=12)	II degree activity (n=37)	III degree activity (n=5)
Harmonious (7,4%)	3,7%	3,7%	-
Ergopathic (37%)	9,2%	25,9%	1,85%
Anxious (33,3%)	7,1%	18,5%	7,4%
Hypochondriac (37%)	1,85%	27,75%	7,4%
Neurasthenic (18,5%)	3,7%	12,95%	1,85%
Melancholic (11,1%)	3,7%	5,5%	1,85%
Sensitive (46,2%)	9,25%	29,9%	7,4%
Egocentric (14,8%)	-	9,25%	5,5%

As our research has shown, the anxious, hypochondriac, and sensitive variants were determined more often in patients with SS with increasing severity of the condition. These types of attitudes to the disease determine the hypernosognostic reaction to the disease - the patient has an excessively bright emotional coloring of experiences related to the disease, while an underestimated model of the expected results of treatment is formed. Emotional and affective sphere of relations in such patients is manifested in maladaptive behavior: reactions like irritable weakness, anxious, depressed state, "withdrawal" into the disease, refusal to fight - "capitulation" to the disease, etc. Sensitive attitude to the disease is also manifested by maladaptive behavior of patients: they are embarrassed about their disease in front of others, "use" it to achieve certain goals, build paranoid concepts about the causes of their disease and its chronic course, show heterogeneous aggressive tendencies, blaming others for their illness.
Conclusion: Assessment of personal reactions to the disease, closely related to the quality of life and adherence to treatment is an important element of successful therapy of the patient with SS.

P1282

THE EFFICACY OF SARCOMEAL® ORAL SUPPLEMENTATION PLUS VITAMIN D3 ON MUSCLE1 PARAMETERS, METABOLIC FACTORS, AND QUALITY OF LIFE IN DIABETIC SARCOPENIA: A RANDOMIZED CONTROLLED CLINICAL TRIAL

R. Heshmat[1], R. Abdi Dezfouli[1], G. Shafiee[1], A. R. Heshmat[1], S. Maleki Birjandi[1], N. Zargar Balajam[1], M. P. Maleki Birjandi[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Abstract
Aim: To investigate the efficacy of Sarcomeal® sachet, as a protein supplement, plus vitamin D3 on muscle parameters, metabolic factors, and quality of life (SarQoL) in individuals with diabetes and sarcopenia.
Methods: Sixty individuals were randomized into the control or intervention group. The intervention group received a daily dose of one Sarcomeal sachet including; whey protein, creatine, glutamine, branched-chain amino acids (BCAAs), hydroxy-methyl-butyrate (HMB), and 1000 IU of vitamin D and both groups were recommended to consume protein-rich food, be educated about the disease, and perform physical activity for 12 weeks. Various assessments including muscle parameters, blood tests, and SarQoL were conducted at the beginning and the end of the trial.
Results: Over 12 weeks, although the intervention group had significant improvements in mean skeletal muscle mass index (SMI) (change: 0.17 [0.016, 0.329] kg/m²; p<0.05) and handgrip strength (change:1.33[0.256, 2.410] kg; p<0.05), differences between groups were not statistically significant. However, significant improvements were observed in lean mass (1.70 [0.749, 2.665] kg; P<0.01) and lean mass index (0.62[0.287, 0.954] kg/m²; P<0.01) between groups. Weight was maintained in the intervention arm, whereas the control arm experienced significant weight loss (1.87 [0.654, 3.109] kg; P<0.01). Participants in the intervention arm did not show significant changes in blood parameters. The mean difference of total SarQol scores between two groups reached statistical significance [mean difference: 13.04 (2.73-23.34); P < 0.05]. There were the significant means difference the activities of daily living (ADL) domain and body composition domain of SarQoL.
Conclusion: The Sarcomeal supplement significantly improved lean muscle mass, preserved physical function, and helped maintain weight, supporting its potential as a strategy to counter muscle loss and enhance the QoL in diabetic sarcopenia patients.

IRAN SARCOPENIA REGISTRY: PROTOCOL FOR A NATIONWIDE REGISTRY FOR ENHANCED RESEARCH AND MANAGEMENT

R. Heshmat[1], G. Shafiee[1], R. Abdi Dezfouli[1], N. Zargar Balajam[1], H. R. Aghaei Meybodi[2]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Evidence Based Medicine Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Abstract

Background: Sarcopenia has emerged as a pressing issue in the context of global aging trends, due to its profound impact on physical function, quality of life, and healthcare systems. The establishment of national registries dedicated to sarcopenia, such as the Iran Sarcopenia Registry (ISR), is a pivotal step for systematically addressing this growing health challenge through enhanced research and informed decision-making.

Methods: ISR is a prospective cohort study, overseen by Tehran University of Medical Sciences, designed to sequentially enroll individuals diagnosed with sarcopenia across Iran while ensuring uniformity in data collection. The registry adopts a non-interventional approach, allowing patients to receive standard care without interference from the registry team. The target population comprises individuals diagnosed with sarcopenia, identified based on diagnostic criteria with cutoff values specifically tailored to the Iranian population. Comprehensive measurements such as demographic data, sarcopenia-specific assessments (e.g., muscle mass, muscle strength, and physical performance), medical history, and lifestyle factors will be recorded. A range of validated tools are employed to assess physical activity, nutritional status, and quality of life. Blood tests alongside anthropometric and functional assessments will also be documented.

Conclusion: Through its comprehensive data collection, ISR aims to enhance understanding of the risk factors and clinical outcomes associated with sarcopenia among Iranian adults. By facilitating integrated data collection, the ISR seeks to support the development of evidence-based decisions and policies to improve the health and quality of life of older adults.

SUBSEQUENT FRACTURE AND MORTALITY AFTER PROXIMAL HUMERUS OSTEOPOROTIC FRACTURE IN PATIENTS INCLUDED INTO A FLS IN SPAIN

R. Izquierdo-Aviño[1], D. Garcia-Aguilera[2], J. V. Badiola- Vargas[2]

[1]Hospital Nuestra Señora de Gracia, Zaragoza, Spain, [2]Hospital Royo Villanova., Zaragoza, Spain

Objective

Fragility fractures increase morbidity and mortality and are an important risk factor for a future fracture. Much attention has been paid to hip and vertebral fractures due to the high impact on subsequent fracture, morbidity and mortality associated to them, as well economic burden. In contrast, few data have been shown for proximal humerus fractures (PHF) despite being the third most commonly observed FF in elderly patients and the second most common upper extremity fractures. The purpose of this study was to investigate the incidence of subsequent fracture and mortality following a proximal humerus fracture.

Material and Methods

This is a prospective study of patients aged 50 years or older who sustained a low energy proximal humerus fracture and were included in a FLS between January 2017 and December 2023). Standard follow-up of 2 years was carried out by consultation at 6 months, 1 year and 2 years after inclusion. Uni and multivariate models were used to evaluate potential risk factors for re-fracture and mortality. Data obtained included patient demographics, previous fractures and falls, comorbidities, fracture risk assessment by FRAX® tool, history of previous anti-osteoporotic treatment, estimated daily calcium intake and vitamin D blood levels.

Results

A total of 372 patients with PHF were available for analysis. Mean age was 81.4 years old, 81.8% females and 18.2% males. A total of 49 subsequent fractures were recorded (6-year cumulative incidence of 6.61%). Re-fractured patients were women in 95.9% of cases, with a mean age of 80.2 years. Subsequent fractures were located in the wrist (26,5%), hip (20,4%), proximal humerus (18,3%), vertebra (14,3%), pelvis (6,1%) and other skeletal sites (14,3%). Cumulative mortality during the 6-year period was 4,91%. Anti-osteoporotic drugs were initiated in 301 patients (80.9%) and 311 patients (83.6%) received calcium/vitamin D supplements. Several variables were evaluated to identify potential risk factors for subsequent fracture and mortality in these patients.

Conclusions

Inclusion of patients with proximal humeral fractures into an FLS increases the percentage of patients initiating anti-osteoporotic drugs after fracture. Re-fracture was more common in women aged >80 years, and wrist was the most common skeletal site of re-fracture. A significant reduction in the incidence of subsequent fractures and mortality has been observed when patients are included into a secondary fracture prevention programme.

P1286

THE SYSTEMIC INFLAMMATION RESPONSE INDEX (SIRI) IS INDEPENDENTLY ASSOCIATED WITH INCIDENT FRACTURE RISK IN OLDER SWEDISH WOMEN

R. Jaiswal[1], M. Zoulakis[1], K. F. Axelsson[1], H. Litsne[1], L. Johansson[1], M. Lorentzon[1]

[1]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Objectives
This study aimed to explore the association between fracture risk in the elderly and the systemic inflammation response index (SIRI), linked to various health outcomes including osteoporosis.
Material and Methods
In a Swedish cohort of 2965 women aged 75-80 years, baseline examinations included blood analyses, DXA, HR-pQCT, physical function tests, and questionnaires. The participants were followed prospectively regarding incident fractures and death. The SIRI was defined as blood counts of neutrophils x monocytes/lymphocytes.
Results
The median follow-up time was 8 years, and 230 hip fractures, 790 major osteoporotic fractures (MOF), and 1059 any type of fracture occurred. Higher levels of SIRI were linked to increased risks of hip fractures (HR per 1 SD increase 1.18, 95% CI [1.07-1.32], p=0.002), major osteoporotic fractures (MOF; 1.10 [1.03-1.18], p=0.003), and any fractures 1.11 [1.05 to 1.17], p<0.001) independent of age, BMI, clinical risk factors (CRFs), and femoral neck BMD. SIRI was related to poorer physical function and activity levels and higher prevalent fall rates. SIRI showed limited associations with bone parameters measured by DXA and HR-pQCT. Higher levels of SIRI were associated with a more favorable trabecular structure and density but increased cortical porosity.
Conclusion
We conclude that SIRI is positively and independently associated with incident fracture risk, highlighting the potential of evaluating SIRI as a tool in fracture risk prediction.

SIRI and physical function, DXA, and HR-pQCT.

	Q1 (n=592)	Q5 (n=599)	p
TUG (s)[y]	8.2 (3.0)[a]	9.7 (4.1)[a]	<0.001
PASE[z]	115.4 (53.4)[a]	90.0 (49.2)[a]	<0.001
Fall (≥1 last 12 months, n [%])	153 (25.8)[a]	203 (33.9)[a]	0.006
FN BMD (T-score)	-1.59 (0.88)	-1.68 (0.92)	0.468
Lumbar BMD (T-score)	-1.05 (1.54)	-0.88 (1.58)	0.168
HR-pQCT:	n=488	n=457	
Trabecular vBMD (mg/cm^3)	118.7 (37.8)	124.1 (42.7)	0.004

P1287

EFFECT OF DUAL TASK TRAINING VERSUS ANALOGY TRAINING ON GAIT SPEED AND BALANCE IN OLDER ADULTS – RANDOMIZED CONTROLLED TRIAL

R. Joshi[1]

[1]Dr D Y Patil College of Physiotherapy, Pune, India

Background: Walking performance is commonly affected due to decline in cognitive and motor functions, in elderly, which result in reduced speed, longer strides, and more variability in stride length. Enhancing gait can benefit from cognitive methods including attentional tactics, self-instruction strategies, or the use of external signals.
Objectives: This study intends to find out the effect of dual training, analogy training on gait speed and balance in older adults.
Methods: This three arm parallel, single blinded randomised control trial was conducted, 116 participants screened out of which 69 individuals (age 60 -75 years) allocated into 3 groups with the allocation ratio of (1:1:1), Group A Dual task training, Group B Analogy training, Group C control group. Exercise sessions were 45 mins for 3 days per week for 4 weeks. For assessment Time up and go test, Modified fall efficacy scale, Activity specific balance confidence scale, Tinetti's Performance oriented mobility assessment scale taken pre and post.
Results: To find out difference between the groups, Mann Whitney U test was performed and within the group analysis was done by Wilcoxon sign rank test. Time up and go test shows significant improvement in group A (P=0.02). 10-meter walk test shows significant improvement in preferred walking speed, maximum walking speed and activity confidence in Group B (P=0.0001) .
Conclusion: This study concludes that analogy training was superior to dual task training and control group and can be administered as an effective mode of gait rehabilitation to improve gait speed and balance in elderly.
Clinical implications: Analogy training and dual task training can be used as gait rehabilitation in older adults.
Keywords: Analogy training, dual task training, gait rehabilitation, geriatric, walking speed and balance.

P1288

TARGETING OSTEOCLASTOGENIC TH9 CELLS : A NOVEL APPROACH TO COMBAT INFLAMMATORY BONE LOSS IN POSTMENOPAUSAL OSTEOPOROSIS

R. K. Srivastava[1], L. Sapra[1]

[1]All India Institute of Medical Sciences (AIIMS), New Delhi, India

Recent research has uncovered a significant role for IL-9-producing Th9 cells in various inflammatory diseases. However, little is known about how Th9 cells contribute to the etiology of inflammatory bone-loss in post-menopausal osteoporosis (PMO). Our study delves into the impact of Th9 cells on postmenopausal osteoporosis (PMO). We observed that IL-9 has a pathological impact on inflammatory bone-loss in ovariectomized (Ovx) mice. Our in-vivo data revealed that estrogen deprivation triggered a pro-inflammatory cascade, upregulating IL-9 and IL-17, culminating in significant bone loss in Ovx mice. Both our ex-vivo and in-vivo studies corroborated these findings in Ovx mice, as estrogen attenuates IL-9's effect on the differentiation of Th17-cells as well as the potential of Th9-cells to produce IL-9. Mechanistically, Th9-cells in an IL-9-dependent manner enhance osteoclastogenesis and thereby establish themselves as a novel and independent osteoclastogenic Th-subset. Blocking IL-9 improves bone-health in Ovx-mice by inhibiting the differentiation and function of both osteoclasts and Th9/Th17-cells. Our clinical findings further attested to the osteoporotic role of Th9-cells in post-menopausal osteoporotic human subjects. Collectively, our data establish IL-9-producing Th cells as a pivotal regulator of bone loss in post-menopausal osteoporosis, highlighting the therapeutic potential of targeting the IL-9/Th9 axis for the management of this condition.

P1289

CHANGES OF TOTAL AND FREE TESTOSTERONE BLOOD LEVELS DUE TO AN 18 MONTHS HIGH INTENSITY RESISTANCE EXERCISE TRAINING IN OSTEOSARCOPENIC SENIORS

R. Kob[1], S. Stengel[2], C. C. Sieber[1], W. Kemmler[2], T. Bertsch[3]

[1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Nuremberg, Germany, [2]Institute of Radiology, University-Hospital Erlangen, Germany, Erlangen, Germany, [3]Institute for Clinical Chemistry, Laboratory Medicine and Transfusion Medicine, Nuremberg General Hospital & Paracelsus Medical University, Nuremberg, Germany

Objective(s): Testosterone is an anabolic hormone that may counteract the age-related decline in muscle mass and function. It has been already shown that testosterone blood levels are directly increased by both high- and moderate-intensity exercise. However, it remains unclear whether these short-term elevations lead to an overall increase in basal testosterone levels after prolonged excercise.
Material and Methods: This is an exploratory analysis of data of the Randomized Controlled Franconian Osteopenia and Sarcopenia Trial (FrOST) in which community-dwelling men over 70 years of age with a skeletal muscle index (SMI) ≤ 7.26 kg/m^2 and a bone mineral density T-Score ≤ -1 SD at the lumbar spine or the proximal femur as measured by dual-energy X-Ray absorptiometry (DXA) were included. These osteosarcopenic men were randomly allocated to a consistently supervised high-intensity resistance exercise training (HIT-RT) (n = 21) or an inactive control group (CG, n = 22). HIT-RT scheduled a single set protocol with high-intensity twice a week for 18 months. Both groups received Vit-D (800 IE/d), calcium (1,0 mg/d) and whey-protein (CG: 1.2 vs. HIT-RT: 1.5–1.7 g/kg/d) as supplements. Blood was drawn after an overnight fast total testosterone and sex hormone-binding globulin (SHBG) were measured and free testosterone was calculated.
Results: 29 men (age 79.7 ± 4.7 years) could be included in this analysis. HIT-RT (n = 15) and CG (n = 14) exhibited no significant differences for all analyzed parameters at baseline (all $p > 0.05$). After 18 months of intervention leg extensor strength, handgrip strength as well as SMI improved significantly in the HIT-RT compared to the CG (all $p < 0.01$). This gain in muscle mass and strength was not accompanied by higher levels of total and free testosterone or changes of SHBG (all $p > 0.05$).
Conclusion(s): Even though long-term HIT-RT improved muscle mass as well as strength it did not change basal levels of SHBG as well as total and free testosterone.

P1290

IMPROVEMENTS IN BMD FOLLOWING TREATMENT WITH ROMOSOZUMAB FOR PEOPLE AT HIGH FRACTURE RISK; REAL WORLD OUTCOMES FROM NHS GREATER GLASGOW & CLYDE

S. Win[1], P. J. Connelly[2], M. R. Talla[3], R. Livingstone[3]

[1]Department of Chemical Pathology, Queen Elizabeth University Hospital, Glasgow, United Kingdom, [2]Department of Endocrinology & Mineral Metabsolism, Queen Elizabeth University Hospital, Glasgow, United Kingdom, [3]Department of Endocrinology & Mineral Metabolism, Queen Elizabeth University Hospital, Glasgow, United Kingdom

Introduction
Romosozumab is a monoclonal antibody that binds and inhibits sclerostin resulting in increased bone formation and fracture risk reduction in patients with osteoporosis. The FRAME study demonstrated a reduction in vertebral fracture (VF) by 70% and improvements in lumbar and hip BMD by 13% and 7% respectively (1).
Methods
The aim of this study was to identify patients within NHS Greater Glasgow & Clyde (GGC) treated with Romosozumab and assess BMD, adverse events and fracture occurrence. Data was collected retrospectively from electronic health records and DXA between September 2022 and September 2024.
Results

Within NHS GGC, 109 patients were commenced on Romosozumab and 58 patients completed 12 months of treatment.
The mean age was 68.3 years (SD 7.4) and there was no history of CV disease. Lipids and BP were assessed in 85.3% and 61.5% respectively, and 48.6% had CV risk assessment using ASSIGN or QRISK3. Fracture history includes 80% with VF (n=87) and 54.1% (n=59) had long bone fractures. Additionally, 94.8% of participants had experienced a fracture in the preceding 24 months. Treatment-naïve patients accounted for 29.3% of the cohort.
Pre-treatment DXA demonstrated mean t-score at lumbar spine (LS), femoral neck (FN) and total hip (TH) of -3.44 (SD 1.0), -2.68 (SD 0.9) and -2.68 (SD 0.9) respectively, whilst mean BMD was 0.76 (0.133), 0.66 (0.107) and 0.68 (0.111) g/cm^2 respectively. Following 12 months of treatment, BMD improved at the LS, FN and TH to 0.85 ($p<0.001$), 0.67 ($p=0.004$) and 0.67 g/cm^2 ($p<0.001$) with t-scores of -2.66, -2.50 and -2.48 respectively ($p<0.001$). This represents an improvement in BMD of 12.73%, 3.83% and 4.04% respectively on post-treatment DXA in 57 patients.
Eight patients reported side effects (7.3%) including injection site discomfort, bone pain and headache. There were no CV events. Eleven patients sustained a fracture during treatment; six VF and five long bone fractures.

Conclusion

The results of this real world retrospective data collection demonstrate that Romosozumab is a well-tolerated and effective treatment for the management of osteoporosis and increased fracture risk. The improvements in BMD in our cohort are in keeping with those in the FRAME study.

A CASE OF FEMORAL HEAD AVASCULAR NECROSIS

R. M. Runcheva[1], M. B. Markoski[2], K. A. Karpicharova[3]

[1]Private orthopedic practice Ortomedik, Shtip, Republic of North Macedonia, [2]Private orthopedic practice Ortomed, Kumanovo, Republic of North Macedonia, [3]PHO Clinical Hospital - Shtip, Shtip, Republic of North Macedonia

Objective:Avascular necrosis (AVN) of the femoral head represents a pathological process characterized by the interruption of blood supply to the bone. Although the pathophysiology of hip AVN remains inadequately understood, it constitutes the final common pathway of both traumatic and non-traumatic factors that compromise the delicate circulation of the femoral head. Ischemia in the femoral head results in the necrosis of marrow and osteocytes, often culminating in the structural collapse of the necrotic segment. The condition was first documented by Munro in 1738. Initially asymptomatic, AVN eventually presents with pain and restricted motion, typically localized to the groin but potentially affecting the ipsilateral buttock, knee, or greater trochanteric region. Magnetic resonance imaging (MRI) is the diagnostic modality of choice for patients presenting with suggestive symptoms of AVN when radiographs appear normal.
Methods: A 60-year-old female patient, with a history of smoking, presented with a 3-4 month history of right hip pain. Notably, she reported a fall one year prior to the onset of pain, experiencing hip pain for several months thereafter, which eventually resolved. Despite administration of anti-inflammatory and anti-edematous therapies for the current episode, her pain persisted. Initial investigations, including comprehensive laboratory tests and plain radiographs of the lumbar spine and pelvis, led to a preliminary diagnosis of incipient coxarthrosis and lumbar disc herniation. Physical therapy was initiated; however, the patient's pain intensified, particularly during movement. Six weeks post-symptom onset, an MRI of the pelvis was performed, confirming a diagnosis of AVN. A dual-energy X-ray absorptiometry (DXA) scan indicated osteopenia.
Results: Following adherence to the preoperative protocol, the patient underwent surgical intervention involving the implantation of a total uncemented hip prosthesis on the right side, approximately three months after symptom onset. The operative and early postoperative courses were uneventful, succeeded by a regimen of physical therapy and balneotherapy.
Conclusion: Total hip arthroplasty remains a highly effective intervention for osteonecrosis of the femoral head in younger patients (aged 50 years or less), demonstrating favorable mid-term outcomes. In active young patients, survival rates of prostheses are reported to be 100% at 7-10 years postoperatively when utilizing ceramic-on-ceramic or highly cross-linked polyethylene bearing surfaces. Nevertheless, further research is warranted to ascertain long-term outcomes. Moreover, the presence of a hematological disorder, such as sickle cell disease, may elevate the incidence of complications and adversely affect implant survival rates.

ASSOCIATION OF DURATION AND CUMULATIVE DOSE OF GLUCOCORTICOIDS WITH RHEUMATIC CACHEXIA

K. Ostrovskyy[1], R. Mnevets[2], S. Kulanthaivel[3], I. Ostrovska[4]

[1]Pharmaceutical Product Development, Warsaw, Poland, [2]ESC Institute of Biology and Medicine of Taras Shevchenko National University of Kyiv, Kyiv, Ukraine, [3]Naarayani Multispeciality Hospital, Erode, India, [4]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine

Objective: To determine the association between glucocorticoid (GC) therapy and rheumatic cachexia (RC).
Methods: The study involved 110 patients with rheumatoid arthritis (RA) (102 women and 8 men). The diagnosis of RA was verified based on the ACR/EULAR criteria. The average age of patients was 54.4±12.6 years (hereinafter M±SD). The composite body composition of patients was determined using dual-energy X-ray absorptiometry with the Total Body program on a LUNAR DPX GE device. The diagnosis of RC was made with a lean mass index (LMI) below the 10th percentile and a fat mass index above the 25th for a given age. Reference values were determined according to the work of Coin et al., where these values were obtained in the Italian population. Statistical analysis was performed using the STATISTICA 12.0 software package.
Results: 25 patients (22.7%) with an average age of 52.2±8.14 years met the RK criteria. No statistically significant correlation was found between age and GC intake at the time of the study (p=0.412) and in the anamnesis (p=0.203). 88 patients had a history of GC use, including 20 with GC and a median cumulative GC dose of 8.5 g [6.2-17.5 g] and 68 without GC and a cumulative glucocorticoid (GC) dose of 5.8 g [3.6-13.7 g] (Z=-1.98; p=0.047]. 77 patients continued daily GC use, including 16 with GC and a median daily GC dose of 5 mg [4-8 mg] (hereinafter Me [Q1-Q3]), and 61 without GC and a GC dose of 8 mg [5-10 mg] (Z=2.58; p=0.01). The incidence of GC did not differ between patients with and without osteoporosis (32.1% vs. 24.6%, $\chi 2$=0.77, p=0.38).
Conclusion: RC was detected in 22.7% of patients with RA using dual-energy X-ray absorptiometry. The presence of RC was associated with an increase in the cumulative dose of GC. However, among patients who continued taking GC at the time of the study, RC was more common if the dose of the drugs was lower. At present, the only generally accepted method for increasing the volume of LMI and, as a result, combating RC is physical exercise. At the same time, it is also important to evaluate the total duration and volume of GC therapy, which can contribute to the development of RC.

P1296

WILTROM TRIPOD-FIX IMPLANTABLE TITANIUM VERTEBRAL AUGMENTATION DEVICE A NEW DEVICE IN THE TREATMENT OF OSTEOPOROTIC COMPRESSION FRACTURES FIRST RESULTS OF A SINGLE ARMED PROSPECTIVE STUDY

R. Pflugmacher[1], C. L. Lin[2], O. Soliman[1], V. Strauss[1], R. Bornemann[3]

[1]Kreiskrankenhaus Mechernich, Klinik für Wirbelsäulenchirurgie, Mechernich, Germany, [2]National Cheng Kung University Hospital, Department of Orthopedics, Tainan City, Taiwan, [3]Universitätsklinikum Bonn, Klinik und Poliklinik für Orthopädie und Unfallchirurgie, Bonn, Germany

Introduction
Balloon Kyphoplasty (BKP) is a commonly performed vertebral augmentation procedure for painful osteoporotic vertebral compression fractures (OVCFs). This study aimed to support the use of a new titanium implantable vertebral augmentation device (Tripod-Fix Vertebral Body Augmentation System).

Materials and Methods
Prospective, single armed, controlled study. Patients were required to meet the following eligibility criteria: one painful OVC F located between T5 and L5, failed conservative treatment, an Oswestry Disability Index (ODI) score ≥30/100 and a VAS score ≥60/100. Anterior vertebral body height, midline vertebral body height, and Cobb angle were measured preoperatively and postoperatively and at 3 and 6 months. Adjacent and subsequent fractures and safety parameters were recorded throughout the study. Cement extravasation was evaluated on X-rays.

Results
Among the 41 patients (31 female, 10 male, mean age 71.2±11.5 years) who underwent surgery. 28 patients completed the 6-month follow-up period. 1 patient developed an adjacent vertebral compression fracture.
The analysis of the primary endpoint showed a significant improvement in VAS and ODI scores.
Prior to treatment, the mean VAS was 85 mm compared to 15 mm immediately after the procedure, and 10 mm after 6 months. Significant Improvements in the Oswestry scores were registered after 6 months. The middle part of the vertebral bodies was increased by an average of 2.8 mm. The average kyphosis angle was improved.
No patient required surgical reintervention or retreatment at the treated level. No symptomatic cement leakage was reported. One adjacent fracture was documented and treated with Kyphoplasty.

Conclusion
The study results demonstrated an excellent risk/benefit profile for patients treated with the Tripod-Fix for up to 6 months.

CZECH NATIONAL POPULATION-BASED PROGRAM FOR EARLY DETECTION OF OSTEOPOROSIS: RESULTS AFTER 20 MONTHS

R. Pikner[1], V. Palicka[2], V. Dvorak[3], P. Sonka[4], J. Bodnar[5], H. Sajdlova[5], D. Kostka[6], Z. Salcman-Kucerova[6], A. Oriskova[5], S. Strolena[6], P. Nemec[7], K. Hejduk[7]

[1]Czech Society for Metabolic Bone Diseases, Prague, Czechia, [2]Czech Society for Metabolic Bone Diseases, Prague, Czechia, [3]Czech Gynaecological nad Obstetrics Society, Prague, Czechia, [4]General Practitioners Associantion of the Czech Republic, Prague, Czechia, [5]General Heallth Insurance Company of the Czech Republic, Prague, Czechia, [6]Ministry of the Interior Public Health Insurance Fund, Prague, Czechia, [7]Institute of Health Information and Statistics of the Czech Republic, Prague, Czechia

Objective: International Osteoporosis Foundation published SCOPE 2021, that comprised a compendium of information available on the burden of osteoporosis and healthcare provision and uptake in the EU 27+2. The Czech Republic SCOPE scores resulted in a 6th place regarding disease burden and 26th place in combined healthcare provision. The Czech Republic belongs to the group of eight high-burden low-provision countries. Low number of DXA units and fact that osteoporosis is not primarily managed in primary care were both identified as main causes of overall low-provision. Therefore, major professional societies together with major health care payers have prepared and launched the Czech National Population-based Program for Early Detection of Osteoporosis since April 2023.We present data from the first 20 months of the program.

Methods: National algorithm for DXA indication and monitoring has been proposed. DXA units 20 per million, 1-2 per district was set as target. GP´s and gynaecologists were allowed to perform DXA scans based on mandatory training and have got access to anti-osteoporosis medication. Patients at risk indicated for DXA assessment are women aged 60 and men aged 70 and over. Furthermore, postmenopausal women up to age 59 and men aged 65-69, if their FRAX exceeds the lower assessment threshold. Specific codes determining BMD T-score ranges are used.

Results: January 2023 were 118 DXA units in Czechia, in 42 of 76 districts (56%), in January 2025 were approved 216 DXA units (183% increase) in 73 districts (96%), 19.85 DXA units per million. Within the period from April 2023 to December 2024 DXA was carried out in 167 022 women (92%), 86 % older 60 years and in 15 539 men (8%), 89.6% older 70 years. We identified 21.2% women and 11.7% men with T-score below -2.5.

Conclusion: the program improved availability of diagnostic care and provide population data. The program is a powerful systematic tool for the diagnosis and treatment of osteoporosis in Czechia.

P1298

AN ARTIFICIAL INTELLIGENCE ALGORITHM TO IMPROVE DIAGNOSIS OF VERTEBRAL FRACTURES EMBEDDED IN FRACTURE LIAISON SERVICES CAN REDUCE FRACTURES AND REDUCE COSTS

R. Pinedo-Villanueva[1], G. Fabiano[1], F. Clemeno[1], M. K. Javaid[1]

[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Objective

To estimate the patient benefit and economic impact of integrating an artificial intelligence (AI)-enabled vertebral fracture (VF) identification algorithm into optimally-run FLSs.

Material and Methods

The Nanox-AI HealthVCF algorithm was implemented into the radiology workstream of three UK NHS hospitals. The AI analysed existing CT scans and flagged those with potential moderate/severe fractures for local clinical confirmation. Patients with confirmed scans were referred to the local FLS for further assessment and management. Using a microsimulation model[1], the impact of the AI on patient outcomes and health and social care costs was estimated for 1,000 male and 1,000 female patients with confirmed VF over five years. We used observed FLS performance metrics before and after AI implementation from the FLS-Database of England and Wales and expert opinion from FLS leads to populate the model comparing results under pre-AI observed FLS to AI optimised-FLS settings.

Results

Subsequent hip, spine or other major osteoporotic fractures were 6.8% and 4.4% lower under the AI + optimised FLS setting for female and male simulated patients, leading to 44 and 59 quality-adjusted life years gained, respectively. Less subsequent fractures led to lower health and social care resource use: AI + optimised FLS would save 378 bed days per 1,000 female patients and 206 per 1,000 male patients, with reduced need for long-term institutional care after a fracture by 17 and 12 fewer years of long-term institutional care, respectively. FLS costs including medication would be higher under the AI + optimised FLS but these would be offset, partially for males and entirely for females, by savings in health and social care leading to extra costs of £62 per male patient and savings of £117 per female patient over the five years. The difference was driven by higher risk of hip after VF for women compared to men.

Conclusion

While VF are common and put patients at high imminent fracture risk, FLSs have struggled to identify this subgroup. Despite differences in age and higher mortality, adding AI to flag potential vertebral fractures can lead to substantial reductions in subsequent fractures and in health and social care costs. These findings support the widespread integration of AI into FLSs as both clinically and cost-effective.

DISTINCT CLUSTERS OF CARERS WITH X-LINKED HYPOPHOSPHATAEMIA BASED ON THEIR QUALITY OF LIFE

N. Njuki[1], M. Sanchez-Santos[1], M. K. Javaid[1], R. Pinedo-Villanueva[1]

[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Objective
To investigate whether distinct clusters of people with X-linked hypophosphataemia (XLH) who are also carers of relatives with the same disease can be identified based on their quality of life.

Material and Methods
Patient-level data were obtained from the RUDY Study in the UK. Study participants with XLH who self-declared being carers of relatives with XLH completed the Caregiver oncology quality of life questionnaire (CarGOQol), composed of 29 items grouped into 10 dimensions: Psychological well-being, Burden, Relationship with health care, Administration and finances, Coping, Physical well-being, Self-esteem, Leisure time, Social support, and Private life. Each item was assessed on a 5-point Likert Scale, with (unweighted) scores calculated for each domain and in total (min 0, max 100), and higher scores indicating better quality of life.
Dissimilarity matrix calculated using Gower's distance was used to identify quality of life clusters of people with XLH. Agglomerative and divisive clustering were explored and dendrograms used to visually assess results. Final decision on number of clusters was made based on the elbow and silhouette methods.

Results
Of 59 adult XLH participants in the dataset, 13 reported being caregivers of a relative with the disease. They were mostly women aged around 40, nearly half of British or Northern Irish ethnicity, from most regions of the UK, and less deprived than the general population. Nearly half of caregivers looked after an adult and the other half after child, with the great majority being caregivers for 1 or 2 people.
Two distinct clusters were identified using divisive clustering, with Cluster 1 grouping six carers and Cluster 2 seven. Cluster 1 participants reported higher mean scores than those in Cluster 2 (Figure 1) in all but three domains (Relationship with health care, Self-esteem, and Social support) and in overall quality of life (68.0 vs. 43.2).

Conclusion
The study confirms a significant and variable impact of caring on the quality of life of people with XLH who look after relatives with the disease. Further work is needed to understand the determinants of carer burden and the need to personalise carer support in the XLH setting.

BRIDGING THE BONE HEALTH GAP: INSIGHTS FROM THE NSHF SPINE & BONE HEALTH TASK FORCE SURVEY

D. Obiri-Yeboah[1], M. Martini[1], L. Orosz[2], D. Lee[2], R. Roy[2], P. Anderson[3], J. Dimar[4], B. Carlson[5], V. Nemani[6], Z. Sardar[7], G. Shankar[8], B. Elder[1]

[1]Mayo Clinic, Rochester, MN, United States, [2]National Spine Health Foundation, Reston, VA, United States, [3]University of Wisconsin, Madison, WI, United States, [4]University of Louisville School of Medicine and Norton Children's Hospital, Louisville, KY, United States, [5]University of Kansas Medical Center, Kansas City, KS, United States, [6]Virginia Mason Franciscan Health, Seattle, WA, United States, [7]Columbia Orthopaedics, New York, NY, United States, [8]Massachusetts General Hospital, Boston, MA, United States

Introduction Bone health is a key determinant of spine surgery outcomes, influencing complication rates and recovery. Despite its importance, pre-operative bone health evaluation is often overlooked, and public awareness remains inconsistent. This study aimed to assess public knowledge and practices related to bone health using data from a diverse survey population.

Methods A public cross-sectional survey gathered responses from 1,440 participants via a 10-question quiz on bone health. Results were assigned letter grades (A: 90-100%,B: 80-89%,C: 70-

79%,D: 60-69%,F: <60%). Responses were analyzed by age, gender, presence of spine conditions, and prior history of spine surgery. Key questions addressed pre-operative bone health evaluation, awareness of spinal conditions, and questions regarding desired bone health-related information. Descriptive statistics were used to summarize responses, and bivariate analyses were conducted using likelihood ratio chi-square test to assess for differences between variables; at $p<0.05$.

Results Overall, 56.6% of respondents achieved high quiz scores (A or B). Among younger respondents (21-34 years), 49.3% scored A or B, compared to 70.0% of older respondents (65+ years). Over 90% across all age groups correctly recognized that bones weaken with age, while awareness of osteoporosis medications and their safety increased with age. Female respondents outperformed males, with 61.8% achieving grades A or B compared to 48.7% of males. Statistically significant gender differences were observed in identifying broccoli as beneficial and caffeine as harmful for bone health.

Among respondents diagnosed with a spine condition, 55.2% achieved grades A or B, and 52.4% reported having had a bone density test, compared to 31.7% of those without a spine condition. Interest in learning about bone health treatments was significantly higher among respondents with spine conditions (78.1%) than those without.

In respondents with a history of spine surgery, only 15.9% reported prior bone health evaluation, while 84.0% expressed interest in learning about treatment options. Most respondents (70.6%) indicated interest in improving or restoring bone health as well as interest in "why bone health matters to everyone" at 70%.

Conclusion This survey highlights significant gaps in public bone health evaluation and awareness, especially in spine surgery contexts. Increased educational initiatives and standardized screening protocols are necessary to improve outcomes and promote spinal health.

The National Spine Health Foundation (NSHF) is the pre-eminent patient and health care professional advocacy organization in spinal health care. It is the only non-profit organization dedicated to helping patients overcome debilitating spinal conditions and take back their lives through patient education, award-winning research, and patient advocacy. NSHF gives patients the tools they need to make informed decisions about their spine health and navigate their own treatment journeys with confidence.

NSHF serves a critical gap in spinal health by representing the voice for patients, in connection with premiere professional societies through the Coalition for Spine Health, and fueled in partnership with industry leaders through our Spine Health Leadership Council. Our stated mission is to improve spinal health through patient education, patient advocacy, and clinical outcomes research.

We achieve much of our mission through our digital outreach efforts including our award winning website, www.spinehealth.org. We steward a vibrant community through our Spinal Champion program where patients share their successful spine health journeys to give hope and help to others seeking real answers. These Spinal Champion stories are featured on our Get Back To It podcast. Our prestigious Medical & Scientific Board volunteer their expertise to contribute to our content primarily through our premiere video education offering, SpineTalks, and through our bi-annual Spine Health Journal.

NSHF has seized this opportunity to educate spine patients as well as help spine surgeons and professionals increase patient outcomes through providing tools and resources on the importance of bone health optimization in surgical patients through the following new platforms:

1. Bone Hub (https://www.spinehealth.org/bonehub**):** An educational site for both patients and professionals on the connection between spine and bone health/osteoporosis (that has channels for patients, women age 50 and above, and health care professionals)

2. Health Care Professional Continuing Education Portal (https://cme.spinehealth.org**):** A health care professional site which hosts an on-demand webinar series, other on-demand continuing education videos, and the NSHF Spine & Bone Health ECHO® (Extension for Community Healthcare Outcomes) program. Project ECHO is a platform based out of the University of New Mexico that provides lifelong learning and guided practice that creates a learning environment for medical education and sharing of challenging clinical cases. ECHO's " hub-and-spoke" model is led by expert teams who use multipoint video-conferencing to conduct virtual clinics/sessions.

FREQUENCY OF VERY-HIGH RISK OSTEOPOROSIS ACCORDING TO THE CURRENT GERMAN GUIDELINE IN A WELL-CHARACTERIZED COHORT OF COMMUNITY-DWELLING GERIATRIC PATIENTS

R. Schmidmaier[1], M. Rippl[1], P. Grupp[1], S. Martini[1], K. Müller[1], O. Tausendfreund[1], M. Drey[1]

[1]Department of Medicine IV, LMU University Hospital, LMU Munich, Ziemssenstr. 1, 80336 München, Munich, Germany

Objective: Bone anabolic treatment has been shown to be superior to oral bisphosphonates, especially in osteoporosis patients with a very high fracture-risk. The current German osteoporosis guideline classifies the very high 3-year fracture-risk based upon a novel fracture-risk model. As age is a severe risk-factor, we examined the distribution and associations to geriatric assessment parameters of the very high-risk group in a well-characterized cohort of community-dwelling geriatric patients.
Methods: Analyses were based on 166 patients (mean age 82±6 years) taken from MUSAR (MUnich SArcopenia Registry). Risk for hip or vertebral fracture within the next three years was calculated as described in the current German guideline. Thereupon, patients were allocated to the low-/moderate (<5%), high- (5-10%) or very high-risk (>10%) group. Associations of geriatric assessment parameters with the group allocation to the fracture-risk group were evaluated by covariate-adjusted linear regression analysis.
Results: More than 80% of the study population were at an increased fracture-risk. Besides, more than 50% were allocated to the very high-risk group. Patients in the very high-risk group showed limitations in all physical performance tests (short physical performance battery (SPPB), gaitspeed, handgrip strength and chair rise test). Also, polypharmacy and a risk for malnutrition (from mini nutritional assessment short form (MNA-SF)), were present. All parameters showed significant associations with group allocation to very high-risk group.
Conclusion: Most of the geriatric patients are at a very high-risk for osteoporotic fractures. Also, this group presented several limitations in the comprehensive geriatric assessment highlighting the vulnerability of this group. Clinicians need to reinforce fracture-risk assessment and familiarize with treatment options.

P1303

ESCAPE OF SERUM BETA CROSS LAPS (CTX) AT 6 MONTHS IN PATIENTS OF OSTEOPOROSIS TREATED WITH DENOSUMAB

R. Sharma Tambe[1], K. Rupwane[1], N. Vaghasia[1], A. Mithal[1]

[1]Max Super Specialty Hospital, Delhi, India

Abstract
Denosumab, a monoclonal antibody targeting RANKL, is commonly used to manage osteoporosis. This analysis aims to examine the characteristics and outcomes of patients receiving denosumab, with a particular focus on those who developed a rise in serum CTx at 6 months.

Methods:
We retrospectively reviewed data of of 200 consecutive patients treated with Denosumab for osteoporosis, between December 2023 and January 2025. Serum beta cross laps (CTx) were measured at 0, 3 and 6 months.by ELISA. Out of these, 18 patients (9%) showed substantial rise in CTx at 6 months - before the next dose was due. Bone Mineral Density (BMD) for these patients was measured at baseline and after 1 year of denosumab treatment.
Results:
Of the 200 patients (173 females, 27 males), 11 (5.5%) patients were < 60 years age. The mean age was 71.81 yrs. Diabetes was present in 107 patients. A total of 92 patients had at least one fracture, and 102 patients received denosumab as first-line treatment.
Among the 18 patients who showed CTx escape at 6 months, 1 was male, 17 females; 2 patients < 60 yrs, 1 had PHPT and 7 had DM.
In the escape group, the mean CTx at baseline was 520.38 pg/ml, at 3 months 104.57 pg/ml and at 6 months it was 447.94 pg/ml. From a low at 3 months, 6 (33%) patients had a 100% rise, 9 (50%) patients 50-100% rise, 2 (11.11%) patients had < 50% rise. All had CTx > 280 pg/ml at 6 months.
The subgroup's characteristics were further analyzed to identify any significant differences in clinical variables, including age, dia-

betes status, and prior treatment history.
Conclusion:
Denosumab remains a key therapeutic option for patients with osteoporosis, but some patients may experience CTx escape at 6 months.
Implications of this rise in CTx on long term management with denosumab remains unclear.

P1304

RELATIONSHIP BETWEEN VIGOROUS ACTIVITY AND MSK SYMPTOMS DURING A USER TRIAL OF THE INTELLIGENT KNEE OSTEOARTHRITIS LIFESTYLE APP

R. Stevenson[1], E. Chowdhury[1], J. Lobo[1], M. Western[1], J. Bilzon[1]

[1]University of Bath, Bath, United Kingdom

Objectives: The purpose of this study was to assess the relationship between the quantity of weekly vigorous physical activity undertaken with the change in musculoskeletal (MSK) health symptoms during a short-term user trial of the intelligent knee osteoarthritis lifestyle app (iKOALA) in individuals with knee osteoarthrosis (KOA).
Materials and Methods: 19 (15 female, 4 male) participants with a mean age of 59 years (range 47-74 years) diagnosed radiographically or clinically with KOA completed a 12-week user trial of the iKOALA app. Participants downloaded the application onto their personal mobile phones and wore a physical activity monitor (Fitbit Inspire 2, Fitbit, USA) for the duration of the trial. Participants completed an in-app physical activity questionnaire which intelligently recommended suitable activities to individuals. Participants then self-selected several activities from the iKOALA library of exercises to create a personalised PA plan and followed this throughout the trial. Participants completed a MSK outcome measure questionnaire (MSK-HQ) for chronic symptoms at the start of the first week and at the end of the final week of the trial.
Results: Over the course of the trial, average MSK-HQ scores improved from 34.2 (week-0) to 40.8 (week-12) (6.6-point change) which was a statistically significant change (t (18) = -5.23; p < .001). In the final week of the user trial (week 12), participants completed an average of 10,441 steps and performed 30.6 minutes of vigorous activity on average. A Pearson correlation revealed a strong positive corelation coefficient between the amount of vigorous physical activity (in minutes) participants performed at week 12 and the change (week 1-12) in MSK-HQ health symptoms (r = 0.706, p = < .001).
Conclusions: The quantity of vigorous weekly physical activity performed as part of a physical activity plan may be an important factor in improving MSK symptoms in individuals with KOA.

P1305

ASSOCIATION OF TRABECULAR BONE SCORE AND OSTEOSARCOPENIA IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

B. Günay[1], R. Terlemez[1], S. Tüzün[1]

[1]Istanbul University-Cerrahpaşa, Cerrahpaşa Medical Faculty, Istanbul, Turkiye

Osteosarcopenia, the coexistence of osteoporosis and sarcopenia, is a geriatric syndrome associated with an increased risk of falls and fractures. This study aimed to evaluate the prevalence of osteosarcopenia and its association with trabecular bone score (TBS) in postmenopausal osteoporotic women with rheumatoid arthritis (RA) compared to a matched control group.

The study included 15 postmenopausal women with RA and osteoporosis (RA group) and 15 postmenopausal women with osteoporosis without RA (control group). Demographic data, lumbar and femoral bone mineral density (BMD), and TBS were assessed. Sarcopenia was diagnosed using the algorithm developed by the Special Interest Group on Sarcopenia (1), incorporating the chair stand test (CST) and hand grip strength (HGS) to evaluate muscle function. Muscle mass was measured using the STAR (Sonographic Thigh Adjustment Ratio) score.

The mean age and BMI were comparable between groups (RA: 65.6 ± 9.4 years,BMI 27.2 ± 4.66; control: 65.5 ± 9.6 years, BMI 27.2 ±3.74). Osteosarcopenia was more frequent in the RA group (47%) compared to controls (20%). The RA group had significantly lower HGS (17.5 kg vs. 21.6 kg, p < 0.05) and STAR values (0.96 vs. 1.11, p < 0.05), but comparable BMD, TBS, and CST results. TBS was not significantly associated with sarcopenia in either group.

Osteosarcopenia is more frequent in postmenopausal women with RA compared to matched controls. RA patients should be routinely evaluated for sarcopenia. Early detection and management of sarcopenia in this population can reduce falls, improve quality of life, and prevent fractures.

IMPROVEMENTS IN BONE DISORGANIZATION AND PROMOTION OF PSEUDOFRACTURE HEALING WITH ASFOTASE ALFA MAY BE DETECTABLE BY THE ALIGNOGRAM BEFORE CHANGES IN BONE RADIOGRAPHY OR SCINTIGRAPHY- A CASE REPORT

R. Zebaze[1], Z. Zheng[1], S.-L. Shore-Lorenti[1], C. Chiang[2], M. Milat[3], R. Ebeling[1]

[1]Department of Medicine School of Clinical Sciences, Monash University Clayton Victoria Australia., Melbourne, Australia, [2]Austin Health, Department of Medicine University of Melbourne Heidelberg Victoria Australia., Melbourne, Australia, [3]Hudson Institute of Medical Research Clayton Victoria Australia, Melbourne, Australia

Objective- *To assess if automated measurement of the magnitude of disarrangement of bone components (disorganization) from readily available standard x-rays allows quantitative assessment of improvements in bone abnormalities (including pseudofractures) during treatment of patients with hypophosphatasia (HPP)*

Hypophosphatasia being a serious genetic disease, it is reasonable to assume that in these settings of a genetic abnormality, impairment in bone cell functions will result in the formation or deposition of wrong bone components leading to a misarranged bone matrix. This produces bone abnormalities including fractures and pseudofractures. Indeed, as we have reported, when matrix elements are improperly stacked up (disorganized), the misfit between components leads to ineffective transfer of loads and energy causing damage, abnormalities and fractures (independently of other properties including BMD) [**1,2**]. An effective therapy by correcting the mineralization defect, should in turn improve bone organization (arrangement) and enhance fracture healing. Hence, *we hypothesized that measurement of the extent of bone disorganization allows (i.) quantification of the severity of bone abnormalities (ii.) and their improvement including healing of pseudofractures during therapy.*

Material and Methods: We analysed serial femoral X-rays and bone scintigraphy images collected at baseline, 3, 6, 12, 24 and 48 months in an 18-year-old female with benign prenatal HPP as reported by Kato et al [**3**]. Automated disorganization analysis was performed using an accurate and reproducible AI-based software (ALIGNOGRAM$_{1.0}$) as previously reported. Pseudofracture was detectable as the location with maximum disarrangement (misalignment) [**2**]. For a detailed analysis, each bone was subdivided into 9 consecutive locations.

Results: As shown in Figure 1, the therapeutic response marked by the improvement in arrangement (organization) of bone components and pseudofracture healing was detectable within 3 months of asfotase alfa initiation, and this was before any improvement was visible on *either X-Rays* or bone scintigraphy.

Conclusion: Bone disorganization (disarrangement) is a novel pathogenic mechanism and biomarker of diseases [**1,2**]. In this first-ever study, we report that quantification of this novel biomarker (Disorganization) from standard readily available standard X-rays using tools such as the ALIGNOGRAM Software may open new and affordable pathways for a quantitative assessment of disease progression and response to therapy in patients with HPP.

P1307

QUANTITATIVE MEASUREMENT OF THE DISORGANIZATION PATTERN FROM STANDARD X-RAYS- A NOVEL APPROACH TO THE ASSESSMENT OF THE SEVERITY OF HYPOPHOSPHATASIA AND RESPONSE TO THERAPY IN CHILDREN – A CASE REPORT

R. Zebaze[1], Z. Zheng[1], C. Chiang[2], M. Milat[3], R. Ebeling[1]

[1]Department of Medicine School of Clinical Sciences, Monash University Clayton Victoria Australia., Melbourne, Australia, [2]Austin Health, Department of Medicine University of Melbourne Heidelberg Victoria Australia., Melbourne, Australia, [3]Hudson Institute of Medical Research Clayton Victoria Australia, Melbourne, Australia

Objective Determine if changes in bone abnormalities in children with hypophosphatasia (HPP) during treatment can be assessed by automatically quantifying the magnitude of disarrangement of bone components (disorganization) from readily available standard plain x-rays.

Quantitative assessment of radiographic features of HPP in children that moreover, does not require radiologic expertise remains an unmet.

As HPP is a genetic disease, it is reasonable to assume that the subsequent impairment in bone cell function will result in the formation or deposition of incorrect bone components leading to a misarranged (disorganized) bone matrix. As we have published, when matrix elements are improperly stacked up (disorganized), the misfit between components leads to ineffective transfer of load and energy causing damage, abnormalities and fractures (independently of other properties including BMD) [**1,2**]. Effective treatments will result in the formation and deposition of right bone components thereby improving or correcting the misarrangement of bone matrix. Hence, *we hypothesized that measurement of the extent of bone disorganization allows quantitative assessment of improvement of bone abnormalities in children with HPP during treatment*.

Material and Methods: We analysed serial distal radius collected at baseline and after 6 months in a 16-year-old male with HPP [**3**]. Automated disorganization analysis was performed using an accurate and reproducible AI-based tool (ALIGNOGRAM1.0) as previously reported [**2**]. For a detailed analysis, each bone was subdivided into 187 consecutive locations.

Results: As shown in **Figure 1**, there was a distinct disorganization pattern observed across all 187 locations before asfotase alfa therapy— a dome-shaped portion in the curve signalling the presence of a lucency. After 6 months of treatment, there was a near or complete disappearance of this dome-shaped in all locations signalling an improved arrangement of bone matrix in the entire bone. Moreover, the severity of baseline disorganization correlated with the magnitude of improvement with therapy (R2=0.62; p<0.0001).

Conclusion: This first-ever study highlights that disorganization analysis is a potentially reliable and sensitive radiological parameter in assessing paediatric HPP. This novel biomarker (disorganization, disarrangement assessment) may open new and affordable pathways for a quantitative assessment of disease progression and response to therapy in these patients.

THE IMPACT OF DYNAMIC BALANCE PLATFORM TRAINING WITH BIOFEEDBACK ON STRENGTH PERFORMANCE FOLLOWING ACL RECONSTRUCTION

R. Zhavoronkov[1], A. Berger[1]

[1]National Medical Research Center for Rehabilitation and Balneology of the Ministry of Health of the Russian Federation, Moscow, Russia

Objective: To assess the effectiveness of training exercises on an balance platform with biofeedback as part of a comprehensive rehabilitation program following anterior cruciate ligament (ACL) reconstruction.

Methods: Thirty-one patients (19 males, 12 females, age 28.6 ± 6.2 years), 6-12 weeks post-unilateral ACL reconstruction, participated in the study. All participants underwent a rehabilitation program that included group gymnastics, gym machines, stationary cycling, massage, magnetic field exposure, neuromuscular

electrical stimulation, and laser therapy. Patients were randomly assigned to the main group (n = 16, 9 males, 7 females, age 29.7 ± 3.6 years) or the comparison group (n = 15, 10 males, 5 females, age 27.3 ± 5.2 years). The main group underwent balance training on a dynamic platform, while the comparison group followed only the standard rehabilitation program. Testing was conducted before and after a 2-week training program, which included isometric single-leg flexion and extension strength tests using an isokinetic dynamometer for both legs.
Results: At the beginning of the rehabilitation program, the strength of the operated leg was reduced by 51.4% compared to the contralateral leg ($p<0.05$) in the main group. After rehabilitation, the muscle strength deficit was reduced to 31.6% ($p<0.05$). In the control group, the deficits were 52.5% and 41.3% ($p<0.05$), respectively. At the end of the two-week rehabilitation course, the mean torque gain (Nm) was 7.9% (1.7 Nm) higher in the main group. Maximal torque was 54.7% higher for extension (8.1 Nm) and 18% higher for flexion (4 Nm) compared to the control group.
Conclusion: A two-week course of rehabilitation, involving training on an unstable platform, significantly reduces the strength imbalance between the operated and contralateral legs 6-10 weeks after ACL reconstruction.

Table 1. Post-rehabilitation changes in biomechanical indices

Isokinetic parameter	Main group	Control group
Peak extension torque (Nm)	56,9 ^ (25%-52,7; 75%-125,2)	44,8 (25%-34,8; 75%-55,1)
Peak flexion torque (Nm)	60,8 ^ (25%-49,9; 75%-82,4)	39,2 (25%-28,7; 75%-59,4)
Mean peak extension torque (Nm)	51,9 ^ (25%-34,4; 75%-96,7)	29,4 (25%-14,9; 75%-41,4)
Mean peak flexion torque (Nm)	51,5 ^ (25%-42; 75%-74,6)	27,6 (25%-15,2; 75%-44,5)
Mean extension torque (Nm)	24,9 ^ (25%-15; 75%-33,2)	12,7 (25%-7,3; 75%-23,1)
Mean flexion torque (Nm)	30,2 ^ (25%-25,5; 75%-44,9)	22,4 (25%-13,8; 75%-31,5)
Mean extension power (Watt)	11 ^ (25%-6,9; 75%-21,9)	4,9 (25%-2,7; 75%-11,2)
Mean flexion power (Watt)	10,2 ^ (25%-8; 75%-16,9)	6 (25%-4,1; 75%-10,8)
Total extension work (J)	562,2 ^ (25%-365,6; 75%-1028,6)	271,4 (25%-196,7; 75%-482,1)
Total flexion work (J)	544,8 ^ (25%-464,6; 75%-883,7)	375,6 (25%-302,4; 75%-627,2)

LOW-LEVEL LASER THERAPY PROTECTS CARTILAGE IN RABBIT EXPERIMENTAL KNEE OSTEOARTHRITIS

R.-A. Ungur[1], L. Irsay[1], V. M. Ciortea[1], I. M. Borda[1]

[1]University of Medicine and Pharmacy "Iuliu Haţieganu" Cluj Napoca, Cluj-Napoca, Romania

Previous studies have shown a beneficial effects of low-level laser therapy (LLLT) in experimental osteoarthritis (OA).
Objective. The purpose of our study was to test LLLT effects on knee articular cartilage of rabbits with knee experimental osteoarthritis (KOA).
Material and Methods. Experimental OA was induced in 18 mature female rabbits by anterior cruciate ligament transection (ACLT). Ten weeks after ACLT, rabbits were randomized in a 3 groups: two control group and one treated groups. The treated group were exposed to LLLT for 10 days. First control group (C1) was sacrificed immediately after the end of the period utilized for OA inducing. The second control group (C2) was exposed to sham LLLT and was sacrificed together with the treated groups, after the treatment ending. The cartilage samples were obtained from OA joints of the sacrificed rabbits and were evaluated by optical microscopy and transmission electron microscopy (TEM).
Results.
LLLT improved chondrocytes division and maintained ECM structure and integrity.
Conclusions. LLLT was efficient in alleviating cartilage damages and can be considered a disease modifying therapy for OA patients.

EXPLORING ULTRASOUND AND SHEAR WAVE ELASTOGRAPHY FOR DETECTION OF MUSCLE CHANGES IN PRESARCOPENIA: INSIGHTS FROM THE FLEXOR DIGITORUM PROFUNDUS MUSCLE EVALUATION

R.-I. Gutiu[1], A.-D. Bilous[1], I. Cozma[1], O. Serban[1], M. Badarinza[1], P. Darau[1], M. A. Pelea[1], D. Fodor[1]

[1]2nd Internal Medicine Department, Cluj-Napoca, Romania

Objective:
Low muscle mass is a key criterion for diagnosing presarcopenia. While computed tomography (CT) and magnetic resonance imaging (MRI) are considered gold standards for muscle assessment, dual-energy X-ray absorptiometry (DXA) is commonly used as clinical alternative. Recently, ultrasound (US) and shear wave elastography (SWE) have been increasingly utilized to evaluate muscle quantity and quality. Although significant results have been achieved for the lower extremities, the role of upper extremity muscle assessment remains less well established. Thus, this study aimed to evaluate the flexor digitorum profundus (FDP) muscle, a critical component of handgrip strength, using US and SWE in patients with low and normal muscle mass.

Materials and Methods:
The study included 50 age- and gender-matched participants, aged over 60 years, divided into two groups based on appendicular skeletal muscle mass (ASM) measured by DXA: low muscle mass (presarcopenia) and normal muscle mass. Clinical evaluation included handgrip strength (HGS) and forearm circumference (FC). Muscle assessment involved US-derived parameters such as echogenicity and cross-sectional area (CSA), as well as SWE measurements in both relaxed and contracted state using a hand dynamometer.
Results:
Findings indicated that HGS was preserved in the presarcopenic group ($p = 0.244$). However, the CSA of the FDP, an ultrasound marker of muscle quantity, was significantly reduced in the low muscle mass group ($p = 0.02$). SWE demonstrated excellent intrarater reliability, with an intraclass correlation coefficient (ICC) of 0.854 in the relaxed state and 0.857 in the contracted state. However, SWE measurements did not show statistically significant differences between groups. In contrast, muscle echogenicity, assessed using a visual semi-quantitative scale, effectively differentiated between groups, indicating reduced muscle quality in presarcopenia ($p<0.001$).
Conclusions:
US demonstrated superior performance compared to SWE in detecting muscle quality changes in the upper extremity, specifically the FDP muscle, at the presarcopenic stage. While muscle strength remains preserved, reduced muscle quantity is reflected by a smaller CSA on ultrasound and decreased FC clinically. These findings highlight the utility of US as a diagnostic tool for early muscle alterations in presarcopenia.
Conflict of Interest Statement: The authors declare no conflicts of interest related to this study.

P1311

OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURE DIAGNOSED BY BONE SCINTIGRAPHY: A CASE REPORT

S. Agić-Bilalagić[1], S. Cerić[1], A. Bašić[1]

[1]Clinical Center University of Sarajevo, Sarajevo, Bosnia & Herzegovina

Background: Vertebral fractures are the most common osteoporotic fractures, and also most difficult and very frequent complications of osteoporosis. Bone scintigraphy is a sensitive method for investigating skeletal pathology. Typical scintigraphic findings for vertebral fracture is markedly increased radiotracer uptake in the linear pattern, throughout collapsed vertebral body. Bone scintigraphy with 99mTc-phosphonates enables early detection of vertebral compression fractures in patients with osteoporosis
Objective. To highlight the importance of bone scintigraphy in diagnosis of osteoporotic vertebral fractures and in diagnosis and management of osteoporosis.
Case study. Report of a patient with prostate cancer referred to routine bone scintigraphy as a part of follow up of therapy. Bone scintigraphy showed increased linear uptake in the second lumbar vertebra. Follow-up X-ray revealed a compression fracture at L2 with loss of vertebral height. Follow up densitometry was consistent with severe osteoporosis and patient was treated with intravenous bisphosphonates.
Conclusions: Bone scintigraphy can have a role in early diagnosis of vertebral fractures because of typical scintigraphic patterns for the latter. Earlier identification and treatment of vertebral compression fractures may reduce pain and associated sequelae in patients with osteoporosis.

PREVALENCE OF FALLS AND ASSOCIATED RISK FACTORS AMONG POSTMENOPAUSAL WOMEN IN IRAN: FINDING FROM NATIONWIDE STEPS SURVEY 2021

P. Zarepour[1], S. Salehi[1], M. Khojasteh[1], S. Akbarpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: The aim of this study is to assess the prevalence of falls and associated risk factors among postmenopausal women in Iran.
Method: A total of 4855 postmenopausal women from the nationwide STEPS survey 2021 in Iran were included in this study. Menopausal status information was self-reported, and associated risk factors, including age, smoking status, years of schooling, BMI, multimorbidity, physical activity, wealth index, and alcohol consumption, were analyzed. A stepwise logistic regression model was employed, with a significance level of 0.2 for variable entry, to identify factors associated with the odds of falling. Odds ratios (ORs) and 95% confidence intervals (95% CIs) were calculated for menopausal status. The data were weighted and the weighting process was done based on the age, sex and area stratifications in province level of 2016 Iranian census.
Results: The prevalence of falling among postmenopausal women was 4.22% (95% CI: 3.62–4.91). In the primary model examining factors associated with the odds of falling, three variables—age, marital status, and comorbidity—were identified as significant. Women aged over 60 years had 72% higher odds of falling (OR: 1.72, 95% CI: 1.22–2.43) compared to those under 60 years. Married women had 76% lower odds of falling (OR: 0.24, 95% CI: 0.10–0.58) compared to single participants. Having one comorbid condition was associated with a 58% increase in the odds of falling (OR: 1.58, 95% CI: 1.09–2.29), while having two or more comorbidities further increased the odds of falling by 66% (OR: 1.66, 95% CI: 1.10–2.51).
Conclusion: This study highlights a notable prevalence of falls among postmenopausal women, with age, marital status, and comorbidities identified as significant risk factors. Targeted interventions addressing older age and managing comorbid conditions could help reduce the risk of falls in this population.

P1313

SMOKING STATUS AND FALL RISK IN IRANIAN MEN: INSIGHTS FROM A NATIONAL CROSS-SECTIONAL STUDY

S. Salehi[1], P. Zarepour[2], S. Akbarpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective:
This study aimed to determine the prevalence of falls among men based on smoking status, including never smokers, ex-smokers, current smokers, and passive smokers and to assess the relationship between smoking status and fall risk.
Method:
Data for this cross-sectional analysis were sourced from nationwide STEPS survey 2021 in Iran. Fall were assessed by using a question about fall events in the past year. Smoking status was categorized as never smokers (reference group), ex-smokers, current smokers, and passive smokers (exposed to secondhand smoke). A stepwise logistic regression model with a significance level of 0.2 for exit was used to identify variables associated with the odds of falling. Odds ratios (ORs) and 95% confidence intervals (95% CIs) were calculated for each smoking category, adjusted for key demographic and health variables such as age, BMI, employment status, wealth index, years of schooling, multimorbidity, and marital status.
Results:
Overall, 12,479 men with a mean age of 46.20 years (95% CI: 45.88–46.52) were included in the analysis. The total prevalence of falls in this population was 2.4% (95% CI: 2.11–2.73). Among men with a history of falls, 36.69% (95% CI: 30.43–43.44) were never smokers (reference group). Ex-smokers comprised 5.31% (95% CI: 3.05–9.10), with an odds ratio (OR) of 1.33 (95% CI: 0.69–2.55) compared to never smokers; however, this association was not statistically significant (p = 0.395). In contrast, 33.84% of individuals with a history of falls were current smokers (95% CI: 28.00–40.22), with an OR of 1.72 (95% CI: 1.23–2.40), indicating a statistically significant association (p = 0.002). Additionally, 24.16% of this population were exposed to secondhand smoke (95% CI: 19.20–29.92), with an OR of 1.37 (95% CI: 0.97–1.94). Although this association showed a trend towards significance, it did not reach statistical significance (p = 0.071).
Conclusion:
The findings indicate that current smoking is significantly associated with an increased risk of falls among men, while exposure to secondhand smoke shows a borderline association. No significant relationship was observed between ex-smoking and falls. These results highlight the potential role of smoking cessation and reducing secondhand smoke exposure in fall prevention strategies.

THE IMPACT OF OBESITY AND DIABETES ON INCIDENT FRACTURE OVER 15 YEARS OF FOLLOW-UP: TEHRAN LIPID AND GLUCOSE STUDY

S. Asgari[1], D. Khalili[1], F. Hadaegh[1], F. Azizi[2], N. Fahimfar[3]

[1]Prevention of Metabolic Disorders Research Center, Research Institute for Metabolic and Obesity Disorders, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Endocrine Research Center, Research Institute for Endocrine Disorders, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, Iran, [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective: We investigated the association between general obesity/ central adiposity and diabetes with fractures, both independently and concurrently, to address the controversy in their associations.
Materials and Methods: This study was conducted on 7,562 participants aged ≥30 years. T2DM was defined as fasting plasma glucose ≥7 mmol/L, 2-hour post-challenge glucose ≥11.1 mmol/L, or diabetes medication use. General obesity was defined as BMI ≥30 kg/m², and central adiposity as waist circumference ≥95 cm for Iranian adults. Age-standardized fracture incidence rates were calculated per 100,000 person-years using Segi's world standard population. Moreover, multivariable stratified Cox regression analysis was used to estimate hazard ratios (HRs (95% CI)) for any fracture incidence.
Results: Over a 15-year follow-up period, around 4% of adults had at least one fracture. The age-standardized incidence rates are presented in **Table 1**. We found that both central and general obesity increased the risk of fractures compared with non-obese adults, regardless of T2DM status with a more prominent association for central obesity. Diabetes without obesity did not show any association with any fracture. (Table 1)
Conclusion: The analysis showed that both central and general obesity, but not diabetes alone, increases the risk of fracture, especially central adiposity.

Table1: Incidence rate and risk of any fracture according to different combinations of obesity and type 2 diabetes

	E/N	ASR (95% CI)	HR(95% CI)	p-value
General obesity				
Non-Obese without T2DM	217/5211	343.4(297.3-394.3)	Reference	
Non-Obese with T2DM	14/367	207.7(113.4-369.6)	0.61(0.27-1.37)	0.231
Obese without T2DM	58/1737	260.0(194.4-340.1)	**1.29(1.02-1.65)**	**0.036**
Obese with T2DM	15/247	459.1(235.9-804.3)	1.35(0.86-2.11)	0.185
Central adiposity				
Non-Obese without T2DM	159/4563	302.5(253.6-357.6)	Reference	
Non-Obese with T2DM	6/234	174.1(63.7-391.8)	0.78(0.34-1.78)	0.556
Obese without T2DM	116/2385	358.4(295.6-430.6)	**1.64(1.17-2.29)**	**0.004**
Obese with T2DM	23/380	416.6(237.2-682.6)	**1.83(1.09-3.07)**	**0.022**

Model included: obesity phenotype, age, sex, systolic blood pressure, triglycerides, non-high-density lipoprotein cholesterol, estimated glomerular filtration rate, current smoking, education levels, family history of diabetes, use of steroid medications, hypertension medications, lipid-lowering medications, body mass index (for central adiposity)/ waist circumference (for general obesity) as appropriate
E: events; N total number; ASR: age-standardized incidence rate; T2DM: type 2 diabetes; HR: hazard ratio; CI: confidence interval.

P1316

THE ASSOCIATION OF GENERAL/CENTRAL OBESITY WITH THE INCIDENCE OF FRACTURE IN THE PRESENCE OR ABSENCE OF METABOLIC DISORDERS: 15-YEAR FOLLOW-UP IN THE TEHRAN LIPID AND GLUCOSE STUDY

D. Khalili[1], S. Asgari[1], F. Hadaegh[1], F. Azizi[2], N. Fahimfar[3]

[1]Prevention of Metabolic Disorders Research Center, Research Institute for Metabolic and Obesity Disorders, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Endocrine Research Center, Research Institute for Endocrine Disorders, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, Iran, [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective: To examine the association of different obesity phenotypes with all fractures in a longitudinal population study.
Materials and Methods: We involved 7,562 participants aged >=30 years, followed for 15 years. Participants were categorized based on their obesity status and the presence of metabolic syndrome (MetS). General obesity was defined as a BMI of ≥30 kg/m², and central adiposity was defined as a waist circumference of ≥95 cm for Iranian adults. MetS was defined according to the Joint Interim Statement criteria. Cox regression analysis was employed to estimate hazard ratios (HRs, 95%CIs), adjusted for age, sex, marital status, smoking, education, physical activity, and the use of steroid medications.
Results: The non-obese without MetS group served as the reference, with an age-standardized incidence rate of 346 (95%CI:291-408) per 100,000 person-years. Non-obese individuals with MetS did not exhibit a significant increase in fracture risk (adjusted HR=0.98, 0.73-1.32). General obesity without MetS was associated with a significantly lower fracture risk (HR=0.64, 0.41-0.99),

which changed negligibly after adjustment. In contrast, abdominal obesity without MetS indicated an increased fracture risk (adjusted HR=1.40, 1.07-1.83). Both types of obesity with MetS did not show any significant increase in fracture risk (Table 1).

Conclusion: These findings highlight the complex relationship between obesity phenotypes and fracture risk. While general obesity may confer some protective benefits, central obesity is associated with an increased risk of fractures. Additionally, the presence of MetS alters this dynamic significantly, although it does not inherently increase the risk of fractures itself.

Table 1: Hazard Ratio (95% CI) of any fracture for different combinations of obesity and metabolic syndrome among a Tehranian population

	E/N	Model 1	Model 2
Obesity phenotypes by BMI			
Non-Obese without MetS	166/4253	Reference	Reference
Non-Obese with MetS	65/1325	0.95(0.71-1.28)	0.98(0.73-1.32)
Obese without MetS	23/945	**0.64(0.41-0.99)**	**0.65(0.42-1.02)**
Obese with MetS	50/1039	1.04(0.75-1.44)	1.07(0.78-1.49)
Obesity phenotypes by waist circumference			
Non-Obese without MetS	143/4206	Reference	Reference
Non-Obese with MetS	22/591	0.79(0.50-1.25)	0.83(0.53-1.32)
Obese without MetS	95/1938	**1.36(1.04-1.76)**	**1.40(1.07-1.83)**
Obese with MetS	44/827	1.17(0.82-1.65)	1.22(0.86-1.73)

Model 1: obesity phenotype, age, sex;
Model 2: model 1 and marital status, current smoking, education levels, physical activity, use of steroid medications

INSIGHTS FROM THE STRONG SURVEY: MAPPING CALCIUM SUPPLEMENTATION PATTERNS ACROSS 924 PHYSICIANS IN INDIA

S. Asokan[1], S. Chandel[2], R. Dhar[3], B. Behera[4], M. Sabir[5], A. Arora[6], K. Viradiya[7], P. Verma[8], J. Panigrahi[6], T. Mehta[9]

[1]City Polyclinic, Muvattupuzha, Ernakulam, India, [2]AIIMS, Bilaspur, India, [3]Consultant, Jammu, India, [4]SCB Medical College and Hospital, Cuttack, India, [5]SP Medical College, Bikaner, India, [6]Consultant, Kurukshetra, India, [7]Arogyam Hospital & Cardio-Diabetes Center, Surat, India, [8]Dr. Ram Manohar Lohia Institute of Medical Sciences, Lucknow, India, [9]Namaha Specialised Healthcare, Mumbai, India

Introduction
Calcium deficiencies and related bone health issues, such as osteoporosis and fractures, are increasingly prevalent across age groups due to changing lifestyles and dietary habits.
Methods
The STRONG survey (Screening Treatment Recommendations Optimization Navigation Guidance) engaged 924 physicians in a nationwide, pan-India mapping exercise as cross-sectional study to comprehensively understand the importance of calcium therapy and calcium supplementation patterns. Conducted via a secure digital platform, the survey ensured data integrity and confidentiality. Statistical analysis, performed using GraphPad 10.4.1,
Results
The mean experience was 9.1 ± 10 years (95% CI 8.4 to 9.7). The cumulative man-years of experience were 8376 years. The findings highlight key patterns in calcium supplementation, with older adults (55+ years, 37.23%) and middle-aged adults (36-55 years, 33.55%) being the primary recipients due to their heightened risk of osteoporosis and fractures, while younger adults (18-35 years, 23.7%) and pediatric patients (5.52%) receive fewer prescriptions, reflecting dietary adequacy in these groups. Postmenopausal women (47.94%) and the elderly (23.7%) dominate clinical indications, emphasizing the focus on preventing osteoporosis and fractures, while adolescents (18.29%) and children (10.06%) are targeted for peak bone mass development and growth. Modern lifestyle changes have resulted in reduced calcium intake for 66.34% of patients, driven by lower dairy consumption and increased reliance on processed foods, although health awareness efforts have improved intake for 23.38%. Calcium gummies, considered beneficial by 75.43%, improve compliance but require careful guidance on dosage. In type 2 diabetes, 80.96% of respondents recognize the relevance of calcium supplementation in addressing bone health risks associated with metabolic changes.
Discussion
The findings highlight significant gaps in calcium supplementation across demographics, emphasizing the need for targeted strategies to address deficiencies. Older adults and postmenopausal women remain priority groups, while lifestyle changes underscore the importance of education on dietary calcium. Novel supplementation forms like gummies improve adherence and play a crucial role in promoting better bone health outcomes

P1318

ADULT AND GERIATRIC VACCINATIONS HELP SIGNIFICANTLY FOR NOT GETTING FRACTURED BY AVOIDING FALLS DUE TO INFECTIONS BY VACCINE PREVENTABLE DISEASES (VPD)

S. Bajaj[1]

[1]KEDARMAL BAJAJ FALLS INSTITUTE OF INDIA (KBFII), Nagpur , India

This is retrospective study of last 28 yrs , between 1 Jan 1997 and 1 Jan 2025 . The presenting author is also PI at KBFII . Total 294 beneficiaries are for this study . Out of this 152 are females and 142 are males . During the course of follow up, those who died , even though they were vaccinated and not suffered any fractures are excluded . The age group included is between 40 yrs and 100 yrs . The age wise break up is as follows :
A)Between 40 and 49 years = T : 35 , F : 21 , M :14
B) Between 50 and 59 years = T : 68 , F : 36 , M : 32
C) Between 60 and 69 years = T : 79 , F : 43 , M : 36
D) Between 70 and 79 = T : 61 , F : 22 , M: 39
E) Between 80 and 89 years = T : 39 , F : 25 , M : 14
F) Between 90 and 100 years = T : 12 , F : 5 , M : 7
The WHO , CDC and AGS guidelines are followed to vaccinate the beneficiaries . The institute has data of last 38

years . Most vaccination were done by home visits . All beneficiaries were also given the advice about Anti-Osteoporosis Medications (AOM) , diet and exercises .

RESULTS : Vaccine Preventable Diseases (VPDs) like Pneumonia , Hepatitis (A&B) , Herpes Zoster etc are the major causes of infections , followed by hospital admissions . The complications include fatigue , inability to walk and stand . The most dreadful complications are falls , leading to fragility fractures . But the beneficiaries are immunised for VPDs , they got the immunity against these diseases . Amongst all 294 , no one have suffered any fracture.
CONCLUSIONS : Vaccinations form as an evidence based tool for preventing VPDs and its associated infections . One of the major complications of VPDs are falls due to infections and reasons of ED visits . Adult and geriatric vaccinations help significantly for not getting fractured by avoiding falls due the infections by VPDs.

ACKNOWLEDGEMENTS :

UNDERDIAGNOSIS AND MANAGEMENT OF OSTEOPENIA AND OSTEOPOROSIS IN YOUNGER WOMEN WITH BREAST CANCER UNDERGOING HORMONE THERAPY

S. Bačević[1], M. Bačević[2], M. Bačević[2]

[1]Health Center "Prokuplje"- General Hospital, Prokuplje, Serbia, [2]Faculty of Medicine, University of Niš, Niš, Serbia

Introduction
Osteopenia and osteoporosis are often underdiagnosed in younger women on hormone therapy for breast cancer. These conditions frequently go unrecognized and untreated, despite increased bone loss risk from aromatase inhibitors and chemotherapy. Early detection and intervention are essential to prevent fractures and other complications. This study highlights the importance of regular bone density monitoring and proactive management in this vulnerable population. It aims to underscore the need for vigilance in their care.
Aim
The aim of this study is to evaluate whether patients aged 50 years or younger with breast cancer at Prokuplje Hospital are being diagnosed and treated for osteoporosis and fracture prevention.
Methods
A survey was conducted involving 118 breast cancer patients undergoing hormone therapy at the oncology department of Prokuplje Hospital. The survey included questions about previous or current bone fractures, possible osteoporosis diagnosis, recommended osteodensitometry, and osteoporosis treatment.
Results
The average age of the patients was 42.36 years, ranging from 32 to 50 years. The duration of hormone therapy spanned from 5 to 10 years, with an average duration of 8.45 years. Among the patients, 24 (20.3%) experienced hip fractures, while 16 (13.6%) had vertebral fractures. Osteodensitometry was recommended to 37 patients; however, 18 (48.6%) did not follow through with this recommendation. They were also advised to increase their calcium and vitamin D intake.
Out of the 19 patients who underwent osteodensitometry, 17 (89.5%) met the criteria for an osteoporosis diagnosis and 2 (10.5%) were diagnosed with osteopenia. Bisphosphonate therapy was recommended to all 19 patients, but only 11 (57.9%) accepted the recommendation. After one year of bisphosphonate therapy, patients underwent follow-up osteodensitometry, which showed statistically significant improvement in bone mineral density for all of them.
Conclusion
The results of this study indicate a need for additional efforts in diagnosing and treating osteoporosis among breast cancer patients aged 50 years or younger to prevent fractures, especially hip fractures. The findings suggest that more proactive measures should be taken to ensure that these patients receive the necessary osteoporosis care and fracture prevention strategies.

FORMATION OF EXTRACELLULAR TRAPS BY BLOOD NEUTROPHILS AND MONOCYTES IN OSTEOARTHRITIS

S. Bedina[1], E. Mozgovaya[2], A. Trofimenko[2], S. Spicina[3], M. Mamus[2], E. Zagorodneva[4]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [4]Volgograd State Medical University, Volgograd, Russia

Objective:
To compare extracellular traps (ET) formation by neutrophils and monocytes in osteoarthritis patients with and without exacerbation.
Methods:
Neutrophils and monocytes were purified with centrifugation procedure using originally designed iohexol density gradients [1, 2]. The cell types in resulting fractions were identified histochemically, and the extent of cell activation was assessed using common NBT test. ET generation was stimulated by phorbol-12-myristate-13-acetate. The shape and size of ET were assessed using fluorescence microscopy with SYBR green [3, 4]. Central tendencies are expressed as means (95% CI).
Results:
23 patients with verified OA (6 males and 17 females, mean age 5.4 years, mean disease duration 12.5 years). 30 healthy volun-

teers were enrolled as a reference group. OA patients were in clinical remission at the time of inclusion in the study. Synovitis was diagnosed in 18 OA patients during the study (3, 8 and 12 months after inclusion in the study). Mean fraction of spontaneous ET exhibition by neutrophils and monocytes was 5.3 (5.1-5.5)% and 7.9 (7.1-8.7)% for OA patients in remission, respectively. Mean fraction of induced ET exhibition by neutrophils and monocytes was 20.6 (18.4-22.8)% and 21.7 (19.2-24.2)% for OA patients in remission, respectively. Mean fraction of spontaneous ET exhibition by neutrophils and monocytes was 13.2 (12.8-13.6)% and 15.0 (14.5-15.5)% for synovitic OA patients, respectively. Mean fraction of induced ET exhibition by neutrophils and monocytes was 28.8 (26.6-31.0)% and 30.2 (28.1-32.3)% for synovitic OA patients, respectively. The growth rate of spontaneous and induced ET formation by neutrophils was 149.1% and 39.8%, respectively. The growth rate of spontaneous and induced ET formation by monocytes was 89.9% and 39.2% respectively.

Conclusion:

Distinct increase of in the intensity of spontaneous ET generation by both peripheral neutrophils and monocytes during OA exacerbation and the development of synovitis, suggesting that circulating monocytes may be primed to ETosis through immune inflammation.

RHEUMATOID ARTHRITIS: ENZYMATIC PATTERN OF PRO- AND ANTIOXIDANT ENZYMES DEPENDING ON CLINICAL FEATURES

S. Bedina[1], E. Mozgovaya[2], S. Spicina[3], M. Mamus[2], A. Trofimenko[2], N. Krayushkina[4]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [4]Volgograd State Medical University, Volgograd, Russia

Background. Rheumatoid arthritis (RA) is an autoimmune rheumatic disease of unknown etiology characterized by chronic erosive arthritis and systemic organ involvement resulting in early disability and shorter life expectancy.

Objective. To assess plasma activities of essential prooxidant and antioxidant enzymes in RA patients.

Methods. 71 RA patients (46 women and 25 men) were enrolled in the study. The diagnosis was verified using ACR/EULAR criteria (2010). RA activity was measured using DAS28. 30 healthy persons comprise control group. Plasma xanthine oxidase (XO; EC 1.17.3.2), xanthine dehydrogenase (XDH; EC 1.17.1.4), superoxide dismutase (SOD; EC 1.15.1.1) activities were measured spectrophotometrically [1, 2, 3]. Statistical analysis was performed using Statistica 6.0. Differences were considered significant when $p<0.05$. Reference ranges were calculated as means ±2SD.

Results. Mean age of patients was 43.2±3.6 years, mean RA duration was 11.9±2.6 years. 24 (33.8%) RA patients had low disease activity, 6 (8.5%) patients had high one. Extra-articular manifestations were found in 30 (42.2%) patients. Reference ranges for XO, XDG, SOD activities were 2.28-5.12 nmol/min/ml, 3,96-7,24 nmol/min/ml, and 3,13-6,58 units, respectively. RA patients had increased both mean XO and mean SOD activities ($p<0.001$). XO activity reached its highest values at maximum disease activity and overt extra-articular involvements, while SOD activity did it in moderate and high disease activities as well as in patients with joint manifestations. XDG activity was increased in low disease activity ($p<0.001$) and solely joint lesions ($p=0.011$), while moderate or high disease activities ($p=0.008$) and extra-articular involvements ($p=0.025$) were characterized by decreased activity of this enzyme.

Conclusion. Plasma enzymatic pattern in RA patients is characterized by activation of both oxidant and antioxidant metabolic pathways. Activities of XO and SOD were positively correlated with RA activity, while XDG activity was negative correlated with RA activity. The differences between selective articular RA type and RA form with extraarticular manifestations were also revealed.

P1322

COMPARISON OF OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS SYNOVIAL HISTOLOGIC FEATURES

S. Bedina[1], E. Mozgovaya[2], S. Spicina[3], A. Trofimenko[2], M. Mamus[2], I. Zborovskaya[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia

Objective.

to compare histological features of synovial tissue in RA and OA patients using previously published data.

Methods.

Methods: Databases of scientific publications (Scopus, Web of Science, PubMed, Russian Science Citation Index) were included in the search using appropriate search terms and period of publication 2000-2024.

Results.
A total of 125 articles were retained for analysis. Synovial membrane samples were preferentially obtained from grossly inflamed synovium. The following histologic features: synovial hyperplasia, lymphocytes, plasma cells, binucleated plasma cells, Russell bodies, synovial giant cells, sublimating giant cells, fibrin, fibrosis, mucin, debris, neutrophils, granulation tissue, mast cells, synovial chondrometaplasia, germinal centers, and vascularization were scored. Histologic features of synovium in RA compared with OA included: lining hyperplasia, lymphocytic inflammation, plasma cells, Russell bodies, binucleate plasma cells, synovial lining giant cells, binucleate plasma cells, sub-lining giant cells, neutrophils, fibrin and detritus. Fibrosis and mast cells are key histologic features in OA. However, lymphatic complexes, plasma cells, Russell bodies, binucleated plasma cells were observed in 27%, 15%, 9%, and 11%, respectively. No differences were found between patients with OA and RA regarding the frequency of mucoid changes and germinal centers. Mucoid changes were common in both diseases. Germinal centers were very rare in both diseases.
Conclusion.
Biopsy specimens obtained from clinically affected joints demonstrate important histological differences between RA and OA. However, the inflammatory features of OA synovitis may sometimes be histologically indistinguishable from rheumatoid synovial infiltration. Assessment of synovium has the potential to provide guidance regarding optimal treatment strategies.

P1323

DO PHYSICIANS FEEL UNCOMFORTABLE WITH MUSCULOSKELETAL COMPLAINTS REPORTED BY THEIR PATIENTS?

S. Ben Dhia[1], L. Kharrat[1], D. Ben Nessib[1], F. Majdoub[1], D. Kaffel[1], H. Ferjani[1], K. Maatallah[1], W. Hamdi[1]

[1]Mohamed Kassab Institute of Orthopeadics, Department of Rheumatology, Manouba, Tunisia

Objective
Identify physicians' perception when seeing patients with non-traumatic musculoskeletal complaints.
Methods
We conducted a cross-sectional study between September 2023 and January 2024 including medical doctors practicing surgical and non-surgical specialties. Rheumatologists and non-clinical specialists were not included. Physicians were invited to respond to a self-administered Google Forms survey, regarding their perception of patients with non-traumatic musculoskeletal complaints.
Results
We included 105 physicians. They were 21 men and 84 women. The mean age was 30.2±3.4 years.
Mean clinical experience was 4±2.1 years. Sixty-three percent of the physicians received training in rheumatology during their medical studies, with an average duration of 2.5±1.5 months [0.5-6 months].
In their daily practice, 40% of the physicians received fewer than 5 patients per week with non-traumatic musculoskeletal complaints, 30.5% saw 5 to 10 patients, 12.4% saw more than 20, and 6.7% did not see any at all.
We found that 53.3% of the physicians felt uncomfortable receiving patients with osteoarticular complaints. Rating this discomfort on a scale of 0 to 5, the average was 1.9±1.4/5. Physicians explained this feeling by stating that these patients were exaggerating when reporting their complaints in 22.9%, 31.4% found it difficult to identify the diagnosis in these patients, 22.9% found that these patients were often not convinced of the diagnosed condition or the treatment approach (20%), 38.1% had the impression that these patients' complaints are consistently recurring, and only one physician believed that some patients denied the chronicity of their illness.
Physicians who have not had a rheumatology training were more likely to feel uncomfortable with these patients (OR=2.9: p=0.012; CI [1.24-6.62]). In addition, discomfort rating was significantly lower in those who have had a rheumatology training (1.7±1.3 versus 2.3±1.6; p=0.034). Female physicians were also more likely to feel uncomfortable (OR=2.8; p=0.04; 95% CI [1.02-7.65]). No significant difference was found between surgical and non-surgical specialties (p=0.806).
During the consultation, 76% of physicians usually or always dedicated time to allow patients to express all their complaints, 5.7% rarely pushed for further questioning, and 31.4% rarely or never performed an osteoarticular examination.
Conclusion
Our study showed that non-rheumatologist physicians, especially those who have not had a rheumatology training, were often uncomfortable receiving patients with non-traumatic musculoskeletal complaints.
Rheumatology training should be encouraged during medical studies for physicians to be more comfortable managing patients with musculoskeletal complaints as they are very common and can reveal serious conditions.

P1324

COMPARATIVE EFFECTIVENESS OF CONVENTIONAL REHABILITATION, GLOBAL POSTURAL REEDUCATION, AND PAIN NEUROSCIENCE EDUCATION IN MANAGING CHRONIC LOW BACK PAIN

S. Bouden[1], S. Ben Hamouda[1], L. Rouached[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Hôpital Charles Nicolle, Tunis, Tunisia

Introduction:
Chronic low back pain is a prevalent and disabling condition with significant physical, psychological, and socio-economic consequences. Effective management requires a multidimensional approach [1]. This study aimed to compare the effectiveness of three distinct rehabilitation strategies: conventional rehabilitation alone, Global Postural Reeducation (GPR), and Pain Neuroscience Education (PNE), each combined with conventional rehabilitation

in addressing pain, functional limitations, and psychological distress in patients with chronic low back pain.

Methods:

A longitudinal comparative study was conducted from March to May 2024, involving patients with chronic low back pain randomized into three groups: a control group receiving conventional rehabilitation alone, a GPR group combining GPR to conventional rehabilitation, and a PNE group combining PNE to conventional rehabilitation. Each intervention lasted four weeks with three one-hour sessions per week. Assessments were conducted at baseline (T0) and after the intervention (T1) using the Visual Analog Scale (VAS) for pain intensity, the Oswestry Disability Index (ODI) for functional impairment, and the Hospital Anxiety and Depression Scale (HADS) for psychological status.

Results:

A total of 48 patients were included in the study, divided into three groups: 24 in the control group, 13 in the GPR group, and 11 in the PNE group. The average age was 51 ± 11 years in the control group, 46 ± 5 years in the GPR group, and 53 ± 9 years in the PNE group. Regarding sex distribution, all participants in the control and GPR groups were female, while the PNE group included 4 males and 7 females. The average BMI was 26 ± 2 Kg/m^2 in the control group, 25.9 ± 3 Kg/m^2 in the GPR group, and 27 ± 4 25.9 ± 3 Kg/m^2 in the PNE group. The average duration of chronic low back pain was 17 ± 2 months in the control group, 18 ± 6 months in the GPR group, and 17 ± 5 months in the PNE group. Following the rehabilitation protocols, pain intensity improved significantly in all groups: from 6.18 ± 1.1 to 3.13 ± 0.3 in the control group, from 5 ± 0.5 to 2 ± 0.1 in the GPR group, while the PNE group achieved the most substantial improvement, with a reduction from 7.18 ± 1.9 to 2.63 ± 0.1, which was statistically superior to the control group (p=0.04). Psychological status also improved across all groups: the control group showed a 7-point decrease from 11 ± 2.3 to 4 ± 0.9, and the GPR group demonstrated an improvement of 7.4 points from 11.07 ± 1.2 to 3.6 ± 0.4. However, the most significant improvement was observed in the PNE group, with HADS scores dropping by 7.9 points from 10.9 ± 2.5 to 3 ± 0.1, a statistically significant difference compared to both the control and GPR groups (p=0.02). Similarly, functional capacity, as measured by the ODI, improved across all groups, with the GPR group achieving the most significant reduction, decreasing from 21% to 8.5% (p=0.03 compared to the control group), while the PNE group showed a reduction of 10.8%, which was not statistically significant.

Conclusion:

This study highlights the effectiveness of combining innovative rehabilitation techniques with conventional approaches in the management of chronic low back pain. PNE was most effective in reducing pain and improving psychological status, while GPR showed superior outcomes in functional capacity. These findings emphasize the value of a multidimensional approach to optimize patient outcomes and recommend the integration of these techniques into routine care.

IS THERE AN ASSOCIATION BETWEEN ALBUMIN LEVELS AND THE RISK OF OSTEOPOROSIS IN POSTMENOPAUSAL PATIENTS WITH RHEUMATOID ARTHRITIS ?

S. Ben Hamouda[1], H. Boussaa[1], Y. Makhlouf[1], S. Miladi[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Fazaa[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Tunis, Tunisia

Introduction

Rheumatoid arthritis (RA) is associated with an increased risk of bone loss and fractures due to chronic inflammation. Serum albumin concentration, as a marker of inflammation and nutritional status, could provide a simple tool for screening patients at high risk of osteoporosis.

The aim of this study was to examine the association between serum albumin level and the risk of osteoporosis in postmenopausal RA patients.

Patients and methods

This was a cross-sectional observational study involving postmenopausal patients with (RA). Sociodemographic data and RA-related parameters were collected. Age at menopause, bone mineral density measurements and serum albumin levels were recorded. A low serum albumin level was defined as less than 35g/l.

The "p" significance level was set at 0.05.

Results

A total of 50 patients with a mean age of 61.4 ±8.6 years [41-83] were included. Mean body mass index was 27.1±8.8 kg/m. Thirty-seven patients (74%) were housewives, 6 (12%) were manual workers and 7 (14%) were office workers. Three patients (6%) were smokers. Co-morbidities objectified were high blood pressure (22%), diabetes (8%), heart disease (2%), dyslipidemia (2%) and asthma (2%). The mean age at menopause was 47.1±5.5 years [26-62]. RA was immunopositive in 84% of cases. The treatments received were Methotrexate in 78% of, Leflunomide in 18% and Sulfasalazine in 28%. Thirteen patients (26%) were receiving biotherapy. Thirty-seven patients (74%) received corticosteroid therapy with a mean dose of 6.1±3.6 mg/day and 20 patients (40%) received boluses of methylprednisolone. The mean DAS28 VS activity was 4.1±1.3 [0.97-6.83]. The densitometric data showed a mean femoral T-score of -2.3±1.1 DS and a mean vertebral T-score of -2.1±1.4 DS. Osteoporosis was noted in 35 patients (70%). Thirty-eight patients (76%) were receiving calcium supplements at an average daily dose of 428.5±288.6 mg/d and 40 patients (80%) were receiving vitamin D at an average daily dose of 744 ±435.2 IU/ml. Fourteen patients (28%) were taking bisphosphonates. The mean albumin level was 36.7±6.1g/L [16.9-50] with a mean of 35.6±6.4g/L in patients with osteoporosis and 37.1±5.9g/L in patients without osteoporosis . There was no significant association demonstrated between albumin levels

and the presence of osteoporosis (p=0.4), the mean value of the vertebral T score (p=0.73) and the mean value of the femoral T score (p=0.21). There was no significant association between low albumin levels and the presence of osteoporosis (p=0.77).

Conclusion

Our study showed no association between albumin levels and osteoporosis, mean femoral T-score and mean vertebral T-score, respectively.

P1326

DIFFERENCES IN BONE MINERAL DENSITY IN TYPE 2 DIABETES MELLITUS WITH AND WITHOUT FRAGILITY FRACTURES

S. Bhattacharya[1], L. Nagendra[2], S. Mondal[3], S. Avarebeel[4], Y. S. Ravikumar[5], H. Gowdappa[5], M. Hiligsmann[6], M. Chandran[7]

[1]Department of Endocrinology, Indraprastha Apollo Hospitals, New Delhi, India, [2]Department of Endocrinology, JSS Medical college, Mysore, India, [3]Department of Endocrinology, NRS Medical College, Kolkata, India, [4]Department of Geriatrics, JSS Medical College, Mysore, India, [5]Department of General Medicine, JSS Medical College, Mysore, India, [6]Department of Health Services Research, Care and Public Health Research Institute, Maastricht University, Maastricht, Netherlands, [7]Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore General Hospital, Singapore, Singapore

Objective: The study compared the bone mineral density (BMD) difference across the various skeletal sites in individuals with and without fragility fractures and type 2 diabetes mellitus (T2DM). We also correlated the T-score that predicted fracture in our study group to thresholds of osteoporosis treatment in T2DM as per current guidelines.(1)

Material and Methods: In this pilot study, 100 participants with T2DM, recruited across two tertiary care institutes in India, were stratified into two cohorts based on the presence of fragility fractures. Areal BMD (aBMD) at key skeletal sites and trabecular bone score (TBS) were assessed using dual-energy X-ray absorptiometry (DXA). A receiver operating characteristic (ROC) curve analysis was conducted to identify a T-score threshold capable of predicting fractures.

Results: Baseline characteristics comparing the two cohorts are depicted in Table 1. T-scores at the femoral neck (FN) [Mean (SD) - 1.99 (1.09) vs. -1.14 (1.38), p=0.03] and one-third radius (1/3 R) [-3.15 (1.42) vs. -1.45 (1.99), p=0.007] were markedly lower in individuals with fragility fractures compared to those without. Though the T-scores at the lumbar spine (LS) were lower in individuals with fragility fractures, they did not reach statistical significance [-1.76 (2.43) vs -0.82 (1.96), p=0.1]. ROC curve analysis determined that a T-score of -1.65 at FN identified individuals with fragility fractures (p=0.03). A T-score of -1.35 at LS differentiated individuals with fragility fractures (p=0.04).

Conclusion: FN T-scores demonstrated a significant association with fragility fractures in T2DM, with a threshold of -1.65 offering moderate predictive accuracy. Large-scale studies are needed to validate these findings and to assess whether the American Diabetes Association's current recommendation to initiate treatment at a T-score of ≤ -2.0 can adequately identify elevated fracture risk in T2DM.

THE IMPACT OF MEDICAL RECOVERY IN OSTEO-ARTICULAR DISORDERS AT THE HIP LEVEL

S. Birsan[1], S. Bodog[1]

[1]Faculty of Medicine Oradea, Oradea, Romania

The hip joint is a common joint that helps humans both in walking as well as in practicing the activities of daily life. Its degradation occurs later overloading the joint leading to the appearance of coxarthrosis which, untreated, becomes complicated and is required hip arthroplasty surgery. Most people who suffer from it operation are people aged between 40 and 80 years.

Material and methods:

In this study, we included a number of 20 patients aged between 46-87 years who underwent hip arthroplasty.

For these patients, anamnesis and radiological investigations were used as evaluation methods.

The patients were tested for muscle strength, which is an important benchmark for the program
physical therapy. Pain is a symptom that affects the patients' quality of life, and
this was measured using the VAS Scale.
Results:
30% of patients obtained an increase in muscle strength 4 and 35% of patients muscle strength 5.
From the results obtained from the VAS Scale, only 35% of patients have a score of 1 and 10% have
score 0 due to the physical therapy sessions performed.
Conclusion:
By practicing the exercises from the physical therapy program, most patients
they noticed an improvement in pain.

P1328

ASSESSING THE CORRELATION BETWEEN PAIN SEVERITY AND STRUCTURAL ALTERATIONS IN KNEE OSTEOARTHRITIS: AN IMAGING-IDENTIFIED APPROACH

G. Gerganov[1], S. Bogdanova-Petrova[2], T. S. Georgiev[2]

[1]Medical University of Varna, Department of Propaedeutics of Internal Medicine, Varna, Bulgaria, Varna, Bulgaria, [2]Medical University of Varna, First department of Internal diseases, Clinic of Rheumatology, Varna, Bulgaria, Varna, Bulgaria

Background: Osteoarthritis (OA) is a leading cause of disability worldwide, with pain being its cardinal symptom (1). The mechanisms underlying pain in knee OA (KOA) are multifactorial, ranging from structural injuries to central sensitization. These complex processes contribute to the observed discrepancy between pain severity and structural damage. Imaging techniques, such as radiography and musculoskeletal ultrasonography, are integral to routine clinical practice for assessing structural changes. However, their association with pain severity in KOA remains poorly understood.
Objectives: This study aims to evaluate the role of X-ray and ultrasound-derived parameters of structural damage in relation to pain perception in patients with KOA.
Methods: Sixty-four knees from 38 patients meeting the ACR criteria for KOA were assessed. Pain severity was evaluated using a 100-mm Visual Analog Scale (VAS). Anteroposterior radiographs of fully extended knees in an upright weight-bearing position were obtained and evaluated using the Kellgren-Lawrence (KL) grading system and the OARSI atlas. All patients underwent ultrasonography using a portable MyLab 25 Gold System equipped with an LA435 transducer (Esaote SpA, Genoa, Italy). Two experienced ultrasonographers assessed the presence of synovial thickening, effusion in the suprapatellar bursa, and popliteal cysts. Medial meniscal extrusion, medial and lateral femoral cartilage thickness were measured in both full extension and flexion positions. Femoral osteophytes were semi-quantitatively scored using a 4-grade scale (0-3).
Results: Pain levels significantly differed across the KL groups (p=0.01) and among groups classified according to medial tibiofemoral compartment narrowing, as defined by the OARSI atlas (p=0.05). Other radiographic characteristics from the OARSI atlas did not correlate with pain. Among the ultrasound parameters, medial meniscal extrusion and medial femoral cartilage thickness showed a weak correlation with pain levels (r=0.254, p=0.043; r=-0.265, p=0.034, respectively). However, in multivariate analysis adjusting for age and BMI, these correlations did not remain significant. No associations were found between synovial effusion, popliteal cysts, and pain severity.
Conclusion: Radiography and ultrasonography provide complementary insights into the structural changes in knee OA that may influence pain perception. These imaging modalities can enhance the overall evaluation of KOA patients, though the relationship between structural changes and pain remains complex and warrants further investigation.

P1329

THE INTERPLAY BETWEEN MOOD DISORDERS AND PAIN ASSESSMENT IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHRITIS

S. Bogdanova-Petrova[1], G. Gerganov[2], T. Shivacheva[3], T. S. Georgiev[1]

[1]Medical University of Varna, First department of Internal diseases, Clinic of Rheumatology, Varna, Bulgaria, Varna, Bulgaria, [2]Medical University of Varna, Department of Propaedeutics of Internal Medicine, Varna, Bulgaria, Varna, Bulgaria, [3]Medical Univeristy of Varna, First Department of Internal Diseases, Clinic of Rheumatology, Varna, Bulgaria, Varna, Bulgaria

Background: Chronic inflammatory arthritis is a leading cause of pain syndromes in rheumatology (1). Inflammatory joint diseases, including rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA), are among the most prevalent rheumatic conditions that contribute to musculoskeletal pain. The pathophysiology of pain is multifactorial, involving complex interactions of biochemical, biological, physiological, and psychosocial factors. While pain intensity is primarily influenced by the inflammatory activity of the underlying disease, the subjective experience of pain is significantly affected by the psycho-emotional state of the patient, which plays a crucial role in assessing pain severity (2)
Objectives: This study aims to evaluate the intensity of musculoskeletal pain (arthralgia and myalgia) and its correlation with anxiety and depressive mood disorders in a Bulgarian cohort of patients with chronic arthritis.
Methods: This was a single-centre, observational study involving patients diagnosed with chronic arthritis (RA, AS, and PsA)

at the Rheumatology Clinic of "St. Marina" University Hospital in Varna. All participants were diagnosed based on established criteria for specific inflammatory joint diseases and were treated with biologic therapies. Pain intensity (both muscular and joint) was assessed using Visual Analogue Scales (VAS), while anxiety and depression were measured using the Zung Self-Rating Scales for Depression (SDS) and Anxiety (SAS). Laboratory markers of acute-phase inflammation were also assessed. Data analysis included descriptive statistics, one-sample t-tests, correlation analysis, and linear regression, with a significance level set at $p<0.01$.

Results: A total of 130 patients with inflammatory joint diseases (RA, AS, and PsA) were included in the study. The mean age of the cohort was 56.37 years (range 21-76 years), with 41.5% women (n=54) and 58.5% men (n=76). No significant gender differences were found in VAS scores for joint and muscle pain ($p=0.177$ for joint pain and $p=0.717$ for muscle pain). Participants were categorised into groups based on their self-reported depression and anxiety levels (mild, moderate, and severe). Women exhibited higher scores for both depression and anxiety, with significant differences ($p<0.001$ for depression and $p=0.001$ for anxiety). The depression scale (SDS) showed a significant correlation with both muscular and joint pain (SDS and VASm $r=0.666$, $p<0.001$; SDS and VASa $r=0.644$, $p<0.001$), while anxiety (SAS) correlated significantly only with joint pain (SAS and VASm $r=0.698$, $p<0.001$; SAS and VASa $r=0.680$, $p<0.001$). The higher the depression and anxiety scores, the more severe pain patients reported on the pain scales. Inflammatory markers accounted for approximately 8% of the variance in pain levels, with R^2 values of 7.8% for joint pain and 8.1% for muscle pain.

Conclusion: Musculoskeletal pain is a frequent and significant clinical manifestation in chronic inflammatory arthritis. The presence of chronic pain can contribute to emotional dysregulation disorders, such as anxiety and depression. The intensity of pain experienced by patients correlates significantly with their emotional state, highlighting the importance of addressing both physical and psychological factors in the management of chronic inflammatory arthritis.

MUSCULOSKELETAL DISORDERS AMONG HEALTHCARE PROFESSIONALS: PREVALENCE AND RISK FACTORS

S. Bouden[1], E. Razgallah[1], L. Rouached[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Rheumatology department, Charles nicolle hospital, Tunis, Tunisia

Objective:
The aim of our study was to determine the prevalence of Musculoskeletal disorders (MSDs) among paramedical staff as well as the risk factors that may influence their occurrence.
Methods:
We conducted a cross-sectional study among paramedical staff at the Maternity and Neonatology Center of Tunis between July 2023 and March 2024. The participants included midwives, nurses, laborers, and supervisors. Sociodemographic characteristics and job-related data were collected using an interviewer-administered questionnaire.
The prevalence and severity of MSDs were assessed using the French version of the Nordic questionnaire.
Results:
The study included 80 paramedical staff members distributed across different roles: 43 nurses (53.8%), 17 laborers (21.3%), 13 midwives (16.3%), and 7 supervisors (8.8%). The sex ratio (M/F) was 0.27. The average age of participants was 49 ± 9 years, and the average work duration was 20 ± 8 years. Regarding working conditions, participants worked an average of 40 ± 7 hours per week, spread over 5 ± 1 days, with a mean of 2.3 ± 1 nightshifts per month. They took an average of 1.05 ± 0.75 breaks per day.
The prevalence of MSDs was 91%, distributed as follows: knees (60%), neck (57%), shoulders (55%), lower back (52%), wrists (47%), upper back (40%), fingers (37%), ankles (37%), elbows (26%), and hips (25%). The presence of MSDs was significantly correlated with older age ($p=0.03$) and the number of hours worked per week ($p=0.04$).
No correlation was found between MSDs and the number of working days per week ($p=0.208$), nor with the number of night shifts per month ($p=0.133$) or breaks per day ($p=0.600$).
Conclusion:
Our study confirmed the high prevalence of MSDs among paramedical healthcare staff, particularly in the knees. Age and the number of working hours appear to be risk factors for their occurrence.

P1331

CORTICOSTEROID INJECTIONS COMPARED TO PRP INJECTIONS FOR TREATING SHOULDER TENDINITIS

S. Bouden[1], S. Mhamdi[1], L. Rouached[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia

Objectives:
To compare the two treatments in terms of pain reduction and improvement in shoulder function.
Material and Methods:
A prospective study was conducted over a 5-month period at the Rheumatology Department of Charles Nicolle Hospital in Tunis. Patients with simple tendinitis were enrolled and divided into two groups: one group received corticosteroid infiltrations, and the other received PRP injections. Assessments were carried out at baseline (T0), one week (T1), and three months (T2). The outcome measures included pain using the Visual Analog Scale (VAS), the Quick Disabilities of the Arm, Shoulder, and Hand (QuickDASH) questionnaire, and the Shoulder Pain and Disability Index (SPADI) questionnaire.
Results:
The study included 37 patients, consisting of 6 men and 31 women, with an average age of 63 ± 8 years. Sixteen patients were diabetic. Tendinitis was present on the right side in 70% (n=26) of the cases. The average duration of symptoms was 37 ± 26 months. 21 patients received corticosteroid infiltrations, and 16 received PRP injections. Regarding prior treatments, all patients had used paracetamol, 70% (n=26) had taken oral nonsteroidal anti-inflammatory drugs (NSAIDs), and 89% (n=33) had used local anti-inflammatory treatments. Rehabilitation was performed in 32% (n=12) of the cases.
The average pain score on the VAS in the corticosteroid infiltration group was 7 at baseline (T0), 5 at one week (T1), and 3 at three months (T2). In the PRP group, the scores were 7 at T0, 6 at T1, and 5 at T2.
The mean QuickDASH scores were 51% and 55%, respectively, at T0, 47% and 51% at T1, and 33% and 45% at T2 for the corticosteroid and PRP groups. For the SPADI, the mean pain, disability, and total scores in the corticosteroid group were 68%, 51%, and 58% at T0, 63%, 51%, and 56% at T1, and 42%, 37%, and 40% at T2. In the PRP group, these scores were 69%, 48%, and 56% at T0, 66%, 48%, and 55% at T1, and 55%, 40%, and 39% at T2.
Pain assessment showed improvement in both groups at T1 with no statistically significant difference (p=0.7).
However, corticosteroid infiltrations provided better pain relief at T2 (p=0.02).
Both treatments led to functional improvements. However, no statistically significant difference was observed
between the two groups in terms of QuickDASH (p=0.6 at T1, p=0.3 at T2) or SPADI (pain: p=0.7 at T1, p=0.2 at T2; disability: p=0.7 at T1, p=0.7 at T2; total: p=0.8 at T1, p=0.9 at T2).
Conclusion:
According to our study, corticosteroid infiltrations provide better long-term pain relief compared to PRP injections in the treatment of simple shoulder tendinitis, but both treatments are equally effective in improving function.

P1332

BIOLOGICAL TREATMENT USE IN RHEUMATOID ARTHRITIS: WHAT IS THE IMPACT OF SOCIODEMOGRAPHIC AND CLINICAL FACTORS?

S. Boussaid[1], E. Razgallah[1], O. Ben Abdallah[1], S. Rahmouni[1], K. Zouaoui[1], M. Abbess[1], R. Dhahri[2], S. Rekik[1], H. Sahli[1]

[1]Rheumatology department, Rabta hospital, Tunis, Tunisia, [2]Department of Rheumatology, Military hospital of Tunis, Tunis, Tunisia

Objective:
In our study, we focused on the sociodemographic and clinical factors related to the resort to biological treatment in RA.
Methods :
We conducted a cross-sectional study among patients diagnosed with RA at a tertiary care university hospital in Tunisia. Sociodemographic, clinical, biological, and follow-up characteristics were collected.
Results :
We included 284 patients diagnosed with RA. The mean age was 60.21 ± 11.2 years, with 83.5% of women. The mean age at diagnosis was 49.33 years, and the mean diagnostic delay was 51.6 ± 62.7 months. Twenty percent were active smokers. Comorbidities including diabetes, hypertension, and dyslipidemia were noted respectively in 23.9, 29.2, and 17.6% of patients. Fibromyalgia was found in 10% of patients. Half of the patients (56.6%) had a sedentary lifestyle. Approximately, 52% of patients were of rural origin. Only 21.4% have reached the secondary education level, while 41% were illiterate. An average of 65.4% were unemployed. Polyarticular onset pattern was seen in 89% of patients, and oligoarticular in 10%. Rheumatoid factor (RF) and anticitrullinated peptide antibodies (ACPA) were positive respectively in 86.6 and 72.5%. Four percent of patients were on corticosteroids with an average dose of 7 ±2.8 mg/l. The delay between positive diagnosis and initiation of methotrexate was 10.6 ± 7.4 months.
Combination therapy (3 concomitant csDMARDs) was noted in 16.2% of patients. Seventy-two percent adhered to their treatment.
A significant correlation was noted between the switch to biological treatment and the number of comorbidities per patient (p=0.007), diabetes (p<0.001), hypertension (p=0.028), sedentary lifestyle (p=0.017), and living in urban areas (p=0.033).
Mood disturbances are insignificantly correlated to the resort to biological treatment (p=0.062).
Conclusion:
Treatment options for rheumatoid arthritis (RA) have evolved beyond traditional disease-modifying antirheumatic drugs (DMARDs) to include biologic DMARDs. Demographic factors as-

sociated with the resort to bDMARDs include diabetes, hypertension, sedentary lifestyle, and urban origin.

P1333

DISEASE-RELATED FACTORS ASSOCIATED TO THE INTRODUCTION OF BIOLOGICAL TREATMENTS IN RA PATIENTS

S. Boussaid[1], E. Razgallah[1], O. Ben Abdallah[1], S. Rahmouni[1], K. Zouaoui[1], M. Abbess[1], R. Dhahri[2], S. Rekik[1], H. Sahli[1]

[1]Rheumatology department, Rabta hospital, Tunis, Tunisia, [2]Department of Rheumatology, Military hospital of Tunis, Tunis, Tunisia

Rheumatoid arthritis (RA) is a chronic inflammatory disorder characterized by symmetrical joint involvement and persistent arthritis. Effective disease management relies on the early initiation of disease-modifying antirheumatic drugs (DMARDs). we aimed to determine the disease-related and management characteristics leading to the use of biological treatments in patients with RA.

Methods :

We conducted a cross-sectional study among patients diagnosed with RA at a tertiary care university hospital in Tunis. Sociodemographic, clinical, biological, and follow-up characteristics were collected.

Results :

We included 284 patients diagnosed with RA. The mean age was 60.21 ± 11.2 years, and the sex ratio (M/F) was 0,2. The mean age at diagnosis was 49.33 years, and the mean diagnostic delay was 51.6 ± 62.7 months. Comorbidities including diabetes, hypertension, and dyslipidemia were noted respectively in 23.9, 29.2, and 17.6% of patients.

Polyarticular onset pattern was seen in 89% of patients, and oligoarticular in 10%. At diagnosis, 35% had extraarticular manifestations, 42% had joint deformities, and 91% had erosive RA. Rheumatoid factor (RF), antinuclear antibody (ANA), and anticitrullinated peptide antibodies (ACPA) were positive in 86.6%, 42%, and 72.5%, respectively. Ten percent of patients developed Coxitis and 10.2% antlanto-axial instability. The mean C-reactive protein (CRP) level was 35 ± 37 mg/L, and the disease activity score 28 with CRP (DAS28(CRP)) was 5.2 ± 3.4 indicating high disease activity. Eighty-four percent of patients were on corticosteroids with an average dose of 7 ±2.8 mg/l. thirty-two percent of patients have received leflunomide (LEF), 64% sulfasalazine (SLZ), and 99% have received methotrexate (MTX). The delay between positive diagnosis and initiation of methotrexate was 10.6 ± 7.4 months. Combination therapy (3 concomitant csDMARDs) was noted in 16.2% of patients. Seventy-two percent adhered to their treatment.

A significant association was found between the use of bDMARDs and positive ANA (p=0.05), previous SLZ (p<0.001), and LEF intake (p<0.001), advanced age at diagnosis (p=0.012), and combination therapy (p<0.001).

However, the value of the DAS28(CRP) at diagnosis was not correlated to the use of biological treatment (p=0.06).

Conclusion: The use of bDMARDs revolutionized the management of patients with RA. Positive ANA, previous SLZ and LEF use, advanced diagnosis age, and combination therapy seem to influence their introduction.

P1334

CLINICAL APPROACH OF THE TREATMENT OF SYMPTOMATIC OSTEOPOROSIS IN THE ELDERLY: COMPARISON BETWEEN AGE RANGES

S. Cotobal Rodeles[1], J. F. Blanco Blanco[1], A. González Ramírez[1], S. Herrero Casillas[1], A. Hierro Estevez[1], R. Hierro Estevez[1], B. Miguel Ibáñez[1], C. Pablos Hernández[1]

[1]Complejo Asistencial Universitario de Salamanca, Salamanca, Spain

Objective: To analyze the clinical approach to treating symptomatic osteoporosis in elderly patients, stratified by age ranges, and to identify patterns of diagnostic and therapeutic management.

Material and Methods: This retrospective observational study reviewed the clinical records of elderly patients aged ≥65 years diagnosed with symptomatic osteoporosis in geriatric department of a tertiary care hospital in Spain. Patients were categorized into two age groups: 65–84 years (younger old, YO) and ≥85 years (older old, OO). Key variables assessed included demographics, comprehensive geriatric assessment (clinical, functional and psychosocial variables), the frequency of bone mineral density (BMD) evaluations, vertebral fracture assessments, initiation of anti-osteoporotic therapies, adherence and tolerability, refracture and mortality in patients with a minimun period of follow-up required of 13 months (mean folow-up for the sample 24 months).

Results: A total of 168 patiens were analyzed (91 YO mean age 79.45±4,35 years, 77 OO, mean age 87.99±2,75 years). BMD testing was performed more frequently in the YO group (88.88% vs. 76.79%). Vertebral fractures were underdiagnosed in both groups but identified more often in the YO group (17.6% vs. 29.7%). Anti-osteoporotic treatment was initiated in both groups in 100% of patients. Denosumab was more frequently prescribed in the OO group (48.4% vs. 67.5%). Other treatments like biphosphonates (36.3% vs. 23.0%) or teriparatide (15.4% vs. 6.8%) were more frequently used among YO patients. Refracture during follow-up occurred in 11.76% (4) of the YO group vs 15.74% (9) of the OO, with no statistical difference; mortality was 17.65% (6) of the YO group vs 14.04% (8). We did not find in our study differences among both groups in terms of basal functional status (Barthel, Physical Red Cross and Lawton indexes), treatment tolerability, secondary effects nor adherence.

Conclusion: The clinical approach to treating symptomatic osteoporosis differs significantly between age ranges, with a notable decline in diagnostic measures in patients ≥85 years. Although pharmacological approach may differ, both groups have similar results in therms of mortality and refracture. Assuming that all these patients are at high risk of new fractures, therapeutic abstention it is no longer an option.

P1335

SARCOPENIA: TODAY HOW TO TREAT IT

S. Dahmani[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]"Rahmani" Pharmacy, Casablanca, Morocco, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Sarcopenia is more common in elderly and senile people, due to the progressive and generalized loss of muscle mass with impaired skeletal muscles. Sarcopenia can occur in violation of nutrition, a decrease in physical activity.

Objective. Adverse outcomes of sarcopenia are falls and fractures. Fractures lead to a decrease in the functional activity of patients, increase the risk of death from all causes, especially in elderly and senile people.

Methods. The study includes 140 people, of which 75 men (53.57%) and 65 women (46.47%), age median - 73 [68; 78] years. Sarcopenia diagnostics were carried out using the criteria Foundation of NIH Sarcopenia (FNIH), European Working Group on Sarcopenia in Older People (EWGSOP2), Sarcopenia Definition and Outcomes Consortium, SDOC Global Leadership Initiative in Sarcopenia (GLIS). To evaluate risk factors, logistic regression analysis and the method of classification criteria were used. Patients were prescribed by native forms of vitamin D3 as drug therapy.

Results. In the sample of patients aged ≥65 years, the frequency of sarcopenia varied from 14.5 to 33%, depending on the diagnostic criteria used. When using the diagnostic criteria EWGSOP2, sarcopenia was detected in 27.5% of patients over 65 years old. The frequency of sarcopenia increased with age, reaching 58.7 % in people 85 years old and older. Significant risk factors were the age of ≥77 years (p=0.023), body mass index BMI <24 kg/m^2 (p<0.001), as well as level 25(OH)D less than 21.7 ng/ml (p=0.007), C-reactive protein (CRP) ≥6.7 mg/l (p<0.001), total blood protein <65 g/l (p<0.001) and estimated glomerular filtration rate (GFR)<60 ml/1.73 m^2 according by the formula GFR-EPI (p=0.004). For treatment, native forms of vitamin D3 were prescribed. As a result of prolonged therapy, we observed an improvement in the function of skeletal muscles (p<0.001).

Conclusion. Sarcopenia is a common disease in elderly and senile people, regardless of the diagnostic criteria used. Native forms of vitamin D3 have a beneficial effect on the function of skeletal muscles.

P1336

USING A SCREENING OF RESPIRATORY SARCOPENIA IN GERIATRIC PRACTICE

S. Dahmani[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]"Rahmani" Pharmacy, Casablanca, Morocco, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Respiratory sarcopenia (RS) is significant for predicting the outcome of sarcopenia in patients in geriatric practice.

Objective. The purpose of the study: to evaluate the peak expiratory flow rate in geriatric patients with various sarcopenic phenotypes and without sarcopenia.

Methods. 67 patients (45 women, 22 men) were examined: 15 - with the presence of sarcopenia, 25 with the presence of sarcopenic obesit, 14 - with obesity without sarcopenia, 17 - without obesity and sarcopenia. Diagnosis of the sarcopenic phenotype was carried out according to the protocol of the European group for the study of sarcopenia. In order to evaluate the peak expiratory flow rate (l/min) was carried out picfluometry.

Results. The average age of the participants was 74.3±6.2 years, the groups were comparable by age. The peak expiratory flow rate was reduced in all groups of patients, but the smallest values of the peak expiratory flow rate were noted in groups of patients with sarcopenia 255 (200; 310) and sarcopenic obesity 216.75 (166; 267.5) without statistically significant differences between these groups (p=0.77). In a group of patients with obesity of the peak expiratory flow rate amounted to 390 (300; 480). In a group without sarcopenia and obesity, the highest indicators of the peak expiratory flow rate 400 (325; 465) are noted. Significant differences in the peak expiratory flow rate were obtained between groups of patients with different sarcopenic phenotypes and these groups (p=0.004–0.019). The connection of muscle strength and peak expiratory flow rate is confirmed by statistically significant straight correlation interconnections of the indicators of the peak expiratory flow rate and hand dynamometry (right, left) in all compared groups. In the group of sarcopeneic obesity: right hand dynamometry and peak expiratory flow rate (r=0.57, p=0.003), left hand dynamometry and peak expiratory flow rate (r=0.58, p=0.016). In the group of sarcopenia, right hand dynamometry and peak expiratory flow rate (r=0.57, p=0.015), left hand dinamometry and peak expiratory flow rate (r=0.59, P=0.013). In the united group of patients without sarcopenia, right hand dynamometry and peak expiratory flow rate (r=0.55, p=0.02), left hand dynamometry and peak expiratory flow rate (r=0.67, p=0.0022). The most pronounced correlation of the peak speed of exhalation with the compression force of the left hand is noted in the group without sarcopenia.

Conclusion. Picfluometry is a widely accessible method for diagnosing respiratory sarcopenia. The peak expiratory flow rate is significantly reduced in patients with different sarcopenic phenotypes. The indicator of the peak expiratory flow rate can be the initial test of assessment of the weakness of the respiratory muscles.

P1337

OSTEOPOROSIS AND NON-ALCOHOLIC FATTY LIVER DISEASE: COMORBIDITY ISSUES

S. Dahmani[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]"Rahmani" Pharmacy, Casablanca, Morocco, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Comorbidity of non-alcoholic fatty disease of the liver and osteoporosis is due to general pathogenetic mechanisms.

Objective. Assess the condition of bone tissue in patients with non-alcoholic fatty liver disease.

Methods. The study was attended by 55 women with non-alcoholic fatty liver and 27 women without liver damage over 50 years old. The investigation criteria in the study was: the presence/absence of ultrasound signs of non-alcoholic fatty liver disease, the exclusion of viral liver damage, and the exclusion of alcohol consumption in hepatotoxic doses.

In order to verify the diagnosis, an ultrasound examination (US) of the abdominal cavity, densitometry with the determination of the T-cross of the hip and the lumbar spine, biochemical indicators of blood (bilirubin, alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, glucose in serum blood, gamma-glutamyltranspeptidase).

Based on the results of blood tests and an ultrasound of the liver, patients were divided into 3 groups. The first group of 35 people with liver steatosis, the second group – 15 patients with steatohepatitis. The control group was 15 women without liver damage.

Results. The average values of the T–criteria in the first and control groups did not have differences (liver steatosis: -0.73±0.54 SD in the femoral neck and -0.85±0.64 SD in the lumbar spine; control: -0,51±0.42 SD in the femoral neck, -0.76±0.38 SD in the lumbar spine). In a group of patients with steatogepatitis, the values of T-criteria were significantly ($p<0.05$) lower in both areas of the study (-1.76±1.012 SD in the femoral neck and -1.63±0.96 in the lumbar spine). Individual indicators of T-criteria revealed that in a group with liver steatosis, osteoporosis was observed in 8 (22.8%), osteopenia-11 (35.1%) examined persons. In the control group, the frequency of detection of osteoporosis and osteopenia statistically did not differ from the first group (two (13.3%) and three (20%) of the patient, respectively). In the second group of patients with steatogepatitis, the frequency of detection of osteoporosis was significantly ($p<0.05$) higher (7 (46.6%) patients); osteophenia was observed in 3 (20.0%) patients.

Conclusion. The identified decrease in the mineral density of bone tissue with non-alcoholic fatty liver disease at the stage of steatogepatitis increases the risk of osteoporosis.

P1338

RHEUMATIC DISEASES: FOCUS ON VITAMIN D

S. Dahmani[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2], O. V. Sharapova[3], L. I. Gerasimova[3], S. A. Yastrebova[2]

[1]"Rahmani" Pharmacy, Casablanca, Morocco, [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia, [3]Russian Biotechnological University, Moscow, Russia

Background. Vitamin D deficiency is a pathological condition that leads to a violation of calcium metabolism and affects the rate of development of osteoporosis.

Objective. Conduct a clinical examination of patients and determine the content of vitamin D in the blood.

Methods. A clinical examination of patients with the determination of the content of vitamin D in the blood was carried out.

Results. The age of the examined was from 25 to 75 years, the average age was 50.6±17.0 years. The gender composition was represented by women (83%). The structure of nosological diagnoses was predominated by rheumatoid arthritis (46.4%), osteoarthritis (33.5%), systemic scleroderma (7.5%), hypermobility of the joints (3.5%), rheumatic polymialgia (3.4%), hyperuricemia (5.7%). The study of vitamin D was carried out only in 70% of patients aimed at the rheumatologist. The level of vitamin D in these patients did not reach the lower boundary of the target values and was in the range from 15.2 to 28.5 ng/ml; the average level was 19.5±6.9 ng/ml. Vitamin D levels were distributed as follows: 45% of people had a deficiency and 55% of people – vitamin deficiency in the blood. Among persons with violations of vitamin D levels (deficiency, insufficiency), the intake of glucocorticoids (prednisolone, methylprednisolone) was observed in 22.5% of the examined, the use of proton pump inhibitors – in 50%.

Conclusions. In the structure of nosological diagnoses in patients directed to the rheumatologist, rheumatoid arthritis and osteoarthritis prevail. The insufficient study of the level of vitamin D in patients with a rheumatological profile (only 70% examined) is noteworthy, and its average level corresponds to a deficiency (19.5±6.9 ng/ml). There is a high prevalence of risk factors for the development of osteoporosis in examined patients: female gender (83%), age (average age – 50.6±17.0 years), the use of drugs (50% are taken by proton pump inhibitors, 22.5% – glucocorticoids). It is necessary to include a study of vitamin D levels in the mandatory standard of examination in patients with a rheumatological profile.

P1339

RETROSPECTIVE SINGLE-CENTER STUDY ON THE RADIOLOGICAL PROGRESSION OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

S. Dimitrov[1], S. Hristova[1], S. Bogdanova-Petrova[1], R. Moraliyska[1], D. Simeonova[1], G. Gerganov[1], T. S. Georgiev[1]

[1]Medical University "Prof. Dr. P. Stoyanov", Varna, Bulgaria

Background: At present, nr-ax SpA is considered to be the early phase of AS. However, there is sufficient evidence that not everyone progresses in the phase of structural changes, and that there are individual rates of development of the disease. Different patient risk characteristics for progression to AS are discussed in the literature. Objectives: To establish the progression of nr-ax SpA to radiographic spondyloarthritis in patients in the Bulgarian population and to indicate the factors associated with it.
Methods: A retrospective single - center study was conducted in patients previously diagnosed with nr-ax SpA in a study conducted in patients from Bulgaria in the period August 2022 to April 2023. Patients who had a rheumatologist confirmed diagnosis of nr-ax SpA were eligible to participate. All patients met ASAS criteria for IBP with duration from 3 months to 2 years, had no changes reported after the conventional X-ray of the sacroiliac joints and a performed subsequent MRI. Sacroiliac joint inflammation was assessed using the Canadian Spondyloarthritis Research Consortium (SPARCC). This study included an assessment of disease activity in the last month from the date of the visit, functional assessment of the patient, analysis of conventional radiographs and MRI of sacroiliac joints or spine performed during the last 12 months before the visit, as well as available composite indices for assessing disease activity.
Results: A total of 62 patients with previously diagnosed non-radiographic SpA were included in this analysis. A higher proportion of patients were male patients (61% vs 39%). The mean age was 38.7±6.51 with mean symptoms duration 5.62±1.36 years. The burden of disease activity measured by BASDAI, ASDAS-CRP and VAS as well as ASQoL did not differ in 62% (n=38) of the patients compared with the data recorded in their last visit (p>0.05). In n=18 (29.03%) consecutive MRI of sacroiliac joints was found in the last 6 months and according to the ASAS criteria remained in the group of patients with nr-ax SpA. Patients who indicate that they have a control MRT without changes and who have no complaints in the last 6 months are 10 (16.12%). In n= 14 (22.58%), objective evidence of clinical and laboratory disease activity was available, but for various reasons, no rheumatologist was visited after the nr-ax SpA diagnosis was made. In 32.25% (n=20) we found progression for the disease to our radiographic phase. Of these, NSAID-treated patients were 6.4% (n=4), 25.% (n=16) were treated with biologically DMARDs, with 9.67% with initiated second biological DMARDs (due to inadequate disease activity control). We found that patients with progression of nr-ax SpA to AS were 80% (n=18) male, 85% (n=17) carriers of HLA B27. They were characterized by baseline elevated CRP values at 95% (n=19) and SPARCC >25 at 75% (n=15). In 75% (n=15) of patients with radiographic progression, the onset of symptoms was before the age of 30.
Conclusion: Nr-ax SpA is a disease characterized by comparable levels of disease activity and functional limitation to patients with AS. We found radiographic structural changes in approximately one-third of patients, and among the factors associated with progression are HLA B27, high levels ot initial biomarkers of inflammatory activity, male sex, early onset of symptoms, and high degree of sacroiliac joints involvement at baseline.

Objectives: Tumoral calcinosis (TC) is an extremely rare condition characterized by lobular calcified masses in the periarticular soft tissues. We have previously characterized a TC-stem cells (SCs) line (TC1-SC) from a primary cell line obtained from a TC biopsy. Since over the last years increasing evidence suggested the involvement of the endocannabinoid system (ES) in the regulation of bone remodeling, we investigated the possible mechanisms underlying TC progression, focusing on the role of ES in TC.
Methods: After the establishment and characterization of TC1-SCs by using cellular and molecular assays, we analyzed the expression of the osteogenesis-related and the ES components genes during the osteogenic differentiation up to 21 days. Furthermore, ALP activity and calcium-phosphate deposition were quantified by fluorometric assays during the osteogenic differentiation of TC1-SCs treated with different concentrations of anandamide (AEA) (i.e., 1nM, 10nM, 100nM, 1μM, and 10μM), a partial agonist of both CB1 and CB2 receptors.
Results: Our preliminary results revealed not only the presence of the ES components (i.e., *CNR1*, *CNR2*, *NAPE-PLD*, *FAAH*, and *DAGLα*) in the TC1-SCs line but also their positive modulation during the osteogenic differentiation process. Preliminary data obtained from the fluorometric analysis showed that all the tested concentrations of AEA caused significant increases in the production of hydroxyapatite crystals compared to the control cells.
Conclusions: In this study, we demonstrated for the first time the presence of ES components in TC, identifying a significant upregulation of the ES-related genes during the osteogenic differentiation. Considering that activation of the CB2 receptor plays an im-

portant role in osteogenic differentiation as well as we observed in this study, we are currently evaluating whether the *in vitro* treatment with a potent and selective CB2 receptor antagonist, could hamper the calcium deposition typically found around large joints in TC patients. These preliminary data could provide a basis not only to evaluate how the ES could be relevant in TC pathogenesis but also to identify novel molecular targets for developing TC-targeted therapies.

MOLECULAR CHARACTERIZATION OF THE EFFECTS OF CALCIFEDIOL ON IN VITRO HUMAN PREOSTEOBLASTIC CELL MODELS

S. Donati[1], G. Palmini[2], I. Falsetti[1], C. Aurilia[1], F. Marini[2], G. Galli[1], R. Zonefrati[2], T. Iantomasi[1], L. Margheriti[3], A. Moro[3], M. L. Brandi[2]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy, [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O. Onlus), Florence, Italy, [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy

Objectives: Notably, calcifediol can modulate the transcriptome through the VDR interaction. Emerging evidence revealed that calcitriol also regulates the expression of a subset of miRNAs with potential regulatory functions in cancer pathways. In this study, we investigated not only the ability of calcifediol to affect the osteogenic differentiation process of mesenchymal stem cells derived from human adipose tissue (hADMSCs) but also to modulate the expression of osteogenic-related genes and miRNAs.

Methods: Two hADMSCs lines were prepared from subcutaneous adipose tissues obtained from health donors. Cells were exposed to different concentrations of calcifediol (10μM, 100nM, 50nM, and 10nM) in osteogenic induction medium for 35 days and the osteogenic phenotype was evaluated by fluorometric assays. In addition, we investigated the expression of a panel of genes and miRNAs involved in osteogenesis for up to 21 days in osteogenic differentiated cells.

Results: Our data showed that ALP activity and mineralization of hADMSCs were both affected by the presence of calcifediol. These results were consistent with miRNAs analysis where we found, depending on the cell line where we investigated the calcifediol-related effects, a higher level of expression at 14 or 21 days of those miRNAs that have been reported to positively regulate the osteogenic process (i.e., miR-27a-3p, miR-29a-3p, miR-125a-5p, and miR-196b-5p) in cells exposed respectively to 100nM and 50nM calcifediol. Preliminary data showed that 10μM calcifediol upregulated the expression of early and late key osteogenic genes (i.e., *RUNX2*, *COL1A1*, and *OCN*) as well as increased the *RANKL*/*OPG* mRNA ratio.

Conclusions: Here, we showed that calcifediol promoted the hADMSCs osteogenic differentiation either by enhancing ALP activity or by inducing extracellular matrix mineralization. Furthermore, we observed that physiological concentrations of calcifediol increased the expression of pro-osteogenic differentiation miRNAs. In this regard, we are currently evaluating whether the different concentrations to which we have observed such modulation could be ascribed to the different expression of *VDR* mRNA on the two hADMSCs lines. These findings could allow the design of novel therapeutic applications of this molecule against metabolic bone diseases in the future.

SEARCHING FOR THE 'WINNER' HIP FRACTURE PATIENT: THE EFFECT OF MODIFIABLE AND NON-MODIFIABLE FACTORS ON CLINICAL OUTCOMES FOLLOWING HIP FRACTURE SURGERY

S. E. Zourntou[1], K. Makridis[1]

[1]IASO THESSALIAS, LARISSA, Greece

Objectives: Various factors, other than the quality of surgery, may influence clinical outcomes of hip fracture patients. We aimed to evaluate the relative impact of several factors on functional outcome, quality of life, re-fracture and mortality rates following surgery for hip fractures.

Material and Methods: We studied 498 (62.2%) women and 302 (37.8%) men with a mean age of 81.3 years (range, 60–95) with hip fractures (femoral neck and pertrochanteric). The mean follow-up was 74 months (range 58–96). Various patient-related and surgery-related parameters were recorded and correlated to both objective and subjective mobility, functional recovery and quality of life scales. Mortality and re-fracture rates were also evaluated.

Results: Using multiple regression analysis, age >80 years (p = 0.000; 95% CI, 1.077–1.143) and ASA score III and IV (p = 0.000; 95% CI, 2.088–3.396) (both non-modifiable factors) both proved to be independent (s.s.) factors affecting mortality rates. Age <80 years (p = 0.000; 95% CI, 0.932–0.974), surgery delay less (modifiable factor) than 48 hours (p = 0.046; 95% CI, 0.869–0.999), low dementia CDR index (p = 0.005; 95% CI, 0.471–0.891) (non-modifiable factor), and osteoporosis medical treatment (modifiable factor) (p = 0.006; 95% CI, 0.494–0.891) were shown to be independent (s.s.) factors affecting HOOS-symptoms. Osteoporosis medical treatment used proved to be an independent (s.s.) factor affecting HOOS-daily activities (p = 0.049; 95% CI, 0.563–1.000) and quality of life (E-Qol-5D) (p = 0.036; 95% CI, 0.737–1.325).

Conclusion: A hip fracture patient aged <80 years old, with an ASA I-II, with low dementia CDR index and on osteoporosis medication has a better chance of an improved outcome (winner patient).

P1343

PREVALENCE OF SMARTPHONE ADDICTION AND ITS IMPACT ON MUSCULOSKELETAL DISORDERS

S. El Arem[1], H. Khlifi[2], I. Haddada[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]Taher Sfar Hospital, Physical and Rehabilitation department, Mahdia, Tunisia, [2]Family Medecine Department, Mahdia, Tunisia

Introduction : In the digital age, smartphone use has become ubiquitous, particularly among medical students, who are exposed to risks associated with excessive use. The aim of this study was to determine the prevalence of smartphone addiction, its association with musculoskeletal disorders (MSDs).

Patients and Methods : A cross-sectional analytical survey was conducted among medical students at the Monastir Faculty of Medicine using a self-administered questionnaire. The tools used included the SAS-SV for addiction assessment, the modified Nordic scale and Neck Disability Index (NDI) for MSD, the PHQ-9 for depression, and the ISI scale for sleep quality.

Results : Of the 203 students who took part in the study, 43.3% were smartphone addicts. MSDs were found in 70.9% of participants, with a marked prevalence of neck pain (49.3%), followed by lower back pain (43.8%) and upper limb pain (35.5%). In addition, 29.6% of participants suffered from depression, and 27.1% from insomnia. Multivariate analysis showed a significant association between smartphone addiction and intensive use after waking up (ORa = 0.97, P = 0.00), frequent checking of the device (ORa = 1.16, p = 0.01), low back pain (p=0.00; ORa=4.44), shoulder/arm pain (p=0.00; ORa=0.29), and insomnia (p=0.00; ORa=2.73).

Conclusion : Smartphone addiction was common among medical students. Education on sleep hygiene and the adoption of support measures for addicted students would be necessary to reduce the harmful consequences of excessive smartphone use on students' physical and mental health.

P1344

DEGENERATIVE LUMBAR SPINAL STENOSIS IN THE ELDERLY: EPIDEMIOLOGICAL PROFILE AND THERAPEUTIC MANAGEMENT

S. El Arem[1], I. Haddada[1], N. Feni[2], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]Taher Sfar Hospital, Physical and Rehabilitation department, Mahdia, Tunisia, [2]Ibn El Jazzar Hospital, physical and rehabilitation medecine, Kairouan, Tunisia

Introduction:
Lumbar spinal stenosis (LSS) can cause symptomatic neurogenic claudication alongside radicular pain and weakness. It is frequent in the elderly. The aim of this study was to describe the epidemiological profile, radiological aspects as well as therapeutic modalities of lumbar stenosis in the elderly.

Patients and methods:
A retrospective study carried out over a period of 3 months on patients aged over 65 years, followed in physical medicine for lumber spinal stenosis. Clinical, radiological, and therapeutic data were collected.

Results:
Fifty patients were included in this study with a sex ratio-ratio of 0.5. Their mean age was 73 years. In their medical history, 55.8% were hypertensive, 77.6% diabetic and 33% had dyslipidemia. All patients had a history of chronic low back pain evolving since an average of 2 years.
Lumbar pain was the most frequent reason for consultation (80%): unilateral in 45% of patients and bilateral in 55% of the cases, associated with radicular claudication in 80% of cases and urinary disturbances in 25% of the cases. Physical examination showed spinal syndrome in 75% of cases, radicular syndrome in 48% of cases and pathological neurologic signs in 22% of cases. On imaging, LSS had varied etiology: disc herniation (35%), facet hypertrophy (45%), cyst formation (25%) and ligamentous hypertrophy.
All patients received medical treatment associated with an individualized rehabilitation program. Epidural corticosteroid injection was done in 55% of cases.

Conclusion:
Lumbar spinal stenosis (LSS) is a debilitating condition associated with degeneration of the spine with aging. It requires multidisciplinary management based on conservative treatment in the first line.

P1345

ASSOCIATION BETWEEN CATASTROPHIZING AND FUNCTIONAL LIMITATION IN PATIENTS WITH KNEE OSTEOARTHRITIS

S. El Arem[1], I. Haddada[1], N. Feni[2], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]Taher Sfar Hospital, Physical and Rehabilitation department, Mahdia, Tunisia, [2]Ibn El Jazzar Hospital, physical and rehabilitation medecine, Kairouan, Tunisia

Introduction :
Knee Osteoarthritis (KO) is a frequent reason for consultation responsible for pain and restriction of autonomy. The aim of this study was to determine the association between catastrophism and functional limitation in patients undergoing Physical and Rehabilitation Medicine PRM for KO.
Patients and methods:
An analytical cross-sectional study was conducted in the physical medicine department. Demographic data, history of KO as well as the Kallegren and Lawrence radiographic stage were collected. Functional discomfort was assessed using the Lequesne knee index and catastrophism was assessed by the PCS questionnaire in its version translated and validated in Arabic.
Results:
We included 90 patients with a mean age of 58.76 ± 9 years. Most were women (88.9%) and 44.4% of them were obese. KO was bilateral in 73.3% of cases. The mean Visual Analog Scale (VAS) for pain at rest was 29.18 ± 19.69 and on walking was 57,14 ±15,81.

The mean Lequesne score in our population was 11.33 ± 3.53 and the PCS score 23.91 ± 11.28. The factors associated with a statistically significant high level of catastrophizing were level of education (p= 0.04), obesity (p=0.007), radiological stage (p= 0.048), Lequesne index (p= 0.019), and the components of the HAD score (p< 10-3).
Conclusion:
Catastrophism influences the severity of KO by exacerbating the perception of pain and limiting patients' functional abilities. It should be assessed during follow-up of these patients in order to adapt therapeutic strategies.

P1346

USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE IN DEGENERATIVE DISEASES: IMPACT ON PAIN AND FUNCTIONAL STATUS

S. El Arem[1], R. Ben Tekaya[1], I. Haddada[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]Taher Sfar Hospital, Physical and Rehabilitation department, Mahdia, Tunisia

Introduction:
Complementary and alternative medicine (CAM) is an approach to health care based in treatments different from those of conventional medicine. The use of CAM has grown significantly in recent years.
The aim of this study was to evaluate tendancy of use of alternative medicine and its effectiveness on pain, functional status on patients suffering from degenerative diseases (common low back pain, cervicarthrosis and gonarthrosis)
Methods:
This was a descriptive cross-sectional study including patients followed in our consultation for degenerative diseases (gonarthrosis, low back pain and cervicarthrosis). Patients were asked about the use of CAM, types of therapies used, the reasons for using these medicines and factors associated with their use.
Results
Eighty four patients were included in this study, 55.9% of them had used CAM at least once in their lives, 47.4% reported starting the use of CAM before the declaration of their illness. Sixty three percent of patients reported using CAM for pain relief, while 36.8% hoped for a cure. Regarding types of CAM, 52.6% of patients used cupping (El hijama), 47.4% used essential oils, 9% took herbal medicine and 5% opted for acupuncture. Not all patients informed their doctor about their use of CAM, 94.7% of the patients thought that CAM could not have any adverse effects and the majority thought that CAM was effective.
Conclusion:
In our study, the prevalence of CAM use remains high, with different types used, namely cupping and essential oil therapy.

P1347

COMPARING THE EFFECTIVENESS OF MANUAL THERAPY AND NEURODYNAMIC TECHNIQUES IN MANAGING MODERATE IDIOPATHIC CARPAL TUNNEL SYNDROME

S. El Arem[1], M. Zina[2], I. Haddada[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]Taher Sfar Hospital, Physical and Rehabilitation department, Mahdia, Tunisia, [2]Higher School of Health Sciences and Technologies of Monastir, Monastir, Tunisia

Introduction: Carpal tunnel syndrome (CTS) is a group of symptoms caused by irritation of the median nerve in the carpal tunnel. It is often idiopathic and frequently found in manual workers. It causes neuropathic pain that negatively affect the quality of life. The aim of this study was to compare the contribution of manual therapy versus neurodynamic techniques in the management of moderate idiopathic CTS.
Patients and methods: A prospective comparative study included patients with moderate CTS divided into group A: manual therapy and group B: neurodynamic techniques. The rehabilitation protocol was carried out over a 4-week period with 3 sessions per week. The evaluation was based the Visual Analog Scale (VAS) for pain and the BCTQ and Quick DASH functional scores.
Results: At the end of the protocol, both groups had an improvement in pain and functional scores with a superiority of the neurodynamic group for the pain score (VAS), the Quick DASH and the BCTQ-SSS score.
Conclusion: Manual therapy and neurodynamic techniques are effective on pain, functional signs in moderate idiopathic CTS but neurodynamic techniques showed superiority in this study on pain and functional scores.

P1348

SUSTAINED EFFICACY, SAFETY AND IMMUNOGENICITY FOLLOWING SINGLE SWITCH FROM REFERENCE DENOSUMAB TO FKS518 PROPOSED BIOSIMILAR IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS (RESULTS FROM THE PIVOTAL LUMIADE 3 STUDY)

S. Ferrari[1], E. Krecipro-Niziska[2], W. Pluskiewicz[3], P. Szeles[4], A. De Souza[4], J. Monnet[4], I. Valter[5]

[1]Division of Bone Diseases, Geneva University Hospital and Faculty of Medicine, University of Geneva, Geneva , Switzerland, [2]FutureMeds – Wroclaw, Wroclaw, Poland, [3]Gabinet diagnostyki i leczenia osteoporozy, Gliwice, Poland, [4]Fresenius Kabi Biopharma, Eysins, Switzerland, [5]Nordestmedical center, Center for Clinical and Basic Research AS,, Tallinn, Estonia

Background: Biosimilars reduce medication costs and improve access to treatments, making the transition from originator biologics to biosimilars of great interest. FKS518 is a candidate biosimilar to denosumab, a RANKL inhibitor, used in osteoporosis.

Objectives: The LUMIADE-3 phase study aimed to demonstrate therapeutic equivalence between FKS518 and reference denosumab (originator) in postmenopausal women with osteoporosis, and to evaluate the impact of transitioning from denosumab to FKS518 on efficacy, safety, and immunogenicity.

Material and Methods: This randomized, double-blind, multicenter trial involved osteoporotic women aged 55-85 with LS-BMD T-scores between -2.5 and -4.0. Patients were randomized 1:1 to originator or FKS518 (60 mg doses, 1 every 6 months) until week 52 (W52, end of Core Period). At W52, those on originator were re-randomized 1:1 to continue or switch to FKS518, while those on FKS518 continued their treatment. The primary objective was to show equivalence in efficacy and pharmacodynamics[1]. Efficacy and safety endpoints at W52 and up to W78 included LS-BMD, BMD at femoral neck and total hip, occurrence of adverse events (AEs), serious AE, local tolerability, and immunogenicity.

Results: A total of 553 patients were randomized to FKS518 (277) or originator (276). Therapeutic equivalence was demonstrated[1]. At W52, 125 patients on originator were re-randomized to continue and 124 to switch to FKS518. Clinically relevant increases in LS-BMD, femoral neck BMD, and total hip BMD were observed at W52 (Figure 1). Increases continued up to W78. At W78, changes from baseline in these BMD measures were similar between those who continued on originator and those who switched to FKS518. No clinically meaningful differences in safety, tolerability, or immunogenicity were observed after switching.

Conclusions: The study demonstrated therapeutic equivalence between FKS518 and the originator, with sustained efficacy and no impact on safety or immunogenicity after transitioning from the originator to FKS518.

A RANDOMIZED, CONTROLLED, MULTICENTER STUDY TO EVALUATE THE THERAPEUTIC EQUIVALENCE BETWEEN FKS518 PROPOSED BIOSIMILAR TO DENOSUMAB AND THE REFERENCE DENOSUMAB IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS (LUMIADE-3 STUDY)

S. Ferrari[1], E. Krecipro-Niziska[2], W. Pluskiewicz[3], P. Szeles[4], C. Petit-Frere[4], E. Simoes[4], I. Valter[5]

[1]Division of Bone Diseases, Geneva University Hospital and Faculty of Medicine, University of Geneva, Geneva , Switzerland, [2]FutureMeds – Wroclaw, Wroclaw, Poland, [3]Gabinet diagnostyki i leczenia osteoporozy, Gliwice, Poland, [4]Fresenius Kabi Biopharma, Eysins, Switzerland, [5]Nordestmedical center, Center for Clinical and Basic Research AS,, Tallinn, Estonia

Background

Treatment with denosumab, a RANKL inhibitor, is growing with patient ageing, and biosimilars can increase patients' access to treatment. FKS518 is a candidate biosimilar to denosumab. LUMIADE-3 study (NCT04934072) was designed to assess the safety and efficacy of FKS518 and evaluate its therapeutic equivalence to the reference denosumab (originator).

Material and Methods

This randomized, double-blind, multicenter trial involved postmenopausal osteoporotic women aged 55-85 with LS-BMD T-scores between -2.5 and -4.0. Patients were randomized 1:1 to the originator or FKS518 (60 mg doses, 1 every 6 months) until week 52 (end of Core Period). The primary objective of the study was to show equivalence in efficacy (percentage change from baseline (%CfB) in LS-BMD at W52) and pharmacodynamics (PD, Area under the effect curve (AUEC) of serum C-terminal cross-linking telopeptide of type 1 collagen (CTX) up to W26). An analysis of covariance model was used to compare the two treatments.

Results

A total of 553 patients were randomized to FKS518 (277) or the originator (276). Clinically relevant increases in LS-BMD were evident at week 52 in both treatment groups (Figure 1). Efficacy and PD equivalence were demonstrated since the 95% CI of the treatment difference for %CfB in LS-BMD at W52 ([0.04%, 1.29%]) laid entirely within the pre-defined equivalence margin [-1.45%; +1.45%] and the 95% CI of the ratio of means for AUEC0-26 CTX ([0.99,1.04] ng*h/L) was entirely within [0.89; 1.12] ng*h/L. No clinically meaningful differences in safety, tolerability, or immunogenicity were observed between treatment groups: 185 (66.8%) patients in the FKS518 group experienced treatment emergent adverse events during the 52 weeks core period and 189 (68.5%) in the originator product group. The number of patients with anti-drug antibodies remained low (1.1% ADA positive in FKS518 and 2.2% in originator group).

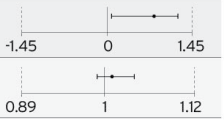
Conclusion

The study demonstrated the therapeutic equivalence of FKS518 with the originator and showed similar safety and immunogenici-

ty profiles between the two products.

Figure 1: Primary efficacy and pharmacodynamic endpoints

	FKS518 n=277	Reference n=276	FKS518 vs. reference *
%CfB in LS-BMD at week 52	5.74 (5.12, 6.35)	5.07 (4.44, 5.70)	0.66 (0.04, 1.29)
AUEC (0-W26) in CTX	1895 (1849, 1941)	1875 (1828, 1923)	1.01 (0.99, 1.04)



Numbers represent least squares mean and 95% confidence interval. Dashed lines indicate pre-defined equivalence margins. Population: ITT Analysis set.
*For %CfB in LS-BMD at week 52, difference in least squares mean is displayed. For AUEC(0-W26) CTX, ratio of geometric least square means is presented.
Abbreviations: AUEC(0-W26) = area under the effect curve from time 0 to Week 26; %CfB = percent change from baseline; LS-BMD = bone mineral density assessed by DXA; ITT = Intention-to-Treat; CTX = serum C-terminal cross-linking telopeptide of type 1 collagen; n = number of subjects included in the analysis.

P1350

PATIENTS PROFILE AND EFFECTIVENESS OF ROMOSOZUMAB IN REAL-LIFE: A PROSPECTIVE MULTICENTER STUDY IN SWITZERLAND

S. Ferrari[1], M. Hars[1], B. Aubry-Rozier[2], O. Lamy[3], E. Gonzalez Rodriguez[3], C. Meier[4], S. Jehle-Kunz[5]

[1]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland, [2]FMH Rheumatology and Bone Diseases, Lausanne, Switzerland, [3]Interdisciplinary Center of Bone Diseases, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland, [4]Division of Endocrinology, Diabetology and Metabolism, University Hospital and University of Basel, Basel, Switzerland, [5]Center for Osteoporosis, St. Anna Clinic, Lucerne, Switzerland

Objective: Romosozumab (Romo) is a monoclonal antibody against sclerostin with dual antiresorptive and anabolic effects. This study aimed to determine patients' profile receiving Romo and evaluate effectiveness of one-year treatment in high-risk osteoporosis patients, in routine clinical practice.
Methods: This prospective study was conducted in five osteoporosis centers in Switzerland among patients who initiated 12 months of treatment with Romo (210 mg subcutaneously monthly) since 2021. The primary outcome was bone mineral density (BMD) changes from baseline to 12 months at lumbar spine (LS), total hip (TH), and femoral neck (FN). Data on bone turnover markers (BTM), carboxy terminal telopeptide of collagen type I (CTX) and procollagen type 1 N-terminal propeptide (P1NP) were also collected.
Results: A total of 340 patients (89.7% female) with mean (±SD) age of 70.4 (±10.3) years were enrolled in this study. Among them, 48.8% were treatment-naïve while 22.9% switched from bisphosphonate or denosumab to Romo and 28.2% received osteoporosis treatment in the past. At Romo initiation, 71.2% had experienced multiple major osteoporotic fracture, 78.5% a recent fracture, and a T-Score ≤ -3.5 was found in half of the patients. In patients who completed the 12-dose course of Romo treatment (86.9%) the median BMD percentage changes from baseline to 12 months were 12.9% at LS, 3.0% at TH, and 3.1% at FN. In patients who discontinued Romo before 12 months (median exposure of 5 months; range 1-11), comparable BMD gains to 12 months completers were observed at LS and FN at month 12, but BMD gains at total hip were lower. BMD gains were significantly higher at all sites in treatment-naïve patients compared to the group previously exposed to anti-resorptives.
Conclusion: This real-world data in a population of Swiss patients contributed to the growing body of evidence that Romo treatment for 12 months substantially increased BMD at LS, FN, and TH in patients at high fracture risk. The increase in BMD was attenuated in patients switching from antiresorptive therapy to Romo compared to treatment-naïve patients, and potentially at the hip in those interrupting treatment prematurely.
Acknowledgement: This study was sponsored by UCB Pharma.

P1351

CARDIOVASCULAR EVENTS IN PATIENTS TREATED WITH ROMOSOZUMAB AND OTHER ANTI-OSTEOPOROTIC AGENTS: A COMPARATIVE ANALYSIS USING REAL-WORLD DATA

S. Ferreira Azevedo[1], C. Vilafanha[1], A. Barcelos[1]

[1]Unidade Local de saúde da Região de Aveiro, Rheumatology Department, Aveiro, Portugal

Introduction
Romosozumab (RMZ) is a recently approved agent with proven efficacy in treating Osteoporosis. However, its use has been associated with increased cardiovascular (CV) events. This study uses real-world data to describe and compare the occurrence of CV events among patients treated with RMZ and other anti-osteoporotic agents.
Methods and Materials
Retrospective study of EudraVigilance reports on CV events associated with RMZ, bisphosphonates (BP), and denosumab (DN) from January 2020 to December 2024. Reports by non-healthcare professionals, duplicates, or possibly related to more than one anti-osteoporotic treatment were eliminated. Demographics, events' outcomes, severity criteria, and associated actions were analyzed descriptively. Comparative analysis was performed to evaluate differences across treatments, stratifying by age, sex, event type, outcome, severity criteria, event duration, treatment indication, and approach. Reporting Odds Ratio (ROR) was calculated for RMZ compared to the other treatment groups.
Results
Healthcare professionals reported 33,348 suspect adverse reactions (SARs) in the EudraVigilance database (5,722 RMZ-, 12,246 BP-, and 15,380 DN-related SARs). Of these, 84 CV events were reported for RMZ, 8 for BP, and 10 for DN (Table 1).
The majority of CV SARs involved females aged 65-85 Years. All CV SARs were associated with at least one severity criteria, and the most reported was the presence of other important medical conditions (78.57% of RMZ -, 50% of BP-, and 90% of DN-related SARs), such as the presence of neoplasia. RMZ was stopped in all cases with available data except one. No significant differences were observed among the treatments regarding event type, outcomes, age or sex distribution, severity criteria, or event duration. Romosozumab was associated with a significantly higher risk of

CV SARs [ROR 22.85, CI (13.72-38.05)].

Conclusion

Our EudraVigilance data analysis revealed that RMZ was associated with a substantially increased risk of CV events (1.47% of all SARs). These findings highlight the need to address this safety issue and consider CV risks in Osteoporosis management. Ensuring the accurate reporting of SARs is essential to enhance the reliability of real-world data, ultimately supporting better-informed decisions in clinical practice.

A COMPARATIVE COHORT STUDY ON PARAFFIN THERAPY IN OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS

E. S. Kang[1], S. H. Baik[2]

[1]Division of Rheumatology, Department of Internal Medicine, Korea University Ansan Hospital, Ansan, Korea, Seoul, South Korea, [2]Department of Orthopedic Surgery, Yonsei University Wonju College of Medicine, Wonju, Korea, Seoul, South Korea

Purpose (the aim of the study): Osteoarthritis (OA) and rheumatoid arthritis (RA) are common rheumatic conditions characterized by joint pain and inflammation. Paraffin therapy has emerged as a potential adjunctive treatment, but its comparative effectiveness in OA and RA remains unclear. This study aims to assess the clinical characteristics, pain scores, and joint parameters in patients with OA and RA undergoing paraffin therapy, providing insights into the differential treatment responses between the two conditions.

Methods: A cohort of 64 OA and 68 RA patients was recruited, and clinical characteristics such as age, sex, BMI, duration of diagnosis, hand nodules, smoking history, and medication use were recorded. Pain scores (Visual Analog Scale) at rest and with activity were assessed at the beginning, after 4 weeks, and after 12 weeks of paraffin therapy. Joint counts for painful, tender, and swelling joints were also documented at these time points.

Results: Clinical characteristics revealed subtle differences between OA and RA groups, with RA patients exhibiting a higher prevalence of hand nodules and concurrent medication use. Pain scores at rest and with activity showed no significant differences between OA and RA groups at the beginning, after 4 weeks, and after 12 weeks. Joint counts demonstrated comparable numbers of painful and tender joints, with a significant reduction in swelling joints after 4 and 12 weeks in OA patients.

Conclusions: Paraffin therapy appears to have a similar impact on pain scores in OA and RA patients, suggesting comparable treatment responses. While both groups exhibit a reduction in swelling joints, the significant decrease observed in OA patients implies a potentially more pronounced anti-inflammatory effect in this group.

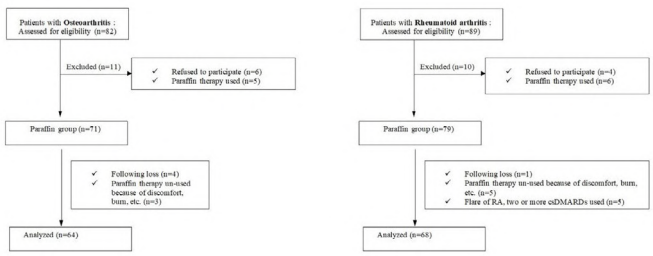

Figure 1. Flowchart of patients

Table 1. Clinical characteristics of the patients with osteoarthritis versus patients with rheumatoid

Clinical characteristics	Osteoarthritis (n=64)	Rheumatoid arthritis (n=68)
Age, years, mean (SD)	59.08 (10.29)	56.23 (9.23)
Female sex, n (%)	47 (73.4%)	56 (82.3%)
BMI (kg/m2), mean (SD)	22.83 (3.35)	21.51 (2.98)
Duration of diagnosis, years, mean (SD)	1.09 (0.32)	0.87 (0.29)
Hand nodule, n (%)	23 (35.9%)	21 (30.9%)
Smoking, n (%)	19 (29.6%)	17 (25%)
Medication, n (%)		
NSAIDs	51 (79.6%)	53 (77.9%)
Acetaminophen	51 (79.6%)	12 (17.6%)
Corticosteroid	1 (1.6%)	9 (13.2%)
Conventional DMARDs		59 (86.7%)

BMI: body mass index; NSAIDs: nonsteroidal anti-inflammatory drug DMARDs: Disease-modifying antirheumatic drugs.

Table 2. Number of painful, tender, and swelling joints in patients with osteoarthritis versus patients with rheumatoid arthritis

Joint Count	Osteoarthritis (n=64)	Rheumatoid arthritis (n=68)	p-value
Painful joint			
Beginning	7.00 (4.00-9.00)	8.00 (6.00-10.00)	0.696
After 4 weeks	5.00 (3.00-7.00)	7.00 (5.00-9.00)	0.271
After 12 weeks	5.00 (2.00-7.00)	5.00 (3.00-7.00)	0.422
Tender joint			
Beginning	5.00 (4.00-7.00)	7.00 (4.00-10.00)	0.398
After 4 weeks	3.00 (2.00-5.00)	5.00 (4.00-6.00)	0.195
After 12 weeks	2.00 (1.00-4.00)	4.00 (3.00-6.00)	0.081
Swelling joint			
Beginning	3.00 (2.00-7.00)	6.00 (4.00-8.00)	0.203
After 4 weeks	1.00 (0.00-3.00)	5.00 (3.00-8.00)	0.045
After 12 weeks	0.00 (0.00-1.00)	4.00 (2.00-7.00)	0.039

P1353

THE ROLE OF LOW-GRADE INFLAMMATION IN THE PATHOGENESIS OF OSTEOARTHRITIS

S. H. Hristova[1], I. M. Momcheva[2], S. B. Bogdanova-Petrova[1], T. G. Georgiev[1], S. H. Dimitrov[1]

[1]UMHAT Varna, Varna, Bulgaria, [2]UMHAT Burgas, Burgas, Bulgaria

Low-grade inflammation is increasingly considered a key factor in the pathogenesis of osteoarthritis and is viewed as a potential therapeutic target. We conducted a study measuring complement fractions (C3 and C4) in blood plasma and synovial fluid. The aim of the study was to establish the involvement of humoral factors of the innate immune response in the disease's pathogenesis. We sought correlations between plasma and synovial levels of C3 and C4 – complement fractions – and aimed to determine the difference in the expression of C3 and C4 in two fractions of synovial fluid: supernatant (A) and sediment (B).

Our results showed that the mean percentage of C3 levels in synovial fluid compared to plasma levels for the sample was 34.90%. The mean percentage of synovial C4 levels compared to plasma levels was 30.97%. The difference in C3 values between cell-bound (fraction B) and soluble (fraction A) fractions in the overall population was positive, meaning that C3 levels in synovial fluid fraction B were higher than those in synovial fluid fraction A. We found that C4 levels in both fractions of synovial fluid, similar to the results for C3, were higher at earlier radiographic stages compared to advanced stages of the disease.

The results confirmed the role of complement in maintaining low-grade inflammation, as well as in clearing the joint space of degenerative and apoptotic products resulting from joint destruction in osteoarthritis.

P1354

VITAMIN D LEVELS IN PREGNANT WOMEN WITH HYPOTHYROIDISM, GESTATIONAL DIABETES, DIABETES MELLITUS AND AFTER BARIATRIC SURGERY

S. H. J. Scharla[1], U. G. Lempert[1]

[1]Practice Endocrinology & Diabetes, Bad Reichenhall, Germany

Introduction: Pregnancy challenges bone metabolism due to an increased mineral demand caused by the growing fetus. Bone resorption is increased while bone formation is decreased. Insufficient intake of calcium and vitamin D are risk factors for pregnancy associated osteoporosis and for development of osteoporosis in later life. Diabetes mellitus as well as bariatric surgery are associated with lower levels of vitamin D and may indicate an increased risk for osteoporosis. Therefore, we determined 25-OH-vitamin D levels in pregnant women with gestational diabetes or pe-existing diabetes mellitus, in women pregnant after bariatric surgery and in pregnant patients with substituted hypothyroidism (controls).

Methods: Patients presented for endocrinological prenatal care in our practice. Blood samples were obtained during routine work-ups. Serum aliquots were stored at -20 Celsius for 25-OH-vitamin D and P1NP (procollagen-Type- 1-N-terminal propeptide) measurements (automated analyses, Roche Cobas).

Results: 25-OH-Vitamin D levels were 105 ± 41 nM (hypothyroidism), 92 ± 29 nM (gestational diabetes), 80 ± 20 nM (pre-existing diabetes mellitus), 98 ± 27 nM (after bariatric surgery). P1NP-levels were 64 ± 34 ng/ml (hypothyroidism), 53 ± 25 ng/ml (gestational diabetes), 36 ± 20 ng/ml (pe-existing diabetes mellitus), 44 ± 22 ng/ml (after bariatric surgery). No significant differences were found in vitamin D-levels. Bone formation marker P1NP was significantly lower in pregnant patients with pe-existing diabetes mellitus ($p = 0.03$) as well as in women pregnant after bariatric surgery ($p=0.03$) compared to pregnant patients with substituted hypothyroidism. Serum calcium levels were lowered in women pregnant after bariatric surgery (2.25 ± 0.09 mM versus 2.30 ± 0.08 mM, $p = 0.04$).

Conclusion: Although only women pregnant after bariatric surgery were taking vitamin D supplements, there was no vitamin D deficiency in either group of pregnant women. Merely a trend to lower vitamin D concentrations was observed in pregnant patients with pe-existing diabetes mellitus. P1NP was lower in pregnant patients with pe-existing diabetes mellitus compared to controls, indicating an increased risk for osteoporosis.

P1355

OVEREXPRESSION OF INOSITOL-REQUIRING ENZYME-1 (IRE-1) INHIBITS CHONDROCYTE DIFFERENTIATION

Y. S. Eom[1], S. J. Kim[1], K. H. Lim[2]

[1]Kongju National University Department of Biological Sciences, Gongju-Si, South Korea, [2]Kongju National University Department of Civil and Environmental Engineering, Gongju-Si, South Korea

Inositol-requiring enzyme 1 (IRE1), an ER-transmembrane protein, is an essential component of the UPR pathway important for sensing and responding to ER stress. However, effect of IRE1 on chondrocytes differentiation has not been studied. Here, We investigated whether IRE1 regulates Type Ⅱ collagen, an indicator of differentiation of chondrocyte. IRE1 cDNA or IRE1 siRNA was transfected into rabbit chondrocytes. Western blot analysis, RT-PCR and immunofluorescence staining analyzed expression of type Ⅱ collagen. These results showed overexpression of IRE1 inhibits differentiation of chondrocytes, knockdown of IRE1 promote differentiation of chondrocytes. Furthermore, we determined whether IRE1-regulated chondrocyte differentiation occurs regardless of ER stress. Treatment of 2-Deoxy-D-glucose (2DG) on IRE1-transfected was assessed using western blot. 2DG-induced dedifferentiated was accelerates with IRE1 cDNA, attenuated with IRE1 siRNA. However, expression of glucose-regulated protein, GRP78, which is activated after ER stress has not been changed. The elucidation of these mechanisms indicates that IRE1 plays critical role in chondrocyte differentiation via ER stress-independent pathway.

THE RHEUMATOLOGICAL MANIFESTATIONS IN DIABETICS: FREQUENCY, CHARECTERISTICS AND ASSOCIATED FACTORS

M. Boudokhane[1], S. Jouini[2], H. Bettaeib[3], C. Besrour[3], R. Bourguiba[3], W. Helali[3], M. H. Douggui[3], S. Bellakhal[3]

[1]Hospital of the Iternal Security Forces of Marsa, Tunis, Tunis, Tunisia, [2]Hospital of the Internal Security Forces of Marsa, Tunis, Bizerta, Tunisia, [3]Hospital of the Internal Security Forces of Marsa, Tunis, Tunis, Tunisia

Introduction:
Diabetes is a challenging condition, primarily due to degenerative complications that increase morbidity and mortality. However, its rheumatological manifestations are rarely described in African literature, despite their functional impact. The objectives of our study were to describe the rheumatological manifestations in patients with diabetes mellitus and to identify the factors associated with their occurrence.
Methods:
We conducted a retrospective, descriptive study on diabetic patients followed at the Internal Medicine Department of the Hospital of the Internal Security Forces of Marsa, Tunis between February and June 2024. The data collected were epidemiological for each patient, followed by clinical and paraclinical information specific to diabetes, as well as to each rheumatological manifestation.
Results:
We collected data from 65 diabetic patients. The average age was 59.29 years, and the sex ratio was 0.72. Forty percent of the patients were smokers. Hypertension and dyslipidemia were present in 52% of the cases, and obesity in 39% of the cases.
Sixty-two patients (95%) had type II diabetes with an average duration of 15 years. Microangiopathies were common, including retinopathy (54%), peripheral neuropathy (35%), autonomic neuropathy (51%), and nephropathy (34%). Regarding macroangiopathies, 22% of the cases had myocardial infarction, 3% had a stroke, and 3% had peripheral artery disease.
In our study, 31% of the patients (n=20) presented musculoskeletal manifestations, distributed as follows: adhesive capsulitis (n=4), carpal tunnel syndrome (n=4), trigger finger (n=4), Dupuytren's disease (n=3), Forestier's disease (n=2), infectious spondylodiscitis (n=2), and osteoporosis (n=1).
The comparative study showed that female sex (p=0.05), age (p=0.029), smoking (p=0.032), the duration of diabetes (p=0.038), and microangiopathies—diabetic retinopathy (p<10-3), diabetic peripheral neuropathy (p<10-3), and diabetic autonomic neuropathy (p=0.048) were factors associated with the development of rheumatological manifestations in diabetes mellitus.
Conclusions:
Osteoarticular complications of diabetes are relatively common. A better understanding of the predictive factors in a multicentric study is needed to optimize a therapeutic strategy tailored to our population.

P1357

OSTEOARTHRITIS AND DIABETES MELLITUS: UNRAVELING THE CONNECTION

M. Boudokhane[1], S. Jouini[2], H. Bettaeib[3], C. Besrour[3], R. Bourguiba[3], W. Helali[3], M. H. Douggui[3], S. Bellakhal[3]

[1]Hospital of the Iternal Security Forces of Marsa, Tunis, Tunis, Tunisia, [2]Hospital of the Internal Security Forces of Marsa, Tunis, Bizerta, Tunisia, [3]Hospital of the Internal Security Forces of Marsa, Tunis, Tunis, Tunisia

Objectives:
Osteoarthritis (OA) is a common and disabling joint disorder, and recent studies have highlighted its strong association with type 2 diabetes. It is now recognized as a key contributor to the development and progression of OA, beyond its association with obesity and metabolic dysfunction.
The objectives of our study were to describe osteoarthritis in patients with diabetes mellitus and to identify the factors associated with their occurrence.
Material and Methods:
We conducted a retrospective, descriptive study on diabetic patients followed at the Internal Medicine Department of the Hospital of the Internal Security Forces of Marsa, Tunis between February and June 2024. The data collected were epidemiological for each patient than clinical, paraclinical, and therapeutic, specific to osteoarthritis as well as to diabetes.
Results:
We collected data from 65 diabetic patients: average age 59.29 years, sex ratio 0.72, 95% with type II diabetes, lasting 15 years on average.
Osteoarthritis was observed in 42% of patients (n=27), with a mean age of 62 years and a sex ratio of 0.42. The most common comorbidities were hypertension and dyslipidemia (100%), followed by obesity in 93% and overweight in 3%. All patients had type 2 diabetes for an average of 20 years with degenerative complications: retinopathy (62%), peripheral neuropathy (42%), autonomic neuropathy (65%), and nephropathy (40%). Regarding macroangiopathies, 30% had myocardial infarction.
Seventy-nine percent had knee osteoarthritis, 15% had hip osteoarthritis, and 4% had cervical osteoarthritis.
Radiologically, 58% of the patients were classified as having severe osteoarthritis, of which 42% underwent surgical intervention. The remaining patients received corticosteroid injections in combination with non-steroidal anti-inflammatory drugs and physical treatment.
The comparative study showed that female sex (p=0.038), age (p=0.03), the duration of diabetes (p=0.032), and microangiopathies—diabetic retinopathy (p<10-3), diabetic peripheral neuropathy (p<10-3), and diabetic autonomic neuropathy (p=0.044) were factors associated with the development of osteoarthritis.
Conclusions:
Chronic type 2 diabetes, especially during the stage of degenerative complications, is linked to the development and progression of osteoarthritis. This relationship may be driven by factors such as oxidative stress, pro-inflammatory cytokines, and the accu-

mulation of advanced glycation end products in joint tissues exposed to prolonged high glucose levels.

P1358

DOES TREAT-TO-TARGET THERAPY PREVENT BONE LOSS IN EARLY RHEUMATOID ARTHRITIS?

S. K. Stojanovic[1], B. N. Stamenkovic[1], N. S. Stojanovic[2]

[1]Institute For Treatment and Rehabilitation „Niška Banja", Niš, Nis, Serbia, [2]University of Niš Faculty of Medicine, Nis, Serbia

Rheumatoid arthritis (RA) is a prototype of autoimmune disease that links the immune system and bone metabolism.
This study aimed to evaluate the association of disease activity with bone mineral density (BMD) changes in the context of T2T strategies in patients with early RA.
Material and Methods: Prospective study consists of 84 patients with early RA. The majority were female (65-77.38%). The average age of the examined group is 56.76±14.6 years. All patients were initially treated with MTX (average dose 17.68 mg per week) with occasional administration of small doses of glucocorticoids (Prednisolone in average dose 7.32±2.64 mg/day). After 6 months, the patients were divided into two groups (A and B). Group A consisted of patients in whom the therapeutic goal was achieved (low disease activity or remission - DAS 28 SE≤3.2) and they continued MTX monotherapy. Group B consisted of patients who, despite the use of MTX, had high or moderate disease activity (DAS 28 SE >3.2) and continued combined therapy (MTX and antimalarial or MTX and Salazopyrin).
BMD was measured on the Hologic device, both at the (LS) lumbal spine and at the femoral neck, at the time of RA diagnosis and one year later. The groups are homogenous according to the other risk factors for osteoporosis (menopausal and smoking status, age, BMI, use of vitamin D).
Results: The initial BMD values in the groups did not differ significantly. Patients who achieved remission or low activity (n = 38) had less yearly bone loss at the LS (1,75% vs 1,34%) and hip (1,45% vs 0,98%). After one year, a significantly greater number of patients from B group, showed a decrease in BMD (31.25% vs 7.69%) (p<0.05). A negative linear correlation between disease activity (DAS 28 SE) and the change of BMD in the LS and hip was found, indicating the key role of the T2T strategy in reducing bone loss (consecutively, r=-0.24, p< 0.05; r=-0.28, p<0.05).
Conclusion: Aggressive treatment of early RA, according to the T2T principle, significantly reduces the rate of bone loss after one year of therapy.
Key words: T2T therapy, rheumatoid arthritis, osteoporosis

P1359

SOCIO-ECONOMIC INEQUALITIES IN FALL AMONG IRANIAN ELDERLY HYPERTENSIVE POPULATION: A CONCENTRATION INDEX ANALYSIS

S. Karimi[1], S. Salehi[1], P. Zarepour[1], S. Emamgholipour Sefiddashti[2], O. Tabatabaei-Malazy[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Department of Health Management and Economics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Background: Falls are a common cause of injury in the elderly with hypertension, as high blood pressure is related to impaired balance and decreased muscle strength. This study explores the degree to which socio-economic inequalities influence the distribution of fall prevalence among elderly hypertensive individuals.
Methods: This research was a cross-sectional study of inequality in fall accidents among hypertensive elderly people, using a representative sample of 3,927 Iranians aged ≥ 60 years from the Iran 2021 STEPwise survey. We estimated the concentration index (CI) and measured socio-economic inequalities in fall accidents, stratifying the analysis by gender, urban/rural residence, and blood pressure control status. Analysis was estimated in STATA-14.
Results: The concentration index for individual elderly people was estimated at (CI=-0.1100, p = 0.010) indicating that there is inequality and falls are more common among individuals in lower socio-economic groups. In accordance to residency, concentration index was (CI=-0.1370, p = 0.005), and (CI=-0.0723, p=0.40), for urban and rural residents, respectively. The other hand, CI for men and women were (CI=-0.099, p= 0.185), and (CI=-0.093, p= 0.078), respectively. Moreover, the inequality of falls among elderly hypertensive patients with uncontrolled blood pressure was (CI=-0.110, p= 0.039), a little bit higher compared to those with controlled blood pressure (CI=-0.126, p= 0.09).
Conclusion: This study shows the neglected issue of falls among hypertensive elderly individuals, particularly those from vulnerable socio-economic groups, urban residents, and those with uncontrolled hypertension. The blood pressure control in fall prevention has a critical role. Since there is a significant impact of falls in elderly individuals with hypertension, it is essential to focus on targeted policies and healthcare strategies to address these disparities, reduce inequalities, and improve the well-being of these at-risk populations.
Keywords: Fall accident, Inequality, Concentration Index, Hypertension

P1360

MIR-335-5P IS A POTENTIAL BIOMARKER AND A THERAPEUTIC TARGET IN POSTMENOPAUSAL OSTEOPOROSIS

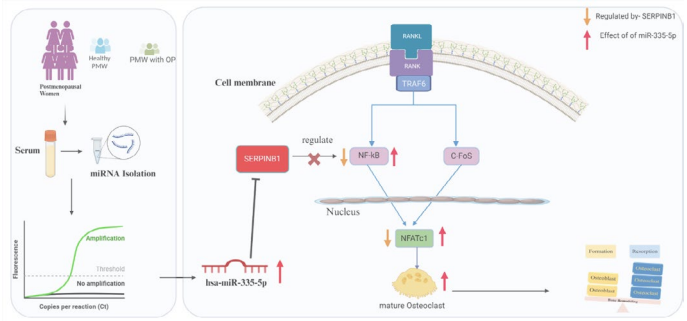
S. Kaur[1], S. Jaiswal[1], P. Basak[1], T. Kumar[1], J. Kaur[2], V. Dhiman[1], G. Singh[3], N. Sachdeva[1], R. P. Barnwal[4], S. K. Bhadada[1]

[1]Department of Endocrinology, PGIMER, Chandigarh, Chandigarh, India, [2]E-Yuva Centre, Panjab University, chandigarh, Chandigarh, India, [3]University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India, Chandigarh, India, [4]Department of Biophysics, Panjab University, Chandigarh, India, Chandigarh, India

Objective: To investigate the role of hsa-miR-335-5p in postmenopausal osteoporosis (PMO), focusing on its regulatory relationship with SERPINB1, a negative regulator of osteoclast differentiation.

Materials and Methods: This study explored microRNA's role in postmenopausal osteoporosis (PMO) using microarray analysis. The microRNAs were validated via qPCR on 50 samples from PMO patients and 50 samples from healthy controls, where miR-335-5p was selected for further investigation. In silico analysis identified potential target genes, followed by functional validation in osteoblast-like cells (MG-63). *In-vivo* effects of miR-335-5p on osteoporotic rats were evaluated by assessing changes in target gene expression, microstructural analysis, and bone histomorphometry by transfecting corresponding antagomir.

Results: Microarray analysis revealed 262 differentially expressed miRNAs, where 232 upregulated and 30 downregulated. Eleven miRNAs exhibited fold change expressions between 7-10. Of these, three miRNAs were validated: miR-148a-5p, miR-335-5p, and miR-656-5p. Notably, hsa-miR-335-5p showed significant upregulation in osteoporotic patients (p = 0.0050). ROC analysis identified hsa-miR-335-5p as a superior biomarker with an Area Under the Curve (AUC) of 0.75. Bioinformatics analysis identified SERPINB1, a negative regulator of osteoclast activity, as a key target of hsa-miR-335-5p. Functional studies in MG-63 cells demonstrated that miR-335-5p overexpression significantly reduced both RNA and protein levels of SERPINB1 at 48 and 72 hours post-transfection, respectively, confirming SERPINB1 as a direct target of miR-335-5p. In vivo experiments involved transfection of miR-335-5p inhibitors in osteoporotic rats yielded compelling results. Increased SERPINB1 expression was observed in both plasma and bone marrow, correlating with notable changes in bone microstructure and histomorphometry. These findings provide strong evidence for the regulatory role of miR-335-5p in bone metabolism and its potential as a therapeutic target. **Conclusion:** This study demonstrates that hsa-miR-335-5p plays a critical role in PMO pathogenesis by targeting SERPINB1 and influencing osteoclast activity. These findings suggest that hsa-miR-335-5p could serve as both a biomarker and potential therapeutic target in the management of PMO.



P1361

SYSTEMATIC AND CRITICALLY-APPRAISED METHODOLOGIES FOR POSITION STATEMENT DEVELOPMENT IN OSTEOPOROSIS

G. Bullock[1], S. Kluzek[2]

[1]Department of Orthopedic Surgery and Rehabilitation, Wake Forest School of Medicine, Winston-Salem, USA.1Department of Orthopedic Surgery and Rehabilitation, Wake Forest School of Medicine, Winston-Salem, USA., NC, United States, [2]Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, University of Oxford, UK., Oxford, United Kingdom

Objectives

Guidelines and position statements provide expert consensus, ensuring consistency in clinical practice and discourse. Best practice methodologies involve systematic approaches and quality appraisal to minimise bias. This study aimed to evaluate methodologies employed in osteoporosis position statements since the 2024 World Congress.

Materials and methods

A PubMed search was conducted using the terms “osteoporosis guidelines” and “osteoporosis position statements”, covering publications from 17th April 2024 to 24th January 2025. Manuscripts were excluded if they did not focus on osteoporosis, were not endorsed by an osteoporosis society, summarised existing guidelines, were living updates without a full revision, or represented primary research. A semi-quantitative descriptive analysis was performed.

Results

Fourteen guidelines and position statements were identified. Six (42.9%) utilised systematic review strategies, and the same proportion incorporated quality appraisal or evidence assessment. The most commonly used tool was the Grading of Recommendations, Assessment, Development and Evaluations (GRADE), applied in 28.6% of publications.

Conclusions

Osteoporosis guidelines and position statements are predominantly based on narrative and non-systematic expert opinions. Although some have adopted systematic methodologies and quality assessments aligned with study designs, this remains a minority practice.

P1362

A RARE CAUSE OF ULNAR NEURITIS - NOT AN EVERY DAY CASE

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], A. Theodoropoulos[1], A. Therapos[1], L. Tsiopos[1]

[1]Orthopaedic Department / General Hospital of Agrinio, Agrinio, Greece

Background

Ulnar neuritis is the second most common peripheral nerve disorder in the upper limb, after carpal tunnel syndrome. It is typically caused by nerve compression in the ulnar groove at the elbow. This study aims to present an unusual cause of ulnar neuritis that was confirmed through radiological and histological examination.

Case Presentation

A 69-year-old female patient presented to the orthopedic outpatient clinic with a palpable mass on the inner surface of the elbow and reported numbness along the distribution of the ulnar nerve. Clinical and electromyographic findings were consistent with ulnar neuritis. Plain radiological check showed calcium deposits in the ulnar groove region, raising suspicion of a uric acid tophus as a differential diagnosis. The patient had previously undergone unsuccessful conservative treatment, so surgical intervention was recommended.

During the surgical investigation of the ulnar nerve at the elbow, following the standard approach for ulnar neuritis, a large calcified mass was found in direct contact with the ulnar nerve while compressing it. The mass was removed, and a biopsy was sent to confirm clinical suspicions.

Clinical Outcomes

The biopsy revealed extensive deposits of weakly basophilic calcified material in the form of multiple foci separated by dense fibrous connective tissue. The patient reported an immediate postoperative relief from her symptoms and has remained fully healed since, with no recurrence in the affected joint or elsewhere

Discussion

Ulnar neuritis is a common upper limb condition, mostly due to anatomical variations in elbow structures.The ulnar nerve has several potential compression sites along its course. Although the elbow is the most common site of compression, the ulnar nerve is also susceptible to injury at the wrist, forearm, and upper arm. At the elbow, the ulnar nerve lacks protective cover in the ulnar groove. This causes its susceptibility to external compression. Repetitive elbow flexion and extension, arthritic changes, and valgus deformities at the elbow increase its vulnerability to injury. In some individuals, the ulnar nerve may be subluxed out of the retroepicondylar groove medially over the medial epicondyle during elbow flexion. This study presents an unusual mechanism of ulnar nerve compression (ectopic calcification) in the elbow that should be considered in the differential diagnosis of the etiology of ulnar neuritis. Although primarily confirmed by electromyography and clinical examination, radiological chech can sometimes reveal the underlying cause, facilitating effective treatment.

P1363

LEIOMYOMA OF THE INDEX FINGER - A RARE CASE

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], A. Theodoropoulos[1], A. Therapos[1], L. Tsiopos[1]

[1]Orthopaedic Department / General Hospital of Agrinio, Agrinio, Greece

Background

Leiomyoma is a rare benign tumor of nonstriated muscles. Its common elective localization is in uterus muscle, but it may involve the hand. Limb localization is rare, usually in the lower limbs. The purpose of this paper is to present a rare case of a tumor on the index finger in a young person, including the diagnostic, prognostic, and therapeutic approach, along with a literature review.

Case Presentation

A 17-year-old female patient came to the outpatient clinic complaining about a painful mass on her left index finger, accompanied by numbness in the affected finger. The mass was soft, mobile, and located subcutaneously. Initial imaging with plain X-rays showed no bone pathology, and an MRI was subsequently recommended. MRI imaging revealed a well-defined lesion with a signal intensity similar to soft tissues and a strong, slightly heterogeneous contrast enhancement). Surgical removal of the mass was planned, performed under local anesthesia with a tourniquet. The excised mass was sent for biopsy.

Clinical Outcomes

The biopsy results identified a degenerated leiomyoma, confirmed by immunohistochemical characteristics. The skin healed completely, and the numbness resolved within a few weeks. The patient retained full mobility in the index finger. No recurrence or other complications were observed up to the most recent examination, one year post-surgery.

Discussion

Leiomyoma is a benign tumor originating from smooth muscle fibers and is rarely found in the hand. Its most common location is in the uterus, and when it appears at the limbs, it is typically found around the ankle and foot. Leiomyoma is most often diagnosed in the third to fourth decades of life, with a definitive diagnosis made exclusively through histological examination following surgical excision. It should be considered in the differential diagnosis of subcutaneous tumors at the limbs, especially in cases of a single, slow-growing, painful nodule. The prognosis is excellent after a complete surgical excision with clear margins, with no risk of recurrence, and it requires no further treatment.

P1364

BRACHYDACTYLY OF THE 3RD, 4TH AND 5TH RAY OF THE HAND - A DIAGNOSTIC APPROACH

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], A. Theodoropoulos[1], A. Therapos[1], L. Tsiopos[1]

[1]Orthopaedic Department / General Hospital of Agrinio, Agrinio, Greece

Background

Brachydactyly ("short digits") is a general term that refers to disproportionately short fingers and toes, and forms part of the group of limb malformations characterized by bone dysostosis. The purpose of this study is to present the diagnostic approach to cases of brachydactyly.

Case Presentation

A 60-year-old female patient visited the outpatient clinic for an examination due to chronic lower back pain. During the clinical examination, it was observed that on both upper limbs, the 3rd, 4th, and 5th rays were notably shorter than the 2nd ray. Upon questioning, the patient reported no discomfort or functional issues, though she had noticed the deformity years prior. Her stature was short, but her facial features were normal. Imaging revealed shortened 3rd, 4th, and 5th metacarpals.

Clinical Outcomes

The patient declined further investigation into the causes of the brachydactyly.

Discussion

Brachydactyly (usually affecting the 4th and 5th rays) is a rare condition with causes that are categorized as follows:

Common Causes

Idiopathic brachydactyly
Post-inflammatory (e.g., osteomyelitis)
Pseudohypoparathyroidism (Type I and II, Albright's hereditary osteodystrophy [AHO]) / pseudopseudohypoparathyroidism
Post-traumatic (especially injuries affecting the epiphysis)
Turner Syndrome

Uncommon Causes

Gorlin Syndrome
Multiple exostoses syndrome
Juvenile idiopathic arthritis
Sickle cell disease
Homocystinuria
Langer-Giedion Syndrome

Investigation should include measurements of blood calcium, phosphorus, and parathyroid hormone, especially for metabolic diseases, along with a complete laboratory check and further imaging studies.

Brachydactyly is a rare condition that appears in a variety of cases, with metabolic disorders being “prominent” among them. Nowadays regarding to brachydactyly is less about treating functional issues and more about investigating and, if possible, treating its underlying cause. The clinical physician’s observational skills are crucial for detecting brachydactyly and possibly diagnosing related chromosomal abnormalities and metabolic disorders.

P1365

HALLUX VALGUS - MEDIUM TERM RESULTS OF CORRECTION WITH TIGHT ROPE

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], A. Theodoropoulos[1], A. Therapos[1], L. Tsiopos[1]

[1]Orthopaedic Department / General Hospital of Agrinio, Agrinio, Greece

Background

Hallux Valgus (HV) is a very common condition that is usually treated with a proximal or distal osteotomy of the first metatarsal. Despite the good correction achieved, these operations have complications such as malunion, pseudarthrosis, shortening of the 1st metatarsal, loosening of osteosynthesis, and osteonecrosis. Correction of the transmetatarsal angle with the use of a non-absorbable suture with a fixation button (tight rope by Arthrex) has also been used for the treatment of HV. This reduces the risks of corrective osteotomies while maintaining the reduction of the intermetatarsal angle (IMA).

Objectives

The purpose of this study was to evaluate the mid-term outcomes of patients who underwent HV correction through soft tissue correction and tight rope fixation.

Study Design & Methods

Over a period of 5 years, 42 patients underwent tight rope HV correction surgery in our clinic. Mean follow-up time was 25.4 months. IMA and Hallux valgus angle (HVA) were measured on radiographs preoperatively, immediately postoperatively, and at the last visit. Postoperative complications, and any additional operative procedures performed were also recorded.

It was very important for the fore foot to be supple enough so as the correction of the IMA was possible without major forces being exerted on the metatarsal.

All surgeries were performed by one of the 3 senior authors. First, an extensive medial release of the metatarsophalangeal joint complex was performed with an inverse L capsulotomy through a medial longitudinal incision, taking care to protect the dorsal medial cutaneous nerve. If necessary a bunionectomy or bony eminence exertion was performed. Through a second incision between the first and second metatarsal heads, the adductor tendon, intermetatarsal ligament, metatarsal-sesamoid ligament, and lateral joint capsule were completely released.

The suture button construct was then inserted.

An approximately 2-cm longitudinal incision was made between the second and third metatarsals. Distally, this incision began at the level of the proximal extent of the lateral release incision.

The lateral aspect of the second metatarsal shaft was exposed and a tunnel was performed with a 1,3 or 1,1 K-wire through the second metatarsal and then through the first metatarsal, exiting through the medial diaphysis just proximal to the first metatarsal head.

Results
All patients reported outcomes through scores were improved. The mean preoperative IMA and HVA were 17.9 and 30.6 degrees, respectively. The mean immediate postoperative IMA was 6.2 degrees and the mean HVA was 10.8 degrees. At final follow-up, mean IMA was 9.2 degrees and HVA was 15.7 degrees. The mean change in IMA was 16.0 degrees and the mean change in HVA from preoperative to final follow-up was 9.6 degrees.

Four patients experienced complications, including one intraoperative second metatarsal fracture, one postoperative second metatarsal fracture, and two superficial surgical wound infections.

Conclusions
The use of a soft tissue procedure combined with tight rope IMA correction is a safe and effective treatment of HV. Our results show that this technique can achieve correction of the IMA and HVA without the need for osteotomy.

P1366
BIPHALANGEAL TOES - A NORMAL AND NOT SO RARE VARIANT?

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], A. Theodoropoulos[1], A. Therapos[1], L. Tsiopos[1]

[1]Orthopaedic Department / General Hospital of Agrinio, Agrinio, Greece

Background
The presence of 2 phalanges in the 5th toe was first described by Leonardo da Vinci in 1492 and is recognized as a normal variant. It is probably a true anatomical variant resulting from incomplete segmentation rather than the result of phalangeal fusion.

Objectives
The purpose of this paper is to present a rare case of bilateral biphalageal 4th and 5th toe and discuss about the prevalence of biphalageal toes in the general population.

Study Design & Methods
A male patient came to the emergency department having a fore foot injury. Physical examination didn't reveal any restriction of movement of the toes or any bruising and swelling. X-ray examination showed no fracture in any bone of the foot. On the contrary, the existence of 2 phalanges in the 4th and 5th toes of both feet was discovered.

He never reported pain or any functional problems with toe movement, walking, or activities. All he mentioned is the similar morphology of the fingers in relatives of his.

He was subscribed with painkillers and given instructions not to walk for a few days and use ice therapy

Results
Looking at the literature, the prevalence of this anatomical variant in one study was for the 5th toe in 41.02% of the cases reported, for the 4th toe in 2.51%, for the 3rd toe in 0.20%, and for the 2nd toe in 0.12% of the cases. In another study the mean prevalence of biphalangealism in the 5th toe was 41.39%, in the 4th toe was 2.15%, and in the 3rd toe was 0.48%. In a third one biphalangeal toe in 0.5%, 1.7%, 3.5%, and 37.6% in the second, third, fourth, and fifth toe was observed, respectively. Unfortunately, in our hospital, due to poor data recording in the radiology department, it was not possible to record the prevalence in the population of our city. Also, no corresponding study of the Greek population was found. Knowledge of these variants is important to prevent misinterpreting them as fractures and malunions.

Conclusions
Biphalangeal fifth toe or more than one toe, is a common pedal anatomic variant seen approximately in one-third of the population. The reason for such evolution of the lateral toes is still debated, but the differences in anatomy most likely have no impact on foot function. A larger radiographic study in the Greek population to confirm the findings of this paper and investigate whether the trend is also being seen in other toes would however be of interest.

P1367
BLUE FINGER SYNDROME - MORE THAN MEETS THE EYE

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], A. Theodoropoulos[1], A. Therapos[1], L. Tsiopos[1]

[1]Orthopaedic Department / General Hospital of Agrinio, Agrinio, Greece

Background
Blue Finger Syndrome (BFS) is a benign and rare condition with an idiopathic aetiology. It is characterised by an acute bluish discoloration of fingers which may be accompanied by pain. The patients present with painless bluish discolouration of hands with sparing of finger tips and no changes in colour when subject to temperature changes. These features enable physicians to distinguish it from Raynaud's phenomenon.

Case Presentation
A 75-year-old female patient was admitted to the "suspected" COVID-19 clinic due to a respiratory infection. Her personal medical history included arterial hypertension and Raynaud's syndrome. She was being monitored solely for the respiratory infection. During her transfer to the pathological clinic, a change in color and impaired function of all fingers on both hands was observed, prompting a consult with the orthopedic team. The fingers showed signs of ischemia, so immediate decompressive incisions were performed, and anticoagulant and antiplatelet therapy was initiated. It was easily differentially diagnosed as having nothing to do with the known personal history of Raynaud's syndrome. Daily changes and needle decompression procedures were carried out until the necrotic areas were clearly defined.

Clinical Outcomes
After a few days there were no clear improvement and it was then decided to amputate the affected phalanges up to the boundaries of healthy tissue.The finger stumps healed without further complications, and the patient began physical and occupational therapy. Her finger mobility was sufficient for self-care.

Discussion
Blue finger syndrome (BFS), typically marked by a purple or blue discoloration of one or more fingers, can be the first symptom

of various diseases. These may directly affect the fingers or be systemic diseases. The most common causes include thrombosis, embolism, severe vasoconstriction, or vascular disruption that may be either inflammatory or non-inflammatory. Blue finger syndrome is relatively rare and can be attributed to numerous causes. Its significance lies in the fact that it is more than just a clinical sign; it often serves as a warning of underlying harmful diseases. Early diagnosis and treatment are essential to prevent comorbidities and, in some cases, mortality, as well as irreversible complications such as necrosis and/or amputation.

P1368

THE SIGNIFICANCE OF ERAP1 GENE POLYMORPHISMS AND ZINC IMBALANCE IN THE BODY OF PATIENTS WITH ANKYLOSING SPONDYLITIS

I. H. Gasanova[1], Z. H. Gasanli[2], S. Kulanthaivel[3], N. G. Nikolashina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]"Crimean Smile" Clinic, Simferopol, Russia, [3]Naarayani Multispeciality Hospital, Erode, India

Objective: To study the association of single nucleotide polymorphisms (SNPs) rs10050860 and rs17482078 of the ERAP1 gene and essential Zinc (Zn) imbalance with the clinical course of ankylosing spondylitis (AS).
Methods: A total of 58 patients (39 men and 19 women, average age 38 [31; 48] years) with a reliable clinical diagnosis of AS were examined. The median BASDAI index averaged 5.05 [3.6; 6.9] points, ASDASES – 3.1 [2.4; 4.1], MASES – 2 [0; 4], BASFI – 5.25 [3.1; 7.3]. HLA-B27 antigen was present in the overwhelming majority of patients – 91.37%. In addition to the generally accepted examination, all patients underwent genotyping of SNP rs10050860 and rs17482078 of the ERAP1 gene by the method of allele-specific hybridization in the format of polymerase chain reaction with fluorescence detection in real time using sets of primers on a detecting amplifier. The Zn content in hair was assessed by atomic adsorption spectrophotometry. The control group consisted of 14 relatively healthy individuals comparable to the main group by gender and age. Statistical processing of the obtained results was carried out using the STATISTICA 10 software package.
Results: In the course of our study, we found that the heterozygous [C/T] genotype of SNP rs10050860 of the ERAP1 gene was detected 1.6 times more often in patients with peripheral arthritis; $\chi2=4.82$, $p=0.029$, than in patients without this extra-axial manifestation. The obtained results were confirmed by factor analysis, according to which SNP rs10050860 of the ERAP1 gene made the greatest contribution to the development of extra-axial manifestations of AS - peripheral arthritis (0.16877), coxitis (0.20425), dactylitis (0.27602), extra-skeletal manifestations - uveitis (0.29707), Crohn's disease (0.17124) and a significant contribution to the value of the BASFI index (0.27308). The heterozygous [C/T] genotype of the SNP rs17482078 of the ERAP1 gene was 1.5 times more common in patients with peripheral arthritis, while the level of reliability was close to significant values; $\chi2 = 3.37$, $p = 0.067$, and, according to factor analysis, influenced the occurrence of peripheral arthritis (0.22494) and coxitis (0.18238), and was also associated with the development of uveitis (0.31885) and made a significant contribution to the value of the BASFI functional index (0.18709). An assessment of the microelement status showed that, compared with the control, in AS, a reliable decrease in the content of essential Zn by 41.32% was detected from 217.8 [163.8; 309] μg/g to 127.8 [100.5; 161.1] μg/g; $p=0.0002$. It is known that Zn deficiency in the body and a decrease in Zn intake into the Golgi apparatus leads to dysfunction of the ERp44 chaperone protein and an increase in the secretion of aminopeptidase 1 encoded by the SNP of the ERAP1 gene [Watanabe S., 2019], which plays one of the key roles in the pathogenesis of AS [Lee Y.H., 2011; Cortes A., 2015; Lee Y.H., 2016] and may affect the features of the clinical course of the disease. In this case, we found a reliable inverse correlation between the BASFI functional index and the Zn level in the hair of the studied patients with AS; $r = -0.299$, $p = 0.023$ and, according to factor analysis, Zn was associated with peripheral arthritis (0.10118) and contributed to the BASFI index (0.05011).
Conclusion: Thus, the carriage of heterozygous [C/T] genotypes of the rs10050860 and rs17482078 polymorphisms of the ERAP1 gene together with a deficiency of essential Zn in the body determine the functional state of patients with ankylosing spondylitis and are associated with the development of some extra-axial manifestations of the disease.

P1369

PREVALENCE AND FACTORS ASSOCIATED WITH FRAILTY AMONG HIP FRACTURE PATIENTS ADMITTED TO NATIONAL HOSPITAL, GALLE, SRI LANKA

S. Lekamwasam[1], H. Dias[2], N. Rathnayake[2], T. Abeygunasekara[2], V. Lekamwasam[1]

[1]Asiri Hospital, Galle, Galle, Sri Lanka, [2]Department of Nursing, Faculty of Allied Health Sciences, University of Ruhuna, Galle, Sri Lanka

Introduction: Frailty is a common geriatric syndrome associated with the decline in health and bodily function and a leading cause of falls and fractures among older adults. This study assessed the prevalence and factors associated with pre-fracture frailty among hip fracture (HF) patients admitted to National Hospital, Galle, Sri Lanka.
Methods: A total of 209 consecutive patients with incident HF, aged 40 years or more were enrolled in this prospective cohort study. Pre-fracture frailty and sarcopenia were assessed soon after admission using the locally validated Frail Non-Disabled (FiND) questionnaire and SARC-F tool. Information related to health and physical function immediately before the fracture were also gathered. Chi square test and independent t- test were used to identify the associated factors.
Results: Among 209 subjects admitted between May 2023 and May 2024, 119 (72%) were females while 138 (71.8%) were mar-

ried. The mean age (SD) of HF patients was 73.8 (11.3) years. Of 209 patients, 107 (51.2%) were disabled before fracture. Of those non-disabled (n=102), 99 (97%) have been frail at the time of fracture. Among the patients with pre-fracture frailty, 29.7% were sarcopenic whereas 85.2% of those with pre-fracture sarcopenia (n=61) were frail. Female gender (p=0.006), living alone (p=0.003), low BMI (p<0.001), poor nutritional status (p=0.004), low Mini-mental score (p=0.02), poor pre-fracture mobility (p=0.024), and impaired activities of daily living (p=0.03) showed significant associations with pre-fracture frailty. Age and ASA scoring did not show significant associations with pre-fracture frailty.

Conclusion: We conclude that a considerable proportion of patients admitted with hip fracture were either physically disabled or frail at the time of fracture. This information can be used in recognizing those with a high fracture risk and these modifiable risk factors should be included in rehabilitation programs of older adults in the community.

Keywords: Associated factors, Frailty, Hip fracture, Prevalence

HOW TO PREVENT THE DEVELOPMENT OF GOUT?

S. Lezhenina[1], E. Guryanova[2], N. Shuvalova[3]

[1]Chuvash State University by I. N. Ulianova, Cheboksary, Russia, [2]Postgraduate Doctors' Training Istitute, Cheboksary, Russia, [3]Chuvash State Pedagogical University by I. Y. Yakovlev, Cheboksary, Russia

Objectives. To evaluate the effect of physical activity and nutrition on the frequency of gout attacks.

Materials and methods. The study was conducted in Turkmenistan from December 2021 to December 2023. The participants were 90 patients with gout who had a history of the disease for more than 5 years. The average age was 52.2 ± 2.9 years (62 men and 28 women). The patients were divided into two groups: experimental and control, with 45 people each. The experimental group visited the pool twice a week for 40 minutes and did physical therapy with gym poles once a week for 30 minutes, and also followed a diet of up to 1800 kcal/day. The control group led a normal lifestyle. To evaluate the results, a questionnaire was conducted, which focused on the frequency of gout attacks. The questionnaire contained the following questions:

1. Have you had a gout attack in the last two years? (yes/no)
2. Have you had a gout attack in the last year? (yes/no)
3. Was there any deterioration during the course of the disease (seizures became more frequent)? (yes/no)

The results were processed in Statistical Analysis Software17.0. Statistical significance was processed using Analysis of Variance analysis

Results. In the experimental group, 31 patients (69%) had not experienced gout attacks in the last two years, 13 patients (29%) had not experienced attacks in the last year, and only 1 (2%) noted a worsening. In the control group, 42 patients (93%) reported an increased frequency of seizures, while only 3 patients (7%) indicated no seizures over the past year.

Conclusion. Preventing the development of gout is associated with lifestyle changes such as going to the pool, exercising, and following a diet of up to 1800 kcal/day. As a result, 69% of the patients in the experimental group had not experienced gout attacks in the last two years.

P1371

INVESTIGATING THE PROTECTIVE EFFECT OF OLEANOLIC ACID IN OSTEOPOROSIS THROUGH NETWORK PHARMACOLOGY AND MOLECULAR DOCKING AND INTESTINAL FLORA

S. Li[1], Y. Zhang[1], L. Hu[1], N. Liu[1], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou, China

Objective: Oleanolic acid is a pentacyclic triterpenoid extracted from Olea, which has a strong anti osteoporosis effect. This study aimed to investigate the potential mechanism of oleanolic acid on bone loss caused by estrogen deficiency through the combination of network pharmacology, molecular docking and in vivo validation.

Methods: we first predicted the drug target and structural interaction between oleanolic acid and osteoclasts on postmenopausal osteoporosis (PMOP) by network pharmacology and molecular docking. An ovariectomized (OVX) mouse model was established to experimentally verify the anti PMOP efficacy of oleanolic acid, which was supported by its protective effect on bone destruction and excessive inflammatory cytokines.

Results: the top 10 core targets of oleanolic acid produced by PPI network were ALB, PPARG, AKT1, ESR1, CASP3, IGF1, MMP9, EGFR, hsp90aa1 and Src. The enrichment results of go and KEGG pathways suggest that OA may participate in the regulation of OP through MAPK, PI3K Akt, estrogen and other signaling pathways. Molecular docking results showed that oleanolic acid had a strong binding force with the core target, and the binding energy was about -6.29 to -10.61kcal/mol. OA could significantly increase BMD and bv/tv of femur in OVX mice, and significantly reduce tb The contents of SP and serum Tracp5b, β -ctx and p1np suggested that OA could increase bone mass, inhibit bone resorption, promote bone formation, reduce bone turnover, and delay bone loss in OVX mice.

Conclusion: In conclusion, this study combined network pharmacology and molecular docking to predict the potential mechanism of oleanolic acid against PMOP. Through in vivo mouse model verification, oleanolic acid alleviates OVX induced bone loss by inhibiting inflammation.

P1372

THIGH MUSCLE QUALITY PREDICTS INCIDENCE OF TYPE 2 DIABETES

H. J. Choe[1], S. Lim[2]

[1]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, South Korea, Hwaseong, South Korea, [2]Seoul National University College of Medicine and Seoul National University Bundang Hospital, Seongnam, South Korea

Background
Ectopic fat infiltration in muscle tissue, particularly in the thigh, has been linked to metabolic dysfunction and may contribute to diabetes risk.
Objective
To investigate the association between low-density muscle (LDM) area at the midthigh level and the risk of incident diabetes in individuals without diabetes at baseline.
Methods
In this prospective study, 2,137 East Asian individuals (mean age 57.4 ± 16.9 years and BMI 25.0 ± 3.9 kg/m2, male 48.3%) with one or more cardiometabolic risk factors but no diabetes were enrolled. A non-contrast cross-sectional scan at the midthigh level was obtained, and areas ranging 0–30 Hounsfield units were defined as LDM.
Results
During a mean follow-up of 7.4 years, 201 males (19.5%) and 156 females (14.1%) developed diabetes. Participants who progressed to diabetes had higher baseline HbA1c than those did not (6.1 ± 0.3% vs. 5.7 ± 0.4%) and larger LDM areas (48.8 ± 14.2 cm2 vs 38.1 ± 13.2 cm2) (Both P < 0.05). A large LDM area was a significant predictor for incident diabetes (HR 2.36, 95% CI 1.52–3.67 for males; HR 2.15, 95% CI 1.28–3.61 for females) in the fully adjusted model including traditional risk factors including baseline HbA1c. Adding LDM area to traditional risk factors improved the predictive ability for diabetes progression, from 0.810 to 0.838 for males and from 0.893 to 0.908 for females in the area under the receive operating characteristic curve.
Conclusions
This study suggests that a large LDM area, indicating fat accumulation in muscle or muscle quality, is an important predictor for development of diabetes, necessitating interventions targeting muscle quality improvement and reducing fat accumulation.

P1373

OSTEOPOROSIS MANAGEMENT AMONG PATIENTS SCREENED THROUGH THE FRACTURE LIAISON SERVICE IN ONTARIO, CANADA

S. M. Cadarette[1], R. Jain[2], L. Plumptre[3], Y. Li[3], S. Aggarwal[1], R. Raj[1], J. E. M. Sale[4]

[1]University of Toronto, Toronto, Canada, [2]Osteoporosis Canada, Toronto, Canada, [3]ICES, Toronto, Canada, [4]Unity Health Toronto, Toronto, Canada

Objectives: Describe osteoporosis management in patients screened through a Canadian provincial Fracture Liaison Service (FLS).
Material and Methods: We linked patients aged 50+ years screened through the Ontario FLS between 2017/04 and 2021/03 to provincial healthcare administrative data at ICES. Inpatient, emergency department and outpatient services were captured for all residents to identify fractures and DXA testing. Drugs dispensed in community pharmacies were available for persons aged 65+ years to identify osteoporosis treatment. Patients presenting with a hip, humerus, radius/ulna or pelvis fracture were eligible. We defined osteoporosis management using the Kaplan-Meier estimator over one-year post-fracture as: DXA testing (radius/ulna only; stratified by 1-year DXA history), and treatment initiation (ages 66+ years; stratified by 1-year treatment history). Patients were followed until date of death, entry into long-term care or 365 days. Results were summarized overall and by sex.
Results: Of 20,914 eligible patients, 20,237 (97%) were successfully linked (4,656 hip, 4,709 humerus, 10,545 radius/ulna, 327 pelvis); 83% female; median age=71, IQR=18; 76% treatment naïve and 13% with DXA history. Almost 70% of DXA-naïve patients with radius/ulna fracture received DXA during follow-up (70% female, 60% male; median time=97 days). At least 90% of patients with treatment history, regardless of fracture site or sex, were dispensed pharmacotherapy post-fracture. Among treatment-naïve patients; half with hip fracture (53%; 55% female, 49% male), and a third with humerus (35%; 37% female, 25% male) or radius/ulna (36%; 39% female, 18% male) fractures started pharmacotherapy.
Conclusions: Over 97% of Ontario FLS patients were successfully linked to provincial healthcare administrative data. ~70% radius/ulna fracture patients receive DXA for the first time, 90+% continued or restarted pharmacotherapy post-fracture, and more than half of treatment-naïve hip fracture patients initiate pharmacotherapy. However, some sex-differences in post-fracture management may exist.
Disclosures: This research was supported by the Ontario Ministry of Health. Authors report no conflicts of interest.

P1374

REAL-WORLD DIFFERENCES IN DENOSUMAB PERSISTENCE, REINITIATION, AND SWITCHING AMONG COHORTS OF OLDER ADULTS IN CANADA AND THE UNITED STATES

K. N. Hayes[1], S. R. Sendhil[1], S. Aggarwal[2], A. R. Zullo[1], S. D. Berry[3], A. Oganisian[1], M. Adegboye[1], S. M. Cadarette[2]

[1]Brown University, Providence, United States, [2]University of Toronto, Toronto, Canada, [3]Hebrew SeniorLife and Harvard Medical School, Boston, United States

Objectives: Describe initial persistence with denosumab, treatment reinitiation following an extended gap, and switching to other osteoporosis therapies in two comparison cohorts.
Material and Methods: We completed two parallel cohort studies leveraging: 1) healthcare administrative data from Ontario, Canada (ON; 100% population); and 2) a 20% random sample of US Medicare beneficiaries (US). The first denosumab claim (US: 1/2010-12/2019; ON: 1/2012-12/2021) was identified using pharmacy claims (ON) and Medicare Parts D and B claims (US). Patients aged <66 years, residing in long-term care (LTC), or with implausible data (e.g., death before first claim) were excluded. We developed and applied an algorithm that used a combination of dosing and days between dispensations to clean denosumab exposure data. We imputed a 183 day coverage for each denosumab dispensation and defined discontinuation as a 60-day gap in coverage. We estimated initial persistence, reinitiation, and switching to other osteoporosis medications using Kaplan-Meier estimators, censoring on death, disenrollment (US only), LTC admission, or study end (12/31/2022 [ON], 12/31/2020 [US]).
Results: We identified 168,339 adults in ON (mean age=78 [SD=7.6] years; 90% female) and 97,595 in the US (mean age=77 [SD=7.2] years; 90% female). In ON, the median length of initial persistence was longer (median 2.3 years [ON] vs. 1.7 years [US]), the proportion persiting with therapy for 3-years was higher (44% [ON] vs. 31% [US]), and time to reinitiate was shorter (median=0.5 years [ON] vs. 1.9 years [US]). About 10% of patients in each cohort switched to another osteoporosis medication during follow-up. Those with prior oral bisphosphonate use had longer durations of denosumab treatment in ON but not the US.
Conclusions: Older adults in Ontario have longer persistence and shorter gaps in denosumab use than those in the US. Research to understand reasons for differences in exposure patterns, and subsequent potential differences in treatment effectiveness and safety is important.
Disclosures: This research was supported by the National Institutes of Health Research Grant R01AG078759. Authors report no conflicts of interest.

OSTEITIS FIBROSA CYSTICA: ANALYSIS & VISUALIZATION OF THE RESEARCH ACTIVITIES

R. Atlasi[1], B. Larijani[1], M. R. Mohajeri-Tehrani[1], S. M. Sajjadi-Jazi[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Background and purpose: Osteitis fibrosa cystica is a serious medical condition caused by hyperparathyroidism. In this study, we aim to analyze all the publications produced in this field and present the view of knowledge in this field.
Methods: By searching the subject heading "Osteitis Fibrosa Cystica" in MESH database and retrieving all of the documents indexed in PubMed/Medline until 27 August 2024, 1665 documents from 772 resources were retrieved. The documents were analyzed using the R bibliometrix package 4.1.1. The networks were mapped and the most active authors, centers, and characteristics of the journals were determined.
Results: The retrieved documents were from 1946 to 2024 and most were published in 1965 (n=81). "Oral Surgery, Oral Medicine, Oral Pathology" and "Revue Du Rhumatisme Et Des Maladies Osteo-Articulaires" equally, had the most published articles in this field (n=21). USA (n=71), Turkey(n=46), India (n=45), China (n=44), and Brazil (n=38) were the most active countries in this area, respectively. Also, the "Post Graduate Institute of Medical Education and Research" and "Santa Croce and Carle Hospital" were the most productive institutions. "Ellisa HA" from Germany was the most prolific author of these articles, with 16 articles in this field. Fluorodeoxyglucose f18, positron emission tomography computed tomography, and parathyroid hormone were the most topic trends in recent years.
Conclusion: In the 50s and 60s, the publication of documents in this field was significant and more than ever before. In recent years, especially the last 3 years, there have been very few studies, and Asian countries have been the most active countries in this field after the USA. This issue may be attributed to earlier diagnosis through routine calcium checks and improved management of hyperparathyroidism. As a result, Osteitis fibrosa cystica has become quite rare in recent times. Further studies in the field are suggested.

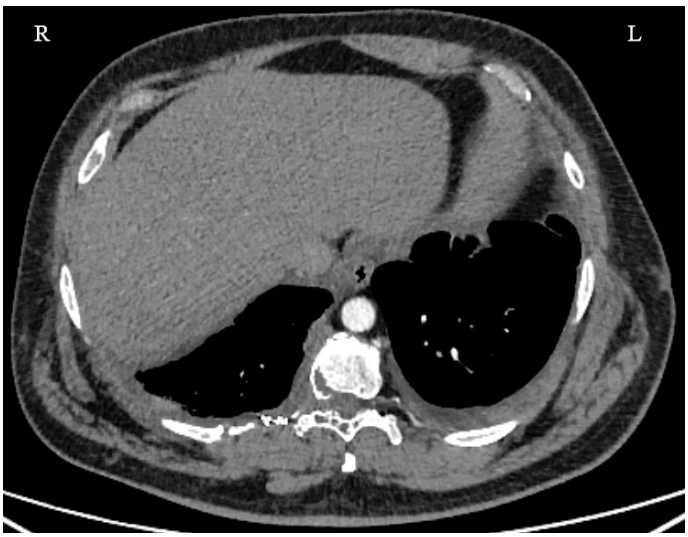
DRAMATIC OUTCOME OF A CASE OF GORHAM-STOUT SYNDROME WITH CHYLOTHORAX AND MULTIPLE BONE DESTRUCTION

S. Mazurenko[1], V. Strizheletckii[1], R. Peskovets[2], N. Shubina[2]

[1]Saint Petersburg State University, Saint Petersburg, Russia, [2]Saint George City Hospital, Saint Petersburg, Russia

Objective. Our goal is to present a case of Gorham-Stout syndrome with chylothorax and multiple bone destruction in a man who was observed for three years until his death in 2024.
Methods. A 48-year-old man with diagnosed Gorham-Stout syndrome was followed from 2021 to 2024 by a multidisciplinary group of specialist from several medical institutions of Saint-Petersburg, Russia.
Results. A year before the first manifestations of the disease, the patient had few health problems: in 2019 at the age of 45, he suffered a chest injury as a result of a traffic accident, traumatic cyst of the spleen, cystectomy with splenic preservation, and in September 2020 pneumonia caused by COVID-19. In August 2021 he began to experience shortness of breath during exercise. During the examination a massive pleural effusion was detected. Thoracentesis was performed, and the test results confirmed chylothorax. Up to 4 liters of exudates were removed. Right-sided osteolytic destruction of Th10-Th12 vertebral bodies and 4, 7, 11 ribs were revealed (Fig.). Pleura biopsy with histological study revealed diffuse lymphangiomatosis. Diagnosis of Gorham-Stout syndrome was supposed. As a result of complex medical interventions including pleurotomy, infusions of zoledronic acid and prescription of sirolimus 11 month remission was achieved. Since November 2023, the patient has repeatedly received hospital treatment for bacterial pneumonia, exacerbations of the underlying disease, and pulmonary embolism, which resulted in death.
Conclusion. Gorham-Stout syndrome is an extremely rare disease characterized by proliferation of lymphatic vessels within bones and related tissues. The etiology is unknown. The presented case may be related to a previous chest injury and pneumonia caused by COVID-19. The osteolytic process was quite easily stopped by repeated administration of zoledronic acid, sirolimus and, possibly, pleurotomy, which helped to achieve remission, but did not cure the disease.



P1377

OSTEITIS FIBROSA CYSTICA: A POST-TRAUMATIC MANIFESTATION OF A BROWN TUMOUR IN A PATIENT WITH SECONDARY HYPERPARATHYROIDISM DUE TO END-STAGE RENAL DISEASE: A CASE REPORT

E. Tarasova[1], O. Spasskaya[1], H. Bagirova[1], A. Eremkina[1], S. Mirnaya[2], N. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia, [2]Fomin Clinic, Moscow, Russia

Introduction: Secondary hyperparathyroidism represents a complex alteration in bone and mineral metabolism that occurs as a direct result of chronic kidney disease. Brown tumors are benign lesions caused by persistently elevated levels of the parathyroid hormone and uncontrolled bone resorption which represent a serious complication of renal osteodystrophy .

Case presentation

A 37-year-old man was admitted to our endocrinology department with severe clavicle and right hand pain developed after the injury. He was diagnosed with end-stage renal disease at the age of 27 due to a congenital anomaly of the urinary system and has been treated with haemodialysis for 10 years. Secondary hyperparathyroidism (sHPT) manifested at the age of 33. During the last follow-up, laboratory tests revealed elevated PTH 624 pg/ml (15-65), Ca adj. at 2,1 mmol/l (2,15-2,55), normophosphatemia – 1,09 mmol/l (0,74-1,52). These results were obtained on multicomponent therapy: cinacalcet 60 mg/day, elemental calcium – 420 mg, selevamer 4800 mg/day, alfacalcidol 0,5 mg/day. BMD assessed by Dual-energy X-ray absorptiometry scan revealed a Z-score of – 2.2 SD at the femur neck and – 4.9 SD at the radius. Computed tomography and magnetic resonance imaging visualized multiple osteolytic lesions of the 3rd right carpal bone (2.2x3.1x1.7 cm) with pathological fracture of the right clavicle (2.7x5.2x3.5 cm) and the right iliac wing (5,1x4,4x2,2 cm). Scintigraphy with 99mTc showed diffuse uptake in the right clavicle and the right iliac wing. According to histological examination giant cell mass

without evidence of cellular atypia was confirmed assessed as a brown tumour. Despite the relatively small increase in PTH above the target range, the patient exhibited severe bone manifestations of MBD-CKD, which indicated the surgical treatment.

Conclusion: Brown tumours are challenging in patients with chronic kidney disease. Healthcare professionals need to be aware of this condition and its further management.

P1378

SEVERE PREGNANCY-ASSOCIATED OSTEOPOROSIS IN YOUNG WOMAN: CASE REPORT

A. Lavreniuk[1], A. Eremkina[1], I. Khagabanova[1], S. Mirnaya[2], N. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia, [2]Fomin Clinic, Moscow, Russia

Objective

Pregnancy and lactation-associated osteoporosis (PLO) is a rare condition typically associated with non-traumatic vertebral fractures during the third trimester and/or the first months of postpartum. We present a clinical case of severe PLO in a young woman with ankylosing spondylitis.

Results

A 26-years-old woman presented with back pain and was immobilised for several months following her first delivery. She was treated with glucocorticoids, analgesics with mild beneficial effects. MRI showed a decrease in the height of Th4-12 (20-44%), L1-4 (21-40%). BMD assessed by DXA scan revealed a Z-score of -3.0 SD at L1-4, -2.0 SD at the femoral neck. She had menarche at 12 years of age, regular menstrual cycle prior to pregnancy, no history of fractures and common risk factors such as smoking, alcohol abuse, use of osteoporosis risk medications. Secondary causes of osteoporosis were excluded. Since 2019 she received teriparatide 20 mcg/day with colecalciferol and calcium for two years, followed by three infusions of zoledronic acid 5 mg/year with positive BMD dynamics: at the L1-4 0.6 SD, femoral neck -1.7 SD. MRI showed no negative vertebral height dynamics. There was no decrease in 1,25(OH)2 vitamin D; 25(OH)vitamin D. After zoledronic acid infusion, we observed suppression of bone remodelling markers. The patient still has moderate back pain, probably due to concomitant HLA-B27 negative ankylosing spondylitis, which was diagnosed in 2019 at additional examination. We decided to discontinue the anti-osteoporotic therapy and to add alfacalcidol 0.25 mcg/day accompanied with calcium carbonate 1000 mg/day. We also emphasized physical activity. In addition, we performed a genetic panel analysis to exclude a hereditary condition of low bone mass (in progress).

Conclusion

PLO is a rare but serious condition and must be considered in the differential diagnosis of back pain and vertebral fractures in the postpartum period.

P1379

PARATHYROID CANCER: A RARE CASE WITH SEVERE HYPERPARATHYROIDISM COMPLICATIONS

K. Meirambek[1], H. Bagirova[1], O. Spasskaya[1], E. Bibik[1], A. Gorbacheva[1], A. Eremkina[1], S. Mirnaya[2], N. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia, [2]Fomin Clinic, Moscow, Russia

Introduction: Parathyroid carcinoma (PC) is a rare malignancy, often associated with severe hyperparathyroidism, hypercalcemia and bone and renal complications.

Case Presentation: A 34-year-old man had suffered from progressive joint pain since 2022, unresponsive to analgesic drug. X-ray imaging revealed destructive changes in the hip and knee joints, and a tumor mass in the right femur with a high risk of low-energy fracture.

Blood tests showed high albumin adjusted calcium level 3.74 mmol/L (2.15–2.55), PTH 2030 pg/mL (15-65), and phosphorus 0.69 mmol/L. Ultrasound (US) visualized nephrolithiasis accompanied with normal filtration rate (101 mL/min/1.73 m^2). DXA scans revealed decreased BMD (Z-score) in the radius, lumbar spine and femoral neck (-5.8 SD, -4.0 SD and -4.4 SD, respectively). We excluded vertebral compression fractures by X-ray. Destructive changes in the upper third of the diaphysis of the right femur were considered as cystic fibrous osteitis. Initial treatment included intravenous hydration (3000 mL/day) and cinacalcet (90 mg/day), with follow-up denosumab 60 mg injection due to poor response.

Neck US and Technetium-99m MIBI scan identified a tumor of left inferior parathyroid gland 2.9 cm. Besides there was a papillary thyroid carcinoma of the right lobe 8 mm, confirmed with FNA biopsy.

In July 2024, the patient underwent selective left inferior parathyroidectomy and right hemithyroidectomy. Histology confirmed PC and thyroid microcarcinoma. Postoperatively, PTH levels dropped to 30.6 pg/mL, and albumin adjusted calcium to 2.1 mmol/L within 24 hours. Patient received calcium carbonate 3000 mg/day, cholecalciferol 10000 UI/day for 2 months with normocalcemia achievement.

Conclusion: The diagnosis of PC is highly challenging and requires integration of clinical, biochemical and radiological data, alongside careful evaluation of systemic manifestations.

P1380

OSTEITIS FIBROSA CYSTICA: AN UNOBVIOUS SIGN OF PRIMARY HYPERPARATHYROIDISM

R. Salimkhanov[1], A. Lutsenko[1], H. Bagirova[1], O. Spasskaya[1], A. Eremkina[1], S. Mirnaya[2], N. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia, [2]Fomin Clinic, Moscow, Russia

Introduction: Osteitis fibrosa cystica (OFC) is a skeletal disorder associated with long-standing, severe hyperparathyroidism.
Case presentation: A 64-year-old female presented with intense headaches persisting for three months. MRI and CT scans revealed two non-cystic lesions in the right frontal and sphenoid bones, measuring 30×25×15 mm and 14×44 mm, respectively, with deformation of adjacent antero-basal sections of the right frontal lobe. Differential diagnosis included fibrous dysplasia, hyperparathyroidism, Paget's disease, and metastatic cancer.
Laboratory tests confirmed primary hyperparathyroidism (PHPT): PTH – 168 pg/mL (15–65), Ca (adj.) – 2.9 mmol/L (2.15–2.55), P – 0.7 mmol/L (0.74–1.52), ALP – 324 U/L (40–150), and elevated urinary calcium excretion – 9.2 mmol/day. Ultrasound revealed nephrolithiasis in both kidneys with normal renal function (eGFR – 92 mL/min/1.73 m²). DXA scans indicated severe bone mineral density reduction in the radius, lumbar spine, and femoral neck (T-scores: -6.6 SD, -6.4 SD, -3.9 SD). Spinal x-ray detected vertebral compression fractures at Th8–9 and L1–4. Neck ultrasound and 99mTc-Sestamibi scintigraphy visualized tumors in the right lower and left upper parathyroid glands (0.9×2.2×1.5 cm and 1.7×0.9×2.2 cm). Hereditary history is unremarkable.
In August 2024, the patient underwent parathyroidectomy, two adenomas were removed. Post-surgery, PTH decreased to 13 pg/mL, Ca – 2.0, indicating remission. She was discharged on alfacalcidol (1 mcg/day) and calcium carbonate (500 mg/day).
Conclusion: This case highlights PHPT presenting with large bone lesions, initially suggestive of Paget's disease or metastatic cancer. Radiologic findings of lytic foci and hypercalcemia should prompt consideration of PHPT in differential diagnosis.

P1381

EOSINOPHILIC FASCIITIS: A RARE CASE WITH INITIAL JOINT INVOLVEMENT IN A MOROCCAN PATIENT

S. Mounsif[1], L. Barakat[1], S. Mourabit[1], K. Khadija[1], M. Moudatir[1], H. Elkabli[1]

[1]Ibn Rochd University Hospital, Casablanca , Morocco

Eosinophilic fasciitis is a rare, localized disease, first described by Shulman in 1974. It belongs to the category of sclerotic connectivites, although its etiology remains unknown. We report the case of a 66-year-old Moroccan female patient with type 2 diabetes and depression, who presented with inflammatory arthralgias affecting mainly the large and medium joints, associated with myalgias. Her symptoms worsened a few months later, with the appearance of progressive induration of the skin on the forearms and legs, resulting in limited joint mobility. The patient had neither Raynaud's phenomenon nor digital sclerosis. Biological tests revealed mild eosinophilia (700/mm³) and a moderate inflammatory syndrome (CRP 12 mg/L), while the immunological work-up was negative. A deep skin biopsy confirmed the diagnosis, demonstrating dermo-hypodermal and fascial fibrosis characteristic of eosinophilic fasciitis. Although rare, eosinophilic fasciitis is a potentially disabling condition. Joint involvement is rarely as initial symptom of consultation. Diagnosis is based on a combination of clinical, radiological (notably MRI) and histological findings, the latter being essential to confirm the pathology. Treatment combines corticosteroids and immunosuppressants or immunomodulators, with generally favorable outcomes.

P1382

A SYSTEMATIC REVIEW COMPARING MEDIALISING CALCANEAL OSTEOTOMY, LATERAL COLUMN LENGTHENING AND A COMBINATION OF BOTH AS A TREATMENT OPTION FOR STAGE 2 ADULT ACQUIRED FLATFEET.

S. Murugesh[1]

[1]university of nottingham, Liverpool, United Kingdom

Background: adult acquired flatfoot deformity (AAFD) is characterised by the collapse of the medial longitudinal arch (MLA), forefoot abduction and hindfoot valgus. Stage II AAFD is where the deformity is flexible and while is initially treated conservatively, as disease progression occurs surgical intervention becomes imperative. Lateral column lengthening (LCL) and medialising calcaneal osteotomy (MCO) are both cornerstone reconstructive procedures for correcting AAFD. However, there is no clear consensus on the degree to which, each procedure can correct deformity.
Objectives: The aim of this study was to perform a systematic review comparing the capacity of LCL, MCO and a combination of both at correcting stage II AAFD.

Methods: The publishing platforms OVID (Medline) and Pubmed were used to search for relevant studies. This review was conducted in line with the Preferred Reporting Items for Systematic Reviews and Meta- Analysis (PRISMA) guidelines.
Results: Ten studies met the eligibility criteria and were included in this review. Procedures were compared using a functional score such as the AOFAS scale and the radiological parameters: lateral talo-first metarsal (LTMT) angle, calcaneal pitch (CP), Kite's angle, anterior posterior talo-first metatarsal (APTMT) angle and talonavicular coverage (TNC) angle.
Irrespective of the type of reconstruction, post-operative improvement in functional scores was observed. Radiologically, LCL had a greater capacity to improve and maintain the LTMT angle, CP, APTMT angle and TNC angle post-operatively. MCO showed the greatest improvement and maintenance of Kites angle. Despite LCL superior corrective capacity, it was also associated with the highest complication rates of all surgeries.
Conclusion: LCL has a greater capacity to realign the midfoot and correct forefoot abduction than MCO however, has a higher complication rate. Alternatively, MCO had a lower complication rate but was limited to correction of the hindfoot valgus.

P1383

EVALUATION OF VITAMIN D LEVELS IN PATIENTS WHO HAD FEMORAL FRACTURE AND WAS ADMITTED IN MAJOR TRAUMA HOSPITAL IN UK

R. Maman[1], R. Prajapati[1], X. Y. Chan[1], Z. A. Yousuf[1], O. Egigba[1], S. Tute[1], I. Philips[1], W. Kashif[1], W. Shore[1], P. Jeswin[1], W. Abbas[1], J. Vaantaja[1], S. Naraen[1]

[1]Aintree University Hospital, Liverpool, United Kingdom

Objective: Vitamin D support skeletal health and improve bone mineralization by increasing intestinal calcium absorption, reducing secondary hyperparathyroidism and decreasing bone turnover.
Vitamin D can cause isolated and generalised musle pain and bone pain
Lower Level of Vitamin D are associated with High risk of fall and Fracture
Aim: To look into which group of patient with femoral fracture were deficent in Vitamin D at the time of admission
Inclusion & Exclusion creteria: All patient admitted with femoral fracture And age more than 60 were included
All patients with other Lower limb fracture and other fracture were excluded
Method & Material Data was collected from the notes and blood result of all the patients who were admitted with femoral fracture.
We looked at the peroid between 1 January 2024 to 30th November 2024. It was a retrospective study of 823 patients admitted during these period.
Result : There were 823 patients admitted in these period , out of which 555 Patients(68%) Female and 268 Patients(32 %) were female.
Patients were between 60-99 years.
There were 148((18%)patients from care home and 675(82%) patients were from thier own home.
Patients admitted from Care home ,63 out of 148 patients (42%) were insufficient ,54 patients were sufficient(36%) and 32 patients (21%) did not had Vitamin D levels checked.
Patient admitted from thier home 288 patien(43%)were insufficient,229 patients(34%) were sufficient and 157 patients(23%) did not had VitaminD level checked
Vitamin D level were checked in 657 (79%) patients. We found 283 (43%) patients were sufficient and 374(56%) patients were insufficient
Of these patients who were sufficient with Vitamin D group- 69% were Female & 30.9% were Male
Amoung Sufficient group ,154 patients had VitaminD level between 50-74. Female in this group were 95 and 54 were male.
Patient who had vitaminD level above 75 were129 in total. Among these group we had 101 female and 28 Male
Conclusion: Most of the patients came from thier home with fracture and were women. More patients were deficients in vitaminD than sufficient Percentage of patients with insufficient vit D level remain same whether they were admitted from home or care home.
Age group with the highest average % of patients who were admitted and sufficient with Vitamin D - 70-74.
Second highest age group was 85-89.
Age groups with the lowest average % of Vitamin D admitted patients - 65-69, 80-84, 90-94.
Patients who are most likely to not have sufficient Vitamin D are Men 65-69 who reside in Care and Wmen 65-69 who reside in Care
Reference Vitamin D and calcium for the prevention of Fracture A systemic review and meta analysis

THE FATTY ACID BINDING PROTEIN 5 INHIBITOR ART26.12 IS A NOVEL ANALGESIC FOR OSTEOARTHRITIS PAIN

A. Bruzzese[1], S. O'Sullivan[2], K. Bou[3], K. Farrell[1], C. Gordon[1], M. Kaczocha[3], D. Komatsu[1]

[1]Department of Orthopaedics and Rehabilitation, Renaissance School of Medicine, New York, United States, [2]Artelo Biosciences, Alderley Edge, United Kingdom, [3]Department of Anesthesiology, Renaissance School of Medicine, New York, United States

Objectives
The chronic pain associated with osteoarthritis (OA) is difficult to treat due to the complex pain signaling pathways involved. Non-steroidal anti-inflammatory drugs (NSAIDs) have short-term efficacy but pose risks such as elevated blood pressure and gastrointestinal ulcers. ART26.12 is an orally active, selective fatty

acid binding protein 5 (FABP5) inhibitor with antinociceptive and anti-inflammatory properties in multiple inflammatory and neuropathic pain models in Phase 1 development. This study aimed to investigate the potential efficacy of ART26.12 in reducing OA pain.

Material and Method

Experiments were conducted by the Stony Brook University Institutional Animal Care and Use Committee (#277150). Female, 12-week-old Sprague Dawley rats underwent surgical destabilization of the medial meniscus. Eight weeks following surgery, rats were subdivided into five groups (all n=10); vehicle, naproxen (8mg/kg), and ART26.12 (10, 25, and 50mg/kg) orally. Static incapacitance (ratio of ipsilateral to contralateral hindlimb weight bearing) was measured 1 h after the first drug dose, and weekly over a 28-day twice daily treatment regime.

Result

No changes in incapacitance were found in the vehicle-treated group at any point over the 28-day treatment regime. ART26.12 increased weight bearing on the ipsilateral (arthritic) limb in a dose-dependent manner (10–50 mg/kg) after the first dose of ART26.12, and at each weekly measurement of incapacitance, with no signs of tolerance. The average increase in weight bearing after 4 weeks of treatment was 20, 24, and 30% in the ART26.12 groups (10, 25, and 50 mg/kg, respectively) and 31% in the naproxen group (versus 4% in the vehicle group).

Conclusion

Acute and repeated oral treatment with ART26.12 reduces OA pain in the ipsilateral limbs with a similar effect size as naproxen. ART26.12 is a promising non-opioid, non-steroidal treatment alternative for chronic OA pain.

P1385

PRESCRIPTION HABITS FOR OSTEOPOROTIC TREATMENTS AMONG SPANISH GYNECOLOGISTS: RESULTS FROM AN AEEM SURVEY

J. C. Presa Lorite[1], S. P. Gonzalez Rodriguez[1], P. Romero Duarte[1]

[1]AEEM (Spanish Menopause Society), Madrid, Spain

Objective(s) To evaluate the prescription habits, clinical practices, and perceived barriers in osteoporosis management among Spanish gynecologists, emphasizing their pivotal role in the prevention and treatment of this prevalent condition in postmenopausal women.

Material and Methods An official online survey was conducted, designed by the Osteoporosis Group and approved by the Board of the Spanish Association for the Study of Menopause (AEEM). The survey consisted of 14 closed-ended questions addressing prescription habits and clinical decision-making in osteoporosis. A total of 205 specialists participated, 87% of whom were gynecologists, with 60.6% having over 15 years of clinical experience.

Results Among respondents, 54% reported seeing 1–10 patients with osteoporosis weekly, while 36% requested 1–5 densitometries monthly. For osteopenia, 50% prescribed calcium + vitamin D, and 57% combined it with osteoporosis treatments. Bisphosphonates and menopausal hormone therapy (MHT) were the most frequently used first-line treatments. Denosumab was prescribed by 57% as a second-line option and by 54% in cases of severe osteoporosis. Following osteoporotic fractures, 28% preferred bisphosphonates and 27% denosumab, with 43% conducting the first densitometric control at 1–2 years.

In terms of professional training, 43% of respondents reported acquiring knowledge through courses, while 30% acknowledged a lack of formal education in osteoporosis management. Notably, 63% expressed feeling little to no confidence in treating patients with osteoporosis.

Conclusion(s) This study highlights significant variability in osteoporosis management among Spanish gynecologists, driven by disparities in training and clinical experience. These findings underline the need for enhanced educational initiatives to standardize practices and improve confidence in managing this condition. The frequent use of menopausal hormone therapy (MHT) among gynecologists, particularly in patients with vasomotor symptoms that compromise quality of life, is notable. Evidence supports MHT's dual role in alleviating symptoms and improving bone mineral density (BMD), making it an essential component of comprehensive osteoporosis care. Strengthening its role in clinical guidelines and training programs could further optimize care for postmenopausal women.

P1386

AREAS FOR IMPROVEMENT IN THE MANAGEMENT OF OSTEOPOROSIS BY GYNECOLOGY SPECIALISTS

P. Romero Duarte[1], S. P. Gonzalez Rodriguez[1], J. C. Presa Lorite[1]

[1]AEEM (Spanish Menopause Society), Madrid, Spain

Objective: To analyze survey results regarding prescription habits for postmenopausal osteoporosis among gynecology specialists, comparing them with current evidence to identify potential areas for improvement.

Materials and Methods: An official online survey was conducted, designed by the Osteoporosis Group and approved by the Board of the Spanish Association for the Study of Menopause (AEEM). The survey comprised 14 closed-ended questions addressing prescription habits and clinical decision-making in osteoporosis. A total of 205 specialists participated, 87% of whom were gynecologists, with 60.6% having over 15 years of clinical experience.

Results: "Gynecology specialists treat a sufficient volume of patients with osteoporosis (OP) to gain experience in its management, as more than 90% care for patients with this condition. Over 80% request bone densitometry as part of active management. Osteopenia is primarily treated with calcium and vitamin D. For first-line treatments of OP, bisphosphonates and hormone replacement therapy (HRT) are most commonly used, with denosumab being the clear second-line treatment (57.9%). In patients with severe OP and high fracture risk, the treatment of choice is teriparatide (32.1%), and bone-forming agents (40%) are also fre-

quently used. The vast majority of specialists prescribe calcium and vitamin D for OP (98%). To assess treatment efficacy, most request bone densitometry within the first two years (80%). In patients with a previous fracture, bone-forming agents are used in 35% of cases.
Only 7% of gynecology specialists have received in-person training on OP. Additionally, 62% of professionals feel either uncomfortable or only somewhat comfortable managing OP."
Conclusions: Osteoporosis can be diagnosed through densitometry, and we should increase its utilization to improve diagnosis rates. The approach to osteopenia should primarily focus on lifestyle modifications. Osteoporosis treatments must be individualized; for patients experiencing hot flashes, hormone replacement therapy (HRT) should be considered as first-line treatment. The use of denosumab as a second-line treatment can be appropriate in many cases due to improved adherence from its ease of use, though this should be individualized. We now recognize that for women at high fracture risk, treatment with bone-forming agents is prioritized for net bone gain. Calcium and vitamin D supplementation must be maintained in patients receiving antiresorptive and bone-forming medications. Treatment effectiveness should be monitored with regular densitometry scans, especially in high-risk fracture patients, every 1-2 years. After a fracture, treatment modification should be considered, including evaluation of bone-forming agents. To improve care for women with osteoporosis, structured training through specialized menopause units is essential. Currently, healthcare professionals' confidence and motivation in managing osteoporosis are low, which are crucial aspects that need addressing to ensure proper medical care.

P1387

REFINING EARLY DETECTION OF LOW BONE MINERAL DENSITY: A DEEP LEARNING MODEL FOR OSTEOPENIA SCREENING USING CHEST RADIOGRAPHS

J. Park[1], S. Park[1], M. Kim[1], H.-J. Bae[1]

[1]Promedius Inc., Seoul, South Korea

Objective(s): We developed and validated a deep learning model to classify osteoporosis, osteopenia, and normal bone mineral density (BMD) from standard frontal chest radiographs. This framework offers finer categorization, enabling earlier identification of osteopenic individuals and more timely DEXA referrals for those at moderate risk.
Materials and Methods: We expanded our PROS CXR:OSTEO product—which initially achieved high accuracy (AUC = 0.94 in internal validation) in classifying osteoporosis versus non-osteoporosis—to further differentiate osteopenia from normal within the non-osteoporosis category. Training data comprised 46,048 chest radiographs from Hospital A (South Korea), categorized by DXA T-scores, augmented with 16,265 unlabeled images from public datasets, totaling 62,313. For internal validation, 1,989 chest radiographs from Hospital A were used. For external validation, we collected datasets from three independent institutions spanning secondary healthcare (Hospital B), a facility serving veterans (Hospital C), and a global platform (Platform D).
Results: Our framework achieved an AUC of 0.93, sensitivity of 0.94, and specificity of 0.72 in classifying normal and osteopenia on External A (88.9% female; mean age 59.0 years), an AUC of 0.83, sensitivity of 0.78, and specificity of 0.82 on Hospital B (55.5% female; mean age 59.3 years), an AUC of 0.83, sensitivity of 0.73 and specificity of 0.67 on Hospital C (44.8% female; mean age 73.6 years), and an AUC of 0.78, sensitivity of 0.75, and specificity of 0.77 on Platform D (95.4% female; mean age 67.2 years).
Conclusion(s): Our model effectively classified osteopenia from normal BMD within the non-osteoporosis category, helping identify individuals at risk of reduced bone density and potentially enabling earlier intervention for osteopenia and osteoporosis.

P1388

ENHANCING OSTEOPOROSIS DETECTION IN CHEST X-RAY WITH A LARGE-SCALE VISION FOUNDATION MODEL: A MULTI-INSTITUTIONAL STUDY

S. Park[1], M. Kim[1], M. Kim[1], H. Bae[1]

[1]Promedius Inc., Seoul, South Korea

Osteoporosis often remains undiagnosed until fractures occur, causing significant individual and societal burdens. Although dual-energy X-ray absorptiometry (DXA) is the diagnostic standard, its limited accessibility hinders early detection. To address this, we developed a large-scale chest X-ray (CXR)-based foundation model for robust osteoporosis classification across multiple institutions in diverse clinical environments, aiming to enable early risk identification.
We developed a vision foundation model trained on approximately 700,000 open-access frontal CXRs using self-supervised learning. This model captured diverse radiographic features from variations in CXR equipment and institutional practices. Subsequently, we fine-tuned the foundation model using a dataset of paired CXRs and DXA T-scores to classify osteoporosis and evaluated its performance on three datasets (A-C). Datasets A and B came from the same institution, representing health screening and outpatient clinic data, respectively, while Dataset C consisted of screening data from a secondary healthcare center. We compared the performance between the foundation model and a simple CNN model, noting significant improvements.
The AUCs and sensitivities using the foundation model were 0.96 and 0.83 for Dataset A, 0.87 and 0.84 for Dataset B, and 0.91 and 0.95 for Dataset C. In comparison, the performance without foundation model achieved AUCs and sensitivities of 0.96 and 0.68 for Dataset A, 0.88 and 0.68 for Dataset B, and 0.91 and 0.57 for Dataset C. While the AUCs were comparable across models, the foundation model demonstrated substantially higher sensitivities for all datasets.
By integrating a vision foundation model trained on large scale, diverse CXR data, we achieved comparable AUCs and higher sensitivities across all datasets compared to a simple CNN model, highlighting its potential to enhance robustness and generalizability in osteoporosis classification.

MODULATION OF INFLAMMATORY AND SKELETAL MUSCLE DIFFERENTIATION MARKERS IN C2C12 CELLS TREATED WITH NARINGENIN AND HESPERETIN PHASE II METABOLITES

S. Perna[1], J. Jessica[1], C. Artale[1], A. Scarafoni[1], P. Riso[1], G. Baron[2]

[1]Division of Human Nutrition, Department of Food, Environmental and Nutritional Sciences (DeFENS), Università degli Studi di Milano, Milano, Italy, Milano, Italy, [2]Department of Pharmaceutical Sciences - DISFARM University of Milan, Milano, Italy

C2C12 cells, a widely used murine myoblast cell line, were treated with varying concentrations of naringenin and hesperetin phase II metabolites (0, 0.1, and 1 mg/dL) alongside LPS (to stimulate inflammation) and DEXA (to stimulate sarcopenia), in order to investigate the modulation of inflammatory and muscle differentiation markers.

The study focused on several key proteins, including TNF-alpha, IL-8, ERK1/ERK2, IGFBP2, MYOD1, Myogenin, N-cadherin, AMPK alpha-1/2, and P53. Naringin and hesperidin, among the main representative polyphenols of bergamot, in vivo are hydrolyzed to the relative aglycones naringenin and hesperetin and further metabolized as phase II metabolites, which are the main circulating species.

Naringin and hesperidin, the primary polyphenols in bergamot, are hydrolyzed in vivo to their respective aglycones, naringenin and hesperetin, and further metabolized into phase II metabolites, which represent the main circulating forms. In vivo studies have demonstrated that naringenin and hesperetin possess significant anti-inflammatory activity, supporting their potential therapeutic applications. [10.1002/ptr.5292].

This study focused on the potential effects of the phase II metabolites on inflammatory responses and myogenic differentiation in C2C12 cells. Notably, TNF-alpha is known to inhibit myogenic differentiation through NF-κB activation, while IL-8 and other markers may play roles in muscle regeneration and inflammation. The signaling pathways involving ERK1/ERK2 and AMPK are crucial for cellular responses to stress and energy metabolism, which are particularly relevant in muscle cells. Preliminary results suggest that treatment with naringenin and hesperetin metabolites may alter the expression levels of these markers, potentially enhancing myogenic differentiation while mitigating inflammation. This indicates that naringenin and hesperetin phase II metabolites derived from bergamot polyphenols could serve as a beneficial agent in muscleskeletal-related therapies, particularly under conditions characterized by elevated inflammatory cytokines. Further analysis will be required to fully understand the underlying mechanisms and confirm these effects in C2C12 models.

P1390

ASSOCIATION OF HYPERTENSION AND CENTRAL OBESITY WITH RADIOGRAPHIC SEVERITY IN HAND OSTEOARTHRITIS: FINDINGS FROM A POPULATION-BASED STUDY

S. Pimenta[1], H. Gonçalves[2], M. Pimenta[3], A. Martins[1], L. Costa[1], T. Guimarães[4], A. Rodrigues[5], R. Lucas[6]

[1]Rheumatology Dept., Centro Hospitalar Universitário de S. João, Porto, Portugal, [2]Community Medicine Dept., Information and Health Decision Sciences, Faculty of Medicine, University of Porto, Porto, Portugal, [3]Radiology Dept., Centro Clínico Universitário D. Pedro V, Armed Forces Hospital, Porto, Portugal, [4]Clinical Pathology Dept., Centro Hospitalar Universitário de S. João, Porto, Portugal, [5]Comprehensive Health Research Centre, NOVA Medical School, NOVA University of Lisbon, Lisboa, Portugal, [6]Epidemiology Research Unit, Institute of Public Health, University of Porto, Porto, Portugal

Objective. Hand osteoarthritis (HOA) is a clinically heterogeneous disease. The role of cardiometabolic factors and obesity in its radiographic progression remains unclear. This study aims to investigate the association between cardiometabolic factors, obesity, and radiographic severity in patients with HOA.

Materials and Methods. A cross-sectional analysis of a community-based cohort in Portugal included participants with HOA (≥1 joint with Kellgren-Lawrence (KL) grade ≥ 2 and/or American College of Rheumatology criteria). Patients with other osteoarticular conditions were excluded. Radiographic severity was assessed using the sum of the KL hand score (range 0-128). Cardiovascular risk factors, anthropometric individual measures and self-reported cardiovascular events were collected. We tested the associations between these factors and radiographic severity by multivariable linear regression, adjusted for age, sex, and education.

Results. Of 858 participants with HOA (61% women, mean age 59.6 years), 807 met radiographic criteria. Among these, 70% were overweight or obese, 80% hypertensive, 94% had dyslipidaemia, and 21% were diabetic. Body Mass Index (BMI ≥ 30), waist circumference, and waist-to-height ratio were associated with radiographic severity (β 1.78, 95% CI 0.10; 3.46), (β 0.06, 95% CI 0.01; 1.12), and (β 0.10, 95% CI 0.08; 0.19), respectively. Hypertension was also associated with radiographic severity (β 1.93, 95% CI 0.02, 3.9), while diabetes and dyslipidaemia showed no association.

Conclusion. Central obesity and hypertension are associated with radiographic severity in HOA, highlighting their potential systemic effects on radiographic progression. These findings underscore the importance of addressing obesity and hypertension as potential modifiable risk factors in the management of HOA progression, with a focus on preventive and early therapeutic strategies. Further research is needed to validate these findings.

P1391

CORRELATION OF BODY MASS INDEX AND BONE MINERAL DENSITY IN MENOPAUSAL WOMEN WITH TYPE 2 DIABETES

S. Popovic Pejicic[1], L. J. Bozic Majstorovic[1], N. Pejicic[2], I. Ovcina[2], J. Mrdja[2], D. Popovic[2]

[1]Faculty of Medicine, University of Banjaluka, Banjaluka, Bosnia & Herzegovina, [2]University Clinical Centre of the Republic of Srpska, Banjaluka, Bosnia & Herzegovina

Introduction : That type 2 diabetes (T2D) may adversely affect bone health was suggested more recently. The pathophysiological mechanisms are complex, particularly as obesity is very common in patients with T2D and is itself associated with an increased risk of fractures at specific sites. The aim of this study was to examine relationship between body mass index (BMI) and bone mineral density (BMD) in a group of menopausal women with T2D.
Material and methods: The study involved a group of 100 post-menopausal women with T2D aged 59,08+- 6,07 All subjects had good glycoregulation (HbA1c 7,2 %) and their BMI has been determined. BMD was determined by DXA method by Hologic QDR 4500 C unit . BMD was measured at central skeleton (lumbal spine and both hips). According to densitometry finding, the criterion for osteoporosis is T score less than −2.5 SD. BMI values were correlated with total T score values of the lumbal spine and both hips, as well as total T score values of spine and hip.
Results: Results have shown that median BMI value was found in 28,27 ± 4,12 . Median lumbal spine T score was − 2,19 SD ± 1,25, and hip T score − 1.11 SD ± 0.95. A statistically significant positive correlation (r = 0.01) was found between BMI and BMD of the hip, whereas between BMI and BMD of lumbal spine there was no statistically significant correlation. There was a statistically significant correlation (r = 0.01) between BMD values of lumbal spine and hip.
Conclusion: In postmenopausal women with T2D , BMI is more important predictor of hip BMD, as compared to spine BMD. BMD is variably elevated in T2D, an effect that would be expected to increase bone strength. BMD of hip is increased with the increase of BMI and height in obese postmenopausal women with T2D, probably caused by alterations in cortical bone microarchitecture and bone matrix. A lack of correlation between BMI and BMD of spine in postmenopausal women with T2D might be due to predominant effect of lack of estrogen and faster bone metabolism in spinal region.

P1392

PREDICTIVE FACTORS FOR HIP INVOLVEMENT IN JUVENILE IDIOPATHIC ARTHRITIS

S. Rahmouni[1], I. Jabrouni[1], M. Dhifallah[1], K. Zouaoui[1], M. Abbes[1], S. Boussaid[1], S. Rekik[1], H. Sahli[1]

[1]Rheumatology Department , La Rabta Hospital, Tunis, Tunisia

Introduction : Juvenile Idiopathic Arthritis (JIA) is a serious and disabling disease that occurs in a growing organism. Among the joints commonly affected by JIA, the hip stands out as a pivotal site that can significantly impact the functional prognosis of the disease.
Objectives : investigate the determinants of hip involvement in patients with JIA.
Methods : A retrospective study was conducted involving patients diagnosed with JIA based on the European League Against Rheumatism (EULAR) criteria. We divided our population into 2 groups: G1 (with hip involvement) and G2 (without hip involvement). Demographic, clinical, and biological data, including the neutrophil/lymphocyte ratio, were studied and compared between the two groups.
Results: The study included a cohort of 42 patients (15 males and 27 females), with a mean age of 37.55 ± 14.26 years [16-76] at the time of the study. The average age at disease onset was 14.63 ± 6,79 years, the mean disease duration was 21.85 ± 12.49 years.
Hip involvement was detected in 16 patients, with bilateral involvement in 10 cases. The average time from disease onset to hip involvement was 13.64 ± 8.98 years.
On biological data, twenty-eight patients (68.3%) exhibited a biological inflammatory syndrome. The mean neutrophils and lymphocytes were 6595 ±4416 per mm³ and 2187 ± 1022 per mm³, respectively. The mean neutrophil-to-lymphocyte ratio was 3.36 ± 3.33.
Statistical analysis revealed that hip involvement was associated with the age of disease onset ((G1 10.81 ± 3.7 vs G2 years 19.52 ± 14.59, p=0.011) and neutrophil-to-lymphocyte ratio (p=0.013). Male gender was associated with lower risk of hip involvement (OR= 0.205 95%IC [0.051 - 0.826], (p=0.021). However, factors such as mean disease duration, smoking status, presence of biological inflammatory syndrome, did not show significant associations with hip involvement.
Conclusion
Hip involvement is a common complication in JIA and represents a significant prognostic factor. Thus, it is imperative to identify associated risk factors such as age and gender. Moreover, the neutrophil-to-lymphocyte ratio holds promise as a potential future predictive marker for hip involvement in this condition.

P1393

HIVO: INVESTIGATING OSTEOPOROSIS IN HUMAN IMMUNODEFICIENCY VIRUS PATIENTS – SCREENING GAPS AND RISK ASSESSMENT IN A CLINICAL COHORT FROM A TERTIARY PORTUGUESE CENTER

S. Rodrigues[1], A. C. Moniz[1], M. Almeida[2], C. I. Santos[2], A. Cartaxo[2], S. Rocha[2], D. Melim[1], M. E. Santos[1], L. Gago[1], J. Tremoceiro[1], A. C. Miranda[2], T. Batista[2], J. C. Branco[1], C. Lopes[1], M. Costa[1]

[1]Rheumatology Department, Hospital de Egas Moniz, Unidade Local de Saúde Lisboa Ocidental, Lisbon, Portugal, [2]Infectious Diseases Department, Hospital de Egas Moniz, Unidade Local de Saúde Lisboa Ocidental, Lisbon, Portugal

Objectives: This study aims to evaluate adherence to the EACS [European AIDS (acquired immunodeficiency syndrome] Clinical Society Guidelines for osteoporosis screening in HIV (human immunodeficiency virus) individuals. The secondary objective is to assess the need of raising awareness among infectious disease specialists about the topic and to evaluate the importance of establishing a standardized referral protocol for Rheumatology appointments.

Material and Methods: this single-center retrospective longitudinal study included a cohort of HIV 1 and 2 patients aged 40-50 years old, randomly selected, followed at the Infectious Diseases Department from January to December 2024. The ones with prior osteoporosis diagnosis and/or treatment, hepatitis B/C co-infection and less than one year of follow-up were excluded. Data was collected from electronic medical record reviews, ensuring patients' confidentiality.

Results: Forty-six patients (15 women and 31 men) were included with a mean age of 44±3SD years. Smoking was reported by 24% of individuals, while alcohol misuse by 4.3%. Early menopause was reported in 1 woman, while no other major risk factors for osteoporosis were identified. Patients had a mean time since AIDS diagnosis of 11±6SD years. 73.9% were either currently or previously treated with osteoporosis-inducing antiretroviral therapy, for an average of 7±5SD years. None of the patients had registered fragility fractures. Neither FRAX (fracture risk assessment tool) nor DXA (dual-energy X-ray absorptiometry) were performed on any of the patients. Vitamin D was prescribed in 4.3% of the patients, but no additional calcium or anti-osteoporotic therapy was administered.

Conclusion: To our knowledge, this cohort study is the first to evaluate adherence to the EACS Guidelines for osteoporosis screening. These findings suggest a lack of adherence to the guidelines and reveal the need to increase awareness among infectious diseases physicians for the screening tools available to calculate bone fracture risk. Prospectively, we intend to create a referral protocol to Rheumatology appointment for those with high risk and reevaluate the outcomes after its implementation.

P1394

RELATIONSHIP BETWEEN VITAMIN D STATUS AND VARIOUS DISEASES: CLINICAL SIGNIFICANCE

S. S. Saric[1], K. A. Kapetanovic[1], Z.-I. M. Zonic-Imamovic[2], A.-A. R. Alimanovic - Alagic[3]

[1]Canton Sarajevo Public Medical Care Institution, Sarajevo, Bosnia & Herzegovina, [2]University of Tuzla Clinical Center, Tuzla, Bosnia & Herzegovina, [3]University of Sarajevo Clinical Center, Sarajevo, Bosnia & Herzegovina

Objective: To assess the clinical significance of vitamin D levels in various diseases in patients living in Sarajevo Canton.

Material and Methods: This study investigates the relationship between vitamin D status and several diseases (osteoporosis, breast cancer, and spinal deformities in children aged 8 to 12 years) in patients residing in Sarajevo Canton. Serum vitamin D levels were measured in nanograms per milliliter (ng/ml). Bone mineral density (BMD) was assessed at the lumbar spine and proximal femur using Dual-Energy X-ray Absorptiometry (DXA). Spinal deformities were diagnosed clinically and radiographically.

Results: In patients with osteoporosis (n=118), the mean vitamin D level was 17.3 ng/ml, ranging from 3 ng/ml to 65.9 ng/ml. Low serum vitamin D levels were observed in 87.2% (n=103) of patients, with a mean value of 14.5 ng/ml, ranging from 3 ng/ml to 29.4 ng/ml. Normal vitamin D levels were recorded in 12.8% (n=15) of patients, with a mean of 34.5 ng/ml, ranging from 30.4 ng/ml to 65.9 ng/ml.

In breast cancer patients (n=60), the mean vitamin D level was 15.6 ng/ml, ranging from 3.2 ng/ml to 45.5 ng/ml. Low vitamin D levels were observed in 93.7% (n=56) of patients, with a mean value of 14.4 ng/ml, ranging from 3.2 ng/ml to 28.4 ng/ml. Normal vitamin D levels were recorded in 6.3% (n=4) of patients, with a mean of 34.5 ng/ml, ranging from 30.6 ng/ml to 45.5 ng/ml.

In children with spinal deformities (n=121), the mean vitamin D level was 28.5 ng/ml, ranging from 11.2 ng/ml to 51.2 ng/ml. Low vitamin D levels were found in 56.4% (n=68) of children, with a mean value of 21.7 ng/ml, ranging from 11.2 ng/ml to 29.8 ng/ml. Normal vitamin D levels were recorded in 43.6% (n=53) of children, with a mean of 34.5 ng/ml, ranging from 30 ng/ml to 51.2 ng/ml.

Conclusion: Our findings indicate that vitamin D deficiency/insufficiency is associated with the examined diseases. This suggests that assessing vitamin D status should be an integral part of the clinical protocol for these conditions.

Keywords: vitamin D status, osteoporosis, breast cancer, spinal deformities.

P1395

VITAMIN D METABOLITES AS MARKERS OF BIOCHEMICAL OSTEOMALACIA IN ADOLESCENTS

S. Sabico[1], N. Al-Daghri[1], E. Cavalier[2], Y. Al-Saleh[3], M. N. K. Khattak[1], K. Wani[1], A. Alnaami[1], M. Alokail[1], J. Y. Reginster[1]

[1]King Saud University, Riyadh, Saudi Arabia, [2]University of Liege, Liege, Belgium, [3]Health Oasis, Riyadh, Saudi Arabia

Background: We previously observed a high prevalence of biochemical osteomalacia among apparently healthy Arab adolescents, using a proposed a combination of altered mineralization markers suggestive of osteomalacia. In this study, we aim to determine whether vitamin D metabolites, including vitamin D metabolite ratio (VMR), can serve as indicators of biochemical osteomalacia among Saudi adolescents.
Methods: A total of n=949 age- and body mass index (BMI) matched adolescents (n=513 girls, mean age=14.9 ± 1.8 years, mean BMI=23.0 ± 5.9; n=436 boys mean age=14.9 ± 1.7 years, mean BMI=23.7 ± 5.8) were included in this cross-sectional study. Anthropometrics were measured and biochemical parameters [25(OH)D (VD), calcium (Ca), inorganic phosphorus, alkaline phosphatase (ALP)] were assessed using assays. Circulating VD metabolites [24, 25 VD; VD2; VD3; total VD] were quantified using liquid chromatography-tandem mass spectrometry (LC-MS/MS). VMR was calculated as [24,25(OH)D/25(OH)D] × 100. VD deficiency cut-offs were defined as 25(OH)D <30nmol/L, 24,25(OH) VD <3.0nmo/L, VD2 limit of quantification (LOQ) <1.8 and VMR <4% based on proposed cut-offs. Biochemical osteomalacia was defined as any two of the four markers, namely low 25 (OH)D, high alkaline phosphatase (ALP), low calcium (Ca), and/or inorganic phosphorous (Pi). Predictive values (PVs), area under the curve (AUC) and Youden's index were calculated.
Results: With the exception of VD2, all VD metabolites were significantly lower in participants with biochemical osteomalacia. In all participants, 25(OH)D had the highest AUC [0.71, 95% CI 0.66-0.76; p<0.001], positive PV (0.11), negative PV (0.98) and Youden index (0.40). When stratified according to sex, the best marker for biochemical osteomalacia in girls was VMR [AUC 0.60, 95% CI 0.56-0.66; p=0.003], positive PV (0.18), negative PV (0.92) and Youden index (0.17)], while VD3 was the best in boys [AUC 0.77, 95% CI 0.6-0.94; p=0.001], positive PV (0.02), negative PV (0.97) and Youden index (0.60)].
Conclusion: VD metabolites as a single test are modest predictors of biochemical osteomalacia in adolescents and differ in accuracy according to sex.

P1396

THE ASSOCIATION BETWEEN MULTIMORBIDITY AND FALL RISK AMONG INDIVIDUALS AGED 50 YEARS AND OLDER IN IRAN- FINDINGS FROM STEPS 2021 SURVEY

S. Salehi[1], M. Khojasteh[2], F. Z. Dehestani[3], S. Akbarpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: The aim of this study is to examine the association between multimorbidity and the risk of falls among individuals aged 50 years and older.
Material and Method: This study utilized data from STEPS 2021 survey and included individuals aged 50 years and older in the analysis. Five chronic disease; diabetes, hypertension, cardiovascular diseases (heart attack and stroke), hypercholesterolemia, and cancer were assesses based on self-reported and history of prior diagnoses. Participants were categorized into three groups: those with no chronic disease, one disease, and two or more diseases. The data were weighted to account for the sampling cluster used in the survey design. Multiple logistic regression with a backward stepwise approach was employed to examine the association between the number of multimorbidity and the risk of falls. The statistical precision and significance were evaluated using 95% confidence interval (95%CI) and P-value.
Result: A total of 10975 participants were included in the study. Of these, 53.14% had no chronic disease (95% CI 52.09–54.18), with a prevalence of falls in this group was 44.74% (95%CI 38.87–50.76). In comparison, 29.13% of participants had one chronic disease (95%CI 28.19–30.10), and 17.73% (95%CI 16.94–18.54) had two or more chronic diseases. The prevalence of falls in these groups was 30.31% and 24.95%, respectively (95%CI 24.99–36.22 for one chronic disease and 20.30–30.26 for two or more). The odds of falls were 1.10 times higher in individuals with one chronic disease compared to those without chronic disease (95%CI 0.81–1.49, P = 0.538). Furthermore, the odds was 1.48 times higher in individuals with two or more chronic diseases compared to those without any chronic disease (95%CI 1.09–2.02, P = 0.012).
Conclusion: The results indicate that the prevalence of falls in individuals over 50 years old with at least one chronic disease compared to those without any chronic diseases. These findings highlight the importance of implementing educational programs and preventive interventions to reduce fall risk in this age group, particularly among those with one or more chronic diseases.

P1397

PREDICTORS FOR AN UNDERLYING LOW BONE MINERAL DENSITY IN OLDER ADULTS POST-ACUTE STROKE IN MALAYSIA: A SINGLE-CENTRE STUDY

S. Salleh[1], H. Sallehuddin[1], H. Mat Din[2], A. M. Abdul Rashid[1], T. I. W. Ong[3], S. Shariff-Ghazali[4]

[1]Department of Medicine, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Selangor, Malaysia, [2]Malaysian Research Institute on Ageing, Universiti Putra Malaysia, Selangor, Malaysia, [3]Department of Medicine, Faculty of Medicine, Universiti Malaya, Kuala Lumpur, Malaysia, [4]Department of Family Medicine, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Selangor, Malaysia

Objective: Stroke is a risk factor of osteoporosis and quadruples the risk of fracture. This study aimed to identify the risk factors associated with low bone mineral density (BMD) among post-stroke older adults in a tertiary teaching hospital in Malaysia.
Material and Methods: This prospective cross-sectional study examined older adults aged 50 years and above admitted for acute stroke in Hospital Sultan Abdul Aziz Shah (HSAAS) Malaysia between March 2023 to July 2024. Areal BMD was assessed using a Dual-energy X-ray absorptiometry (DEXA) scan. Low BMD included both osteoporosis and osteopenia and was defined as T-score <-1.0. The chi-square test was used to compare the association between risk factors and low BMD, followed by binary logistic regression analysis. Data analysis was done using SPSS version 29.
Results: A total of 55 patients were included in the study. The mean age of participants was 64±7.06 years and 36% (n=20) were women. Malay-Bumiputera made up 92% (n=51) of the study population. The prevalence of low BMD was found to be 56.4% (n=31), with eight osteoporosis and 23 osteopenia detected. More women had osteoporosis compared to men (75% versus 46%, respectively). Gender (p-value 0.035, χ^2 = 4.438), ethnicity (p-value 0.018, χ^2 = 5.572) and National Institutes of Health Stroke Scale (NIHSS) score (p-value 0.033, χ^2 = 4.539) showed significant associations with low BMD. Binary logistic regression showed that higher NIHSS scores (OR: 7.632 95% CI: 1.079 – 53.96, p-value 0.042) and female gender (OR: 4.055 95% CI: 1.052 – 15.62, p-value 0.042) increased the likelihood of low BMD. We added HBA1C to the final model and found that elevated HbA1c levels reduced the odds of low BMD with borderline significance (OR: 0.746 95% CI: 0.557 – 1.00, *p*-value 0.05).
Conclusion: There was a high prevalence of low BMD in our study. After adjusting for gender, ethnicity, NIHSS and HBA1C, only high NIHSS and being female remained as significant positive predictors of low BMD in post-stroke older adults. Future research should focus on larger studies, screening and intervention in this cohort.

P1398

FALL RISK IN UNDERWEIGHT, OVERWEIGHT, AND OBESE INDIVIDUALS: EVIDENCE FROM NATIONAL SURVEY IN IRAN

S. Sarrafzadeh[1], Y. Azizpour[1], S. Mozafari[2], N. Rezaei[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Falls are significant cause of fractures, and body weight has been identified as a key factor associated with fall risk. Low body weight is often associated with muscles weakness, whereas obesity is associated with balance difficulties. Therefore, this study aims to assess the association between central obesity and body mass index (BMI) with falling.
Method: Data from STEPwise Approach to Non-communicable Disease Risk Factor Surveillance (STEPs) survey in 2021 were utilized. The study included adults aged 18 years and older excluding pregnant women and individuals with severe physical or mental conditions. Body mass index (BMI) was used to classify participants into underweight (BMI≤19), overweight (25<BMI≤30) and obese (BMI≥30). The central obesity was assessed using waist-to-height ratio with values exceeding 0.5 considered indicative of obesity. The fall was assessed with a single question: Did you experience a fall in the past year? All analyses were conducted while controlling for age and sex, using logistic regression.
Results: A total of 27,490 individuals participated in the study, of whom 15,209 (55.3%) were female, and 663 (2.4%) experienced a fall in the past year. Falls were not associated with gender but showed a statistically significant relationship with age group. After adjusting for age, being underweight and overweight were not associated with an increased risk of falls compared to the individuals with normal BMI (OR=0.9 and OR=1.1, respectively). However, the odds of falling in obese individuals were 1.3 times higher than those with normal BMI (OR=1.3, 95% confidence interval (CI): [1.07, 1.59]). In this study, the association between central obesity and fall (adjusting for age) was not statistically significant. The odds of falling in individuals with central obesity was 1.2 times than in those without obesity (95% CI: [0.96, 1.48]).
Conclusion: According to the BMI, obese individuals had higher chances of falling. However, no significant relationship was found between central obesity and the occurrence of fall. Additionally, being underweight was not associated with fan increased risk of falling.
Key words: fall, BMI, underweight, obesity, central obesity

EXAMINE DAIRY INTAKE HABITS OF IRANIANS OVER 50: EMPHASIS ON FAT COMPOSITION

S. Sarrafzadeh[1], S. Naderian[2], M. Saberian[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [3]Sleep Breathing Disorders Research Center, Tehran University of Medical Sciences, Tehran, Iran

Objective: The objective of this study was to examine dairy consumption patterns, with a focus on fat content, among Iranians aged 50 and older.
Methods: Data from participants over 50 years of age from the 2021 Iranian STEPS study (STEPwise approach to non-communicable disease risk factor surveillance) were used. Dairy products were categorized into three groups: low-fat (approximately 1.5% fat), high-fat (2.5 to 3% fat) and non-industrial/traditional dairy. Non-industrial dairy products do not usually undergo a defatting process, thus retaining their full fat content.
Results: A total of 10,883 participants were enrolled, of which 53.5% were women. The frequency of low-fat, high-fat, and traditional dairy product consumption was 40.3%, 24.1%, and 35.5%, respectively. The largest proportion of both males (39.5%) and females (40.9%) indicated they consumed low-fat dairy products. Most participants living in rural areas tended to consume traditional dairy products (60.9%), and most people living in urban areas tended to use low-fat dairy products (45.9%).
Conclusion: Considering rural residents' preference for traditional dairy products, it is essential to educate them about the potential health risks associated with these items. Emphasis should be placed on the benefits of switching to low-fat alternatives. Additionally, it is advisable to encourage the increased consumption of dairy products to help mitigate the risk of osteoporosis.
Key words: Dairy Products, Fat, Nutrition
Conflict of Interest: All authors declare that they have no conflicts of interest.

MITRAL AND AORTIC VALVE CALCIFICATIONS ASSOCIATED WITH HYPERCALCEMIA DIET AND CALCIUM SUPPLEMENTS

S. Sokolovic[1], I. Sokolovic-Tahtovic[2]

[1]ASA Hospital Sarajevo, Sarajevo, Bosnia & Herzegovina, [2]KCUS, Sarajevo, Bosnia & Herzegovina

Introduction:
There is a certain role regarding the association between the calcium supplementation and high calcium diet with cardiovascular calcifications, particularly with mitral and aortic valves. A systematic analysis of randomized controlled trials, cohort studies, observational studies and expertise opinions provides a different observations about the role of calcium on the vascular and bone health. Our date indicate that high intake of calcium supplements either dietary or calcium supplements are correlated with built-up calcium at mitral and aortic valves increase.
Material and Method:
Total of 56 female post-menopausal women with a history of high calcium diet or calcium supplements were analysed in open clinical randomized study compared with 62 control female individuals without this history in a group 2.The questionnaire about calcium and supplementation diet and transeoesophageal echocardiography with Doppler Ultrasound were the main method used in detection of heart valve calcifications. The exclusion criteria was other comorbidities like diabetes, chronic kidney disease and hyperparathyreoidism.
Results:
The results obtained in this study showed that all female patients with a history of high calcium intake either in a diet or supplements had increased heart valve calcifications. These calcifications were mainly detected as single heterogenic valve deposits especially in a mitral valve leaflets. The posterior mitral valve was mire affected that anterior one. The aortic valve in these patients were more diffuse. The average age of female patients was 63 years. The group 2 of investigated control individuas was 61 years old.
Conclusion:
High calcium intake either as a diet or calcium supplements contribute to ectopic calcifications where calcium is deposited in heart valves, particularly mitral valve is mainly affected. Adeqate magnesium and vitamin K2 intake may help regulate calcium metabolism in high cardiovascular risk patients.

P1401

HIGH-DOSE VITAMIN D THERAPY (300,000 IU MONTHLY): IMPLICATIONS FOR OSTEOARTHRITIS, OSTEOPOROSIS AND ARTERIAL STIFFNESS IN VITAMIN-D DEFICIENT PATIENTS

S. Sokolovic[1], I. Sokolovic-Tahtovic[2]

[1]ASA Hospital Sarajevo, Sarajevo, Bosnia & Herzegovina, [2]KCUS, Sarajevo, Bosnia & Herzegovina

Introduction:
Vitamin D deficiency is associated with skeletal disorders such as osteoarthritis (OA) and osteoporosis (OP), as well as non-skeletal conditions like arterial stiffness, a marker of cardiovascular health. The use of high-dose vitamin D therapy (300,000 IU monthly) has gained interest as an efficient means to correct deficiency and improve related health outcomes. In Osteoarthritis, high-dose regiemens may enhance anti-inflammatory effects. in Osteoporosis, clinical studies have shown improvements in lumbar spine and femoral neck BMD following high-dose vitamin D supplementation in deficient individuals. Vitamnin D may reduce arterial stiffness by modulating endothelial function, reducing vascular calcifications, improvement in pulse wave valve velocity and vascular compliance.

Material and Method:
The open prospective clinical study of 124 female patients suffering from Osteoarthrits and Osteoporosis, divided in a two groups by 62 each. The inclusion criteria was Vitamin D deficiency. Arterial stiffness was measured using Agedio device providing parameters from pulse wave velocity, central blood pressure, augmentation index, stroke volume etc. All. cardiovasular risk factors were included in a study and analysed accordingly. High-Dose Vitamin D Therapy (300,000 IU monthly) was applied intramuscularly and Vitamin D levels were measured one month later. Arterial stiffness was measured in all after one month accordinigly.
Results: The average age for Osteoarthritis group was 68,5 years and for Osteoporosis patients 66 years. The vascular age expressed as the value of arterial stiffness in Osteoarthritis group was app 5 years older than biological age. In Osteoporosis group this values wass 3 years difference. Vitamin D level in average was 16,7 ng/ml. After one month, following high dose Vitamin D application, the vitamin D level significantly increased to 24,5 ng/ml. Arterial stiffness was improved to 4 years in group I and to 3 years in group II respectively.
Conclusion: The high dose of vitamin D (300,000 monthly) is highly effective in a rapidly restoring adequate levels of 25-hydroxyvitamin D, particularly in individuals with severe deficiency. This regime has shown efficiency in achieving appropriate serum levels within one month. This improvement had a postive effectiveness on arterial stiffness in osteoarthritis and osteoporosis patients.

P1402

DO DIETS WITH GREATER INFLAMMATORY POTENTIAL INCREASE THE RISK OF DISABILITY IN BASIC ACTIVITIES OF DAILY LIVING IN OLDER PEOPLE?

S. Souza Lima[1], N. Cochar-Soares[1], T. Batista de Souza[1], V. R. Guandalini[2], S. Price[3], J. R. Hébert[3], A. Steptoe[4], C. De Oliveira[4], T. Da Silva Alexandre[1]

[1]Federal University of Sao Carlos, Sao Carlos, Brazil, [2]Federal University of Espirito Santo, Vitória, Brazil, [3]University of South Carolina, Columbia, United States, [4]University College London, London, United Kingdom

Objective: The aim of this study is to determine whether a diet with higher inflammatory potential; indicated by the highest tertile of Dietary Inflammatory Index (DII) score, is a risk factor for the incidence of disability in basic activities of daily living (BADL). Materials and Methods: This is a longitudinal incidence study with 1,777 participants from the *English Longitudinal Study of Ageing (ELSA)* aged 60 years or older and without difficulty to perform basic activities of daily living at baseline. The exposure studied was the inflammatory potential of the diet, measured by the DII and with the score divided into tertiles by sex, where the lowest tertile represents a lower inflammatory potential (men: ≤ 0.419; women: ≤ -0.375), the second tertile represents a moderate inflammatory potential (men: > 0.419 and ≤1.863; women: > -0.375 and ≤ 1.441) and the highest tertile represents a greater inflammatory potential of the diet (men: > 1.863; women: > 1.441). After two years of follow-up, performance in BADL using the adapted Katz scale was reassessed and then the incidence of disability in BADL was analysed using a Poisson regression model, controlled by socioeconomic, behavioural and clinical variables. Results: Participants with moderate dietary inflammatory potential had a 66% (RR = 1.66 95% CI 1.02 – 2.71) higher risk of developing disability in BADL than those with the least dietary inflammatory potential, while those with the highest dietary inflammatory potential had a 104% (RR = 2.04 95% CI 1.26 – 3.28) higher risk of developing disability in BADL than those with lower dietary inflammatory potential. Conclusion: The greater the inflammatory potential of the diet, the greater the risk of incidence of disability in BADL. Therefore, given that diet is a modifiable factor, it can be adjusted to decrease its inflammatory potential and, consequently, reduce the risk of disability in older people.

P1403

ANTIBODY GENERATION TO CERULOPLASMIN AS AN IMMUNOLOGIC MARKER IN SYSTEMIC LUPUS ERYTHEMATOSUS

S. Spitsina[1], O. Emelyanova[2], O. Rusanova[2], S. Bedina[1], E. Mozgovaya[2], A. Trofimenko[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Ceruloplasmin is a copper-containing glycoprotein of blood plasma that is a component of the antioxidant system. In patients with various rheumatic diseases, including systemic lupus erythematosus (SLE), hyperproduction of active oxygen forms is found, in which a compensatory increase in the synthesis of antioxidants, including ceruloplasmin, that should inhibit oxygen free radicals, can be expected.
Objective: To determine antibodies to ceruloplasmin, to study their effect on the oxidase activity of ceruloplasmin, to determine the relationship of antibodies to ceruloplasmin with the activity of SLE.
Methods: Serum of 56 SLE patients and 30 practically healthy individuals was studied. Among SLE patients there were 52 women (93%) and 4 men (7%) at the age from 18 to 65 years. The activity of SLE was evaluated by SLEDAI-2K: 8 patients (14%) had minor activity, 25 (45%) had moderate activity, and 23 (41%) had high activity. The most of patients with SLE had subacute disease course (61%), the other patients - chronic (39%). The duration of the disease was from 6 months to 18 years. Antibodies to ceruloplasmin were determined by indirect ELISA, measured in units of optical density (u.o.d.).
Results: A group of patients with SLE had a significant increased content of antibodies to ceruloplasmin, which appeared at early stages of the disease and directly correlated with the degree of activity (r=0.436; p<0.005). Antibodies to ceruloplasmin were determined in 47% of patients. In this group of patients, the oxidase activity of ceruloplasmin did not significantly change depending on the activity (p>0.05). But in the group of SLE patients without

antibodies to ceruloplasmin, the oxidase activity was significantly higher than in patients with antibodies to ceruloplasmin. However, as SLEDAI-2K elevated, ceruloplasmin oxidase activity also increased. Thus, autoantibodies to ceruloplasmin have an effect on its oxidase activity by inhibiting it. The study of antibody synthesis to ceruloplasmin according to the course and duration of SLE did not find significant differences, that allows to use this marker in diagnostics of early stages.
Conclusion: In SLE there is an increase in the synthesis of autoantibodies to ceruloplasmin, as well as its enzymatic activity, which can be used as an additional criterion for the diagnosis of activity and prognosis in SLE.

P1404

CARDIOVASCULAR MANIFESTATIONS OF RHEUMATOID ARTHRITIS: ELASTIN ANTIBODIES

S. Spitsina[1], O. Emelyanova[2], O. Rusanova[2], S. Bedina[1], A. Trofimenko[2], E. Mozgovaya[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Rheumatoid arthritis belongs to chronic autoimmune diseases, characterized by hyperplasia of synovial tissues, lesions of connective tissue and its derivatives, the structural protein component of which is elastin. However, elastin in large quantities is contained not only in the synovium, but also in the walls of blood vessels, valve apparatus of the heart. Autoantibodies to elastin lead to a disorder of its metabolism, respectively, to the generation of new antigens and synthesis of more antibodies, which then leads to chronic systemic inflammation, including vascular walls. This is one of the factors of cardiovascular pathology development.
Objective: To determine the level of autoantibodies to elastin in patients with rheumatoid arthritis, to reveal their correlation with cardiovascular manifestations in rheumatoid arthritis.
Methods: The study included 80 patients with rheumatoid arthritis (62 women (77.5%), 18 men (22.5%)), whose mean age was 49.6±12.8 years. The control group consisted of 30 conditionally healthy, comparable in sex and age. Moderate degree of activity was in 32 people (40%), low activity - in 12 (15%), high activity - in 36 (45%). According to the stages of the disease: 49 (61%) patients had advanced clinical stage, 31 (39%) - late stage. Some patients (55%) had extra-articular manifestations in addition to joint syndrome: skin, muscular, renal, and cardiac manifestations, among which myocarditis and pericarditis were registered. Among the manifestations of vascular lesions, vasculitis, including cerebral vasculitis, prevailed. Determination of the elastin antibody content was performed using indirect enzyme immunoassay method. The results were indicated in units of optical density (u.o.d.).
Results: Antibodies to elastin were detected in 31 patients (39%) with rheumatoid arthritis, and all of them had significantly high blood values of antibodies to elastin than the control group ($p<0,05$). Patients with extra-articular manifestations of rheumatoid arthritis in the form of cardiovascular pathology (17 patients, 21.25%) were characterized by increased levels of autoantibodies to elastin (0.112±0.108 e.o.p.) compared to the control group ($p<0.05$).) as against both the control group (0.050±0.027 e.o.p.; $p<0.001$) and in comparison with patients without extra-articular manifestations of arthritis (0.054±0.062) and with other systemic manifestations excluding vasculopathies (0.054±0.032 e.o.p. and 0.076±0.108 e.o.p., respectively; $p<0.005$).
Conclusion: Increased synthesis of autoantibodies to elastin as a component of the vascular wall may be a cause of systemic vasculopathy and, as a result, a factor in the development of early atherosclerosis, as well as a marker of systemic cardiovascular appearances of rheumatoid arthritis.

P1405

CHANGES IN HEMATOLOGIC PARAMETERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Spitsina[1], S. Bedina[1], E. Mozgovaya[2], A. Trofimenko[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Introduction: Rheumatoid arthritis (RA) is a chronic immunoinflammatory disease characterized by both erosive arthritis and systemic involvement of internal organs. At the same time extra-articular manifestations from the blood system can occur in the course of the disease or against the background of its drug therapy, aggravating the course of RA and complicating the adequate therapy.
Objective: To identify changes in hematologic parameters in RA patients, their possible connection with the course and peculiarities of clinical manifestations of the disease.
Methods: 30 RA patients participated in the study. Exclusion criteria were the presence of hematologic and nephrologic pathologies. Laboratory data of the patients were evaluated: erythrocytes, hemoglobin, color index, leukocytes, neutrophils, eosinophils, lymphocytes, monocytes, thrombocytes, ESR. Statistical processing of the obtained data was carried out in the program "Microsoft Excel 2010" using the methods of descriptive statistics.
Results: There were 8 (26.7%) males and 22 (73.3%) females among the subjects. The mean age of the patients was 57.03±14.35 years, and the disease history ranged from 6 months to 20 years. 26 (86.7%) patients had high disease activity and the rest (13.3%) had moderate disease activity. 18 (60%) patients were seropositive. All patients were receiving baseline anti-inflammatory drugs. The mean erythrocyte concentration was 4.18±0.58^10^{12}/L and hemoglobin was 120.00±15.81 g/L. Mild anemia was registered in 11 (36.7%) patients and moderate anemia in 1 (3.3%) patient. Leukocyte count in all patients was within the reference values (7.02±2.33^10^{9}/L), no abnormalities in leukoformulas were registered. Moderate thrombocytopenia (128.03±16.78^10^{9}/L) was detected in 3 (10%) patients. Elevation of ESR and CRP was recorded in 25 (83.3%) patients (42.30±14.65 mm/h) and 24 (80%)

patients (24.73±15.32 mg/L), respectively. Correlation analysis showed a negative relationship between hemoglobin concentration and CRP level (r=-0.32), as well as with DAS28-CRP(4) (r=-0.34), duration of RA (r=-0.12), and duration of high-dose methotrexate intake (r=-0.18). There was also a correlation between platelet count and RA activity: ESR (r=0.25), CRP (r=0.14).
Conclusion: Thus, one third of patients with RA have hematopoiesis disorders in the form of anemic syndrome, which may be due to both the disease activity and the side effect of baseline anti-inflammatory drugs (methotrexate, leflunomide). Detected cases of thrombocytopenia may also be associated with the use of baseline anti-inflammatory drugs. Therefore, regular hematologic monitoring is necessary in the treatment and monitoring of patients with RA and, if necessary, timely and adequate correction of the resulting disorders.

P1406

RESISTIN AS A MARKER OF METABOLIC SYNDROME IN PSORIATIC ARTHRITIS PATIENTS

S. Spitsina[1], L. Shilova[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia, [2]Volgograd State Medical University, Volgograd, Russia

Objective: To consider resistin as a novel serum biomarker for monitoring the risk of metabolic syndrome in patients with psoriatic arthritis (PsA).
Methods: Data from clinical trials were searched in the databases of PubMed, Google Scholar. The association of resistin with clinical and laboratory manifestations of PsA and concomitant pathology was studied.
Results: Patients with PsA have a high risk of complications associated with the metabolic syndrome (obesity, dyslipidemia, diabetes mellitus or insulin resistance) and cardiovascular disease. Chronic inflammation in PsA partially explains the development of atherosclerosis and cardiovascular disease. Adipokines are involved in the regulation of various processes such as lipid or glucose metabolism as well as inflammation. Among the adipokines with pro-inflammatory effects, patients with PsA have significantly higher levels of resistin than those without PsA (Oguz Dikbas, 2014; Dikbas O., 2016). Sofia Makishi Schlenker et al. showed associations of resistin with insulin resistance (p=0.008) and metabolic syndrome (p=0.01), correlations with total cholesterol (r=0.26) and triglycerides (r=0.33). All key studies proved the role of resistin in the development of insulin resistance. No correlation was found with disease activity, DAPSA index. High levels of resistin correlate with body mass index. Trang Nguyen-Mai Huynh et al described the association of resistin with non-calcified atherosclerosis. Resistin is able to induce IL-6, TNF-α and IL-1β production by peripheral blood mononuclear cells.
Conclusion: Resistin is associated with coronary artery disease and may be a marker of coronary atherosclerosis progression in patients with PsA. Also, resistin may be considered as a marker of metabolic syndrome in PsA. Resistin contributes to the development of insulin resistance and mild inflammation. Therefore, further study of resistin is required in order to introduce it into clinical practice.

P1407

THE ROLE OF ADIPOKINES IN THE DEVELOPMENT OF METABOLIC SYNDROME

S. Spitsina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia

Objective: To study and summarize the data on the role of adipokines (apelin, resistin, visfatin) in the development of metabolic syndrome.
Methods: PubMed Central, Google Scholar data were analyzed.
Results: Data from studies based on the determination of plasma concentrations of apelin, resistin, and visfatin in patients with cardiovascular pathology and obesity have been accumulating over the past decades.
Apelin-13 is considered the most active form of this cardiovascular adipokine, where it exhibits positive inotropic and vasodilatory effects by increasing nitric oxide production. Thus, apelin plays an important role in blood pressure regulation, may influence some immune cells and has proangiogenic properties. In metabolic syndrome, apelin has a favorable effect on insulin sensitivity, associated with effects on both glucose metabolism and lipid metabolism. The associated antidiabetic and antiatherosclerotic effects suggest that apelin may be a promising target in the study and treatment of metabolic diseases.
Resistin is a hormone produced by adipocytes that has been linked to obesity and type 2 diabetes mellitus. Resistin is thought to be a molecular factor linking obesity and diabetes mellitus. It is also reported that resistin plays an important role in inflammation, either directly or through various cytokines such as interleukin 6, tumor necrosis factor α, which may regulate resistin gene expression. Resistin decreases endothelial nitric oxide synthase expression in human coronary artery endothelial cells and stimulates vascular smooth cell migration, thereby causing pathologic changes in the vessels.
Visfatin is a hormone whose plasma concentration is directly related to the development of type 2 diabetes mellitus. This biomarker is expressed mainly by visceral adipose tissue. Visfatin is involved in the regulation of cell proliferation, glucose and lipid metabolism. Visfatin levels are associated with insulin resistance, which may suggest its role in the development of cardiometabolic risk.
Conclusion: Thus, apelin and visfatin may exert favorable effects in diabetes, while resistin exhibits opposite effects, which may lead to vascular lesions such as atherosclerosis. Overall, this topic is relatively new and still poorly understood, requiring additional experimental studies.

P1408

IMPACT OF HYPOBARIC HYPOXIA ON BONE MICRO-ARCHITECTURE AND MINERAL CONTENT IN MALE SPRAGUE DAWLEY RATS

S. Sudha[1], M. Singh[1]

[1]Defence Institute of Physiology and Allied Sciences, Delhi, India

Objective: To study the impact of hypobaric hypoxia on bone micro-architecture and mineral balance.
Material & Method: Male Sprague Dawley (SD) rats (n=6) weighing 300±25g were divided into two groups: Hypobaric hypoxia and Normoxia. 3 Male SD rats were exposed to an altitude of 25,000ft for 35 days in a decompressor chamber, while other three rats were housed at sea-level and sacrificed at day 0. The decompression chamber was opened daily once to facilitate food and water replacement and to measure body weight. After completion of the exposure, rats were sacrificed, and bones (femur & tibia) were collected to analyze micro-architectural changes and alterations in mineral composition.
Result: The results indicated a reduction in body-weight by 25% in hypobaric hypoxia-exposed rats. The micro-architecture analysis through micro-CT in the femur revealed a significant 62% reduction in bone volume and a 69% reduction in the bone surface. Additionally, a 65% reduction in trabecular numbers with an increase in trabecular spacing by 68% at distal metaphysis was observed compared to normoxia rats. Moreover, in tibia a 91% reduction in bone volume and an 88% reduction in bone surface was observed. An 87% reduction in trabecular numbers with an increase in trabecular spacing by 89% was observed. The mineral content evaluation using ICP-MS indicated significant reductions in key minerals like calcium, magnesium and phosphorus by 38%, 22%, and 36%, respectively in femur, and 26%, 32%, and 12%, respectively, in tibia compared to normoxia, signifying impaired bone mineral balance.
Conclusion: The study indicates a pronounced loss in both the tibia and femur; notably, the bone loss was higher in the tibia. The depletion of essential minerals indicating compromised bone mineralization that may increase fracture risk under chronic hypobaric hypoxia. These findings shed light on the adverse effects of high-altitude conditions on bone health and emphasize the need for interventions to mitigate bone deterioration at high altitudes.
Acknowledgment: I would like to thank the Director, DIPAS, and my supervisor, Dr. Mrinalini, for their invaluable guidance and support. I also acknowledge the facilities and resources provided by DIPAS-DRDO.
Disclosures: Author(s) declare no conflict of interests.

Gennimatas', Athens, Greece, [7]Department of Endocrinology, Ippokration General Hospital, Thessaloniki, Greece, [8]Laboratory for the Research of Musculoskeletal System "Th. Garofalidis", Medical School, National and Kapodistrian University of Athens, KAT General Hospital, Greece, Athens, Greece, [9]Department of Biochemistry, KAT General Hospital, Athens, Greece, [10]1st Department of Orthopedic Surgery, Medical School, National and Kapodistrian University of Athens, Attikon General Hospital, Athens, Greece, [11]Department of Craniofacial Surgery, KAT General Hospital, Athens, Greece, [12]Centre of Expertise in Rare Endocrine Diseases, C.E.R.E.D - Disorders of Calcium and Phosphate Metabolism, Endocrinology Unit, 1st Department of Propaedeutic Internal Medicine, LAIKO General Hospital of Athens, National and Kapodistrian University of Athe, Athens, Greece

Objectives: The presentation of tumor-induced ostemalacia (TIO) patient characteristics from a greek cohort.
Material and Methods: Case series of patients diagnosed with TIO in greek reference centers.
Results:

- Seven cases are presented in total.
- Three patients were male and four female. They were mostly middle-aged (45-60 years0, although one case was 25 years old and another was 79 years old.
- All patients presented with muscle weakness, abnormal gait and fatigue. All of them had suffrered insufficiency fractures and had a low bone mineral density.
- All patients had hypophosphatemia with phosphaturia and increased serum fibroblast growth factor 23 (FGF23).
- The responsible tumor was located in all cases except for one. Both functional (68Ga DOTATOC PET/CT ή/και 18-F FDG PET/CT) and anatomic imaging (localized or whole-body CT ή/και MRI) were used.
- Total surgical excision in wide margins was possible in only four cases. One case had a non-excisable sinonasal tumor, another had a non-excisable osseus tumor and in a third case the responsible tumor could not be detected.
- The respective biopsies suggested benign tumors, with the

exception of one case who had a malignant tumor (malignant histiocytoma). Histological types included: 1) giant cell tumor of tendon sheaths, 2) solitary fibrous tumor/hemangiopericytoma, 3) phosphaturic mesenchymal tumor, 4) glomangiopericytoma.
- All cases received a conventional supplementary treatment with alfacalcidol and phosphate salts. Two cases received burosumab in the recommended dosage and an intensified regimen was required in one case to reverse hypophospatemia.
- In all cases, medical and surgical treatment led to the amelioration of clinical manifestations, to the stabilisation of serum phosphate and to an increase of bone mineral density.

Conclusions: These are the first data to be published from a greek cohort of TIO patients. The cases are characteristic and in coherence with the international literature.

Garofalidis", Medical School, National and Kapodistrian University of Athens, KAT General Hospital, Greece, Athens, Greece

Objectives

The role of sclerostin in rheumatoid arthritis (RA) is controversial. Study results show a beneficial action against inflammation in the articular microenvironment and a detrimental role in systemic bone loss (1). Anti-citrullinated protein antibodies (ACPA) promote RANKL-mediated bone absorption in RA patients (2).

Materials and methods

A cross-sectional study in a RA cohort of post-menopausal women in a greek tertiary hospital. Patients underwent clinical evaluation to record disease characteristics. Whole-body dual-energy X-ray absorptiometry (DEXA) was used to calculate bone mineral density (BMD) and appendicular skeletal muscle mass (ASMI). Serum samples were collected to calculate serum sclerostin, parameters of inflammation and parameters of bone metabolism. Osteoporosis was defined according to the national recommendations by the Hellenic Society for the Study of Bone Metabolism (HSSBM).

Results

In total, 97 RA patients were enrolled. Patients' mean age was 67 ± 7 years and mean BMI was 29 ± 5 kg/m^2. Median disease duration was 8 (1-10) years and 40% had seropositive disease. All the patients were under treatment (65% under biotherapy). The mean DAS28-ESR score was 3.8 ± 1.7 and 27% were in disease remission. The majority (80%) suffered from osteoporosis, 38% reported at least one fragility fracture and 48% were receiving anti-osteoporotic treatments at the time of enrolment. Median serum sclerostin was 1.5 pg/ml and it was only associated with the positivity of ACPA (p=0.043).

Conclusion

Serum sclerostin is associated with positivity of ACPA in rheumatoid arthritis suggesting a possible pathophysiological role of the latter in systemic bone loss mediated through the direct inhibition of the Wnt signalling pathway.

Acknowledgements

This study has received funding by the Hellenic Society of Rheumatology and Professional Association of Rheumatologists of Greece.

THE LONG-TERM IMPACT ON BONE MINERAL DENSITY OF SWITCHING FROM 24-MONTH DAILY TERIPARATIDE TO DENOSUMAB OR ZOLEDRONIC ACID IN POSTMENOPAUSAL OSTEOPOROSIS

V. Lainis[1], O. Katsouli[1], E. Mole[1], M. Krikelis[1], S. Gazi[1], D. S. Evangelopoulos[2], G. Trovas[2], S. Tournis[2], E. Chronopoulos[2]

[1]Rheumatology Department, KAT General Hospital, Athens, Greece, [2]Laboratory for Research of the Musculoskeletal System "Theodoros Garofalidis", School of Medicine, National and Kapodistrian University of Athens, Greece, Athens, Greece

Objectives: Comparison of the effects on bone mineral density (BMD) after switching from a 24-month course of daily teriparatide (TPTD) to either Denosumab (Dmab) or intravenous (iv) Zoledronic acid (ZOL) in patients with postmenopausal osteoporosis.
Material and Methods: We retrospectively analyzed 49 postmenopausal women at our outpatient clinic who had previously received 24 months of teriparatide (20μg/d) for severe osteoporosis, followed by either Dmab 60mg (n=28) or iv ZOL 5mg (n=21), along with daily vitamin D and calcium, according to each physician's decision. Lumbar spine (LS) and total hip (TH) bone densitometry were performed at 0, 12, 24, and 36 months. Analyses

were performed using t-tests, and statistical significance was set at p<0.05.

Results: No significant differences were found between the two groups in baseline characteristics such as mean age, BMI, years since menopause, and prior antiosteoporotic treatment. Baseline LS and TH BMD were also similar between groups (LS: 0.823±0.15 vs 0.841±0.11, p: 0.651; TH: 0.746±0.11 vs 0.707±0.06, p: 0.141). At 36 months, patients receiving Dmab showed significantly larger BMD increases across all evaluated skeletal sites compared to those on ZOL (ΔBMD_{LS}=0.079±0.06 vs. 0.013±0.03, p<0.001; ΔBMD_{FN}=0.088±0.06 vs. 0.022±0.03, p<0.001). After 36 months, the BMD gain was significantly higher in the Dmab group compared to the ZOL group: LS (10.25 vs. 1.83 %; P < 0.001) and TH (12.35 vs. 3.28 %; P < 0.001) (Figure 1).

Conclusion:

Switching from 24 months of daily TPTD to Dmab vs. ZOL for 36 months is more effective in terms of BMD increase at both the LS and the hip.

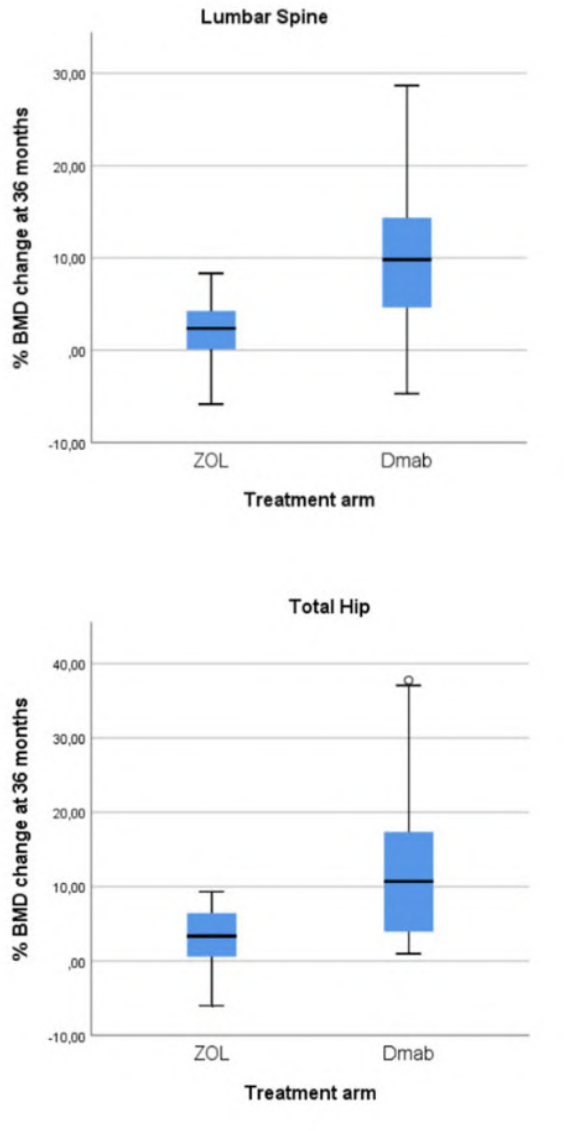

***Figure 1:** % BMD change in LS and TH at 36 months*

P1413

TREATMENT OF VANCOUVER B1 PERIPROSTHETIC FRACTURES WITH A CONTRALATERAL REVERSED FEMORAL LISS PLATE: CLINICAL EXPERIENCE AND RESULTS

S. Valle López[1], A. Espinel Riol[1], P. Almena Rodríguez[1], E. Cebrián Rodriguez[1], I. Aguado Maestro[1], E. Paredes Herrero[1]

[1]Hospital Universitario Rio Hortega de Valladolid, Valladolid, Spain

OBJECTIVES

To present a series of cases on a specific surgical technique for the treatment of Vancouver B1 periprosthetic fractures, using a contralateral and inverted femoral Liss plate.

MATERIAL AND METHODS

Retrospective study of all patients treated with inverted Liss plate (Synthes) fixation in our department (2015 to 2020). Variables: demographics, pathology and type of fracture, laterality, type of surgery, plate size, number of screws and screw-plate ratio, elastic or rigid mounting, use of cerclages and other systems, surgical time, intra- and postoperative complications, transfusion rate, days of hospitalization, follow-up at one month and one year, consolidation time and death.

RESULTS

29 patients (30 femurs, 59% right), mean age 84 years (39-96), of which 72.5% women. 25 Vancouver B1 periprosthetic fractures (22 on total hip prostheses and 3 on partial hip prostheses), 4 on femur fractures with total knee prostheses to achieve overlapping (3 subcapital and 1 pertrochanteric) and 1 femur pseudoarthrosis. Contralateral inverted Liss plates were used, 15 with 15 holes, 14 with 13 holes and 1 with 17 holes; elastic synthesis was achieved in 85%. In 23.3% the LAP plate and cerclages were added to the fixation. Mean surgical time 144 minutes, with a transfusion rate of 70% and a mean hospital stay of 13 days. Intraoperative complications, 2 material mobilizations (reoperated during admission), 1 intraoperative death and 1 bleeding from surgical wound. 2 infections during follow-up, surgically washed (one of them we performed re-osteosynthesis) and 2 constant thigh pains (removal of osteosynthesis material). 90% of the indications were consolidated, most of them within 5 months. 50% were walking one year after the consultation. And the death rate was 58%.

CONCLUSIONS

Due to the increase in the life expectancy of the population and the increase in the implantation of hip prostheses, the incidence of periprosthetic femur fractures is increasing. There are many therapeutic options, depending on the type of fracture, prosthetic stability and comorbidities of the patient. The use of contralateral inverted femoral Liss plates in Vancouver type B1 fractures has proven to be a good treatment alternative with a consolidation rate and results similar to those present in the current literature and comparable to those obtained with specific anatomical plates.

P1414

MINIMALLY INVASIVE LOCKING PLATE FOR PROXIMAL HUMERUS FRACTURES: RESULTS IN A THIRD LEVEL HOSPITAL

S. Valle López[1], A. Espinel Riol[1], P. Almena Rodríguez[1], A. E. Sanz Peñas[1], J. M. García García[1], I. Aguado Maestro[1], E. Paredes Herrero[1]

[1]Hospital Universitario Rio Hortega de Valladolid, Valladolid, Spain

OBJECTIVES:
The results obtained after surgical treatment with a minimally invasive polyaxial locking plate (MIPO) are analyzed and compared with the current literature.
MATERIAL AND METHODS:
Retrospective study of all patients treated for proximal humerus fracture using the MIPO technique (NCB-PH or PHILOS) from January 2013 to December 2020. Variables analyzed: demographics, classification (Neer), surgical time, joint balance, VAS, DASH and Constant scales (at 1 month, 3 months, 6 months and 1 year) and surgical complications. Minimum follow-up 1 year.
RESULTS:
80 patients with a mean age of 68 years (21-86) were included, of which 75% were women. 20 cases were Neer type II, 50 type III and 10 type IV. The most commonly used implant was NCB-PH (55.6%), requiring a cancellous graft in 14 patients. The surgical time was 75 minutes (75 +- 11.58). 21.4% of patients had some complication, including 5 stiffnesses, 4 necrosis and 3 material removals. The mean decrease in the DASH scale one year after the fracture was 0.15 points. The mean value of the VAS scale one month after surgery was 4.17 (3.48-4.85), at three months it was 2.91 (2.20-3.62) and at six months it was 2.51 (1.78-3.23). The mean value of the Constant scale at three months was 62.88 (58.38-67.38) and at six months 71.38 (66.59-76.18). Postoperative mobility was maintained in the middle segment (40-60% of the contralateral) in terms of anteflexion, abduction, and rotations during the first month, with the upper segment (80-100%) being reached by 65% of patients at the end of the follow-up.
CONCLUSIONS
Proximal humerus fractures are a challenge for the orthopedic surgeon, since the "Gold Standard" continues to be conservative treatment. Several meta-analyses agree on the need to conduct studies that provide sufficient evidence. Osteosynthesis with plates and screws is a therapeutic option in the treatment of fractures of the proximal end of the humerus, with good clinical results, although not without complications and whose indications are yet to be defined. The results obtained are similar to those present in the current literature.

P1415

USE OF LOCKED INTRAMEDULLARY NAIL FOR PROXIMAL HUMERUS FRACTURES. EXPERIENCE IN A THIRD LEVEL HOSPITAL

S. Valle López[1], A. Espinel Riol[1], P. Almena Rodríguez[1], A. E. Sanz Peñas[1], A. Quintanilla García[1], I. Aguado Maestro[1], E. Paredes Herrero[1]

[1]Hospital Universitario Rio Hortega de Valladolid, Valladolid, Spain

OBJECTIVES:
The objective is to analyze the functional and radiological results of the use of the intramedullary nail for the treatment of proximal humerus fractures.
MATERIAL AND METHODS:
Descriptive-retrospective study of all patients with proximal humerus fractures treated with Multiloc endomedullary nail (Synthes) using a minimally invasive approach in our hospital from 2018-2022. Variables: demographic (sex, age), laterality, type of fracture according to NEER, surgical time, hospitalization time, rate of consolidation, pain scales (VAS), functionality (Constant score and ASES questionnaire) with a minimum follow-up of 1 year and complications.
RESULTS:
30 patients, 21 women and 9 men, with a mean age of 58 years (42-68), presented a displaced proximal humerus fracture in two fragments (18), in three (10) and in four (2) according to NEER. With right dominance (63%). The mean surgical time was 75 minutes (58-110), with a mean hospitalization of 3 days (1-5). The mean time to consolidation observed in radiography was 4 months (100% of cases). An anatomical cervicodiaphyseal angle was obtained in 90% at one year, with a mean of 128 (133)º. We had a 16% of complications, 2 avascular necrosis of the head, two varus collapses of the fracture and 1 infection. At twelve months of follow-up, we obtained a mean joint balance in flexion of 139º ± 30, abduction 145º ± 25, external rotation to the ipsilateral ear and internal rotation to L5; a mean score on the Constant scale of 74 ± 10 and on the ASES scale 83 ± 7 and the resulting VAS was 2 ± 1.5. Better results with less severity on the NEER scale.
CONCLUSIONS:
The choice of implant for the treatment of surgical displaced proximal humerus fractures is one of the keys to clinical, functional and radiographic success, however it is a matter of controversy. After the results obtained, in terms of healing rate, functional and radiographic results and the low rate of complications, we consider medullary nailing to be effective as a treatment for displaced proximal humerus fractures, if we compare it with other therapeutic approaches. However, comparative studies with other techniques are necessary to evaluate the results.

P1416

SUPRAPATELLAR OR INFRAPATELLAR TIBIA MEDULLARY NAILING? DESCRIPTIVE ANALYSIS OF THE RESULTS OBTAINED IN OUR CENTER

S. Valle López[1], A. Espinel Riol[1], P. Almena Rodríguez[1], A. Quintanilla García[1], I. Aguado Maestro[1], E. Paredes Herrero[1]

[1]Hospital Universitario Rio Hortega de Valladolid, Valladolid, Spain

OBJECTIVES:
To analyze the clinical and radiological results obtained from the use of the suprapatellar approach in tibial fractures treated with an intramedullary nail. To analyze advantages, indications, and comparison with the infrapatellar approach.

MATERIAL AND METHODS
Retrospective longitudinal studies of all tibial fractures treated in our hospital with an intramedullary nail via the suprapatellar approach from 2018-2022.
Variables: demographics, type of fracture, radiological results, surgical time, and complications. Minimum follow-up of one year. Comparison with fractures treated via the infrapatellar approach as a control group.

RESULTS
22 patients in the case group (64% men) and 20 patients in the control group (60% women).
In the cases: 18 distal metaphyseal fractures with fibula fracture and 4 proximal fractures.
In the controls: 14 distal metaphyseal fractures with fibula fracture and 6 proximal metaphyseal fractures.
Average surgical time: 85 minutes in cases and 110 in controls.
Radiological result of cases: 15 correct reduction in axis, 5 had 4-5º residual valgus and 2 had 4-5º recurvatum.
Radiological result of controls: 8 correct reduction in axis, 7 had 4-5º residual valgus and 5 had 3-4º recurvatum.
Complications in cases (27%): 3 dynamization of the bald spot, 1 axonotmesis of the external popliteal sciatic nerve, and 2 postoperative gonalgias.
Complications in controls (40%): 4 dynamization of the nail, 1 hypertrophic pseudoarthrosis and 3 postoperative gonalgias.
Functional results ICKD scale at one year: cases 89 vs controls 72. According to Lyscholm scale 85 in cases vs 77 controls

CONCLUSION
With a good indication the suprapatellar approach is a good alternative for the treatment of tibia fractures. It has certain advantages in relation to other approaches described in the literature: in fractures of the proximal third of the tibia, the insertion of the entry point is easier, in more distal fractures it simplifies the freehand locking in different planes and if a fibula fracture is associated, its reduction and synthesis is simpler, there is less post-surgical gonalgia, less surgical time, technical ease and comfort for the surgeon. The rate of complications is similar in both approaches.

P1417

OSTEOPOROSIS IN TURNER SYNDROME ASSESSED WITH RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY (REMS)

S. Vladeva[1], N. Kirilov[2], F. Bischoff[3], E. Bischoff[4]

[1]Department of Health Care, Faculty of Medicine, Trakia University, 6007 Stara Zagora, Bulgaria, Stara Zagora, Bulgaria, [2]Institute of Medical Informatics, Heidelberg University Hospital, 69120, Heidelberg, Germany, Heidelberg, Germany, [3]IPSMP Rheumatology, 6000 Stara Zagora, Bulgaria, Stara Zagora, Bulgaria, [4]Faculty of Global Health and Health Care, University "Prof Dr Assen Zlatarov", 8010 Burgas, Bulgaria, Burgas, Bulgaria

Objective:
Turner syndrome, a chromosomal disorder, is often associated with osteoporosis due to estrogen deficiency and abnormal bone remodeling. This case report investigates the use of Radiofrequency Echographic Multi-Spectrometry (REMS) to assess bone fragility and fracture risk in a patient with Turner syndrome (45,X iso Xq).
Material and Methods:
A 45-year-old female with Turner syndrome was evaluated using REMS at the lumbar spine and both femora. REMS scans were performed with the EchoStudio device (Echolight S.p.a., Lecce, Italy) using a 3.5 MHz convex transducer. Lumbar spine scans were conducted trans-abdominally under the sternum, visualizing L1 to L4, with 20 seconds per vertebra. Proximal femur scans were done by positioning the transducer parallel to the femoral head-neck axis for 40 seconds. The REMS system generated a patient-specific spectrum to calculate bone mineral density (BMD), T-scores, and the fragility score (FS), which ranges from 0 to 100 to assess bone fragility independently of BMD. The FS provides an overall risk for major osteoporotic fractures (MOF) over the next 5 years.
Results:
The patient, on estrogen replacement therapy and vitamin D supplementation, had a prior history of left tibia fracture. Physical examination confirmed Turner syndrome, and DXA scans showed osteopenia in the lumbar spine (-2.3 SD) and femur (-2.4 SD). REMS revealed a lumbar spine T-score of -2.2 SD (osteopenic range), left hip T-score of -2.5 SD (osteoporotic range), and right hip T-score of -2.4 SD (osteopenic range). The FS was 52.3, placing her in the R6 category, indicating a high fracture risk for MOF over the next 5 years.
Conclusions:
This case highlights the value of REMS in assessing bone quality and fracture risk in Turner syndrome. Although DXA showed osteopenia, the higher FS indicated significant bone fragility and a high fracture risk, suggesting the need for more aggressive osteoporosis management. REMS provides crucial additional information that can guide treatment decisions for osteoporosis in Turner syndrome patients.
Key Words: Turner syndrome, osteoporosis, fragility score, REMS, bone mineral density

OBESITY-DRIVEN MOLECULAR ENDOTYPES OF SYNOVIAL FIBROBLASTS SHAPE INFLAMMATORY PROFILES IN OSTEOARTHRITIS

S. N. Wijesinghe[1], D. E. Nanus[1], M. Pearson[1], M. A. Lindsay[2], E. T. Davis[3], S. W. Jones[1]

[1]University of Birmingham, Birmingham, United Kingdom, [2]University of Bath, Bath, United Kingdom, [3]Royal Orthopaedic Hospital, Birmingham, United Kingdom

Objective

Increasing evidence supports the role of joint inflammation in osteoarthritis (OA) cartilage damage and joint pain (1-2). Our research has highlighted the central role of synovial fibroblasts (SFs) in mediating OA joint inflammation (3), particularly in patients who are obese (4). This study (5) characterised the obesity-associated inflammatory phenotype of SFs and defined molecular endotypes by examining transcriptomic, metabolic, and inflammatory SF profiles from different OA joints, including both load-bearing and non-load-bearing sites, in patients who were either of normal-weight or obese.

Materials and Methods

Synovium was collected from OA patients (n=32) undergoing joint replacement surgery (UK NRES 16/SS/0172), stratified by BMI into obese (BMI >30) and normal weight (BMI 18.5–24.9). SFs were isolated and characterised using targeted proteomics (Olink), metabolic flux assays, bulk RNA sequencing, and single-cell RNA sequencing (scRNAseq). Inflammatory mediator expression was validated by Luminex assays, and immunohistochemistry performed by Vectra.

Results

Targeted proteomic, metabolic and transcriptomic analysis found the inflammatory landscape of OA SFs are independently impacted by obesity, joint loading and anatomical site with significant heterogeneity between obese and normal weight. scRNAseq further defined four molecular endotypes: "activated fibroblasts", "immune cell recruiters", "proliferative fibroblasts", and "stressed/arresting fibroblasts". Notably, the inflammatory fibroblast endotypes were predominant in OA patients with obesity, which in contrast to normal-weight SF subsets, were characterised by upregulated CXCL12, CFD and CHI3L1 expression, and spatially localized to both lining and sublining synovial layers distinguished by the differential expression of MYC and FOS.

Conclusion

This study demonstrates that obesity influences the inflammatory landscape of synovial fibroblasts in both load-bearing and non-load-bearing joint types, likely contributing to OA pathogenesis through distinct molecular endotypes. The identification of these obese fibroblast subsets provides a framework for stratifying OA patients and the rationale for therapeutically targeting specific fibroblast subset pathotypes.

RUFY4 DEFICIENCY IN OSTEOCLASTS ENHANCES BONE MASS VIA IMPAIRED CATHEPSIN K SECRETION AND PERIOSTIN DEGRADATION

M. Kim[1], S. Y. Lee[1]

[1]Ewha Womans University, Seoul, South Korea

Objective(s) This study aims to elucidate the osteoclast-specific role of RUN and FYVE domain-containing protein 4 (RUFY4) in bone remodeling.

Material and Methods We generated osteoclast-specific *Rufy4* knockout mice (*Ctsk*$^{Cre/+}$; *Rufy4*$^{fl/fl}$; hereafter referred as *Rufy4*$^{\Delta 0c/\Delta 0c}$) using the Cre-loxP system. Trabecular and cortical bone parameters were evaluated via micro-CT. Osteoclast formation and activity were assessed by TRAP staining of bone sections. Bone marrow-derived macrophages were differentiated into mature osteoclasts *in vitro* and subjected to resorption pit assays and c-telopeptide of type I collagen (CTX-1) ELISA. Lysosomal trafficking and the distribution of cathepsin K and periostin were visualized using immunofluorescence staining. Supernatants from mature osteoclast cultures were assessed for active cathepsin K and degraded periostin secretion via immunoblotting.

Results *Rufy4*$^{\Delta 0c/\Delta 0c}$ mice showed significantly increased trabecular bone mass and cortical bone volume *in vivo*, with lower CTX-1 and higher periostin levels. *In vitro*, these mice showed impaired bone resorption activity, as evidenced by reduced resorption pits, CTX-1 levels, and cathepsin K release into the extracellular space, despite normal osteoclast differentiation. Immunofluorescence analyses revealed disrupted lysosomal trafficking and periostin accumulation within osteoclasts, along with impaired periostin degradation in the absence of RUFY4.

Conclusion(s) RUFY4 plays a critical role in bone remodeling by regulating CTSK secretion and Postn degradation in osteoclasts. These findings suggest that targeting RUFY4-mediated pathways could provide therapeutic strategies for bone diseases characterized by excessive resorption.

P1420

APPLICATION OF THE FRAX ALGORITHM FOR SCREENING OSTEOPOROSIS AMONG PATIENTS OF MULTIDISCIPLINARY HOSPITALS

N. A. Sergeev[1], S. Y. Tsarenok[1], S. E. Pinyugin[1], Z. Balzhinimaeva[1], A. A. Balanyuk[1], T. A. Aksenova[1], V. V. Gorbunov[1]

[1]Chita State Medical Academy, Chita, Russia

Background: Osteoporosis is the most common chronic metabolic bone disease characterized by a decrease in their mineral density, which subsequently leads to an increased risk of low-energy fractures in people over 50 years of age. One of the criteria for establishing a diagnosis and starting therapy is a high risk according to FRAX. The use of this algorithm is a simple method that does not require the use of special diagnostic equipment and laboratory tests.

The aim: to assess the prevalence of osteoporosis and osteoporotic fractures among patients of multidisciplinary hospitals using the FRAX calculator.

Materials and methods: The study involved 300 patients aged from 50 to 91 years, the average age was 68 [60.75; 76] years, men - 125 people with an average age of 64 [59; 70] years, women - 175 people with an average age of 70 [64; 80] years. Patients gave voluntary consent to participate in the study. The patients were surveyed using a specialized questionnaire. The patients were assessed for the presence of concomitant pathology that significantly affects of bone mineral density - diabetes mellitus, rheumatoid arthritis, chronic heart failure. The risk of osteoporosis and osteoporotic fractures was assessed using the FRAX online calculator. The risk of major osteoporotic fractures was assessed as high if the indicator was above the threshold of therapeutic intervention; a fixed value of more than 3% was used to assess the risk of hip fracture. Statistical data processing was performed using GraphPad Prism v8.02. Taking into account the distribution of features that differed from normal, correlation analysis was performed using Spearman's rank correlation and γ-correlation in the case of establishing relationships between qualitative and quantitative indicators. The dependence of relative indicators was assessed by constructing four-field contingency tables using the Pearson $\chi 2$ criterion, the odds ratio. Differences between groups were considered reliable at $p<0.05$.

Results: All patients were divided into groups: Group 1 - 50-59 years old, which included 31 women (10.33%) and 37 men (12.33%); 2 group 60-69 years old, which included 55 women (18.33%) and 44 men (14.67%); 3 group 70 years and older, which included 89 women (29.67%) and 44 men (14.67%). In terms of the frequency of comorbid pathology among women and men of all groups, chronic heart failure prevails. Thus, 42 (33.6%) men and 89 (50.1%) women had chronic heart failure. Diabetes mellitus type 1 and 2 and rheumatoid arthritis were also common among women: 40 (22.9%) and 21 (12%) cases, respectively. Among men, diabetes mellitus and rheumatoid arthritis are much less common, 7 (5.6%) and 4 (3.2%) cases, respectively, $p <0.05$. The main risk factors for osteoporosis that were identified in the examined patients were distributed as follows: 27 (21.6%) men and 66 (37.7%) women had a burdened family history of hip fracture in their parents. More than half of the men in all groups are smokers - 64 people (51.2%), but only 22 (12.6%) women were current smokers. Oral glucocorticoids for more than 3 months at a dose of 5 mg of prednisolone and more were taken by 2 (1.6%) men and 11 (6.3%) women. In the studied groups, fractures due to low-energy falls or spontaneously did not occur in the first group, they were revealed as a result of questioning in 17 patients of the second group (17.17%) and 42 (31.58%) of the third group. It was found that in the second group 11.1% of fractures and 24.8% of fractures in the third group occurred in women. Thus, the incidence of fractures among women was 2.58 times higher than that of men ($p<0.01$). The majority of fractures occurred in the femoral neck, 9 (60%) cases in men and 31 (70.5%) in women, as well as in the distal forearm, 4 (26.7%) cases in men and 10 (22.7%) in women. In each group, the risk of osteoporotic fractures was assessed according to FRAX, and patients with an osteoporotic fracture risk above the intervention threshold were identified. Thus, when assessing the risk of osteoporotic fractures according to FRAX, it was found that in the first group, 2 women (2.94%) had an increased risk of osteoporotic fracture. In the second group, patients with an increased risk of osteoporotic fracture amounted to 14 women (14.14%). In the third group, an increased risk of osteoporotic fracture was observed in 33 patients (24.81%), of whom 32 were women (24.06%) and 1 man (0.75%). When assessing the risk of hip fracture in the first group, no patients with a high risk of hip fracture were identified. In the second group, an increased risk of osteoporotic fracture was observed in 33 patients (24.81%), of whom 32 were women (24.06%) and 1 man (0.75%). When assessing the risk of hip fracture in the first group, no patients with a high risk of hip fracture were identified.

Conclusion: It was established that 19.33% of patients in somatic hospitals received low-energy fractures. Among the patients, the largest proportion is women aged 60 to 91 years. At the same time, an increased risk of osteoporotic fracture and hip fracture was also observed mainly in women aged 60 to 91 years. 34% of patients in somatic hospitals need drug treatment for osteoporosis.

OLDER PATIENTS WITH OSTEOPOROSIS AND CHRONIC KIDNEY DISEASE-MINERAL AND BONE DISORDER (CKD-MBD): A SERIES OF CHALLENGING CASES

S. Z. Şahin Tırnova[1], E. Pınar[1], Z. Fetullahoğlu Durmuş[1], S. Ozkok[1], T. Erdoğan[1], S. Ozturk[2], O. Soyluk Selçukbiricik[3], G. Yenidoğan Yalın[3], N. Gül[3], A. S. Artan[2], M. A. Karan[1], G. Bahat[1]

[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Geriatrics, Istanbul Musculoskeletal Health Consortium (IMHeal), Istanbul, Turkiye, [2]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Nephrology, Istanbul Musculoskeletal Health Consortium (IMHeal), Istanbul, Turkiye, [3]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Endocrinology and Metabolism, Istanbul Musculoskeletal Health Consortium (IMHeal), Istanbul, Turkiye

Objective:
The prevalence of osteoporosis (OP) and chronic kidney disease (CKD) increases with age, significantly affecting health and posing a societal burden. While OP management is well-defined in guidelines, treatment decisions in cases with CKD-mineral and bone disorder (MBD) remain challenging. We will present a series of cases evaluated for OP and CKD-mineral and bone disorder (MBD) by Istanbul Musculoskeletal Health Consortium.

Participants and Methods:
Cases managed between December 2023-December 2024 were analyzed. Routine tests, including eGFR, serum calcium, phosphorus, albumin, PTH, ALP, 25-OH vitamin D levels, DXA T-scores, were documented. FRAX tool components, geriatric syndromes, comorbidities, and sociodemographic data were assessed. CKD-MBD was diagnosed based on biochemical findings, with no bone biopsies performed.

Results:
The study included 20 participants (mean age,77.4; female,50.0%). Mean eGFR,31.9 mL/min/1.73m², with 2 patients on dialysis. Fragility fracture history was present in 65.0%(13 patients;3 hip, 8 vertebra and 2 both), but only 15.3% were on current OP treatment. The diagnosis were made OP-only in 50.0%, while the other 50.0% had OP+CKD-MBD (10 patients: 7 adynamic bone disease [ABD], 3 osteomalacia [OM]). All 7 ABD patients were discontinued calcium and Vitamin D supplements, and/or started phosphorus binders. After biochemical correction, 71.4%(5/7) were started teriparatide, 1(14.2%) denosumab, one followed without treatment due to to low FRAX scores (shared-decision with the patient). After vitamin D replacement, 2 of 3 CKD-MBD (OM) patients (66.7%) received denosumab, and 1 (33.3%) teriparatide. Among 10 OP-only patients, denosumab was the chosen treatment in 40.0%. Bisphosphonates and romosozumab were chosen each in 15.3% (2) patients and teriparatide in 1(10.0%) case. One bedridden patient with advanced co-morbidities was managed palliatively.
In the total population, 35.0%(7) received teriparatide, 35.0%(7) denosumab, 10.0%(2) romosozumab, 10.0%(2) bisphosphonates, and 10.0%(2) were followed without treatment (one palliative, one by shared-decision) (Table-1).

Conclusion:
In this series, half of CKD patients with OP had overt biochemical CKD-MBD, with ABD being the most common form (70.0%). Treatment options varied based on CKD-MBD type and patient characteristics, highlighting the complexity of metabolic bone diseases in older adults with CKD and the need for individualized care.

Table-1: Characteristics, diagnosis and management of the participants

Patient Age/Sex	Previous Fragility Fracture	Fragility Fracture Location	T Score L1-4	T Score Femur Neck	T Score Femur Total	T Score distal forearm	FRAX hip (%)	FRAX major (%)	Creatinine (md/dl)	Calcium[3] (mg/dl) (8.6-10.3)	Phosphorus (mg/dl) (2.7-4.5)	PTH Pg/ml (15-65)	ALP (35-105)	Bone spesific ALP (6-21 µg/L)	25-OH Vit D (ng/ml)	Diagnosis	Management

TOWARDS A CORE OUTCOME SET (COS) FOR SARCOPENIA INTERVENTION STUDIES: A SYSTEMATIC REVIEW IDENTIFYING THE MOST FREQUENTLY REPORTED OUTCOMES ACROSS RANDOMIZED CONTROLLED TRIALS IN SARCOPENIA

S. van Heden[1], Y. M. Chan[2], Z. Baoubbou[1], M. Surquin[3], D. Sanchez-Rodriguez[3], C. Beaudart[1]

[1]Public Health Aging Research & Epidemiology PHARE Group, Research Unit in Clinical Pharmacology and Toxicology URPC, Department of Biomedical Sciences, Namur Research Institute for Life Sciences NARILIS, Faculty of Medicine, University of Namur, Namur, Belgium, [2]Department of Dietetics, Faculty of Medicine and Health Sciences, University Putra Malaysia, 43400 Serdang, Malaysia. Malaysian Research Institute on Ageing, University Putra Malaysia, 43400 Serdang, Malaysia, Serdang, Malaysia, [3]Geriatrics Department, Brugmann University Hospital, Université Libre de Bruxelles, 1020 Brussels, Belgium, Bruxelles, Belgium

Objective:
This study aimed to identify the most frequently reported outcomes in sarcopenia trials through a systematic review, as a basis for developing a Core Outcome Set (COS).
Material and methods:
A systematic review was conducted using MEDLINE, Embase, and Cochrane Central (PRISMA guidelines; PROSPERO: CRD42024525506). Eligible studies were randomized controlled trials (RCTs) on sarcopenia treatment, conducted in patients with the disease, and using a consensus definition of sarcopenia. Outcomes were extracted and grouped into predefined subcatego-

ries, with a focus on primary outcomes.
Results:
Of the 3985 references reviewed, 58 RCTs met the inclusion criteria. These included 216 efficacy and 39 safety outcomes. The most frequently reported outcomes, after unifying synonyms terms, were muscle mass (50 RCTs, i.e., present in 86.2% of the trials), muscle strength (50 RCTs, 86.2%), physical performance (47 RCTs, 81%), nutrition-related outcomes (41 RCTs, 70.7%), and biomarkers (31 RCTs, 53.4%).
Among the primary outcomes, change in muscle mass was the most commonly reported outcome (23 RCTs, 39.7%), with appendicular muscle mass index and fat-free mass as the predominant measures (4 RCTs, 6.9%). Change in muscle strength was the second most frequently reported primary outcome (16 RCTs, 27.6%), mainly assessed by handgrip strength (12 RCTs, 20.7%). Change in physical performance was the third most common outcome (13 RCTs, 22.4%), with gait speed (7 RCTs, 12.1%) and lower limb physical function (4 RCTs, 6.9%) were the most reported physical performance-related outcomes.
Secondary outcomes included fat mass, physical status, quality of life, activities of daily living, cognitive function, psychological status, bone mass, and unclassified outcomes.
Conclusions:
This review highlights the large heterogeneity of outcomes in sarcopenia trials. Muscle mass, muscle strength, and physical performance are the most frequently reported outcomes. A sarcopenia-specific COS is needed to standardise reporting, improve comparability and strengthen evidence for treatments, to support better and more efficient research and to improve the care of patients with sarcopenia.
Disclosures: The authors have no conflicts of interest to declare.

P1425

EVALUATING THE PRAGMATISM OF SARCOPENIA CLINICAL TRIALS USING PRECIS-2: A SYSTEMATIC REVIEW

S. Van Heden[1], Z. Baoubbou[1], D. Sanchez-Rodriguez[2], C. Beaudart[1]

[1]Public Health Aging Research & Epidemiology PHARE Group, Research Unit in Clinical Pharmacology and Toxicology URPC, Department of Biomedical Sciences, Namur Research Institute for Life Sciences NARILIS, Faculty of Medicine, University of Namur, Namur, Belgium, [2]Geriatrics Department, Brugmann University Hospital, Université Libre de Bruxelles, 1020 Brussels, Belgium, Bruxelles, Belgium

Objectives:
This study aims to review interventional clinical trials in sarcopenia to assess their level of pragmatism and identify gaps to improve the clinical relevance and feasibility of future trials in the real world.
Material and Methods:
A systematic review was conducted using MEDLINE (via Ovid), Embase, and Cochrane Central Register of Controlled Trials (PRISMA guidelines; PROSPERO: CRD42024571027). Eligible studies included randomized controlled trials (RCTs) on sarcopenia treatment using a consensus definition. The PRECIS-2 tool was used to assess the level of pragmatism of these RCTs across nine standard domains (eligibility, recruitment, setting, organisation, flexibility of delivery, flexibility of adherence, follow-up, primary outcome, and primary analysis), with an additional "control" domain. Total PRECIS-2 scores were calculated, and subgroup analyses were conducted by intervention type, geographical location, sample size, study duration, and sarcopenia definition.
Results:
Of the 3,985 references reviewed, 58 RCTs met the inclusion criteria. The mean PRECIS-2 score across its 10 domains was 2.92 (SD 1.30), reflecting a balance of explanatory and pragmatic characteristics. Organisation, recruitment, and primary outcome were identified as the most pragmatic domains, whereas eligibility, adherence, and follow-up were the most explanatory. Subgroup analyses revealed that geographical location and sarcopenia definitions impacted significantly the overall PRECIS-2 score. More precisely, studies conducted in Asia achieved higher pragmatism scores, with significant differences in setting ($p = 0.016$), follow-up ($p = 0.009$), and control ($p = 0.011$). Studies using Asian sarcopenia criteria (e.g. AWGS) were also more pragmatic, particularly in the setting ($p = 0.036$) and control ($p = 0.010$).
Conclusion:
Due to the reversible nature of sarcopenia, clinical trials in this area have increased significantly in recent years. Although some methodological aspects of these RCTs follow pragmatic approaches, this systematic review highlights the need for improvements in areas such as exclusion criteria, follow-up and adherence. Specifically, there is an urgent need to design RCTs that more accurately reflect the complexity of real-world interventions in the multifaceted landscape of sarcopenia.
Disclosures: The authors have no conflicts of interest to declare.

VERTEBRAL FRACTURES IN CHRONIC KIDNEY DISEASE PATIENTS - A POPULATION-BASED COHORT STUDY FROM TCVGH-OPC DATABASE

S.-C. Tseng[1], Y.-H. Lin[1], Y.-C. Wu[1], C.-M. Shih[1], C.-C. Pan[1], K.-H. Chen[1], C.-H. Lee[1]

[1]Taichung Veterans General Hospital, Taichung City, Taiwan

Objectives
This study aims to evaluate the prognosis of surgical interventions for vertebral fractures (VFs) in patients with chronic kidney disease (CKD) and identify the risk factors for mortality, complications, and refractures.
Materials and Methods
Patients were enrolled from the Osteoporosis Prevention Center at Taichung Veterans General Hospital. Those who underwent vertebroplasty or spinal fusion for VF between 2011 and 2023 were included. All participants underwent dual-energy X-ray absorptiometry (DXA) to assess bone mineral density (BMD). Patients with incomplete data or follow-up periods of less than three months were excluded. The cohort was analyzed for mortality

rates, complication rates, and refracture rates. Additionally, the use of osteoporosis-related medications and the presence of comorbidities were examined.

Results

From 2011 to 2023, 1,280 patients underwent vertebroplasty or spinal fusion for VFs. Of these, 1,007 (78.7%) were female, and 273 (21.3%) were male. A total of 349 patients (27.3%) were classified as having CKD based on an eGFR < 60 mL/min/1.73 m². Patients in the CKD group had lower BMD and a higher prevalence of comorbidities compared to non-CKD patients. CKD patients exhibited higher mortality rates (hazard ratio = 2.07) in the Cox regression model and a greater risk of complications (odds ratio = 1.78) in the logistic regression model following surgery. Multivariate regression analysis revealed that mortality was significantly associated with eGFR < 60 mL/min/1.73 m², older age, male gender, diabetes, and lower serum albumin levels. The risk of complications was correlated with diabetes, coronary artery disease, and lower serum calcium levels. Refracture rates were associated with rheumatoid arthritis, hypertension, and the use of calcium supplements postoperatively.

Conclusion

Surgical treatment for vertebral fractures in patients with chronic kidney disease is associated with higher mortality rates and increased risks of complications. Spine surgeons should be vigilant about these risks when managing CKD patients undergoing such procedures.

P1427

LONG-TERM ANTI-RESORPTIVE THERAPY: IDENTIFYING THE OPTIMAL TREATMENT STRATEGY THROUGH A RANDOMIZED CONTROLLED TRIAL

S.-H. Fu[1], C.-Y. Li[2], R.-S. Yang[3], C.-Y. Wang[4]

[1]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan, Douliu, Taiwan, [2]Department of Public Health, College of Medicine, National Cheng Kung University Tainan, Taiwan, Tainan, Taiwan, [3]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan, Taipei, Taiwan, [4]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan, Huwei, Taiwan

【Introduction】

Osteoporosis requires lifelong management, with available treatments including anabolic and anti-resorptive agents. Anabolic agents are limited to short-term use, often requiring sequential therapy. Anti-resorptive agents also have drawbacks: denosumab can cause rapid bone loss upon stopping, and bisphosphonates show bone mineral density (BMD) gains that plateau after 3-5 years. Studies suggest denosumab after bisphosphonates can still improve BMD. We aim to evaluate whether sequential use of denosumab and zoledronate can achieve BMD gains comparable to continuous denosumab therapy.

【Materials and Methods】

This randomized controlled trial includes patients who have received 4 or 5 doses of denosumab (2 or 2.5 years). Baseline characteristics, BMD, and bone turnover markers (BTMs), including P1NP and CTX, are assessed before randomization.

The intervention group receives zoledronate six months after their last denosumab dose, then resumes denosumab in the second and third years. The control group continues regular denosumab for three years. BMD and spinal X-rays are assessed annually, and BTMs every six months. The primary outcome is the change in lumbar spine BMD over three years, with secondary outcomes including changes in hip and femoral neck BMD, CTX, P1NP, and fragility fracture incidence.

【Results】

Fifty-nine patients were recruited, 91.5% female, with a mean age of 71.2 years. After three years, the intervention group had BMD gains of 4.8% in the lumbar spine, 3.2% in the femoral neck, and 2.0% in the total hip, while the control group showed gains of 4.6%, 2.9%, and 2.3%, respectively. BMD changes did not differ significantly between groups. In the intervention group, P1NP levels rose after zoledronate in the first year and decreased significantly after resuming denosumab. Few osteoporotic fractures were reported.

【Discussion】

This treatment strategy increases BMD non-inferior to continuous denosumab, offering several advantages, such as increased treatment flexibility and eliminating concerns about rebound effects upon drug discontinuation. The elevated P1NP during the transition year to zoledronate also provides an opportunity to repair accumulated microdamage from long-term anti-resorptive therapy.

【Conclusions】

Our treatment strategy appears to be a promising approach for long-term osteoporosis management. However, the effectiveness and safety of sequential treatment with denosumab and zoledronate require further validation.

P1428

ANTIRESORPTIVE MEDICATION USE PRIOR TO TERIPARATIDE AND FRACTURE-RELATED HOSPITALIZATIONS IN PATIENTS AT VERY HIGH FRACTURE RISK: A POPULATION-BASED COHORT STUDY

S.-H. Fu[1], S.-C. Fu[2], Y.-C. Lu[3], N.-H. Sie[3], C.-Y. Wang[3]

[1]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan, Douliu, Taiwan, [2]Department of Obstetrics and Gynecology, Taichung armed forces general hospital, Taichung, Taiwan, [3]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan, Huwei, Taiwan

Introduction:

Transitions from long-term antiresorptive therapy to anabolic agents may cause a temporary decline in bone mineral density and probably increase fracture risk. To assess the effect of prior anti-osteoporosis medication(AOM) use on osteoporotic fracture-related hospitalisations in patients at very high fracture risk who started teriparatide therapy, focussing on the influence of AOM type and duration.

Materials and Methods:
This nationwide population-based longitudinal cohort study utilised data from Taiwan's National Health Insurance Research Database spanning the years 2013–2019. 21,814 patients were prescribed teriparatide, of whom 14,770 met the inclusion criteria and were analysed. Patients were categorised into two groups according to prior AOM use: AOM use, n = 9,127; non-AOM use, n = 5,643. The primary outcome was hospitalisation for osteoporotic fractures within 3 years of teriparatide initiation. This study further evaluated fracture-related hospitalisations based on specific subgroups, namely, prior AOM type and duration.
Results:
9,127 participants received AOM treatment within 2 years prior to teriparatide initiation, whereas 5,643 did not. Over a median follow-up period of 36.3 months, no significant differences in fracture-related hospitalisations were observed between the two groups. Hazard ratios (HRs) for fracture-related hospitalisation were lower in the AOM group compared with the non-AOM group (1 vs. 0.92, respectively; CI 0.83 to 1.02; p = 0.10), but the difference was not statistically significant. However, patients who had used denosumab for ≥3 years before switching to teriparatide had a significantly higher risk of vertebral fracture-related hospitalisations (adjusted HR 1.86, p = 0.0118), particularly within the first 6 months of transitioning (aHR 1.98, p = 0.01).
Discussion:
Prior AOM therapy does not increase fracture-related hospitalisation risk after starting teriparatide in patients at very high risk, except in cases of long-term (≥3 years) denosumab use. Clinicians should exercise caution with long-term denosumab treatment before transitioning to teriparatide therapy. Further research is warranted to optimise sequential therapy strategies.

P1429

COMBINED DENOSUMAB AND CORE DECOMPRESSION DELAY CONVERSION TO TOTAL HIP ARTHROPLASTY IN FEMORAL HEAD OSTEONECROSIS

S.-Y. Lin[1], L. Kang[2], C.-H. Chen[3]

[1]Department of Orthopedics, Kaohsiung Medical University Gangshan Hospital, Kaohsiung, Kaohsiung Medical University, Taiwan, Kaohsiung, Taiwan, [2]Department of Obstetrics and Gynecology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Taiwan., Tainan , Taiwan, [3]Department of Orthopaedics, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, Kaohsiung, Taiwan

Objective(s): To evaluate the impact of denosumab on femoral head osteonecrosis (ONFH) in patients undergoing core decompression surgery, focusing on time to total hip arthroplasty (THA) and radiographic progression.
Material and Methods: This retrospective study included 53 patients (67 hips) with Steinberg stage IIC or IIIC ONFH over five years. Patients were divided into two groups: the denosumab group (n=32), receiving two 60 mg doses postoperatively, and the control group (n=35), undergoing core decompression alone. Primary outcome was time to THA, while secondary outcomes included radiographic progression and functional outcomes. Statistical analysis assessed survival rates and progression differences.
Results: The denosumab group demonstrated a higher THA-free survival rate (87.5% vs. 64.71%), though the difference was not statistically significant (P=0.0821). Radiographic progression rates were similar between groups (56.25% vs. 58.82%; P=0.85). Subgroup analysis suggested potential benefits in stage IIC patients, with trends indicating reduced THA conversion rates in the denosumab group (P=0.095).
Conclusion: Denosumab may improve outcomes following core decompression by delaying femoral head collapse in ONFH, particularly in earlier stages. While results show promising trends, further randomized studies are needed to confirm its efficacy in combination with core decompression.

P1430

THE PHENOMENON OF CLINICAL INERTIA IN GOUT THERAPY

T. A. Fominykh[1], A. N. Zakharova[1], E. R. Zagidullina[1], T. S. Pronkina[1], N. G. Nikolashina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: One of the reasons for the ineffective treatment of gout is the low "survival" of therapy due to insufficient patient compliance. However, it is known that patient education can increase adherence to therapy and achieve target uric acid levels in 8 out of 10 people [Rees F, 2013], which indicates, among other things, the insufficient quality of patient management. The so-called phenomenon of "clinical inertia" - the inability to initiate or intensify therapy in accordance with evidence-based guidelines - seems to be a possible explanation for this situation. The aim of the study: to evaluate the dynamics of patient management with gout in real clinical practice.
Methods: The study was conducted in 2 stages. At the first stage in 2017, a voluntary anonymous survey of 97 doctors was conducted, at the second, in 2021 - 46 doctors, represented mainly by therapists and rheumatologists, as well as doctors of other specialties (surgeons, cardiologists, traumatologists, neurologists). The questions touched on the treatment of gout in the acute and interictal period, and the opinion of doctors regarding patient compliance.
Results: Almost all doctors who answered the questionnaire indicated that they treat gout. The exception was neurologists at stage 2 (a total of 6 people), who were excluded from the analysis. When answering the question "How many patients with gout do you observe on average per month?" At stage I, from 1 to 40 patients were indicated, at stage II - from 0.5 to 25. As a therapy for an exacerbation of the disease, the majority of doctors chose NSAIDs: 100% at stage I and 86.9% at stage II, colchicine was used prophylactically almost exclusively by rheumatologists - 38.9% at stage I and 100% at stage II, p = 0.18, while therapists used it quite rarely - 1.7% at stage I and 20% at stage II, p = 0.02.

Also, 20% of therapists at stage I and 26.7% at stage II used urate-lowering therapy (ULT) drugs - allopurinol and febuxostat - to "stop an attack". The prescription of ULT at both stages of the study was quite high and amounted to 100% for rheumatologists; 75% and 93.3% for therapists. The time of therapy prescription varied on average from 7 to 14 days after the attack, immediately after the exacerbation UST was prescribed by 5% of therapists at stage I and 13.3% at stage II; during the attack - 20% of therapists at stage I and 13.3% at stage II. The dose of allopurinol in practice varied on average from 100 to 300 mg/day - 61.1% of rheumatologists at stage I and 100% at stage II; for therapists, the figures were 81.6% and 73.3%, respectively. The possible use of a dose higher than 300 mg was indicated by only 38.9% of rheumatologists and 11.3% of therapists at stage I and 33% of rheumatologists and 13.3% of therapists at stage II. It is noteworthy that the most frequently cited reasons for such a dose of UST are “existing recommendations”, side effects of the drugs, creatinine clearance control, and also the maximum permissible dose of allopurinol at 300 mg/day (!). The assessment of the “survival” of UST according to rheumatologists and therapists was 63.1% and 59.4% at stage I, 55% and 54.3% at stage II, respectively. At the same time, the expectation of attacks in patients decreased from 36.5% by rheumatologists and 49.1% by therapists at stage I to 10% and 28.75% at stage II, p=0.14.

Conclusion: Despite some increase in the number of doctors using UST in gout therapy, real clinical practice seems to be quite inert. The low use of colchicine for the treatment and prevention of attacks, frequent (26.7%) prescription of UST for the relief of acute attacks and low average doses of allopurinol remain at the same level.

P1431

DEEP LEARNING-BASED OSTEOPOROSIS SCREENING: LEVERAGING CONVOLUTIONAL NEURAL NETWORKS FOR HIP X-RAY ANALYSIS

T. Chobpenthai[1], R. Suwanaratana[1], P. Achararit[1], P. Nonthasaen[1], L. Yurasakpong[2], P. Kulworasreth[1]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand, [2]Department of Anatomy, Faculty of Science, Mahidol University, Bangkok, Thailand

Objective: To assess the effectiveness of Convolutional Neural Networks (CNN) for osteoporosis screening using plain hip radiographs.

Material and Methods: Osteoporotic fractures, particularly spine and hip fractures, can lead to severe health consequences like long-term disability and increased mortality. Osteoporosis is underdiagnosed, and the current gold standard screening tool, Dual-energy X-ray Absorptiometry (DEXA), is expensive and inaccessible to most of the population– especially in rural areas [1]. Most diagnoses are not made until fractures occur. There is a need for an accessible, affordable, and accurate osteoporosis screening method to prevent fracture risks while simultaneously improving patient outcomes. With the current technological advances, deep learning techniques should be considered to offer a solution by analyzing plain hip radiographs to determine the presence of osteoporosis for early diagnosis [2]. We collected a dataset of standard hip radiographs from both healthy and osteoporotic patients. A deep learning model based on the Xception architecture was developed and trained on this dataset. The model was designed to classify radiographs as indicative of osteoporosis or normal, using image preprocessing techniques and data augmentation to enhance model robustness. We implemented a training pipeline using TensorFlow, with the dataset comprising 287 images (99 abnormal, 188 normal) split into training, validation, and test sets. The model was trained for 100 epochs with a batch size of 32, using Adam optimizer and categorical cross-entropy loss. We employed techniques such as dropout and early stopping to prevent overfitting. The model’s performance was evaluated using accuracy, precision, recall, F1 score, and Area Under the Receiver Operating Characteristic Curve (AUC-ROC).

Results: The CNN model demonstrated high performance in classifying hip radiographs, achieving an accuracy of 94.44%, with 95.00% precision, 94.44% recall, 94.43% F1 score, and an AUC-ROC of 0.944 in identifying osteoporosis through recognition of hip abnormality in radiographs(Figure 1). The model is robust in distinguishing between normal and abnormal hip X-rays(Figure 2).

Figure 1

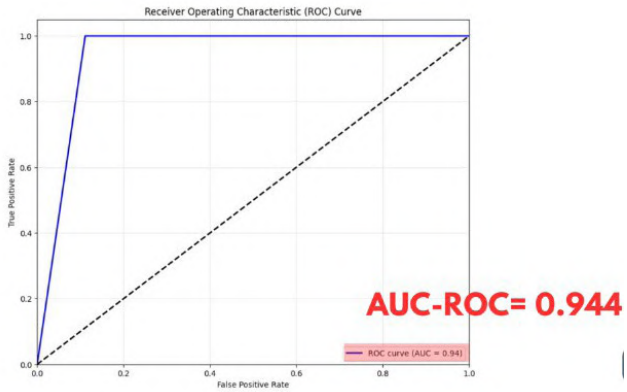

Figure 2

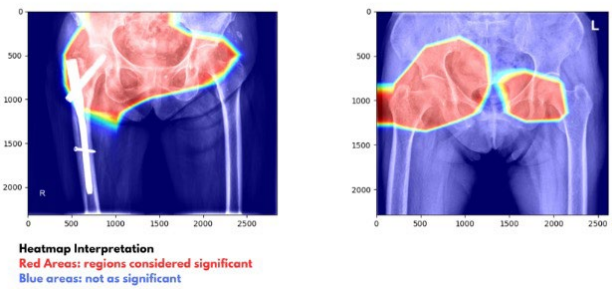

Conclusion: Our study demonstrates the potential of CNN in analyzing hip X-rays for osteoporosis screening. The model’s high performance in our dataset suggests that AI-based methods could serve as a promising tool to assist in the initial screening process, especially in rural locations where access to affordable diagnostic services is limited.

METABOLIC DYSFUNCTIONS IN CHRONIC PAIN PATIENTS THROUGH THERMOGRAPHIC ANALYSIS

A. Franca[1], T. Franca[2], T. Pereira[2]

[1]Instituto de Ortopedia e Traumatologia Prof. Dr. Alexandre Felipe França, Catanduva, Brazil, [2]Universidade de Franca, Franca, Brazil

Objectives
To utilize infrared thermography in patients with musculoskeletal pain and recognize associated metabolic dysfunctions.
Material and Methods
Clinical thermography provides a rapid, radiation-free method, generating images of varying surface skin temperatures and allowing for arbitrary repetitions of measurements (KACZMAREK e NOWAKOWSKI, 2016). This method can detect subtle alterations in underlying tissues, indicating musculoskeletal and metabolic pathologies. Infrared imaging cameras, following the standardized parameters of the BodyScan InfraRed Med® Sequence, capture infrared radiation emitted from the body's surface, converting it into electrical signals to create a thermogram campable of displaying temperatures of diverse colors and tones (DIAKIDES, DIAKIDES, *et al.*, 2006).
In this retrospective and analytical observational study, 138 patients of both sexes with musculoskeletal pain, who required orthopedic consultation between 2022 and 2024, were analyzed. Thermographic analysis revealed various gastrointestinal alterations, periocular congestion and reduced metabolic activity directly linked to the pain exhibited by these patients.
Results
A total of 138 individuals diagnosed with musculoskeletal pain were evaluated, comprising 69.6% women and 30.4% men. Thermographic analysis proved to be a reliable complementary method, showing statistically significant results ($p < 0.05$). The thermography detected notable metabolic conditions and disruptions in the sleep-wake cycle among chronic pain patients.
Conclusion
Clinical thermography proved itself to be a non-invasive, complementary and diagnostic method for identifying metabolic imbalances related to gastrointestinal dysfunctions, emotional states, and sleep-wake cycle disruptions in chronic musculoskeletal pain patients.

DOES LOW QUADRICEPS STRENGTH INFLUENCE THE RISK OF DISABILITY? - THE ROAD STUDY-

T. Iidaka[1], C. Horii[2], G. Tanegashima[2], S. Muraki[1], H. Oka[3], K. Nakamura[4], S. Tanaka[2], N. Yoshimura[1]

[1]Department of Preventive Medicine for Locomotive Organ Disorders, 22nd Century Medical and Research Center, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [2]Department of Orthopaedic Surgery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [3]Division of Musculoskeletal AI System Development, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [4]Towa Hospital, Tokyo, Japan, Tokyo, Japan

[Objective] We investigated the association between low quadriceps muscle strength (i.e., muscle weakness) and the incidence of disability among Japanese men and women, using data from a large-scale, population-based cohort study called ROAD (Research on Osteoarthritis/Osteoporosis Against Disability).
[Methods] We analyzed data from 1,558 participants (505 men and 1,053 women; mean age: 65.5 years) residing in mountainous and coastal communities during the 3rd survey of the ROAD study. All participants underwent measurements of both muscle mass and quadriceps muscle strength. To define muscle weakness, we determined cutoff values for quadriceps strength by conducting an ROC analysis, using quadriceps strength as the independent variable and the presence or absence of sarcopenia as the dependent variable, stratified by sex.
Additionally, among participants aged 65 years or older who had not been certified as disability at the time of the third survey, we used 3-year and 6-year follow-up data to ascertain new cases of disability certification and calculated the incidence rate using person-year methods.
[Results] Among participants aged 65 years or older, the prevalence of muscle weakness was 46.0% (48.1% in men and 45.0% in women). The incidence of disability was 19.9 per 1,000 person-years (13.3 in men and 23.1 in women). After adjusting for age, sex, body mass index, and residential area in a Cox regression analysis, muscle weakness was associated with a significantly higher risk of disability certification (hazard ratio: 2.69, 95% confidence interval: 1.54–4.96).
[Conclusion] Based on the results of a 6-year longitudinal study from a large-scale, population-based cohort, we estimated the prevalence of muscle weakness and the incidence rate of disability. Our findings suggest that low muscle strength is a risk factor for disability.

P1434

PREVALENCE OF AND FACTORS ASSOCIATED WITH MRSA AMONG PATIENTS WITH HAND INFECTION TREATED IN A PUBLIC TERTIARY HOSPITAL

T. J. Arellano[1]

[1]Jose B. Lingad Memorial General Hospital, SAN FERNANDO, Philippines

Background: Methicillin-resistant Staphylococcus aureus (MRSA) poses significant challenges in managing hand infections, especially in resource-limited settings like the Philippines. Despite its global prevalence, data on MRSA-specific hand infections in Filipino patients remain scarce. This study aimed to determine the prevalence of MRSA and identify associated factors among patients treated for hand infections at a public tertiary hospital.
Methods: A retrospective, cross-sectional study was conducted at Jose B. Lingad Memorial General Hospital from February 2022 to January 2024. Data from 233 patients treated for hand infections were analyzed. Variables examined included demographics, employment status, infection etiology, comorbidities, traditional medicine use, infection location, and classification. Statistical analyses were performed to identify associations with MRSA.
Results: MRSA prevalence was 30%, with bite wounds and use of traditional medicine showing significant associations (p = 0.002). Educational attainment was also linked to MRSA status, with unschooled individuals having a higher prevalence (p = 0.027). Other variables, such as age, gender, employment, comorbidities, and infection classification, showed no significant associations.
Conclusion: This study highlights the high prevalence of MRSA in hand infections, with traditional medicine use and bite wounds as key risk factors. The findings underscore the need for targeted educational campaigns, early intervention protocols for bite wounds, and community engagement to address traditional medicine practices. These measures could improve MRSA management and prevention in similar settings.

P1435

THE INFLUENCE OF AGE, GENDER, AND THE UPPER EXTREMITY ANTHROPOMETRY ON THE PALMAR GRIP STRENGTH IN PATIENTS SUFFERING FROM RHEUMATOID ARTHRITIS

A. Cvetinovic[1], J. Krasic[1], J. Zvekic - Svorcan[2], T. Jankovic[2], T. Nikolic[3], K. Boskovic[2], R. Krasnik[4]

[1]University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia, [2]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [3]Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [4]University of Novi Sad, Faculty of Medicine Novi Sad. Institute of Child and Youth Health Care of Vojvodina, Novi Sad, Serbia

Objective: To examine the influence of age, gender, and upper extremity anthropometry on the palmar grip strength in patients with rheumatoid arthritis (RA).
Material and methods: This 6-month prospective study included 56 patients of both sexes treated at the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia. All participants signed an informed consent form and completed a sociodemographic questionnaire compiled by the researcher. They also underwent tape measurements (cm) to establish total upper limb length, the length of the upper arm, forearm, and hand, and the wrist and hand circumference for both upper limbs. The palmar grip strength (kg) was evaluated using the Baseline Mechanical Pinch Gauge dynamometer via three measurements separated by 60 s breaks. The relationship between two numerical variables was examined via the non-parametric Spearman correlation coefficient, with p≤0.05 indicating statistical significance. Statistical processing and analyses were performed using the SPSS ver. 24 statistical package.
Results: All participants (92.9% women, average age 63) were right-handed. No statistically significant correlation between the palmar grip strength in either hand and age was noted (p>0.05). However, male subjects performed statistically significantly (p=0.012) better on the left-hand grip strength test (Me=9.17) compared to females (Me=4.75). Moreover, the right-hand length and the right-hand grip strength were positively correlated (rho=0.290, p=0.030). The remaining variables, such as upper limb length (p=0.137), upper arm length (p=0.433), forearm length (p=0.251), wrist circumference (p=0.263), and hand circumference (p=0.700), did not show statistically significant correlation with the right-hand palmar grip strength.
Conclusion: Male RA patients, as well as those with a longer right hand, achieved better left-hand palmar grip strength results, which were unaffected by age. In future research, it is necessary to analyze the impact of disease activity and the number of painful and swollen joints of the upper extremities on the palmar grip strength.

P1436

THE INFLUENCE OF BODY HEIGHT AND BODY MASS ON GROSS HAND MUSCLE STRENGTH AND PINCER GRIP IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Krasic[1], A. Cvetinovic[1], J. Zvekic - Svorcan[2], T. Jankovic[2], T. Nikolov[3], N. Berberski[1], R. Krasnik[4]

[1]University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia, [2]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [3]Special Hospital for Rheumatic Diseases, Novi Sad, Serbia, [4]University of Novi Sad, Faculty of Medicine Novi Sad. Institute of Child and Youth Health Care of Vojvodina, Novi Sad, Serbia

Objective: To examine the influence of body height and body mass on gross hand muscle strength and pincer grip in patients with rheumatoid arthritis (RA).
Material and methods: The present study, based on a prospective research design, was conducted at the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia, after obtaining approval

of the hospital's Ethics Committee. The study sample included 56 rheumatoid arthritis (RA) patients, all of whom were on a stable disease-modifying antirheumatic drug (DMARD) dose and were right-handed. Prior to commencing the study, all participants signed an informed consent form. Their sociodemographic data was gathered via a questionnaire developed specifically for this research. For all patients, body height and body mass, as well as pincer grip strength and gross muscle strength in both hands, was measured in triplicate with a 1-minute break between consecutive measurements. The SPSS (Statistical Package for the Social Sciences) ver. 24 was used for data analysis and processing.

Results: The median age of the participants (most of whom were women, 92.9%) was 63 years. Their average body height and mass were Me = 163 cm and Me = 76.50 kg, respectively. A statistically significant positive correlation was noted between body height and gross muscle strength in both hands (R: rho = 0.459, p = 0.000; L: rho = 0.428, p = 0.001). Likewise, body height was in a statistically significant positive relationship with pincer grip strength in both hands (R: rho = 0.379, p = 0.004; L: rho = 0.445, p = 0.001). In the left hand, there was also a statistically significant positive correlation between body mass and gross muscle strength (rho = 0.289, p = 0.031) as well as pincer grip (rho = 0.275, p = 0.040).

Conclusion: In RA patients, gross hand muscle strength and pincer grip tend to increase with body height and body mass.

P1437

THE CLINICAL PROFILES OF PEOPLE WITH KNEE OSTEOARTHRITIS WITH OR WITHOUT A PRIOR KNEE SURGERY. A REGISTRY-BASED STUDY FROM THE SWEDISH OSTEOARTHRITIS REGISTRY WITH 77 000 INDIVIDUALS

T. Jönsson[1], K. Gustafsson[2], A. Cronström[1], E. Ageberg[1]

[1]Department of Health Sciences, Faculty of Medicine, Lund university, Lund, Sweden, [2]Unit of Physiotherapy, Department of Health, Medicine and Caring Sciences, Linköping University, Linköping, Sweden

Objectives: To compare individual and clinical characteristics of individuals with knee osteoarthritis (OA) with or without prior knee surgery.

Methods: This observational registry-based study includes data from the Swedish Osteoarthritis Register between 2008-2022. The Swedish Osteoarthritis Register contains data about individuals participating in first-line OA treatment (education and exercise) in primary care in Sweden. Individuals with a self-reported prior knee surgery were compared to individuals without a prior knee surgery with regards to individual characteristics (sex, age, BMI) and clinical characteristics (Charnley classification, intake of OA medication, fear of movement, walking difficulties, willingness of surgery, physical activity level, pain, and health-related quality of life) using logistic regression and Odds ratio (OR).

Results: The analysis included 77 791 individuals with knee OA of which 13 558 (21 %) reported a prior knee surgery. Individuals with a prior knee surgery had lower odds of being a woman (OR 0.439, 95% CI 0.416 to 0.464) were younger, (OR 0.957, 95% CI 0.954 to 0.959), had a lower BMI (OR 0.966, 95% CI 0.969 to 0.972), and less fear of movement (OR 0.913, 95% CI 0.852 to 0.979) compared to those without prior surgery. On the other hand, those who reported a prior knee surgery had higher odds of being physically active (OR 1.159, 95%CI 1.095 to 1.228), having walking difficulties (OR 1.856, 95%CI 1.744 to 1.975), having a wish for surgery due to OA symptoms (OR 1.856, 95%CI 1.744 to 1.975) and higher health-related quality of life (OR 1.228, 95% CI 1.028 to 1.466). There was no difference between individuals with and without a prior knee surgery for Charnley classification, pain intensity, pain frequency or intake of OA medication.

Conclusion: Individuals with knee OA, with and without a prior knee surgery differ in both individual and clinical characteristics. Individuals with knee OA and a prior knee surgery seem to enter first-line treatment at a younger age, with a lower BMI, with less fear of movement, a higher level of physical activity, a higher self-reported health-related quality of life but with more walking difficulties and a higher willingness of surgery. These group differences need to be considered in clinical practice to enhance individualized OA treatment in this group of individuals.

P1438

PREVALENCE OF OSTEOPOROSIS, LOW TRABECULAR BONE SCORE, AND FRACTURE RISK IN RHEUMATOID ARTHRITIS PATIENTS

T. K. H. Nguyen[1], C. M. Doan[2], D. K. Nguyen[3]

[1]Nguyen Tri Phuong Hospital, Ho Chi Minh City, Vietnam, [2]Pham Ngoc Thach Medical University, Ho Chi Minh City, Vietnam, [3]Cho Ray Hospital, Ho Chi Minh City, Vietnam

Overview: Rheumatoid arthritis (RA) patients are at high risk of osteoporosis and fractures, particularly with prolonged glucocorticoid use. Trabecular Bone Score (TBS), an indicator of bone microarchitecture, complements bone mineral density (BMD) in fracture risk prediction.

Objective: To assess the prevalence of osteoporosis, low TBS, fracture risk, and treatment indications in RA patients.

Methods: A cross-sectional study of 131 RA patients, at Nguyen Tri Phuong Hospital, measured BMD and TBS. Osteoporosis was defined using Tscore according to WHO criteria with Asian reference ranges, while TBS thresholds were set at ≤1.23 and ≤1.32. Fracture risk was assessed with FRAX and TBS-adjusted FRAX. Treatment recommendations followed Asia Pacific Consortium on Osteoporosis (APCO) guidelines. Kappa coefficients assessed concordance between BMD, TBS, and fracture risk tools (FRAX).

Results: Most patients were female (83.2%), with a mean age of 60.2 ± 9.3 years and BMI of 23.0 ± 3.4 kg/m². Fractures occurred in 21.4% of patients, and 33.6% were on bisphosphonates. Hypertension (44.3%), sarcopenia (20.6%), and diabetes (17.5%) were common comorbidities. The median disease duration was 7 (3–11) years, with structural damage in 41.2%. Glucocorticoid use was reported in 61% of patients, mostly at low doses (<5 mg/day).

Osteoporosis prevalence was 22.1%, while osteopenia was ob-

served in 60.3%. Low TBS was found in 26%, and partially degraded TBS in 35.1%. Concordance between TBS and BMD was low (Kappa = 0.2), but combining tools identified 32.8% of patients as high risk. High concordance (Kappa > 0.8) was observed between FRAX and TBS-adjusted FRAX, identifying 5.3% and 31% additional high-risk osteopenic patients for major osteoporotic fractures (MOF) and hip fractures (HF), respectively. According to APCO, 58.8% of patients required treatment.

Conclusion: Combining TBS and BMD enhances the identification of high-risk RA patients. Over half require osteoporosis treatment, emphasizing the need for comprehensive bone health management to reduce fracture risk.

Keywords: Rheumatoid arthritis, Osteoporosis, Trabecular bone score, Fracture risk.

P1439

RISK OF OSTEOPOROSIS AND DEGRADED TRABECULAR BONE SCORE IN RHEUMATOID ARTHRITIS PATIENTS

T. K. H. Nguyen[1], C. M. Doan[2], K. Hind[3], D. K. Nguyen[4]

[1]Nguyen Tri Phuong Hospital, Ho Chi Minh City, Vietnam, [2]Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Vietnam, [3]Faculty of Health and Medicine, Lancaster University, UK., Lancaster, United Kingdom, [4]Cho Ray Hospital, Ho Chi Minh City, Vietnam

Background: Patients with rheumatoid arthritis (RA) are at an increased risk of developing osteoporosis and fractures, particularly when treated with glucocorticoids [1]. Trabecular bone score (TBS) is a valuable complementary tool for evaluating bone microarchitecture, enhancing the prediction of fracture risk beyond bone mineral density (BMD) [2].

Objective: To determine factors associated with osteoporosis and degraded TBS in RA patients.

Methods: A cross-sectional study was conducted on 131 RA patients treated at Nguyen Tri Phuong Hospital. BMD and TBS were evaluated according to Asian reference standards, osteoporosis defined according to WHO criteria and TBS categorized using two cut-off points of <1.23 (degraded) and >1.32 (normal). General risk factors and RA-specific factors were analyzed using univariate analysis, followed by multivariate logistic regression to identify factors associated with osteoporosis (T-score ≤ -2.5) and degraded TBS (<1.23).

Results: Osteoporosis was identified in 22.1% of patients, while more patients (26%) exhibited degraded TBS. Combining BMD with TBS identified 32.8% of patients as high risk. Factors associated with osteoporosis included advanced age (OR = 1.05, p = 0.05), lower body weight (OR = 0.94, p = 0.02), and sarcopenia (OR = 2.99, p = 0.08). Degraded TBS was significantly associated with older age (OR = 1.13, p < 0.005) and structural RA associated bone damage (OR = 2.50, p = 0.09).

Conclusion: The study highlights that advanced age, low body weight, and sarcopenia are key factors associated with osteoporosis in RA patients. Similarly, older age and RA associated structural damage, are associated with degraded TBS. The combination of BMD and TBS is recommended for bone health assessment in RA. Comprehensive management strategies that address both bone integrity and joint health should be prioritized to mitigate fracture risks and improve outcomes in this patient population.

P1440

A STUDY OF FACTORS ASSOCIATED WITH THE CONTINUATION RATE AND DISCONTINUATION OF 329 CASES OF ROMOSOZUMAB IN OUR HOSPITAL

K. N. Kaoru[1], T. K. Tomonori[1]

[1]Kobayakawa Orthopedic & Rheumatologic Clinic, Fukuroi, Japan

【Background】 Although musculoskeletal diseases are one of the major causes of bedridden patients, the treatment rate of osteoporosis is low, and even when treatment is initiated, the drug continuation rate has been noted to be very low. Therefore, we investigated the drug continuation rate of patients treated with romosozumab at our hospital.

【Methods】 We investigated the continuation rate of 329 romosozumab patients who received 12 injections of romosozumab per year between January 2021 and January 2023. Patients were classified into two groups: those who completed the study and those who discontinued the study. Factors related to discontinuation were examined. Reasons for discontinuation were also investigated.

【Results】 249 patients (76%) completed the treatment. The overall patient background at induction was 77.6±8.0 years of age, 299 (91%) were female, BMI 24.9±3.9 kg/m2, and mean T-score was -3.11±0.98 for the lumbar spine, -2.72±0.79 for the proximal femur, and -3.23±0.82 for the femoral neck. There were 213 patients (65%) with a history of vertebral fracture, 192 (58%) without prior treatment, 218 (66%) living in the city, with a mean history of 1.9 non-orthopedic diseases and 138 (42%) with injection site reaction. Bone density in the completion group increased significantly at all sites after 1 year (mean T-scores at 1 year: lumbar spine -2.48 ± 1.17, proximal femur -2.55 ± 0.75, femoral neck -2.97 ± 0.86). The completion group had a significantly lower percentage of patients with a history of 3 or more non-orthopedic conditions. Of the 80 patients who dropped out of the study, 34 did not return to the hospital and the reason for the dropout

was unknown. Other reasons included hospitalization, injection site reaction (13 patients), poor physical condition (7 patients), difficulty going to the hospital (6 patients), financial reasons (4 patients), relocation (4 patients), institutionalization (3 patients), family reasons (2 patients), and one patient who did not want to receive the drug because of weight loss after administration.

【Conclusion】 The lomosozumab retention rate for the 329 patients was 76%. The completion group was less likely to have a history of 3 or more non-orthopedic conditions.

P1441

SURROGATE MARKERS OF SARCOPENIA AND SARCOPENIC OBESITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Karasevska[1], N. Grygorieva[2], A. Musiienko[2]

[1]Bogomolets National Medical University, Kyiv, Ukraine, [2]D.F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

Background. Sarcopenia and sarcopenic obesity are associated with frailty and disabilities such as cardiovascular disease, fractures, dementia, cancer, and increased all-cause mortality. The incidence and risk factors for sarcopenia and sarcopenic obesity remain unclear in patients with rheumatic diseases, particularly rheumatoid arthritis (RA).

Our study **aimed** to estimate the incidence of possible sarcopenia and sarcopenic obesity in patients with RA.

Materials and methods. Fifty-nine female patients with RA aged 50-79 years old were examined (62,9±7,9 years; height 161,6±7,7 cm; weight 68,8±13,2 kg; BMI 26,4±5,0 kg/m^2). The control group consisted of practically healthy subjects (n=86) who did not differ in age (64,7±7,8 years), height (161,0±4,9 cm), weight (69,4±12,2 kg), and BMI (26,8±4,8 kg/m^2). We used dual-energy X-ray absorbtiometry (DXA) by estimating appendicular lean mass (ALM) and appendicular lean mass index (IALM) and considered possible sarcopenia as ALM <15 kg and/or IALM <5.5 kg/m^2 (EWGSOP2 criteria). Possible sarcopenic obesity was defined by ESPEN/EASO Consensus [Donini LM, et al., 2022] as the simultaneous presence of two criteria: the ratio of ALM to body weight (ALM/body weight) was <22% for women and fat mass (FM) increasing, the cut-off values for the Ukrainian population were >41% for females [Grygorieva NV et al., 2023].

Results. The incidence of possible sarcopenia in RA was significantly higher compared to controls by ALM and/or IALM (45.8 vs. 24.4%; p<0.05). The incidence of sarcopenic obesity was also higher registered in RA than in controls (33.9 vs. 8.1%; p<0.05). A significantly reduced muscle mass was found in RA compared to controls concerning ALM (15,4±3,8 kg vs 17,8±3,3 kg; p<0.05) and IALM (6,0±1,4 kg/m^2 vs 6,9±1,4 kg/m^2; p<0.05). Significant impact of RA on possible sarcopenia development (OR 5.2; 95% CI 2.34-11.54; P<0.001) and sarcopenic obesity (OR 5.78; 95% CI 2.26-14.85; P=0.0003) were detected.

A limitation of our study was that only DXA criteria were used to determine possible sarcopenia and sarcopenic obesity.

Conclusions. Possible sarcopenia and sarcopenic obesity in RA are more common in comparison with healthy subjects. The potential impact of RA on the muscular system may dominate the effect of age on the development of sarcopenia and sarcopenic obesity in this disease. Future research is needed to identify predictors of sarcopenia and sarcopenic obesity in RA.

RECOGNIZING AND MANAGING SARCOPENIA IN CHILDREN: REFERENCE MUSCLE MASS VALUES FROM A EUROPEAN COHORT

T. Aydın[1], E. Bahat[2], B. Arpacı Sağlar[3], C. E. Meral Öner[4], I. Karacan[5], T. Kızılkurt[6], D. Dıraçoğlu[7], A. Karan[7], M. A. Karan[8], G. Bahat[8]

[1]Department of Physical Medicine and Rehabilitation, Hamidiye Faculty of Medicine, Health Sciences University, İstanbul, Turkiye, [2]Division of Pediatric Nephrology, Department of Pediatrics, Karadeniz Technical University Faculty of Medicine, Trabzon, Turkiye, [3]Department of Family Medicine, Faculty of Medicine, Biruni University, İstanbul, Turkiye, [4]Bahçelievler State Hospital, İstanbul, Turkiye, [5]Istanbul Physical Therapy Rehabilitation Training and Research Hospital, Physical Therapy and Rehabilitation Department, İstanbul, Turkiye, [6]Department of Orthopedics and Traumatology, Istanbul Medical Faculty, Istanbul University, İstanbul, Turkiye, [7]Department of Physical Medicine and Rehabilitation, Istanbul Medical Faculty, Istanbul University, İstanbul, Turkiye, [8]Division of Geriatrics, Department of Internal Medicine, Istanbul Medical Faculty, Istanbul University, İstanbul, Turkiye

Background & Aims: Sarcopenia, traditionally considered an aging-related condition, is increasingly recognized in pediatrics, where low muscle mass (LMM) affects growth and health outcomes. LMM is also a hallmark of malnutrition. Normative muscle mass values are critical for assessing LMM in children, yet current references are limited to a few studies conducted in specific populations, underscoring the need for further research. This study aimed to establish age- and sex-specific reference values for muscle mass in healthy children, representing a new population cohort.

Methods: A cross-sectional analysis of healthy children aged 5–14 years was conducted. Muscle mass was measured using Bioelectrical Impedance Analysis (BIA) after a minimum 8-hour fasting period. Percentile values for Fat-Free Mass (FFM) and Lean Body Mass (LBM) were calculated by age and indexed to weight, height squared, and BMI.

Results: A total of 844 healthy children (388 girls, 456 boys) were included. Age- and sex-specific percentiles for FFM and LBM were established. Comparative analyses with previously studied populations were performed. Reference values for FFM and LBM adjusted by BMI were reported for the first time.

Conclusion: This study provides normative reference values for muscle mass in children, offering a valuable tool for monitoring growth and diagnosing conditions such as sarcopenia and malnutrition. Further research in diverse populations is recommended to enhance the accuracy of LMM assessment.

A STANDARD EFFECTIVE TECHNIQUE FOR SHOULDER CAPSULITIS

T. L. Rodríguez Araya[1], I. Pomés[2], L. Polino[1], A. Arias[1], X. Torres[3], T. Mota[4]

[1]Unit of Primary Chronic Pain and Fibromyalgia, Rheumatology department, Hospital Clínic, Barcelona, Spain, [2]Musculoskeletal Radiology Department, Hospital Clínic, Barcelona, Spain, [3]Psychology Department, Hospital Clínic, Barcelona, Spain, [4]Anatomy department, University of Barcelona, Barcelona, Spain

Objective:
This pilot observational study aimed to evaluate the effectiveness and side effects of a standardized shoulder hydrodilatation technique in patients with capsulitis, to inform the design of a future clinical trial.

Materials and Methods:
Patients with capsulitis of at least 3 months' duration, attending a rheumatology clinic in 2024, were included if they had no history of trauma, diabetes, or tumors, and had not responded to NSAIDs ± corticosteroids, physiotherapy, or corticosteroid injections. Pain (VAS), ultrasound findings (other lesions and capsule size), and shoulder range of motion were recorded before and one month after treatment. The procedure involved a suprascapular nerve block under ultrasound guidance, followed by injection of 4 ml lidocaine2%, 4 ml bupivacaine0,25%, and 1 ml triamcinolone. Shoulder hydrodilatation was performed using ultrasound to guide needle placement into the joint capsule, with a mixture of 1 ml triamcinolone, 4 ml bupivacaine, 4 ml lidocaine, and 11 ml saline (20 ml total) injected under hydrostatic pressure.

Results:
A total of 26 patients were referred, mean age 52.7 years; 17 (65.4%) were women,. One patients missed follow-up. 10 (38.5%) did not meet clinical or radiological criteria for capsulitis. Fifteen patients (57.7%) with clinical and radiologica criteria (>4 mm capsule thickness) received the treatment. VAS pain decreased from 8/10 pre-treatment to 1.33/10 post-treatment.

Ten patients (66.7%) experienced complete pain and functional relief (VAS: 8 to 0.6; flexion: 94.5º to 179/180º; abduction: 72º to 175.5/180º; external rotation: 20º to 72/80º). Five patients (33.3%) showed partial improvement due to comorbid conditions like supraspinatus tendinosis and osteoarthritis, with VAS pain decreasing from 8 to 2.8 and significant gains in range of motion (flexion: 77 to 146ª; abduction 61 to 146º; external rotation 13 to 52º). No secondary effects were reported, except for mild pain in one patient.No statistically significant differences in the time elapsed from diagnosis to treatment, or in the previous use of NSAIDs, physiotherapy or intra-articular corticosteroids were observed between these 2groups.

Conclusion:
The standardized shoulder hydrodilatation technique was highly effective in treating capsulitis, providing significant pain relief and functional improvement, even in patients with comorbid shoulder conditions.

P1445

COMORBIDITY, INCLUDING OSTEOPOROSIS, AND INTERFERON STATUS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: IS THERE AN ASSOCIATION?

T. Panafidina[1], T. Popkova[1], Y. Gorbunova[1], L. Kondrateva[1], A. Avdeeva[1], A. Lila[1], E. Nasonov[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Background Type I interferon(IFN-I) play a central role in the pathogenesis of Systemic lupus erythematosus(SLE). Overexpression of IFN-I occurs in 60-80% patients with SLE. Type I IFN-inducible gene expression, measured using the IFN gene signature (IFGNS), provides a method to asses IFN-I pathway activation in individual patients. Against a background of genetic predisposition, a trigger stimulus, possibly microbial, induces the production of IFN-I and autoantibodies leading to inflammation. The risk of osteoporosis (OP) and fractures in SLE patients is higher than age- and sex- matched individuals from the general population. The aim of our study was to evaluate the possible association of comorbidities, including OP, with IFN gene signature in SLE.

Material and methods This observational retrospective-prospective study included 76 patients (86% women, median aged 33 [25;43] years (median [interquartile range 25;75%]), with a definite diagnosis of SLE (SLICC 2012) attending a routine visit at our Clinic between February 2021 and June 2024. Baseline demographics, menopausal and smoking status, body mass index(BMI), cardiovascular disease/stroke risk factors, renal disease, standard therapy (glucocorticoids, antimalarial, immunosuppressants,vitamin D) and IFNGS status (high/low) were analysed in SLE patients. Universally, dual energy X-ray absorptiometry (DEXA) is the mainstay for the diagnosis and monitoring of bone status. IFN status was assessed by the expression of IFN-inducible genes (MX1, RSAD2, EPSTI1) using real-time polymerase chain reaction. IFNGS was calculated as the average expression value of three selected genes. In patients, IFNGS was considered high when the average value of gene expression exceeded the average value of gene expression in donors. The control group consisted of 20 healthy donors comparable in sex and age with the SLE patients.

Results The median SLE duration was 2.3 [0.2;11.0] years, SLEDAI-2K 7 [4;11] score, SDI 0 [0;2] score.

At the time of inclusion in the study, SLE patients had the following manifestations: hematological disorders - 49%, most commonly leucopenia – 45%, inflammatory arthritis - 39%, nephritis - 33% (most commonly class IV), cutaneous lupus - 28%, serositis -18%, mucosal ulcers - 8%, nervous system involvement - 7%. Among 'non-criteria' symptoms the most common were: livedo – 20%, Raynaud's phenomenon - 12%, interstitial lung disease - 12%, lymphadenopathy - 8%, unexplained fever - 7%. Concomitant APS and Sjogren's syndrome were found in 12% and 38% of patients, respectively.

The majority of patients at the time of inclusion were taking glucocorticoids (83%) at low doses (10.0 [7.5; 20.0] mg/day prednisolone) in combination with hydroxychloroquine (80%) at a dose

of 200 mg/day. Immunosuppressants were used less frequently (in 36% of patients), mainly - mycophenolate mofetil (18%), cyclophosphamide, methotrexate and azathioprine in single cases. In addition, 13/76 (17%) patients were not receiving any therapy. Anti-B-cell biologic (mainly rituximab) according to the inclusion criteria were used more than 2 years ago in 8% of patients.
Fractures of various localizations were detected in 9% of SLE patients, OP was diagnosed in 7%pts, menopause - in 11% patients. Coverage by therapy was as follows: all patients with OP (100%) received vitamin D and 80% - anti-resorptive medications (bisphosphonates only).
IFNGS-high was detected in 72% of SLE patients. IFNGS-high patients were younger at the time of inclusion (31 [25; 41] and 40 [32; 49] years, p<0.05). We identified less hypertension (24% and 52%) and dyslipidaemia (13% and 38%) in IFGNS-high patients versus IFNGS-low patients with SLE(p<0.05). No association with incidence of OP, fractures, smoking, menopause, BMI, obesity, CVD, diabetes mellitus, chronic kidney disease was found with IFN. No effect of standard therapy for SLE on IFN-inducible genes expression was found.
Conclusions In SLE patients, IFN-I is independent of family history of autoimmune disease, any provoking factors, gender, weight, smoking, and any comorbidity. The lower incidence of hypertension and dyslipidemia in IFNGS-high patients is due to the younger age of them. Standard therapy has no significant effect on the expression of certain IFN-inducible genes.

THERMOGRAPHY IN THE SCREENING OF CHRONIC LOW BACK PAIN

A. Franca[1], T. Franca[2], T. Pereira[2]

[1]Instituto de Ortopedia e Traumatologia Prof. Dr. Alexandre Felipe França, Catanduva, Brazil, [2]Universidade de Franca, Franca, Brazil

Objectives
The objective of this study is to evaluate the use of infrared thermography as a screening method in the clinical assessment of patients with chronic low back pain associated with musculoskeletal postural changes.
Material and Methods
Infrared thermography is a rapid, painless, radiation-free, and non-invasive method that enables the creation of a two-dimensional image of tissue physiology, detecting early metabolic and musculoskeletal alterations. Thermographic devices capture infrared radiation emitted by the body and convert it into electronic signals (LASANEN, 2015), generating images with temperature gradients in different colors based on standardized parameters of the BodyScan InfraRed Med® Sequence.
In this retrospective and analytical observational study, 138 patients with chronic low back pain who required evaluation in an orthopedic clinic between 2022 and 2024 were analyzed. Postural variations identified through thermographic examination included forward head posture, shoulder elevation, lumbar paravertebral muscle contraction, reduced lumbar curvature, lumbosacral mechanical overload, and abdominal muscle weakness.
Results
A total of 138 individuals diagnosed with chronic low back pain were evaluated, comprising 69.6% women and 30.4% men. Thermography revealed postural changes significantly when associated to chronic low back pain, with a statistically significant relevance ($p < 0.05$). This finding underscores the value of complementary screening or diagnostic methods, such as thermography, as many of the assessed changes involve inflammation or muscular hyperactivity. Thermography serves as a potentially useful tool for identifying thermal patterns consistent with these conditions.
Conclusion
Infrared thermography is an excellent method for screening musculoskeletal postural alterations in patients with chronic low back pain. It facilitates not only early treatment but also the identification of other hidden dysfunctions associated with long-term conditions.

SARCOPENIA SCREENING IN PATIENTS WITH OSTEOPOROSIS AND OSTEOARTHRITIS

E. R. Zagidullina[1], T. S. Pronkina[1], I. A. Yatskov[1], Y. V. Usachenko[1], N. A. Shadchneva[1], A. A. Gorlov[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To screen for sarcopenia in elderly patients being treated by a rheumatologist for a combination of osteoporosis (OP) and osteoarthritis (OA).
Methods: A survey was conducted among 146 outpatient patients older than 65 years, with an average age of 74±5.3 years, including 120 women and 26 men. The survey was carried out during an outpatient appointment with a rheumatologist using the SARS-F questionnaire for sarcopenia screening. The key to interpreting the test results is as follows: 0-3 points – no sarcopenia; more than 4 points – probable sarcopenia.
Results: The patients were divided into three groups:
- Group 1: OA + OP without fractures (52 patients: 52 women, 0 men)
- Group 2: OA + OP with fractures (38 patients: 32 women, 6 men)
- Group 3: OA without OP (56 patients: 26 women, 20 men)

Women predominated in all study groups. According to the survey results, the absence of sarcopenia was distributed as follows, both quantitatively and in percentage terms: Group 1 – 20 (38.5%), Group 2 – 8 (21%), Group 3 – 36 (64.3%). Accordingly, the probability of sarcopenia was as follows: Group 1 – 32 (61.5%), Group 2 – 30 (79%), Group 3 – 20 (35.7%).
In total, for patients with OA + OP (Group 1 + Group 2: 90 people), the probability of sarcopenia was detected in 62 (68.9%) patients, while 28 (31.1%) patients showed no signs of sarcopenia. In patients with OA alone, the probability of sarcopenia was found in 20 (35.7%) respondents, with 36 (64.3%) showing no signs

Conclusion: The probability of sarcopenia was lowest in men with OA without OP. Among women with OP and OA, the probability of sarcopenia was higher in the group with fractures. The number of patients with probable sarcopenia in the combination of OP and OA exceeded the number of those without sarcopenia according to the screening data. In contrast, in OA without OP, the opposite results were observed: the probability of sarcopenia was detected in a third of the respondents.

ADVERSE EFFECTS OF SARCOPENIA ON PATIENTS WITH OSTEOPOROSIS: AN AGE- AND SEX-MATCHED CROSS-SECTIONAL ANALYSIS

T. T. B. Nguyen[1], A. P. Lin[2], Y.-J. Kuo[3], Y.-P. Chen[3]

[1]The International Ph.D. Program In Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan, [2]Department of Medical Education, Taipei Veterans General Hospital, Taipei, Taiwan, [3]Department of Orthopedics, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan

Introduction
Understanding the relationship between osteosarcopenia, the risk of falls and fractures, daily living activities (ADL), and quality of life (QoL) is vital for identifying high-risk individuals and optimizing patient care. This research focuses on examining how muscle loss affects elderly patients with osteoporosis.
Materials and Methods
This cross-sectional study collected data from bone health assessments at a single medical center in Taipei, Taiwan, for patients aged 50 and above, between 2020 and 2022. We divided osteoporosis patients into two groups—those with sarcopenia and those without—matched by age and sex. Baseline characteristics, fall and fracture risks (using the STRATIFY scale and FRAX, respectively), ADL (assessed through the Barthel Index), and QoL (assessed through EQ5D3L) were compared between the two groups.
Results
The study included 200 osteoporotic patients, with 100 having sarcopenia and 100 without. The average age was 76.17 years, with females making up 82% of the cohort. In comparison with osteoporotic patients without sarcopenia, those with sarcopenia showed lower bone mineral density (T-scores: -3.64 vs. -3.28, $p = 0.002$), a higher fall risk (0.90 vs. 0.49, $p = 0.007$), greater risk for major osteoporotic fractures (21.25% vs. 17.97%, $p = 0.019$) and hip fractures (11.35% vs. 9.07%, $p = 0.014$), reduced functional independence (Barthel Index: 91.80 vs. 97.60, $p = 0.036$), and a diminished QoL (EQ5D3L: 0.93 vs. 0.96, $p = 0.036$).
Conclusions
Sarcopenia negatively impacts osteoporotic patients. The findings underscore the urgent need for early detection and appropriate interventions for sarcopenia in managing elderly patients with osteoporosis. These measures are crucial in improving patient outcomes and enhancing their QoL.

P1449

THE EFFECTS OF SARCOPENIA ON OUTCOMES FOLLOWING VERTEBRAL AUGMENTATION FOR OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURE: A META-ANALYSIS

T. T. B. Nguyen[1], T. T. Nguyen[2], Y.-J. Kuo[3], S.-J. Cheng[3], Y.-P. Chen[3]

[1]The International Ph.D. Program In Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan, [2]Department of Orthopedics, Faculty of Medicine, Can Tho University of Medicine and Pharmacy, Can Tho, Vietnam, [3]Department of Orthopedics, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan

Background
Vertebral augmentation is a safe and effective treatment for osteoporotic vertebral compression fractures (OVCFs) in elderly patients. However, the role of muscle loss and reduced strength in post-procedure outcomes remains controversial. This meta-analysis investigates the impact of sarcopenia on clinical outcomes following vertebral augmentation in OVCF patients.
Materials and Methods
A systematic search of electronic databases was conducted up to August 2024 to identify studies comparing sarcopenic and non-sarcopenic patients who underwent kyphoplasty or vertebroplasty for OVCFs. The primary outcome analyzed was vertebral refracture, while secondary outcomes included residual back pain and mortality. The pooled results are reported as odds ratios (ORs) or mean differences with 95% confidence intervals (CIs).
Results
After a thorough screening, 14 studies were included, involving a total of 2197 OVCF patients treated with vertebral augmentation. Among these, 813 were sarcopenic, and 1384 were non-sarcopenic, with an average age of 73.06 years. Sarcopenic patients had a significantly higher risk of vertebral refracture compared to non-sarcopenic patients (OR: 2.92, 95% CI: 1.34-6.34, $p = 0.007$), with the risk increasing with age. Non-sarcopenic patients had a 64% lower likelihood of experiencing residual back pain than sarcopenic patients (OR: 0.36, 95% CI: 0.23-0.56, $p < 0.001$). Additionally, sarcopenic patients were found to have a significantly elevated risk of both 1-year mortality (OR: 30.65, 95% CI: 4.05-231.82, $p < 0.001$) and long-term mortality (OR: 14.4, 95% CI: 6.49-31.97, $p < 0.001$).
Conclusion
Sarcopenia negatively influences outcomes in patients undergoing vertebral augmentation for OVCFs. Early detection of sarcopenia in these patients, along with comprehensive strategies to improve and sustain muscle health, is recommended.

P1450

FACTORS INFLUENCE THE IMPACT OF INFLIXIMAB ON SERUM GLUCOSE STATUS IN RHEUMATOID ARTHRITIS PATIENT

T. T. H. Tran[1], D. V. Hoang[2], H. V. Nguyen[3]

[1]Tam Anh Hospital, Hanoi, Vietnam, [2]Hai Phong International Hospital, Hai Phong, Vietnam, [3]Bach Mai Hospital, Hanoi, Vietnam

Background: Infliximab is one of biological agents that considered as a treat – to – target therapy for rheumatoid arthritis. Infliximab is not only show efficacy in improving clinical responses, reducing damages of main disease but also has affection on comorbid conditions, such as blood glucose management and there are some factors that altering this impact. **Objectives:** To describe some factors that have influenced impact of infliximab on blood glucose status in rheumatoid arthritis patients treated with infliximab within 3 months. **Methods:** 22 patients were diagnosed with rheumatoid arthritis and treated with infliximab for 3 months at Bach Mai Hospital's Rheumatology Department from January 2017 to December 2018. Quantification of fasting plasma glucose by quantitative hexokinase, quantification CRPhs by immunological methods of turbidity measurement and clinical assessment to calculate DAS 28 - CRP at each time of drug administration for 03 months. **Results:** Mean fasting plasma glucose decreased 24.8%, the difference was stastically significant with $p < 0.05$. The ability of elevated fasting plasma glucose of the group with disease active (DAS 28 – CRP ≥ 3.2) was 4.952 times higher than that of the group with disease remission (DAS 28 – CRP < 3.2), OR was stastically significant with CI = 95% (IQR 1.329 ÷ 18.452). The ability of elevated fasting plasma glucose of the group with medium dose of methylprednisolon (≥ 12mg) wais 6.840 times higher than that of the group with low dose of methylprednisolon (< 12mg), OR was was stastically significant with CI = 95% (IQR 2.075 ÷ 22.548). **Conclusion:** In addition to controlling and improving clinical symptomps of rheumatoid arthritis, infliximab also helps reduce fasting plasma glucose, in order to control serum glucose better, these effects were affected by DAS 28 – CRP and dose of methylprednisolon.

Keywords. *Rheumatoid arthritis, fasting plasma glucose, infliximab, DAS 28 – CRP, methylprednisolon*

EVALUATE THE SAFETY OF MESENCHYMAL STEM CELLS DERIVED FROM ALLOGENEIC UMBILICAL CORD TISSUE FROM NEWBORN UMBILICAL CORD TISSUE THERAPY IN THE TREATMENT OF KNEE OSTEOARTHRITIS

H. H. Dang[1], T. T. H. Tran[1], N. T. T. Tham[1], N. D. Che[1], V. T. Nguyen[2], T. C. Luu[1], L. V. Nguyen[1]

[1]Tam Anh Hospital, Hanoi, Vietnam, [2]Tam Anh Hospital, Ho Chi Minh, Vietnam

Mesenchymal stem cells derived from allogeneic umbilical cord tissue from newborn umbilical cord tissue (hUCB-MSCs) have the following advantages: non-invasive collection, hyaline embryonic tissue structure similar to tendon, low immunogenicity, expected to treat knee osteoarthritis (OA) because of the ability to proliferate and differentiate into connective tissue cells, secrete immunoregulatory factors, anti-inflammatory, regenerative blood vessels, prevent apoptosis, but there are still many concerns about safety. **Objective**. Evaluate the safety of hUCB-MSCs therapy in treatment of primary OA. **Subjects and methods**. Prospective, open-label, placebo-controlled study on 65 patients with stage I-III OA according to Kellgren-Lawrence, 32 patients received intra-articular injection of hUCB-MSCs, 33 patients received hyaluronic acid. **Results**. The most common adverse event was pain at the time of injection with a rate of 40.6% in the study group and 36.4% in the control group, increased pain after injection was 37.5% and 6.3%, respectively, the difference was statistically significant with $p < 0.05$; there was no infection in the joint and soft tissue around the joint, post-injection joint bleeding, the level of post-injection effusion did not have a statistically significant difference in the 2 groups. **Conclusion**. Using hUCB-MSCs by intra-articular injection to treat OA is safe, however, research with larger sample sizes and longer follow-up time is needed for better evaluation. **Keywords**. Allogeneic mesenchymal stem cells from umbilical cord tissue, knee osteoarthritis, hyaluronic acid, safety.

COEXISTENT OF SPONDYLOARTHRITIS AND RHEUMATOID IN A SINGLE PATIENT: SERIES OF FIVE CASES

H. H. Dang[1], T. T. H. Tran[1], C. H. Dang[2]

[1]Tam Anh Hospital, Hanoi, Vietnam, [2]E Hospital, Hanoi, Vietnam

Rheumatoid arthritis (RA) and Spondyloarthritis (SpA) are most common inflammatory joint diseases, which chronically progress to reduce physical fitness and joint function, leading to disability. Their manifestations, etiology, and genetic factors are distinctive, therefore cases of coexistence of RA and SpA are rare. In clinical practice, patients often present with symptoms typical of one disease, and later exhibit symptoms of another, both clinically and on imaging. This makes diagnosis and treatment more challenging. There were reports of similar cases since 1970s. There have

been reports of similar cases since the 1970s. This study aims to describe the clinical symptoms, laboratory tests, and imaging of five patients with a concomitant diagnosis of SpA and RA at Tam Anh General Hospital.

Keywords: Rheumatoid arthritis, Spondyloarthritis, coexistent, concomitant.

P1453

THE RELATIONSHIP OF OSTEOPOROSIS SCREENING WITH SOCIOECONOMIC STATUS

T. Thacher[1], J. Sosso[1], K. Fischer[1], D. Jegen[1], J. Maxson[1], D. Rushlow[1]

[1]Mayo Clinic, Rochester, United States

Objective: Bone density screening for osteoporosis is recommended for all women in the U.S. by the age of 66 years. Our objective was to test the hypothesis that women with lower socioeconomic status were less likely to complete osteoporosis screening.

Material and Methods: We analyzed retrospective data from a large family medicine practice in the U.S. Midwest states of Minnesota, Wisconsin, and Iowa. All women empaneled in family medicine, aged 66 years and older in 2022, were eligible for inclusion. We collected data for any bone density testing completed in the 16 years between 2007 and 2022. Individual level housing-based socioeconomic status was determined with the HOUSES index, by linking patient addresses in the electronic health record to publicly available property data. The HOUSES index was stratified into quartiles, with Q1 representing the lowest socioeconomic status.

Results: Of the 11,196 women included, 8539 (76.3%) had completed at least one bone density measurement in the prior 16 years. Women who had completed bone density screening were younger (75.7±6.9 vs 78.4±8.5 years; P<0.001) and more likely to reside in urban (79.9% completion) than rural locations (73.0% completion; P<0.001). Women in the HOUSES Q1 were less likely to complete bone density screening (74.3%) compared with the Q4 (78.6%; P=0.007). Among women with specific social risk factors identified in the medical record, transportation risk was associated with a lower likelihood of completing screening (74.2% vs 81.8%; P=0.001), but food insecurity, limited financial resources, housing risk, and intimate partner violence risk were not.

Conclusion: Women with lower socioeconomic status in a U.S. Midwest primary care setting were less likely to complete bone density screening for osteoporosis than those of higher socioeconomic status. Strategies to make bone density screening more accessible and utilized by women with lower socioeconomic status and in rural areas are indicated.

P1455

CORRELATION BETWEEN NESFATIN-1 LEVELS, BODY COMPOSITION AND BONE METABOLISM MARKERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Z. Kvlividze[1], Z. B. Zavodovsky[1], B. S. Bedina[1], E. Papichev[1]

[1]Volgograd State Medical University, Volgograd, Russia

Nesfatin-1 is a molecule associated with the melanocortin signaling system. The effects of nesfatin have been studied in the regulation of appetite, glucose and lipid metabolism, thermogenesis processes, the development of anxiety and depression, and the functioning of the cardiovascular and reproductive systems [1]. There is information regarding the pro-inflammatory activity of nesfatin-1 [2]. Among the pleiotropic effects of nesfatin, its osteogenic activity is noteworthy. In experiments on ovariectomized rats (OVX), intravenous administration of nesfatin for two months has been shown to increase bone mineral density (BMD) in the vertebrae and femur. Treatment of mouse pre-osteoblasts leads to enhanced differentiation and mineralization. Some inhibition of osteoclastogenesis has been observed in mice [3]. The degree of activity of bioactive molecules depends on the expression of target cells, and their functions may differ in health and disease.

Objective: To study the correlation of nesfatin-1 levels with BMD, body composition, and markers of bone formation and resorption in patients with rheumatoid arthritis (RA).

Materials and Methods: A total of 110 patients with RA were studied (mean age 54.07 ± 11.32; M ± Std.dev). The diagnosis of RA was established according to the ACR/EULAR criteria for RA (2010). All RA patients underwent examination using the LUNAR DPX-Pro densitometer and completed clinical and laboratory assessments. Serum levels of nesfatin-1 were measured using a commercial test system (RaiBiotech, cat. EIA-NESF) according to the instructions provided with the kit.

Results: The mean concentration of nesfatin-1 in RA patients was 50.49 ± 34.05 ng/mL. RA patients were divided into two groups: Group 1 (n = 44) with normal serum nesfatin-1 levels (<37.95 ng/mL) and Group 2 (n = 66) with elevated nesfatin-1 levels (>37.95 ng/mL). No differences were found in serum C-terminal collagen type I peptide levels between Groups 1 and 2. A statistically significant correlation was identified between nesfatin-1 and N-terminal propeptide of type I collagen (P1NP) (r = 0.218, p = 0.022). No significant relationships were noted between serum nesfatin-1 levels and BMD, muscle, or fat mass.

Conclusions: We did not find a relationship between elevated serum nesfatin-1 levels, BMD, and body composition in RA patients. However, we noted a correlation between nesfatin-1 and P1NP, indicating the influence of nesfatin-1 on the differentiation and function of osteoblasts.

P1456

THE RELATIONSHIP OF NESFATIN-1 WITH BODY MASS INDEX AND FAT, BONE, AND MUSCLE MASS IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Z. Kvlividze[1], Z. V. Zavodovsky[1], S. A. Bedina[1], E. Papichev[1]

[1]Volgograd State Medical University, Volgograd, Russia

Nesfatin-1 (NF-1), also known as nucleobindin 2 (NUCB2), is a neuroendocrine peptide involved in maintaining homeostasis through the regulation of metabolism, energy homeostasis, and food intake. Several studies have demonstrated that individuals with obesity, particularly those with morbid obesity, have higher serum levels of NF-1 compared to individuals without obesity, and it is associated with serum insulin levels, the Homeostasis Model Assessment of Insulin Resistance (HOMA-IR), and absolute and relative fat mass. However, there are also contradictory data in the international literature, where in a group of patients with obesity, serum levels of NF-1 were statistically significantly lower than in the group without obesity.
Objective of the study: To investigate the association of serum nesfatin-1 (NF-1) levels with body mass index (BMI), indicators of body composition, and rheumatoid cachexia (RC).
Materials and Methods:The study included 110 individuals with rheumatoid arthritis (RA) and 60 conditionally healthy subjects. A standard clinical and laboratory examination was conducted for all participants. The level of NF-1 was determined using an enzyme-linked immunosorbent assay (ELISA). Dual-energy X-ray absorptiometry (DEXA) was performed with the Total Body program.
Results:The level of NF-1 in the RA patient group was higher than in the conditionally healthy group (50.49 ± 34.05 vs. 31.61 ± 3.17 ng/ml, t = 4.28; Conclusion: Although we found a relationship between serum NF-1 levels and lean mass in specific areas in RA patients, this neuroendocrine peptide cannot be used as a marker for diagnosing RC. Further studies are needed to clarify the mechanism of the association between NF-1 levels and lean mass, which may contribute to the development of new approaches for monitoring this indicator.

DEPENDENCE OF NESFATIN-1 ON BONE REMODELING INDICATORS

T. Z. Kvlividze[1], Z. V. Zavodovsky[1], S. A. Bedina[1], E. Papichev[1]

[1]Volgograd State Medical University, Volgograd, Russia

INTRODUCTION: The role of nesfatin-1 in bone metabolism in health and disease is currently poorly understood. Although systemic inflammation is characteristic of most rheumatic diseases (RD), the pathological processes of bone metabolism are most pronounced in rheumatoid arthritis (RA).
OBJECTIVE : To investigate the relationship between nesfatin-1 levels, bone mineral density (BMD), and body composition.
METHODS: The study included 110 patients with RA (mean age 54.07 ± 11.32; M ± Std.dev) and 30 individuals in the control group. All RA patients underwent examination using dual-energy X-ray absorptiometry with an osteodensitometer, which determined body composition. Levels of nesfatin-1, bone metabolism markers, and vitamin D in serum were measured using an indirect solid-phase enzyme-linked immunosorbent assay with commercial test systems.
RESULTS: The mean concentration of nesfatin-1 in RA patients was 50.49 ± 34.05 ng/mL, which was significantly higher than that of healthy individuals. The average level of nesfatin-1 in the serum of healthy individuals was 31.61 ± 3.17 ng/mL (M ± σ). Based on these values, the reference range for nesfatin-1 in healthy individuals, defined as M ± 2σ, was from 25.27 to 37.95 ng/mL. According to nesfatin-1 levels, all RA patients were divided into two subgroups. Group 1 included patients (n = 44) with normal serum nesfatin-1 levels (less than 37.95 ng/mL), while Group 2 (n = 66) included those with elevated nesfatin-1 levels (greater than 37.95 ng/mL). The study did not reveal a significant correlation between nesfatin-1 levels and body composition in RA patients, nor were there any significant differences in serum C-terminal collagen type I peptide (β-CTx) levels between Groups 1 and 2. A statistically significant correlation was found between nesfatin-1 and N-terminal propeptide of type I collagen (P1NP) (r = 0.218, p = 0.022). No significant relationships were identified between serum nesfatin-1 levels and BMD at any site, nor was there a correlation between nesfatin-1 levels and muscle or fat mass in RA patients.
CONCLUSION: Thus, our study identified a relationship between nesfatin-1 and the marker of bone matrix formation (P1NP), indicating a possible influence of nesfatin-1 on the differentiation and function of osteoblasts.

P1458

BABY-SHAKEN SYNDROME

T. Zagorskaya[1], A. Filipovich[2]

[1]Minsk Regional Children's Clinical Hospital, Minsk, Belarus, [2]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Shaking baby syndrome, shaken baby syndrome – injuries caused to the baby as a result of strong shaking. In total, there are about 27 cases of Baby-Shaken syndrome per 100,000 infants worldwide. Most often, the culprits of shaking are fathers and stepfathers (68-83%), followed by nannies (8-17%) and mothers (9-13%). A constantly crying child can infuriate even a well-balanced adult. A few sudden movements are enough for a child to get a serious injury. The head of a child under the age of one year is too large for a weak neck, it swings intensely and abruptly. Blood vessels can be damaged, leading to hemorrhages, due to the immaturity of the brain, the processes of nerve cells, which in children are not protected by the membrane, break off when shaken. In case of rough shaking of the baby, it is possible to separate the spinal cord from the brain at the level of the brainstem. The visual apparatus in infants is often affected, which is associated with the movement of the layers of the retina of the eye relative to each other. The classic triad of shaken baby syndrome is intracranial hemorrhage (predominantly subdural hematomas), cerebral edema, retinal hemorrhage. In 25% of cases, the shaking syndrome ends in the death of the infant from damage to vital brain centers, severe spinal injuries in the cervical spine. Complications of shaking syndrome include cortical blindness, hydrocephalus, convulsive seizures, cerebral palsy, delayed psychospeech and motor development, learning disabilities, and mental retardation. In the mildest cases, symptoms of severe brain dysfunction remain. In the clinic, we observed a case of Baby-Shaken syndrome in a 4-month-old child. The child was born from a second pregnancy due to grade 1 gestational anemia, colpitis, chronic nicotine intoxication, second vaginal birth at 37 weeks with a weight of 3.100 grams. The child's father is 53 years old, the mother is 29 years old, the mother suffers from epilepsy. From the age of 2 months, the baby began to hold his head.
At the age of 4 months, the child was admitted to inpatient treatment with complaints from the parents of a short-term loss of consciousness against the background of crying, similar to a respiratory affective attack. During the examination of the child, no data on cranial nerve damage were revealed, tendon-periosteal reflexes were not altered, a large fontanelle 1.5x1.5 cm, not strained. He holds his head while lying on his stomach well. Support on the forefoot. No changes in blood tests were detected. The child underwent an ultrasound of the brain - an echo picture of a subdural ganglion cyst on the right, an X-ray of the skull in 2 projections - no violation of the integrity of the bones of the cranial vault was revealed. The child underwent an MRI of the brain, revealed subacute chronic subdural liquor-hemorrhagic clusters over both hemispheres of the brain and cerebellum in varying degrees of resolution, the largest in the frontal region - 12 mm thick, in the posterior cranial fossa 2-3 mm thick with a shift of the median structures to the right at the level of the ventricles by 1.5-2 mm without compression of the brain. Mild expansion of the subarachnoid convexital and cisternal spaces of the brain. The ventricles of the brain are not dilated or deformed, the anterior horns of the lateral ventricles are at the level of the foramen of Monroe 6 and 4 mm, the width of the third ventricle is 5 mm, the width of the fourth ventricle is 12 mm. There is no occlusion of the cerebrospinal fluid pathways. He was examined by a neurosurgeon and diagnosed: Bilateral subdural cerebrorogemorrhagic clusters (Baby-Shaken syndrome). Given the absence of focal symptoms and signs of intracranial hypertension, surgical treatment is not currently required. Conservative treatment with glycine and magnetab was carried out.
Examined by a VisOD|OS-object vision, the optic nerve discs on the fundus of the eye are normal, no pathology was detected at the time of examination. The child's parents are registered as socially dangerous, for more frequent visits by the district pediatrician and visiting nurses. The inadmissibility of rough shaking and other options for careless treatment of children, the involvement of relatives in caring for the baby, and the help of psychologists are explained

P1459

REHABILITATION OF CHILDREN WITH CEREBRAL PALSY AND CONVULSIVE SYNDROME AT THE MINSK REGIONAL CHILDREN'S CLINICAL HOSPITAL

T. Zagorskaya[1], A. Filipovich[2]

[1]Minsk Regional Children's Clinical Hospital, Minsk, Belarus, [2]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Children with cerebral palsy (ICP) undergo courses of rehabilitation: medication and physiotherapy, massage repeatedly, sometimes up to 10 courses on the basis of the neurology departments of the Minsk Regional Children's Clinical Hospital (MRCH). Comprehensive rehabilitation is aimed at restoring motor functions, normalizing muscle tone, normalizing or developing weakened or absent innate motor reflexes (stepping, protective, head-to-body, head-to-head reflex, support reflex), teaching the skills of sitting, standing, walking, manipulative activity, and speech functions.
In the presence of convulsive syndrome, the selection of anticonvulsants is carried out: carbamazepine, depakine, convulsofin, lamictal, topamax, clonazepam in mono- or in case of ineffectiveness in duotherapy. The presence of convulsive seizures in a patient with cerebral palsy is a contraindication to physiotherapeutic treatment (FTL), therapeutic exercise (exercise

therapy), massage, drug treatment has a number of limitations - a number of nootropic drugs that can provoke convulsive seizures are contraindicated: nootropics (aninalone, cerebrolysin, encephalobol, piracetam), anticholinesterase drugs: proserin, neuromidine. Of the nootropic and vascular drugs, pantogam, gliatilin, cortexin, actovegin, emoxipine, mexibel, glycine, B vitamins (neurobex, magne-B6), vitamin E, muscle relaxants (midocalm) are used.

In the absence of convulsive syndrome in children with cerebral palsy for 3 months, the patient begins to undergo FTL, exercise therapy, massage, acupuncture against the background of taking anticonvulsants. Anticonvulsants are taken for a long time – 2-3 years after the last attack. Massage is of particular importance for the treatment of cerebral palsy, the work with each muscle group should be approached selectively, taking into account its tone, the presence of contractures in the joints. Physiotherapeutic treatment includes electrotherapy: electrical stimulation of the back muscles, foot extensors, thigh muscles, buttocks; Phototherapy: UV, laser therapy, polarized light therapy, ultrasound therapy and drug phonophoresis: euphylline-dibazole biphoresis on the limbs and segments of the spinal cord, heat therapy (paraffin-ozokerite applications), hydrotherapy: hydromassage, whirlpool baths, reflexology.

As of January 1, 2012, there are 857 children with cerebral palsy in the Minsk region. In 2011, 226 patients with cerebral palsy (29.65% of morbidity) were treated at the Neurology Department. 47 case histories of children with cerebral palsy who underwent treatment in 2011 were analyzed. Convulsive seizures were observed in 18 patients (38%) In 3 patients (6%) children with cerebral palsy, convulsive seizures in the stage of drug remission (that is, they regularly take anticonvulsants), sulorogenic seizures were noted during the rehabilitation treatment, as a result of which rehabilitation by physiotherapeutic methods, massage was stopped, only permissible drug treatment was preserved.

P1460

INCIDENCE OF FRACTURES IN PATIENTS WITH TYPE 1 AND TYPE 2 DIABETES MELLITUS: A SURVIVAL ANALYSIS

T.-C. Lee[1], S.-Y. Lin[2], P.-S. Ho[3], C.-H. Chen[1]

[1]Department of Orthopedics, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [2]Department of Orthopedics, Kaohsiung Medical University Gangshan Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [3]Faculty of Dental Hygiene, College of Dental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan

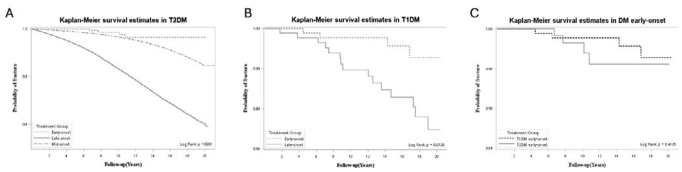
Objective(s): This study aims to investigate the incidence of fractures in patients with Type 1 Diabetes Mellitus (T1DM) and Type 2 Diabetes Mellitus (T2DM), focusing on the influence of age at diabetes onset.

Material and Methods: Data were extracted from the Longitudinal Generation Tracking Database 2000 (LGTD 2000), covering the years 2000 to 2019. Patients were categorized based on diabetes type and age at diagnosis. Fracture incidence was assessed using Kaplan-Meier survival analysis, with specific attention to the time-to-event relationships.

Results: A total of 988 patients with T1DM and 146,549 with T2DM were included in the analysis. The average follow-up duration was 13.33 ± 5.98 years for T1DM, revealing fracture rates of 0.8% for early-onset and 3.2% for late-onset. In the T2DM cohort, fracture rates were reported at 0.8%, 2.9%, and 10.7% across early, mid-, and late-onset subgroups, respectively. Late-onset groups exhibited a steeper increase in fracture risk over time, but no significant difference in risk was found between early-onset T1DM and T2DM patients (Fig. 1).

Conclusion(s): This study highlights the temporal relationship between diabetes onset age and fracture incidence, demonstrating that late-onset diabetes significantly increases fracture risk. Understanding these dynamics may aid in developing effective fracture prediction and prevention strategies for diabetes patients.

Disclosures: The authors declare that they have no conflict of interest.



P1461

EARLY MENOPAUSE AND FRACTURE RISK: A RETROSPECTIVE ANALYSIS IN TAIWAN

T.-F. Lu[1], H.-T. Lee[2], Y.-L. Deng[3]

[1]Department of Gynecology and Obstetrics, Taichung Veterans General Hospital, Taichung, Taiwan, [2]Lee's Medical Corporation, Taichung, Taiwan, [3]Department of Nursing, Taichung Veterans General Hospital, Taichung, Taiwan

Objective

To analyze the impact of early menopause on fracture risk in women and to investigate the potential roles of chronic diseases and bone density in this process.

Methods

This retrospective study included women who underwent their first bone density examination at Taichung Veterans General Hospital between January 2010 and December 2024. Among the participants, 530 women experienced early menopause (EMP group), and 1,883 women underwent normal menopause (NMP group). Data were collected on menopause age, age at fracture, bone density, and the prevalence of chronic diseases before fracture. Statistical analyses, including the Mann-Whitney U test, Chi-square test, and logistic regression, were used to examine the relationship between EMP and fracture risk.

Results

This study found that women with early menopause (EMP) had a significantly younger age of fracture onset compared to those with normal menopause (NMP) (67.5±9.6 vs 70.3±8.4 years, p<0.001), and the proportion of fractures occurring before the

age of 65 was significantly higher in the EMP group than in the NMP group (38.7% vs 27.5%, p<0.001). In addition, EMP women were more likely to have pre-fracture chronic diseases such as hypertension, diabetes, and chronic kidney disease, with prevalence rates significantly higher than those in NMP women (p<0.01). Multivariate logistic regression analysis showed that EMP was an independent risk factor for fractures (adjusted OR=1.89, 95%CI: 1.52-2.34, p<0.001). Other significant risk factors included hypertension (OR=0.40, 95%CI: 0.32-0.51, p<0.001), coronary artery disease (OR=0.62, 95%CI: 0.48-0.80, p=0.003), and rheumatoid arthritis (OR=1.64, 95%CI: 1.22-2.22, p=0.001). After adjusting for vitamin D and calcium supplementation, the fracture risk in the EMP group remained significantly higher than in the NMP group (OR=1.69, 95%CI: 1.38-2.07, p<0.001).

Conclusion

These findings highlight that EMP is significantly associated with an increased fracture risk, particularly in women under 65 years of age. The coexistence of chronic diseases such as hypertension, coronary artery disease, and rheumatoid arthritis further exacerbates this risk. These results emphasize the importance of bone health management and early intervention for chronic diseases in women with EMP to reduce fracture incidence.

P1462

GERIATRIC SYNDROMES IN OSTEOPOROTIC AND OSTEOPENIC ELDERLY PATIENTS

U. Durak[1], K. Cıngar Alpay[1], G. K. Avlagı[1], D. Ozata[1], S. Bılgın[1], A. Doventas[1]

[1]Istanbul University Cerrahpasa Faculty of Medicine Department of Geriatrics, Istanbul, Turkiye

Objective: Geriatric syndromes (GS) are clinical conditions associated with aging. Osteoporosis, linked to almost all GS, increases 1.2-2.5 times in individuals over 65. Early diagnosis of osteoporosis and GS is crucial, as they lower quality of life, increase healthcare use and raise morbidity and mortality. This study investigates GS related to osteoporosis and osteopenia in the elderly.

Methods: The study included 64 patients aged 65 and above, diagnosed with osteoporosis (Dual-energy x-ray absorptiometry [DEXA] T score <-2.5) and osteopenia (DEXA T score between -1 and -2.5). Exclusion criteria were acute organ failure, chronic diseases, musculoskeletal or neurological disorders and mobility limitations. Nutritional status was assessed using the Mini Nutritional Assessment (MNA) (<24 impaired nutritional status), sarcopenia was evaluated with the SARC-F questionnaire (≥4 possible sarcopenia) and handgrip test (woman <16, man <27 possible sarcopenia), frailty with the Frail scale (robust [0 score], pre-frail [1-2 score], frail [≥3 score]), depression with Geriatric Depression Scale (GDS) (>5 depression). Data were analyzed with IBM SPSS Statistics version 26 (p<0.05).

Results: In the osteoporosis group, the female/male (F/M) ratio was 30/4, and the average age was 78.09 ± 5.11 years. In the osteopenia group, the F/M ratio was 25/5, and the average age was 76.4 ± 5.70 years (p: 0.72, 0.21 respectively). The MNA score in the osteoporosis group was 24.24 ± 3.27, and in the osteopenia group, it was 23.72 ± 3.98 (p: 0.56). Handgrip strength was 20/24.5 (p: 0.10), and the average SARC-F score was 3/2 (p: 0.49). Depression was found in 9 individuals in the osteoporosis group and 11 in the osteopenia group (p: 0.61). Frailty assessment showed 15 pre-frail and 10 frail patients in the osteoporosis group, compared to 11 pre-frail and 10 frail patients in the osteopenia group (p: 0.62).

Conclusion: Osteoporosis is a geriatric syndrome linked to other geriatric conditions. In our study, although the MNA score and handgrip strength were lower and the SARC-F score and the number of frail patients were higher in the osteoporosis group, no statistical significance was found. This may be due to the small sample size, and larger studies are needed.

P1463

ATYPICAL FRACTURES IN PATIENTS ON DENOSUMAB THERAPY FOR OSTEOPOROSIS

U. Farrell[1], R. Lannon[1], D. Fitzpatrick[2], N. Maher[1], N. Fallon[1], C. O'Carroll[1], K. Mccarroll[1]

[1]Bone Health Unit, St James's Hospital Dublin, Dublin, Ireland, [2]Mater Misericordiae University Hospital Dublin, Dublin, Ireland

Objectives:

Our objective was to identify patients with Atypical Femoral Fracture (AFF) on denosumab therapy and report on patient features and management.

Material and Methods:

Atypical femoral fractures (AFFs) are rare in the treatment of osteoporosis and occur in about 1/1000 patients on long-term bisphosphonate therapy. However, the occurrence of AFF in patients on denosumab is much less frequent with the vast majority having prior bisphosphonate treatment. We identified 4 patients with AFF on denosumab therapy and analysed each case.

Results:

Two patients were bisphosphonate naïve and had no prior fractures: one was on denosumab for 8 years and her most recent lowest T-score was -1.0. Her denosumab was stopped and she was monitored. The other was on denosumab for 4 years and had a lowest T-score of -2.2 (lumbar spine). After MRI femur ruled out a contralateral incomplete AFF, he was treated with zoledronic acid (4mg) six months after his last denosumab injection. Two patients had prior bisphosphonate therapy and presented with complete AFF. One is being monitored closely and the other was treated with zoledronic acid 9 months after her last denosumab injection (contralateral incomplete AFF first excluded).

Conclusion:

AFF is rare on denosumab with the optimal future treatment strategy unclear. However, up to 15- 30% of all AFFs occur in patients not on antiresorptives. In those at high risk of bone loss and fracture, further treatment with bisphosphonates should be considered (ECTS guidelines). In those with AFF and at very high risk of rebound fracture (low spine T-scores and recent vertebral fractures), continuing denosumab and adding in teriparatide might also be a potential strategy but data is lacking.

P1464

IN-HOSPITAL MORTALITY OF FRAGILITY HIP FRACTURE IN OLDEST-OLD PATIENTS

N. Sirirotchanakun[1], S. Kantachote[1], A. Lerdprajakwong[1], U. Naknarong[1], T. Rattanakitkoson[1], U. Piyapromdee[1]

[1]Maharat Nakhon Ratchasima hospital, Nakhon Ratchasima , Thailand

Background: With an aging population, hip fractures in the elderly have become a growing concern. Oldest-old patients aged 80 years and above are particularly vulnerable to complications and in-hospital mortality. This study aimed to determine the prevalence of in-hospital mortality and identify associated risk factors in Oldest-old patients with hip fractures.
Methods: This retrospective cohort study analyzed data from a hip fracture database at Maharat Nakhon Ratchasima Hospital from January 2020 to December 2021. Patients aged 80 years and above were included. Statistical analysis was performed to compare characteristics between patients who died and survived during hospitalization.
Results: A total of 485 patients aged 80 years and above were included. The in-hospital mortality rate was 5.52%. Renal dysfunction was significantly associated with increased mortality. Patients who died had significantly higher creatinine levels and lower estimated glomerular filtration rates (eGFR) compared to survivors. Moreover, 25% of deceased patients had stage 4 or higher chronic kidney disease (CKD) or eGFR less than 30 ml/min/1.73 m², compared to 8.27% of survivors. Postoperative pneumonia was another significant complication observed in the deceased group.
Conclusion: Elderly hip fracture patients aged 80 years and above have a high risk of in-hospital mortality. Renal dysfunction and postoperative pneumonia were identified as significant risk factors. Proactive assessment and management of these risk factors may help reduce mortality in this vulnerable population.

CONCENTRATION OF SERUM ANGIOPOIETIN-LIKE PROTEINS DEPENDING ON THE SEVERITY OF METABOLIC DISORDERS IN PATIENTS WITH PSORIATIC ARTHRITIS

V. A. Aleksandrov[1], L. N. Shilova[2], N. V. Golovina[2], A. V. Aleksandrov[1], N. V. Aleksandrova[3]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, VolgogradState Medical University, Volgograd, Russia, [2]Volgograd State Medical University, the Department of Hospital Therapy, Volgograd, Russia, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Increased levels of angiopoietin-like proteins of various types are detected in serum in the presence of a number of signs of metabolic syndrome (MS) (hyperlipidemia, hyperinsulinemia, arterial hypertension, obesity, endothelial dysfunction, etc.).
Purpose of the study:
To determine the clinical and laboratory relationship between serum angiopoietin-like proteins (types 3, 4 and 6) and the patterns of metabolic disorders in PsA patients.
Materials and Methods.
The content of serum Angptl types 3, 4 and 6 was studied in 45 PsA patients (women 55.6%) using immunoassay method.
Results and Discussion.
The content of Angptl of different types depending on the presence or absence of MS in patients with PsA is presented in the Table.
Table.
Content of Angptl types 3,4 and 6 in PsA patients depending on MS

Indices	Patients with MS (n=27)	Patients without MS (n=18)
Angptl3, pg/mL	1113 ± 372	1024 ± 311
Angptl4, pg/mL	402 ± 188	362 ± 149
Angptl6, pg/mL	5,45[4,1;6,9]	4,04[3,5;4,6] #

Note: # - p<0.05.
When patients with PsA were categorized by presence/absence of MS according to the International Diabetes Federation (IDF) criteria, MS was diagnosed in 60% of cases. Intergroup comparison of Angptl indices demonstrated an increase in Angptl6 levels in the presence of MS (M-W U test, p=0.018) and showed no difference in Angptl 3 and 4 types. Only in the group of patients with low-activity PsA in the presence of MS was an increase in Angptl3 levels observed (Newman-Keuls test; p=0.49) when compared with patients without MS.
In the general group of PsA patients, the main laboratory indicators of MS (blood glucose level, HDL-cholesterol, blood triglycerides(TG)) in the constructed regression model described an association with Angptl3 within 10% (R2=0, 099, p=0.22), with Angptl6 within 15% (R2=0.148, p=0.08) and with Angptl4 around 17% (R2=0.168, p=0.05), with TG values making the main contribution (β=0.33, p=0.04; β=0.31, p=0.044; β=0.32, p=0.037; for Angptl 3, 4 and 6, respectively).
Conclusions.
Angptl types 3,4 and 6 can be used as diagnostic markers of metabolic disorders in PsA patients.

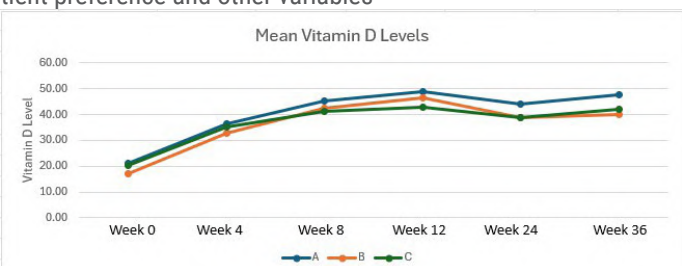
P1466

KINETICS AND CONCENTRATIONS OF CIRCULATING 25-HYDROXYVITAMIN D (25-OH D) USING HIGH-, MEDIUM-, AND LOW-DOSE REGIMENS

V. B. Babalyan[1], N. H. Hutchings[2], M. Q. Qefoyan[1], S. B. Baghdasaryan[1], S. K.-P. Kara-Poghosyan[1], J. P. B. Bilezikian[2]

[1]Osteoporosis Center of Armenia, Yerevan, Armenia, [2]Columbia University, College of Physicians & Surgeons, New York, United States

Objectives: Vitamin D deficiency is widespread, but guidelines for vitamin D replacement therapy in Armenia are not clearly defined. This study aimed to investigate the efficacy of three administration regimens to replete vitamin D: low dose - high frequency; medium dose - medium frequency; high dose - low frequency.
Material and Methods: We recruited community dwelling adults in Yerevan, Armenia, who were found to be deficient in vitamin D. Participants were subsequently randomized to receive vitamin D according to one of three arms: A) 7 000 IU via oral drops daily for 12 weeks followed by 3 500 IU daily for 24 weeks; B) 50 000 IU oral solution weekly for 12 weeks followed by 25 000 weekly for 24 weeks; and C) 100 000 IU every other week for 12 weeks, followed by 50 000 every other week for 24 weeks. After 36 weeks, all subjects received the same amount of vitamin D. Levels of 25-OH D were measured at baseline and then at weeks 4, 8, 12, 24, and 36.
Results: The mean baseline 25-OH D level of the 60 adults who participated in the study (average age 46, 80% female), was 19.37 ng/mL. All three arms showed statistically significant increases in 25-OH D levels from baseline to 4 weeks, and again from 4 to 8 weeks, after which levels plateaued in the mid-40s for all groups. Group A had slightly higher mean 25-OH D level than Group B at baseline (21.03 vs 16.94, *p*-value 0.03) as well as at week 36 (47.71 vs 40.19, *p*-value 0.007); otherwise there were no significant differences between the groups at any other time points.
Conclusion: This study supports a recommendation that different dosing regimens of vitamin D replacement will reach similar, desirable levels when steady state is reached at weeks 12 to 36, thus enabling health care providers an option to determine the most appropriate replacement strategy based on individual patient preference and other variables



P1467

MACROELEMENTAL COMPOSITION OF THE MANDIBULAR RAMUS IN WHITE RATS WITH A DEFECT IN THE TIBIA AFTER 60-DAY TARTRAZINE INTAKE

V. Bibik[1], V. Luzin[1], T. Gorbatykh[1], M. Miroshnichenko[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia, Lugansk, Russia

Objective: The aim of the study is to analyze macroelemental composition of the mandibular ramus in white rats with a defect in the tibia after 60-day tartrazine intake. Material and Methods: 140 male rats with the body weight of 200-210 grams were distributed into four groups like the following: group 1 - controls, group 2 - animals that received per os tartrazine in dosage of 1500 mg/kg of body weight for 60 days, group 3 - animals with tibia fracture (modeled as 2.0 mm reach-through round opening between the proximal metaphysis and the shaft), and group 4 - animals with tibia fracture and administration of tartrazine. Upon expiration of observation terms (the 3rd, the 10th, the 15th, the 24th, and the 45th day), rami of the mandible were prepared for chemical analysis. Results: In the group 2 calcium level and calcium/phosphorus ratio in the mandibular ramus in the period from the 3rd to the 45th day were lower than those of the group 1 by 5.27%, 9.13%, 8.66%, 11.59% and 4.42%, and by 9.70%, 13.56%, 11.59%, 12.51% and 3.43% respectively. In the group 3 calcium level and calcium/phosphorus ratio in the mandibular ramus in the period from the 3rd to the 24th day were lower than those of the group 1 by 5.12%, 6.72%, 8.70% and 11.81%, and by 5.12%, 11.50%, 11.79% и 12.73% respectively. In the group 4 calcium level and calcium/phosphorus ratio in the mandibular ramus by the 45th day were lower than those of the group 2 by 5.16% and 6.59%. Conclusion: Intragastric administration of tartrazine in dosage of 1500 mg/kg/d for 60 days was accompanied by destabilization of the mandibular ramus macroelemental composition. Tibia fracture after 60-day tartrazine intake administration was accompanied by aggravation of the destabilization of the mandibular ramus macroelemental composition.

P1468

THE CHARACTERISTICS, ADHERENCE AND TREATMENT PATTERNS OF MEN TREATED FOR OSTEOPOROSIS IN JAPAN: A RETROSPECTIVE COHORT STUDY

V. C. Brunetti[1], C.-H. S. Chang[2], S. Komatsu[2], G. Papageorgiou[1], K. De Silva[1], M. Kim[3], M. Hatano[4]

[1]Amgen, London, United Kingdom, [2]Amgen, Tokyo, Japan, [3]Amgen, Thousand Oaks, United States, [4]University of Tokyo, Tokyo, Japan

Objective:
Osteoporosis (OP) is underdiagnosed and more poorly managed among men than among women[1]. The objective of this study was

to assess the characteristics, adherence and treatment patterns of men treated for osteoporosis in Japan.

Material and Methods:

This retrospective cohort study was conducted using the MDV hospital-based and DeSC payer-based claims databases in Japan. Men aged ≥50 years were included upon initiation of a new OP treatment, including romosozumab, parathyroid hormone (PTH) analogs (teriparatide, abaloparatide), denosumab, or oral bisphosphonates (BPs; alendronate, ibandronate, risedronate), between Jan 1, 2019 and Aug 31, 2023 (DeSC) or Dec 31, 2023 (MDV). Patients were excluded if they had <15 months enrolment, received a cancer diagnosis within ≤3 months prior or were diagnosed with Paget's disease or metastatic cancer at any time prior to index date. Adherence to treatment was estimated using proportion of days covered (PDC), calculated as the total number of days of supply divided by the patient's follow-up time.

Results:

DeSC patients were on average older than MDV patients, and patients on Oral BPs were the youngest in both data sets. Use of previous OP treatment was highest among denosumab users, and history of any fracture was highest in PTH analog users. Recent history of myocardial infarction and stroke was similar across treatment groups, but slightly lower for romosozumab and denosumab users. Patients using PTH analogs and romosozumab had a greater history of hospitalizations in DeSC and MDV, respectively. Adherence to treatment was highest among users of denosumab, followed by users of romosozumab, PTH analogs and oral BPs (12-month mean PDC in DeSC: 87.4%, 72.9%, 70.8% and 57.6% respectively).

Conclusions:

Across 2 data systems in Japan, close to two thirds of men using PTH analogs and romosozumab experienced any fracture within 15 months prior to initiating treatment. In contrast, recent history of cardiovascular disease was similarly low across all treatment groups, though slightly lower in romosozumab and denosumab users in both databases.

Table 1: Characteristics of male patients initiating osteoporosis treatments in Japan

Description*	DeSC database				MDV database			
	Romosozumab (n=5,420)	PTH Analogs (n=12,069)	Denosumab (n=11,497)	Oral BP (n=30,595)	Romosozumab (n=2,697)	PTH Analogs (n=7,410)	Denosumab (n=7,775)	Oral BP (n=35,690)

THE CHARACTERISTICS, ADHERENCE AND TREATMENT PATTERNS OF WOMEN TREATED FOR OSTEOPOROSIS IN JAPAN: A RETROSPECTIVE COHORT STUDY

V. C. Brunetti[1], C.-H. S. Chang[2], S. Komatsu[2], G. Papageorgiou[1], K. De Silva[1], M. Kim[3], M. Hatano[4]

[1]Amgen, London, United Kingdom, [2]Amgen, Tokyo, Japan, [3]Amgen, Thousand Oaks, United States, [4]University of Tokyo, Tokyo, Japan

Objective:

The objective of this study was to assess the patient characteristics, adherence and treatment patterns of women treated for osteoporosis (OP) in Japan.

Material and Methods:

This retrospective cohort study was conducted using the MDV hospital-based and DeSC payer-based claims databases in Japan. Women aged ≥50 years were included upon initiation of a new OP treatment, including romosozumab, parathyroid hormone (PTH) analogs (teriparatide, abaloparatide), denosumab, or oral bisphosphonates (BP; alendronate, ibandronate, risedronate), from Jan 1st 2019 until Aug 31st 2023 (DeSC) or Dec 31st 2023 (MDV). Patients were excluded if they had <15 months enrolment, received a cancer diagnosis within ≤3 months prior or were diagnosed with Paget's disease or metastatic cancer at any time prior to index date. Adherence to treatment was estimated using proportion of days covered (PDC), calculated as the total number of days of supply divided by the patient's follow-up time.

Results:

A total of 45,177 romosozumab initiators, 66,080 PTH analogs initiators, 97,163 denosumab initiators and 154,845 oral BP initiators were included from the DeSC data (Table 1). Patients were on average younger in the MDV data, and users of oral BPs were the youngest in both databases. In both MDV and DeSC, PTH analog users had a greater history of fracture, while denosumab users had a greater history of any OP treatment use. History of recent myocardial infarction and stroke was similar across treatment groups, although slightly lower among patients using romosozumab or denosumab. In both databases, adherence to treatment was highest among users of denosumab, followed by users of romosozumab, PTH analogs and oral BPs.

Conclusions:

Across 2 data systems in Japan, approximately half of women with OP using PTH analogs and romosozumab experienced any fracture within 15 months prior to initiating treatment. In contrast, recent history of cardiovascular disease was similarly low across all treatment groups, though slightly lower in romosozumab and denosumab users in both databases.

Table 1: Characteristics and adherence of female patients initiating osteoporosis treatments in Japan

BILATERAL OSGOOD - SCHLATTER DISEASE IN A YOUNG SPORTSMAN

V. Dimitrioski[1], D. Jovanovska-Jordanovski[1]

[1]PHI Health Center Skopje, Polyclinic Jane Sandanski, Republic of North Macedonia, Skopje, Republic of North Macedonia

Background: Osgood Schlatter (OSD), referred as osteochondrosis, tibial tubercle apophysitis, or traction apophysitis of the tibial tubercle, is a cause of anterior knee pain in the skeletally immature athletic population.

It is a common condition in active young athletes and is associated with a period of growth spurts. Clinical features include mild to severe, intemittent or continuous pain, tenderness, swelling and a limp. Radiological features include enlarged and fragmented tibial tubercle.

Case description: Here we have a case of a fifteen years old male presenting with pain, tenderness, swelling and a discrete limp while walking. He was referred to us by a primary care physician. His detailed evaluation was carried out and was diagnosed on the basis of history, clinical findings on both knees and plain radiographs, again on both knees as Osgood Schlatter Disease.

Treatment: Treatment for Osgood Schlatter consists of reduced physical activity, decreased or entirely secession from intensive sport activities, analgesia and pyhsical therapy.

Results: Since the symptoms are typically self limiting, the patient was instructed for a gradual return to activity once the pain improved, of course under the supervision of a physiotherapist. The return to full athletic performance was made with changes to the playing style and with inclusion of the team`s coach.

Conclusion: Initial Assessement, detailed investigations and making changes in the level of activities of the athlete helps improvement in Osgood Schlatter disease.

Keywords: Osgood Schlatter disease, young athlete, evaluation, Patellar tendon, Tibial tuberosity

TREATMENT OF OSTEOPOROSIS IN THE FIELD OF RHEUMATOID ARTHRITIS

V. Duraj[1], J. Isaku[2]

[1]Mother Teresa University Hospital, Tirana, Albania, [2]University of Medicine, Faculty of Technical Medical Sciences, Lecturer, Tirana, Albania

Background. Individuals with RA are at increased risk of developing osteoporosis.

Chronic inflammation associated with RA, medications used to treat the disease, particularly prednisone and other corticosteroid (“steroids”) drugs, all contribute to this risk.

Inadequate intake or absorption of bone-building calcium, and less exercise due to fatigue and pain, may contribute to reduction in bone formation, bone mineral fractures due to osteoporosis than the average population, as well as a 40% increase in hip fractures, as well as loss of height and periodontal bone loss (loss of bone around the teeth in the jaw and skull).

Objectives. This study aims to identify the risk of fractures of osteoporosis in patients with RA with a prolonged treatement with corticosteroids. On the other hand we will evaluate how Osteoporosis has changed under treatment with Alendromat.

Methods. The study included 68 cases presented at the Rheumatology ward, QSUT and Trauma Hospital Tirana,Albania who had been under systematic treatment with AIJS for some time and have developed fractures due to Osteoporosis. Cases has been taken from patient with AR witch have developed fractures due to Osteoporosis.

Results. In the sample taken in the study, it was found 82 % (56) of the patients with AR developed Osteoporosis.It is known that the usage for a prolonged time of AIJS increase the risk of these condition. From this, 89% (61) patients have developed fractures due to Osteoporosis.52% (30) patients have fracture of bachin, 32% (18) patients developed fracture of toracal colon, 28% (16) patients fracture of femur.

After the treatment with bisphosphonate (Alendronat) for more than 3 years it was seen that there was a significant improvement in the reduction of fractures. We have a reduction in the number of cases with fractures over 68% (38) patients of the cases that had developed at least one such before.At the same time in these patientis DEXA showed noticeable improvements.

Conclusions Loss of bone mineral density occurs naturally with the normal aging process. Rheumatoid arthritis and its treatment with corticosteroids can increase an individual’s chance of developing a low bone mineral state such as osteopenia or osteoporosis.

Screening tests to identify poor bone mineralization are important along with treatment with Alendronat. Conservative measures such as diet, supplements, exercises and fall prevention are all important to include in a bone-healthy lifestyle. We have a reduction in the number of cases with fractures over 68% (38) patients of the cases that had developed at least one before.

CASE REPORT ON THE MANAGEMENT OF OSTEOPOROSIS IN A 24-YEAR-OLD PATIENT WITH CELIAC DISEASE

V. Duraj[1], J. Isaku[2], J. Hankollari[3]

[1]Mother Teresa University Hospital, Tirana, Albania, [2]University of Medicine, Faculty of Technical Medical Sciences, Lecturer, Tirana, Albania, [3]Vora Health Center, Tirana district, Tirana, Albania

Introduction

Osteoporosis is a generalized skeletal desease characterized by low bone density and alterations in bone microarchitecture. There are many barriers to optimal management of osteoporosis in younger adults, further enhanced by a limited research focus on this cohort. Current definitions and recomandations are focused in the evaluation of the desease in young ages.

Presentation of case

A 24 years olf female patient come to our department with hip pain on the left side.She refered that this pain has started since 8 months ago and continued increasing in frequence since nou that a fracture is present. Tha patient refers that suffer from celiac desease.

Objectives. This study aims to identify the risk of fractures of osteoporosis in patients with Celiac desease . On the other hand we will evaluate how Osteoporosis can be treated in young ages.

Materials and methods

The study included a 24 years old female who presented to the rheumatology department, QSUT and Trauma Hospital Tirana,Albania with fragile fracture in pelvis. For this study our patient underwent a series of examinations such as radiography of the fractured bone, BMD of Z- score or T-score. On the other hand based on the primary desease were evaluated the nivel of D vitamin, Calcium, Magnes etc.

Results:

Untreated celiac disease is associated with increased fracture risk by up to 43% and abnormal bone microarchitecture.Malabsorption secondary to celiac disease also causes vitamin D deficiency. Although a gluten-free diet, and vitamin D and calcium supplementation improve bone microarchitecture, complete restoration was not observed.

1. Fragility fracture in the setting of chronic disease/medication exposure.
2. The role of BMD in the diagnosis of osteoporosis in YA with fractures in the absence of clinical risk factors is unclear. Given previously described evidence to support the presence of microarchitectural abnormalities in YAs with fragility fracture and varying aBMD (with average aBMD *Z*-scores >−2.0 at the spine and hip) in the absence of clinical risk factors, consideration of fragility fracture alone as a diagnostic criterion for osteoporosis in young ages is relevant.

Treatment: Vitamin D supplementation; Increased dietary calcium to1000 mg/daily;Smoking cessation; Individualised therapy based on underlying cronic desease (Celiac desease).

Conclusions Osteoporosis is a generalized skeletal desease characterized by low bone density and alterations in bone microarchitecture . Loss of bone mineral density occurs naturally with the primary celiac desease. Screening tests to identify poor bone mineralization are important along the malabsorbing minerals caused by Celiacy. Conservative measures such as diet, supplements, exercises and fall prevention are all important to include in a bone-healthy lifestyle.

Key words: *Celiac desease, Osteoprosis, Fracture, young age, healthy lifestyle, prevention.*

GENETIC FACTORS ASSOCIATED WITH SARCOPENIA AND FRAILTY IN THE LITHUANIAN ELDERLY

V. Gineviciene[1], K. Gutauskaitė[1], A. Urnikyte[1], E. Pranckeviciene[1], R. Dadeliene[1], J. Kilaite[1], I. E. Jamontaite[1], A. Mastaviciūte[1], I. I. Ahmetov[2], V. Alekna[1]

[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [2]Liverpool John Moores University, Liverpool, United Kingdom, Liverpool, United Kingdom

Objective: to evaluate and identify genetic factors associated with sarcopenia and frailty in the elderly using a large-scale whole genome association analysis.

Material and Methods. A total of 192 Lithuanian older adults (42 men, 150 women, aged 82.2±7.6 years) participated in the study: 57 individuals with sarcopenia and/or frailty (17 men, 40 women, aged 85.3±6.7 years), and 135 healthy controls without sarcopenia or frailty (25 men, 110 women, aged 80.2±7.5 years). Phenotypic data were collected via the questionnaires, scales, and testing of physiological characteristics. Sarcopenia measured according to the "European Working Group on Sarcopenia in Older People", and frailty determined by Fried's criteria. Select phenotypes (lean body mass, walking pace and grip strength) were used for genome-wide association study (GWAS). DNA was isolated from peripheral blood leukocytes. Infinium Global Screening Array24 v3.0 Kit was employed to genotype 700,000 single nucleotide polymorphisms (SNPs) for each participant. Data quality control was performed using *GenomeStudio* software tools. SNPs were included in the analysis, with a genome-wide significance threshold set at <5×10-8 and a suggestive significance threshold set at 1.0×10−5. GWAS was performed using the PLINK v.1.07 tool.

Results: The results of GWAS showed no statistically significant association of SNPs with sarcopenia and frailty status. Two SNPs rs75652203 (regulatory region variant) and rs17102732 (intergenic variant) were found to be statistically significantly associated with grip strength (p values 8.134e-12 and 3.373e-09, respectively; p values after Bonferroni correction 1.416e-06 and 0.000587 respectively). In addition, 4 suggestive SNPs (*ACACA* intronic rs3744589 variant, *RN7SL509P* gene rs850577 upstream variant, intergenic variant rs10043030 and regulatory region variant rs8066532) were associated with grip strength, and 2 suggestive intergenic variants rs60001950 and rs10903128 with walking pace.

Conclusion: We found significant association of two SNPs

(rs75652203, rs17102732) with grip strength in patients with sarcopenia and/or frailty. Additionally, four SNPs showed suggestive association with grip strength, and two SNPs with walking pace. These findings highlight specific genetic loci that may contribute to key functional components of sarcopenia and frailty, warranting further investigation to clarify their biological roles.

This project has received funding from the Research Council of Lithuania (LMTLT), agreement No S-MIP-22-36.

TELOMERE LENGTH SHORTENING IN ELDERLY WITH SARCOPENIA AND FRAILTY

L. Jurkūnaitė[1], V. Ginevičienė[1], E. Pranckevičienė[1], A. Urnikytė[1], R. Dadelienė[1], J. Kilaitė[1], I. E. Jamontaitė[1], A. Mastavičiūtė[1], I. I. Ahmetov[1], A. Alekna[1]

[1]Vilnius University, Vilnius, Lithuania

Objective: to investigate the properties of leukocyte telomere length in older adults with sarcopenia and frailty.

Material and Methods. 197 elderly participants (43 male and 153 female, average age of 82.2±7.6 years) were included in this study: 121 individuals with sarcopenia and/or frailty (26 male and 95 females, aged 85.3±6.7 years) and 75 healthy socially active older adults (17 male and 58 female, average age of 80.2±7.5 years) without sarcopenia and/or frailty. Phenotypic data were collected via questionnaires, scales, and testing of physiological characteristics. Sarcopenia was measured according to the European Working Group on Sarcopenia in Older People (EWGSOP), and frailty was determined by Fried's criteria. Leucocyte relative telomere length (LrTL) was determined by real-time quantitative polymerase chain reaction on DNA extracted from blood samples (using *PureLink™ Genomic DNA Mini Kit)* and quantified as the telomere/single-copy gene (T/S) ratio. Statistical analysis was performed in R Studio version 4.3.1.

Results. We found that the average LrTL for older adults participating in this study was 0,40±0,26 T/S units. Individuals with sarcopenia and frailty had shorter LrTL (0.30 [95% CI 0.27–0.34]) than the healthy older adults (0.479 [95% CI 0.43–0.53]; p<0.001). Elderly participants with LrTL below the average had higher odds of having sarcopenia and/or frailty compared to those with LrTL above the average (OR = 4.51; 95% CI 2.22–9.18). A significant negative correlation was observed between LrTL and the age of older adults (r = −0.45, p<0.001). No significant differences in LrTL were found between genders.

Conclusions. Shorter telomeres correlate with older age as well as frailty and sarcopenia. Older adults with shorter telomeres have a 4.5 higher odds of sarcopenia and/or frailty. Our findings provide evidence for an additional determinant of sarcopenia and frailty.

This project has received funding from the Research Council of Lithuania (LMTLT), agreement No S-MIP-22-36.

Keywords. Sarcopenia, frailty, telomere length

P1476

FEATURES OF ASSESSING THE RISK OF FRACTURES IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES AND SEVERE METABOLIC DISORDERS

L. Ametova[1], I. Bykovskiy[1], A. Useinova[1], V. Kaliberdenko[1], E. Kulieva[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Osteoporosis (OP) and increased fracture risk are common comorbidities in chronic inflammatory rheumatic diseases. Bone loss and increased bone fragility are characterized by a high prevalence among patients with rheumatoid arthritis (RA) and conflicting data in patients with psoriatic arthritis (PsA). However, OP, along with other comorbidities (cardiorenal disorders, metabolic syndrome, obesity, infections, depression, etc.), can affect both clinical outcomes and management tactics in such patients. Objective: to study the features of osteoporosis-associated fracture risk assessment in patients with RA and PsA with concomitant metabolic disorders.Materials and methods. A total of 46 patients with RA according to the ACR/EULAR criteria (2010) aged 40 to 76 years (mean age 56.7±8.85 years, women – 80.4%) and 43 patients with PsA according to the CASPAR criteria (2006) aged 45 to 75 years (mean age 58.0±8.1 years, women – 67.4%) were examined. The presence of metabolic syndrome (MS) in patients was diagnosed according to the criteria of the National Cholesterol Education Program / Adult Treatment Panel III (NCEP/ATPIII; 2004). The harmonized NCEP/ATPIII criteria included: (1) an increase in waist circumference ≥ 102 cm for men and ≥ 88 cm for women; (2) fasting glucose ≥ 6.1 mmol/L or drug treatment for elevated glucose; (3) triglyceride (TG) ≥ 1.7 mmol/L; (4) high-density lipoprotein (HDL) less than < 1.0 mmol/L in men or < 1.3 mmol in women; (5) BP ≥130/85 mmHg or history of antihypertensive treatment. In accordance with these indicators, all study participants were assigned a binary assessment of MS ("yes/no") and a categorical assessment of MS was calculated for all available criteria (from 0 to 5).

Results and discussion. Signs of MS were detected in 22 patients with RA (47.8%) and 19 patients with PsA (44.2%). Of all the criteria for MS, the most common in both RA and PsA patients was an increase in waist circumference (10 people, 45.5% and 8 people, 42.1%, respectively), which is an important tool in assessing visceral adipose tissue. It is noteworthy that the structure of the categorical assessment of MS in patients with RA and PsA was almost identical (the presence of 3 categorical signs in 54.5% (in 12/ of 22) and 52.6% (in 10/ of 19), 4 signs in 41% (9/22) and 36.9% (7/19) and all 5 signs in 4.5% (1/22) and 10.5% (2/19) of cases, respectively). The prevalence of OP according to the data provided by patients during the initial examination in RA significantly exceeded the indicators of PsA patients (36.6% and 14%, respectively, p<0.001). When interviewing patients, it was found that 95.6% of RA patients had previously (at an outpatient appointment, in a hospital setting) calculated the FRAX index, and in 74% of cases, patients had undergone osteodensitometry. Among PsA patients, such measures were carried out significantly less

frequently (32.6% and 20.9%, respectively). Given the ambiguous data on the state of mineral density and the level of bone metabolism, as well as contradictory data on the frequency and risk of fractures in patients with PsA, we calculated the 10-year probability of fracture in the entire cohort of PsA patients included in the study. When calculating the FRAX index, only clinical risk factors were used, since bone mineral density (BMD) had not previously been studied in a significant number of patients, and some patients were unable to provide the necessary information. When processing the obtained data, a moderate association was found between a high risk of fractures (10-year probability according to FRAX) and the presence of metabolic syndrome in patients with PsA (association coefficient φ = 0.37). When comparing age- and gender-matched groups of PsA patients with MS (group I) and without it (group II), statistically significant differences were observed in the 10-year probability of an overall fracture (9.8 [6.9; 15.0]% compared with 7.4 [6.3; 9.2]%; M-W U test, p = 0.029), but not a hip fracture (0.9 [0.4; 2.1]% compared with 0.6 [0.4; 1.0]%; M-W U test, p = 0.105). The number of PsA patients with a high fracture risk (≥16%, which corresponded to the table intervention threshold for the age of 58 years) statistically significantly prevailed in the group of patients with signs of MS (Chi-square with Yates correction=4.01, p=0.045). Fracture risk assessment using the FRAX tool, even without osteodensitometry data, identified 7 (16.3%) patients with PsA (including 6 people with MS) who deserved anti-osteoporotic treatment. All patients in this group (n=7) underwent DEXA at the Zborovsky Research Institute of Cardiovascular and Radiology. When processing the obtained results, four people had T-criterion indicators that corresponded to osteopenia (from -1 to -2.4 SD), and three people had osteoporosis (< -2.5 SD). Thus, the results of the study show that in patients with PsA, in addition to the previously described predictors of the 10-year probability of fractures (such as age, BMD, disease activity), the presence of MS and the severity of metabolic disorders can also be risk factors. Conclusions. The use of the FRAX index as a tool for assessing the risk of fractures is easily applicable and should be widely used not only in the population of patients with RA, but also in patients with PsA, especially in the presence of severe metabolic disorders, for earlier identification of patients with potentially low BMD and timely drug prevention of fractures associated with osteoporosis.

P1477

ADDITIONAL EXAMINATION OF THE FOREARM IN THE TARGET GROUP OF POSTMENOPAUSAL WOMEN INCREASES THE DETECTION OF OSTEOPOROSIS

Y. Polyakova[1], V. Katasonova[2], D. Dragunova[2], Y. Kropocheva[2]

[1]Research institute of clinical and experimental rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Volgograd State Medical University, Volgograd, Russia

A bone mineral density (BMD) examination of the forearm according to currently approved guidelines is performed when other skeletal areas are inaccessible, when the patient's weight exceeds the limitations of the device, and to obtain data on the cortical bone (in hyperparathyroidism).
In older patients, the loss of BMD in standard areas may be offset by concomitant diseases of the spine, osteoarthritis of the hip joint, and calcification of the abdominal aorta.
It is also known that patients with osteoporosis (OP) have a higher prevalence of spinal deformities than people without OP. The study was performed on a Stratos dR X-ray densitometer in 2024 using the Eurasian normative curve from DMS normality curves, 2003/2004.
A total of 258 BMD studies of female patients (age (M ± σ) 66 ± 0.567) with a scan of the forearm were analyzed.
The norm for 1/3 of the radius (TR1/3) was detected in 61 (23.6%) patients.
Low bone mass (LBM) - in 82 (31.8%), of which 48 (58.5%) had normal spine and 13 (15.9%) had normal proximal femur.
OP - in 115 (44.6%), of which 56 (48.7%) had normal spine and 6 (5.2%) had normal proximal femur.

Table 1. BMD values of the Femoral Neck, Total Hip and Radius in patients with normal lumbar spine density values.

Parameter	N 56 (48,7%)	N 48 (58,5%)	Reliability (p)
Age	70 [63;76]	65,5 [57;70]	0,003
TL1-L4, CO, Me [Q25; Q75]	0,2 [-0,3;+0,7]	0,5 [-0,4;+1,3]	0,26
Femoral Neck	-1,5 [-1,9;-1,2]	-1,3 [-1,7;-0,5]	0,022
Total Hip	-1,1 [-1,6;-0,6]	-0,6 [-1,3;0]	0,019
1/3 Radius	-3,7 [-4,5;-3,0]	-1,6 [-1,9;-1,4]	0,0000

*Differences were considered statistically significant at p<0.05.
The study of the p-ka was not performed in 20 (3.5%) patients due to the presence of metal structures in more than 2 vertebrae of the studied range.
The results of the study show that very low BMD in 1/3 of the radius was detected mainly in patients over 70 years old.
Additional examination of the forearm in postmenopausal women increases the detection of OP with normal and reduced BMD determined by standard zones.

P1478

VITAMIN D LEVELS IN PATIENTS WITH POSTMENOPAUSAL OSTEOPOROSIS: A PILOT STUDY

V. Koevska[1], B. Mitrevska[1], C. Gjerakaroska-Savevska[1], M. Gocevska[1], B. Kalcovska[1], M. Manoleva[1], D. Gecevska[1], A. Krsteska[1]

[1]University "St. Cyril and Methodius", Skopje, Republic of North Macedonia, Skopje, Republic of North Macedonia

Introduction: Determining the level of vitamin D in patients with Postmenopausal Osteoporosis (PMOP) is important for two reasons. First, vitamin D deficiency reduces calcium resorption from the gastrointestinal tract and second, vitamin D deficiency increases the risk of fracture.

Objective: To show the level of vitamin D in patients with PMOP in relation to age.
Material and method: The study included 90 patients who were diagnosed and treated at the University Clinic for Physical Medicine and Rehabilitation. The level of vitamin D was determined by measuring 1.25 (UN) vitamin D in serum by electrochemiluminescence. The value ≥30ng/ml is considered normal, the value between 10 and 30ng/ml for insufficiency and the value ≤10ng/ml for very low.
Results: Patients had a mean age of 60.64 ± 6.7 years. The largest number, or percentage of patients, were aged 60 to 69 years - 53 (57.61%). The mean serum vitamin D level in the age group 40-49 years was 22.47 ± 9.9, 50-59 years 13.61 ± 6.5, 60-69 years 20.37 ± 8.7, 70-75 years 16.31 ± 7.2. Vitamin D levels were non-significantly lowest in the 50-59 year old group compared to the other age groups (13.61 ± 6.5µg) (p=0.16). Serum vitamin D levels were low regardless of age group of PMOP patients.
Conclusion: Mean serum vitamin D levels did not differ significantly between age groups of PMOP patients. Vitamin D should be recommended for all PMOP patients regardless of age group.

Keywords: vitamin D, Postmenopausal Osteoporosis

ADHERENCE TO OSTEOPOROSIS THERAPY AMONG RURAL WOMEN AGED 50+: THE IMPACT OF PRIOR FRACTURES AND COMORBIDITY

V. Kondakova[1], A. Zakroyeva[2]

[1]Nevyanskaya CRH, Nevyansk, Russia, [2]Ural State Medical University, Ekaterinburg, Russia

Objective. This study aimed to assess adherence to anti-osteoporotic therapy among rural women aged 50 years and older and to determine the influence of prior low-energy fractures and comorbidity on treatment adherence.
Materials and Methods. From 2021 to 2022, a health assessment was conducted among all women aged ≥50 years (n=576) registered at a rural healthcare unit (Kalinovo village, Sverdlovsk region). Among these women, 113 (21.2%) had a confirmed diagnosis of OP and were prescribed therapy in accordance with national clinical guidelines. Adherence was evaluated at 12 months (via telephone survey) and again at 18 months (during an in-person follow-up visit). Comorbidity was assessed using the Charlson Comorbidity Index.
Results. Overall adherence to bisphosphonate therapy after one year was 44%. Among patients with a history of fractures, 51.22% adhered to the prescribed regimen, compared to only 8.33% of those without a fracture history (OR=11.55, p=0.00043). The mean age did not differ significantly between groups (68.6±11.3 years in the fracture group vs. 71.7±9.1 years in the non-fracture group; p=0.161). The Charlson Comorbidity Index was significantly higher in the group without a history of fractures (p=0.028), possibly reflecting a greater burden of chronic conditions and polypharmacy.
Conclusions. Adherence to anti-osteoporotic therapy in rural women aged 50 years and older remains low (44%). A previous low-energy fracture is a key predictor of higher adherence (51.22% vs. 8.33%), whereas women without fractures, who typically have a higher comorbidity burden, show poorer adherence. Personalized and comprehensive strategies, taking into account the risks associated with polypharmacy and adverse effects, are crucial to improving treatment outcomes in this patient population.

P1480

THE POTENTIAL OF CORNELIAN CHERRY IN SUPPORTING THE TREATMENT OF BONE-RELATED DISEASES THROUGH MODULATION OF OSTEOBLAST GENE EXPRESSION

V. Kovacova[1], V. Mondockova[1], R. Biro[1], N. Penzes[1], S. Budzak[2], J. Blahova[1], M. Capcarova[3], M. Martiniakova[1], R. Omelka[1]

[1]Constantine the Philosopher University in Nitra, Nitra, Slovakia, [2]Matej Bel University in Banska Bystrica, Banska Bystrica, Slovakia, [3]Slovak University of Agriculture in Nitra, Nitra, Slovakia

Objective: Cornelian cherry (Cornus mas, CC), known for its antioxidant and anti-inflammatory properties, has been studied for its potential effects on bone health, in conditions such as diabetic bone disease and osteoporosis. Despite promising findings, the mechanisms behind these effects remain unclear. This in vitro study aimed to examine the effects of CC extract on the expression of genes associated with bone structure, metabolism, and development using cultured osteoblasts.
Material and Methods: The extract of CC pulps was prepared via methanol extraction, filtration, and evaporation, then dissolved in cell culture medium and administered to rat primary osteoblasts at concentrations of 0, 10, 100, and 200 µg/ml (C0, C10, C100, and C200, respectively). After 72 hours, mRNA was isolated, cDNA was synthesised and the expression of 15 target genes (RUNX2, BMP2, BMP7, TGFB1, TGFBR1, BGLAP, ALPL, SPP1, VDR, COL1A1, IBSP, CDH11, VEGFA, TNFSF11, TNFRSF11B) was analysed using real-time PCR.
Results: The CC extract upregulated the expression of RUNX2, BMP7, TGFBR1, BGLAP, ALPL, CDH11, and VEGFA genes in all groups. In addition, CC treatment resulted in a dose-dependent increase in the expression of certain genes: TGFB1 in group C10, VDR in groups C10 and C100, BMP2 and IBSP in groups C100 and C200, and TNFRSF11B in group C200. Conversely, significant downregulation was observed for SPP1 in all groups and for TNFSF11 in groups C100 and C200.
Conclusion: These findings suggest that CC extract promotes osteoblast differentiation, bone mineralisation, and osteogenesis while inhibiting bone resorption. The results point to the potential of CC in supporting the treatment of bone-related diseases.
Acknowledgments: This study was supported by the grant KEGA 012UKF-4/2023. Funded by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I03-03-V02-00038.

P1481

OSTEOPOROSIS IN PATIENT WITH MULTIPLE ENDOCRINE NEOPLASIA

V. Labashova[1], Y. Dydyshka[1], V. Vadzjanava[1], N. Vasilyeva[1]

[1]Belarusian State Medical University, Minsk, Belarus

Objective: An important part of diagnostic and treatment of osteoporosis is the exclusion of secondary forms resulting from various pathological conditions and diseases. Multiple endocrine neoplasia type 1 (MEN 1) is an autosomal-dominant disease. Primary hyperparathyroidism (PHPT) is often associated with MEN 1 and often had a recurrent course, despite successful parathyroidectomy. Osteoporosis is considered a complication and an indication for parathyroidectomy.
Case report: 50 years old female had a complain on lumbar bone pain. She was operated earlier for insulinoma and received oral hypoglycemic therapy. The patient had a history of right nephrectomy for urolithiasis. On admittion DXA showed L1-4 T-score=-2,9 SD. During the examination ultrasound showed pathological zone near the left lobe of thyroid gland (parathyroid gland?) Later laboratory investigations confirmed primary hyperparathyroidism: parathormone (PTH) 184 pg/ml (15-65). Subtotal parathyroidectomy was performed. In the postoperative period PTH became normal range 39.5pg/ml (15-65), but 2 years later increase in PTH 82 (15-65) and serum calcium 2.59 mmol/l (2.2-2.55) was revealed again. Creatinine was 108.9 umol/l, GFR 53 ml/min/1.73 m2 HbA1c 6.61%. Scintigraphy was performed and a parathyroid adenoma near the right lobe of thzroid gland was detected. Right parathyroidectomy was performed. All the time the patient was treated with bisphosphonates. DXA showed increase in BMD; L1-4 T-score improved to 0.3 SD, total hip – 0.6, -0.7 SD.
Conclusion: In this case parathyroidectomy improves bone mineral density in patient with primary hyperparathyroidism in the setting of MEN 1.

P1482

THE IMPACT OF DAILY CALCIUM CONSUMPTION ON OSTEOPOROSIS-RELATED FACTORS IN SLOVAK POSTMENOPAUSAL WOMEN

V. Mondockova[1], V. Kovacova[1], N. Penzes[1], R. Biro[1], D. Galbavy[2], M. Martiniakova[1], R. Omelka[1]

[1]Constantine the Philosopher University in Nitra, Nitra, Slovakia, [2]Private Orthopedic Ambulance, Nitra, Slovakia

Objectives: Calcium (Ca) is essential for maintaining bone health, growth, and strength, as well as fracture healing. The International Osteoporosis Foundation (IOF) and the World Health Organization (WHO) have recommended a daily intake of 1,200 mg of calcium for postmenopausal women. However, the observed intake frequently falls short of this recommendation. This study aimed to evaluate daily Ca intake in a sample of 352 Slovak postmenopausal women and analyse the relationship between dietary Ca intake and variations in femoral (FBMD) and lumbar spine bone mineral density (LBMD), alkaline phosphatase (ALP), osteocalcin (OC), and beta-CrossLaps (CTx).
Material and Methods: Dietary Ca intake was assessed using a validated questionnaire. The women were divided into three groups based on their daily Ca intake: A (≤250 mg; N=87), B (250-750 mg; N=198), and C (>750 mg, N=67). The association between Ca intake and BMD, as well as markers of bone turnover, was analysed using analysis of covariance.
Results: The average daily calcium intake among Slovak postmenopausal women was determined to be 485 mg/day, with no individual reporting an intake exceeding 1,000 mg. Furthermore, our study revealed no significant associations between calcium intake groups and osteoporosis-related parameters (FBMD, LBMD, ALP, OC, CTx). These findings suggest that changes in calcium intake among women consuming less than 1,000 mg daily do not significantly affect their risk of developing osteoporosis.
Conclusion: While studies suggest that increasing calcium intake from dietary sources or supplements can modestly boost bone density, this effect is often temporary. Ensuring adequate calcium, vitamin D, and a balanced diet is crucial for maintaining overall bone health

AGE-RELATED FEATURES IN THE TREATMENT OF SUBACROMIAL IMPINGEMENT SYNDROME

V. Nesterenko[1], A. Karateev[1], M. Makarov[1], E. Bialik[1], S. Makarov[1], V. Bialik[1], A. Roskidaylo[1], A. Chramov[1], E. Naryshkin[1], S. Maglevanniy[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Москва, Russia

Periarticular administration of platelet-rich blood plasma (PRP) and hyaluronic acid (HA) is widely used in acute joint injuries. However, the effectiveness of these drugs in patients of different ages has not been sufficiently studied.
Objective: To evaluate the effectiveness of PRP and HA in patients with subacromial impingement syndrome, depending on age and individual characteristics. Materials and methods: The study involved 100 patients, 54% of them men and 46% women, with an average age of 51.5±15.1 years, with a duration of subacromial impingement syndrome of more than 3 months. Patients under 45 years of age accounted for 34%, over 45 years of age – 66%. After the examination, all patients were randomized into 2 groups. Group 1 received 3 subacromial injections of PRP with an interval of 7 days each, Group 2 received 2 subacromial injections of HA with an interval of 7 days each. Pain dynamics were assessed using a 100-millimeter visual analog scale (VAS), functional disorders according to the American Shoulder and Elbow Joint Surgeons Assessment Scale and the CSS (Constant Shoulder Score) scale, as well as a decrease in the need for nonsteroidal anti-inflammatory drugs (NSAIDs) 6 months after the course of therapy.
Results: The dynamics of pain and function in the treatment of PRP and HA did not differ. Pain decreased from 56.0±14.6 to

31.8±26.3 and from 57.6±17.8 to 30.2±26.3 (p=0.768), AS increased from 54.8±13.8 to 74.6±22.4 and from 54.7±15.1 to 77.3±22.5 (p=0.552), CS from 59.2±14.4 to 66.9±17.4 and from 47.8±16.9 to 65.6±19.3 (p=0.245). However, in the treatment of PRP and HA, the dynamics of pain and function were significantly better in patients younger than 45 years than in patients older than 45 years. The VAS pain level after 6 months was 22.4±26.3 and 35.5±26.2 (p=0.022), ACC 83.3±20.9 and 72.1±22.6 (p=0.017), CS 76.2±16.1 and 63.2±18.2 (p=0.001). During follow-up, 82.4% and 65.2% of patients (p=0.103) did not need to take NSAIDs. No serious adverse reactions were observed. The following factors did not affect the treatment: the initial pain level, the number of affected tendons, gender, body mass index (BMI).
Conclusions: The effectiveness of PRP and HA in subacromial impingement syndrome does not differ. The clinical response to both drugs was higher in those under 45 years of age.

P1484

THE ROLE OF ORTHOTICS IN OSTEOARTHRITIS AND VARUS DEFORMITY OF THE KNEE JOINT

V. Nesterenko[1], A. Karateev[1], M. Makarov[1], E. Bialik[1], S. Makarov[1], S. Arhipov[1], V. Bialik[1], I. Kushnareva[1], A. Dybunin[1], E. Naryshkin[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Москва, Russia

Orthosis is one of the widely used methods of conservative treatment of osteoarthritis (OA) of the knee joint (CS). However, there is relatively little data in the literature on the use of functional, unloading (varus-valgus) orthoses.
The purpose of the study: to evaluate the effectiveness and safety of using a functional, unloading (varus-valgus) orthosis in patients with OA 3st and varus deformity of the knee joint.
Material and methods: The study involved 15 patients with OA 3st and varus deformity of the CS, confirmed by X-ray examination under stress (30.0% of men and 70.0% of women, average age 64.5±8.9 years, BMI 30±3.4). The inclusion criteria were: Osteoarthritis of the knee joint stage III according to Kellgren-Lawrence, established according to clinical and X-ray examination, age from 45 to 85 years, pain range ≥40mm. All patients used a functional, unloading (varus-valgus) orthosis for 3 months. The orthosis was adjusted four times every 7 days for 4 weeks.
Result: When using an orthosis, 12 patients noted a significant decrease in pain intensity, but the dynamics of functional parameters was minimal. The average pain and function indicators among all patients participating in the study were: VAS initially 49.0±11.3, in the first hour of use 27.0±13.9, after 1 month. 18.0±9.7, after 3 months. 15.0±8.5. KOOS initially, after 1 and 3 months 48±10.3, 56.7±10.6, 60.0±10.6. No adverse reactions were observed against the background of the use of a functional, unloading (varus-valgus) orthosis.
Conclusions: The relief (varus-valgus) orthosis significantly reduces the intensity of pain starting from the first hours of its use and maintains positive dynamics throughout the wearing of the orthosis, however, it does not significantly affect the function of the joint.

P1485

THE VALUE OF HIGH MOLECULAR WEIGHT HYALURONIC ACID IN POST-TRAUMATIC OSTEOARTHRITIS OF THE KNEE JOINT

V. Nesterenko[1], A. Karateev[1], M. Makarov[1], E. Bialik[1], S. Makarov[1], V. Bialik[1], A. Roskidaylo[1], E. Naryshkin[1], A. Chramov[1], I. Kushnareva[1], S. Maglevanniy[1], A. Dybunin[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Москва, Russia

The incidence of osteoarthritis (OA) of the knee joint (CS) in the world is constantly growing, this is due to many factors, including joint injuries. Intra-articular injections of high-molecular hyaluronic acid are one of the means of helping patients with stage 3 OA. However, there is little data in the literature on the effectiveness of high molecular weight hyaluronic acid with chondroitin sulfate, depending on the frequency of administration.
The purpose of the study: to evaluate the effectiveness of single or double administration of high molecular hyaluronic acid with chondroitin sulfate in post-traumatic osteoarthritis of the knee joint
Materials and methods: The treatment of 61 patients with stage 3 post-traumatic osteoarthritis of the knee joint was evaluated. All patients underwent intra-articular administration of high molecular weight hyaluronic acid with chondroitin sulfate, 36 patients received a single injection and 25 received a double injection with an interval of 7 days. To evaluate the results, the pain intensity was determined on a visual analog scale (VAS) and the total score on a numerical rating scale (NRS) before the start of treatment, after 1, 3, 6 and 12 months. after a course of intra-articular injections of hyaluronic acid by telephone survey.
Results: In all patients, pain at rest at baseline, after 2 weeks, 1, 3, 6, 12 months was 2,7±3,1, 1,5±2,6, 1,8±2,6, 2,1±2,6, 2,2±1,8, 2,6±1,3 cm (VAS). Pain when moving 6,7±3,1, 4,0±3,2, 4,3±3,1, 4,6±2,8, 4,5±2,5, 5,3±1,4 cm VAS. The function indicators at baseline, after 2 weeks, 1, 3, 6, 12 months were 4,9±3,6, 3,5±2,9, 4,2±2,9, 4,0±3,2, 3,5±2,7, 4,3±1,9 according to the NRS. In the first group, there are similar indicators: pain at rest 2,7±3,1, 1,5±2,6, 1,8±2,6, 2,1±2,6, 2,2±1,8, 2,6±1,3 cm VAS. Pain when moving 6,7±3,1, 4,0±3,2, 4,3±3,1, 4,6±2,8, 4,5±2,5, 5,3±1,4 cm VAS. Function 4,9±3,6, 3,5±2,9, 4,0±2,9, 4,0±3,2, 3,5±2,7, 4,3±1,9 according to the NRS. In the second group, pain at rest initially, after 2 weeks, 1, 3, 6, 12 months 2,6±2,4, 1,9±1,7, 1,8±1,6, 1,8±1,7, 1,5±2,2, 0,6±1,0 cm VAS. Pain when moving 5,6±2,1, 3,3±1,7, 3,6±1,8, 3,4±1,6, 3,7±2,4,3,0±1,2 cm VAS. Function 4,0±3,1, 3,3±2,6, 3,6±2,7, 3,4±2,6, 3,3±3,1, 2,6±1,7 according to the NRS.
Conclusions: Double administration of high molecular weight hyaluronic acid with chondroitin sulfate with an interval of 7 days has a higher effectiveness in reducing pain and increasing function.

P1486

WHAT IS THE EFFECTIVENESS OF LOW MOLECULAR WEIGHT HYALURONIC ACID IN PERIARTICULAR DISEASES OF VARIOUS LOCALIZATION?

V. Nesterenko[1], A. Karateev[1], M. Makarov[1], E. Bialik[1], S. Makarov[1], V. Bialik[1], S. Arhipov[1], A. Roskidaylo[1], A. Chramov[1], E. Naryshkin[1], I. Kushnareva[1], S. Maglevanniy[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Москва, Russia

Pathologies of the periarticular tissues, which include tendinitis, enthesitis, tendovaginitis, bursitis, fasciitis, are a common cause of musculoskeletal pain. Treatment is based on the combined use of nonsteroidal anti-inflammatory drugs, physiotherapy, rehabilitation, and local injection therapy, including the administration of hyaluronic acid (HA). However, there is relatively little data on the evaluation of the effectiveness of HA in these pathologies.

The purpose of the study: to evaluate the efficacy and safety of HA 500-730 kDa in patients with various lesions of periarticular tissues.

Materials and methods: The study involved 30 patients with various lesions of the periarticular tissues (subacromial impingement syndrome (SIS), lateral/medial epicondylitis, plantar fasciitis), 10 people with each pathology. Of these, 60.0% were women and 40.0% were men, with an average age of 56.1±14.9 years. All patients underwent a course of periarticular injections using low molecular weight Ha 500-730 kDa into the pericondinal region. All patients received 3 injections of HA with an interval of 7 days. The inclusion criteria were: Age over 18 years, significant periarticular pathology of SIS, lateral/medial epicondylitis, plantar fasciitis, moderate or severe pain above 40 mm on a visually analog pain scale (VAS), insufficient effect from the use of glucocorticoids. The result of therapy was assessed after 1 and 3 months according to the outpatient examination. The study was approved by the local ethics committee.

Results: During treatment, the pain and function indicators were as follows: at baseline, after 1 and 3 months. 57,5±15,8, 37,5±13,8, 33,7± 14,0, VAS initial, after 1 and 3 months. 54,2±13,7, 64,5±10,3, 65,5±9,8. With lateral epicondylitis, VAS baseline is after 1 and 3 months. 54,0 ±13,4, 35,0±9,7, 34,0± 11,0, The Mayo Elbow questionnaire is initial, after 1 and 3 months 72.0 ±11.5, 79.2±9.0, 82.7± 7.7. With plantar fasciitis, VAS baseline is after 1 and 3 months 60,0 ±16,5, 36,6±19,3, 34,4± 15,8. Functional index of the foot initially, after 1 and 3 months Compiled 47,2%±22,8, 39,6%±29,7, 39,0%±29,9. No adverse reactions were observed during the study.

Conclusions: Subcutaneous administration of low molecular weight HA is an effective and safe method of treating periarticular pathology of various localization.

Introduction: Aromatase inhibitors are essential in the treatment of hormone receptor-positive breast cancer patients. In addition to their cancer risk-reducing benefits, they also have some adverse drug reactions, such as accelerating bone loss. One promising approach for therapeutic intervention is the use of intravenous bisphosphonates. Estrogen plays a crucial role in maintaining bone density, and aromatase inhibitors such as anastrozole, letrozole, and exemestane effectively lower estrogen levels and slow the progression of HER2-positive breast cancer patients. The benefits of parenteral administration are undeniable for bisphosphonates, due to their higher bioavailability, lack of gastrointestinal side effects, and lack of Barrett's esophagus, better adherence, and treatment monitoring.

Materials and methods: Patients diagnosed with osteoporosis aged over 45, visited in Rheumatology outpatient . Comparative analysis between three groups of patients:

1st group - 22 postmenopausal women HER2-positive with breast cancer, treated with Zoledronic acid - 5 mg. intravenously every 12 months for 3 years

2nd group - 20 postmenopausal women HER2-positive with breast cancer, treated with Denosumab 60mg subcutaneously every 6 months for 3 years.

3rd group of patients 1st group - 20 postmenopausal women, treated with Zoledronic acid 5 mg. intravenously every 12 months for 3 years

The age of the patients is between 45 and 75 years in all three groups.

The first two groups of patients are treated together with aromatase inhibitors.

The parameters analyzed in all three groups are: BMD and tumor markers.

Results: Tumor markers did not become positive in both groups of patients with breast cancer throughout the entire follow-up period. In the first group - treated with bisphosphonates - at 12 months

the improvement in BMD was (+4.5%), in the second group-+ 4.7%, and in the third with + 4.3%. The results at 24 months were respectively - an improvement in BMD of + 7.2% in the first group, + 6.9% in the second and + 10.2% in the third, and the results at 36 months were as follows: an improvement of 10.3% in the first group, 10.2% in the second and 11.3% in the third (p< 0.001).
Conclusions: The better results in the control group of patients not taking aromatase inhibitors were discussed as a result of the lack of effect of aromatase inhibitor treatment, which affects not only BMD, but also the therapeutic effects of the treatment. There was no significant difference between the two groups of patients - those on intravenous bisphosphonates and those on subcutaneous denosumab. The benefits of intravenous administration of bisphosphonates are: higher bioavailability and the absence of gastrointestinal side effects.
Limitations - a small group of patients.
Keywords: bone mineral density (BMD), human epidermal growth factor receptor 2(HER2) -positive

CHARCOT ARTHROPATHY - A CHALLENGE IN OUR DAILY PRACTICE

V. P. Popova[1], M. G.-P. Geneva-Popova[2], S. P.-B. Popova-Belova[2], R. K. Karalilova[3], Z. B. Batalov[3], K. B. Batalov[3], I. P. Popov[4], R. Y. Ronchev[5], S. V. Valkanov[6]

[1]Department of Propedeutic of Internal Diseases, Faculty of Medicine, Medical University of Plovdiv, University General Hospital "Kaspela", Plovdiv, Bulgaria, Plovdiv, Bulgaria, [2]Department of Propedeutic of Internal Diseases, Faculty of Medicine, Medical University of Plovdiv, Clinic of Rheumatology, University General Hospital "Sveti Georgi", Plovdiv, Bulgaria, [3]Department of Propedeutic of Internal Diseases, Faculty of Medicine, Medical University of Plovdiv, University General Hospital "Kaspela", Plovdiv, Bulgaria, [4]Faculty of Medicine, Medical University of Plovdiv,student, Plovdiv, Bulgaria, [5]Faculty of Medicine, Medical University of Plovdiv, University General Hospital "Kaspela", Plovdiv, Bulgaria, [6]Department of Urology and General Medicine, Medical Faculty, Medical University of Plovdiv, Plovdiv, Bulgaria

Aim: The International Working Group on the Diabetic Foot (IWGDF) has published evidence-based guidelines on the prevention and management of diabetic foot disease since 1999. This is the first guideline on the diagnosis and treatment of active Charcot neuro-osteoarthropathy. This serious complication in patients with diabetes mellitus manifests itself with a joint syndrome, mainly involving the feet, therefore early diagnosis is of utmost importance in order to avoid disability and amputation of limbs. The most important recommendation in the presence of soft tissue changes with edema and redness of the overlying skin is to perform comparative thermometry and temperature analysis with an infrared thermometer, imaging diagnostics - X-ray screening, and if necessary, MRI, CT and scintigraphic examination in case of negative X-ray results.
Methods: A retrospective analysis of 82 patients with diabetes mellitus (of which 52 women/n=52/ and 30 men/n=30/, aged 48-69 years) has been made. The duration of the diabetic condition with these patients is between 10 and 25 years. 12 patients have been diagnosed with Charcot arthropathy, which occurs after an average of 20 + / -5 years and is linked to poor metabolic control. 8 of the patients are in the acute stage, and the rest are in the chronic stage, with the late manifestation of the arthropathy being striking.
Results: The change in skin temperature was recorded in all 12 patients, in which Charcot arthropathy was diagnosed, while X-ray changes were detected in 8 patients during the screening examination, and MRI was required in the remaining 4. All patients diagnosed with Charcot arthropathy had poor metabolic control and diabetes duration of more than 15 years.
Conclusions: Charcot arthropathy is a serious medical problem, leading to disability and amputation in late diagnosis. That is why its early recognition is essential for prevention of late consequences

PREGNANCY AND LACTATION-ASSOCIATED OSTEOPOROSIS WITH MULTIPLE VERTEBRAL FRACTURES TREATED WITH TERIPARATIDE

M. Hrabar[1], J. Andric[1], J. Jaksic[2], D. Perovic[1], V. Pandzic Jaksic[1]

[1]Dubrava University Hospital, Zagreb, Croatia, [2]University of Zagreb School of Medicine, Zagreb, Croatia

Introduction: Low-trauma fractures in premenopausal women, indicative of osteoporosis, are often driven by secondary causes that require targeted treatment. Pregnancy and lactation-associated osteoporosis (PLO) is a rare condition with an unclear etiology frequently unrelated to known secondary factors. The growing recognition of monogenetic causes highlights the importance of genetic evaluation. PLO imposes severe pain and disability, significantly impairing quality of life during vulnerable periods and complicating future family planning.
Case report: A 32-year-old primipara developed lower back pain without trauma one month before a cesarean delivery. Four days postpartum, she experienced worsening back pain and difficulty walking. A spine X-ray revealed vertebral compression fractures at T11-L3. Bone mineral density (BMD) at L4 (the unaffected lumbar vertebra) showed a Z-score of -4.3; the femoral neck and total hip Z-scores were -1.9 and -1.7, respectively. Her menarche was at 13 years old, and her cycles were regular. Her medical history included only a metatarsal stress fracture at age 25. During adolescence, she had a low body mass index but attained normal weight afterward. There was no history of smoking, alcohol use, oral contraception, or heparin use, and no family history of fragility fractures. She was managed with a thoracolumbar orthosis, vitamin D supplementation, and orthopedic monitoring. Two years later, persistent pain and gait disturbance due to post-traumatic

spinal deformity necessitated elective surgery. Endocrinological reevaluation, including anti-transglutaminase antibodies and homocysteine levels, found no secondary causes again. The patient desired another pregnancy but was fearful of new painful fractures. Two months postoperatively, teriparatide was introduced. Shortly after, she was free of back pain. Teriparatide was continued for two years, during which no new fractures occurred. The patient now plans another pregnancy.
Conclusion: The fracture risk in future pregnancies is significantly elevated in PLO. Evidence suggests that osteoanabolic therapy improves BMD and bone microarchitecture, potentially reducing fracture risk. Furthermore, BMD gains appear to be maintained to some extent, even without subsequent antiresorptive therapy. Teriparatide also seems to be a safer choice for women of childbearing age, avoiding the teratogenic risk associated with antiresorptive treatments. Despite addressing the secondary cause of osteoporosis, skeletal fragility may persist. While PLO is a rare condition, the use of teriparatide for skeletal enhancement may serve as a therapeutic model for treating osteoporotic fractures caused by other secondary factors in women planning pregnancy.

P1490

ASSOCIATIONS BETWEEN SERUM VITAMIN D AND CORTISOL IN PATIENTS WITH TYPE 2 DIABETES MELLITUS DURING ARMED CONFLICT

V. Pankiv[1]

[1]Ukrainian Scientific and Practical Center of Endocrine Surgery, Transplantation of Endocrine Organs and Tissues of the Ministry of Health of Ukraine, Kyiv, Ukraine, Kyiv, Ukraine

Assessment of the role of vitamin D and stress hormones under the influence of a long-term psychotraumatic factor provides information necessary for the prevention of type 2 diabetes mellitus (T2DM) complications. **The aim of the study** was to evaluate the dynamics of vitamin D status and the stress hormone cortisol in patients with T2DM during the full-scale war in Ukraine compared to the pre-war state.
Materials and methods. In 2021–2024, a prospective study was conducted, which included patients with T2DM and a glycated hemoglobin (HbA1c) level ≥ 7 %, individuals with insulin resistance without DM and people without DM aged 19–75 years.
Results. Patients with T2DM have a lower mean level of vitamin D and it decreases during the war, being significantly lower in 2023 and 2024 compared to 2021. When determining the dynamics of serum cortisol in patients without DM in 2024, the following is observed. It was significantly higher than before the war, and in patients with T2DM, it was highest in 2022 with a gradual downward trend in 2023 and a return to an increase of the average level in 2024. When determining the dynamics of serum cortisol, we observe an increase in the average level during the war in patients without DM, and an increase in the average level during the war with a peak in 2023 in patients with insulin resistance without DM. In patients with T2DM, there is an increase in cortisol during the war, which was also present before it began. The lowest level was observed in this group of patients in 2022.
Conclusions. Patients with T2DM during the war compared to the pre-war period had a stably increased level of salivary cortisol. In people without T2DM, there is a significant increase in the average level of serum cortisol during the war compared to the pre-war period. It is recommended to reduce the level of insulin resistance through lifestyle modification, maintaining an adequate level of vitamin D.

P1491

PRIMARY AND SECONDARY FIBROMYALGIA IN BULGARIA

V. Reshkova[1]

[1]Clinic of Rheumatology, UMHAT "St. Ivan Rilski", Sofia, Bulgaria

Background:
Fibromyalgia (FM) is characterized by a chronic widespread pain, general fatigue, anxiety, depression, sleep disturbances and functional disorders. FM affects both women and men in 9:1 to 20:1 ratio
Objectives:
The purpose of this clinical study is to analise clinical manifestations in patients with primary and secondary fibromyalgia. Methods. Eighty-three patients with primary FM, 39 patients with FM and osteoarthritis (OA), 23 patients with FM and systemic lupus erythematosus (SLE), 27 patients with SLE and 36 healthy subjects were included
Material and Methods:
The present study compared chronic pain, fatigue, depression and anxiety in patients with primary FM, patients with SLE, FM+OA, FM+SLE and healthy subjects. 1. Evaluation of the diagnosis of fibromyalgia according to the 2011/2016 ACR criteria. 2. Assessment of fatigue on the physical, cognitive and psychosocial subscales of MFIS. 3. Assessment of anxiety and depression on the HADS scale for anxiety. 4. Assessment of the number of the fibromyalgia tender points
Results:
1. Assessment of the number of chronic widespread pain areas in the three FM groups, healthy individuals and SLE results. The most chronic widespread pain areas were reported in patients with FM+OA 14.05±2.75; followed by the FM + SLE group 13.96±1.8. Patients with primary FM had a mean number of chronic widespread pain areas of 13.8±2.1. Healthy individuals had 7.47±3.57. In SLE patients the chronic widespread pain areas were 4.56±1.63. Based on 2011/2016 criteria for number of chronic widespread pain areas, there is a statistically significant difference of $p < 0.05$ in the mean values of the control group, compared to the number of chronic widespread pain areas in all FM groups of patients. 2. Assessment of the number of tender points results in the three groups of patients with FM, healthy individuals and people with SLE. The average number of tender points is an important parameter for diagnosis. It can be used in practice for comparison of the patients, monitoring the treatment effect and for choosing the most adequate treatment for FM. 3. Assessment of MFIS fatigue results. A statistically significant difference of $p<0.05$ for the MFIS clinical parameter chronic fatigue

was found in the mean values of the control group, compared to the values of all FM groups. 4. Assessment of HADS anxiety results. A statistically significant difference of p<0.05 for the HADS clinical parameter anxiety was found in the mean values of the healthy individuals group, compared to the values of all FM groups, in the mean values in patients with SLE.
5. Assessment of HADS depression results. The HADS depression score in patients with FM+OA was 8.92±4.46, followed by the results of 8.71±4.17 in the FM group. A statistically significant difference of p<0.05 for the HADS clinical parameter depression was found in the mean values of the healthy individuals group, compared to the values of all FM groups of patients; in the mean values in patients with SLE, compared to the values of all FM groups and the group of patients with FM+OA
Conclusion:
1. Patients with primary FM, osteoarthritis and FM, SLE and depression. 2. Patients with SLE without fibromyalgia have fewer areas with chronic widespread pain and a lower degree of depression, anxiety and fatigue, comparable to these symptoms in patients with SLE + FM and healthy individuals. 3. Patients with SLE and FM have additional symptoms of moderate pain, depression, anxiety and fatigue that are not related to SLE and require treatment for FM, regardless of their current SLE treatment

P1492

ROLE OF EPSTEIN-BARR VIRUS IN PATIENTS WITH PRIMARY FIBROMYALGIA IN BULGARIA

V. Reshkova[1]

[1]Clinic of Rheumatology, UMHAT "St. Ivan Rilski", Associate professor in Sofia University "St. Kliment Ohridski", Sofia, Bulgaria

Fibromyalgia (FM) is characterized by a chronic widespread pain, general fatigue, anxiety, depression, sleep disturbances and functional disorders. The cause of fibromyalgia is unknown. The hypotheses for etiology include genetic predisposition, immune dysfunction, infectious agents, metabolic disturbances, brain dysfunction, toxins, stress, trauma, circulatory abnormalities or a combination of any of these factors. This theory for "central sensitization" proposes that fibromyalgia patients have a lower threshold for pain because of increased reactivity of pain-sensitive neurons in the spinal cord or brain. Some researchers supposed that different neurotransmitters (serotonin, catecholamine) could be involved in the pathophysiology of fibromyalgia-associated symptoms. The connection of FM to different viral infections has been proposed. Epstein Barr Virus (EBV) has been considered a possible cause of FM because of similarity of symptoms, but so far, the connection has not been proven. **Objective.** The objective of this study was to determine the prevalence of antibodies (Abs) IgM and IgG against EBV, and respectively the presence of a viral infection in a group of patients with FM. **Patients and methods.** Forty-one patients (women, men) with fibromyalgia were included in the investigation. Sera and plasmas were collected from all patients. Sera were tested by enzyme linked immunosorbent assay for antibodies (Abs) IgM and IgG against Epstein Barr-virus (EBV)**.** The neurotransmitters serotonin, adrenaline and noradrenaline were tested in the plasma. We also analysed the association between the titter of the antiviral antibodies, some neurotransmitters (serotonin, noradrenaline and adrenaline) and different clinical symptoms. **Results.** When we tested the plasma serotonin concentrations in the patients, we determined levels below 50 ng/l in 35 % of the patients, 52.4% of patients were with low plasma serotonin levels (less than normal range). The remaining patients (47,6%) were with normal plasma serotonin levels. The obtained results revealed that high EBV IgG concentrations in the serum of patients with FM correlated with pain intensity and associated clinical symptoms. When we analysed the association between the fatigue and antiviral IgG Abs, it was found a negative correlation or higher serum levels of IgG Abs against EBV were observed in patients with severe fatigue (r = -0.14), as the associations wasn't statistically significant (p = 0.55). We determined similar correlations between the IgG Abs and other clinical features. The association between the headache and adrenaline (r = -0.27) and noradrenaline (r = -0.58) plasma concentrations in the patients was negative. The stronger headache in patients was associated with lower concentrations of noradrenaline and adrenaline. The dependence between headaches and the concentration of noradrenaline was statistically significant (p = 0.0068). **Conclusions.** Some neurotransmitter can be used as potential markers for evaluation the effects of the applied therapy. The investigation of the levels of neurotransmitters and analyse associations with different clinical symptoms can be useful for daily rheumatology practice. Positive antibodies against some viruses in patients with fibromyalgia suggest the role of some viruses in the pathogenesis; through induce of different immune mechanisms.
This is consistent with the fact that FM is connected to the immune response to certain infectious agents (e.g. EBV, CMV).

P1493

SAFETY AND EFFICACY OF ANTIRESORPTIVE TREATMENTS IN PATIENTS WITH OBESITY: A REGISTRY-BASED STUDY

V. Rouach[1], I. Goldshtein[2], A. Buch[1], G. Chodick[3], Y. Greenman[1]

[1]Institute of Endocrinology, Diabetes, Hypertension and Metabolism, Sourasky Medical Center, Tel Aviv, Israel, [2]KI Research Institute, Kfar Malal, Israel, [3]Epidemiology Department, School of Public Health, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: Despite the classic concept of obesity as a protec-

tive factor for fractures, recent evidence has shown that these patients are at increased risk of fractures. Obesity has been linked to compromised bone quality, and impaired bone healing, despite normal or even elevated bone mineral density (BMD) in some cases. Anti-resorptive treatments, including bisphosphonates and denosumab, have been the cornerstone of osteoporosis management, however, their efficacy on fracture prevention and mortality in patients with obesity remains less established.

Aim: Evaluate the relationship between anti-resorptive therapy, fracture risk reduction and mortality in a population of patients with obesity.

Methods and subjects: The study population was identified by electronic records of an osteoporosis registry of a large healthcare organization in Israel. Demographics, Comorbidity Index (CCI), bone mineral density (BMD) T-scores, purchase of anti-resorptive agents were collected. Exposure groups were matched using propensity score. Kaplan-Meier curves were generated to assess the time to outcomes. Multivariable Cox's proportional hazards survival model was performed.

Results: Between January 1998 and December 2021 a total of 11604 patients with osteoporosis and a BMI above 30 were identified. The mean BMI was 34.6 (4.2), 37% had a BMI over 35. The mean age was 71.4 (8.3), 75.2% were women. The mean FN T-Score -1.6 (1.0), the mean eGFR was 67.9 (23.1), the mean CCI was 3.6 (2.6). A total of 5412 (46.6%) patients purchased an anti-resorptive agent: 3370 (62.2%) alendronate, 1562 (28.9%) risedronate, 270 (5%) zoledronic acid, and 210 (3.9%) denosumab. Compared to non-treated patients, before matching, the treated patients were slightly older (71.8 vs 70.8, p<0.01), had a lower FN T-Score (-1.7 vs -1.3, P<0.01), and a lower eGFR (65.2 vs 69.5, p<0.01). The proportion of women was higher (83% vs 68.7%) and falls were more frequent (24.2% vs 20.7%) in treated versus non-treated subjects. After matching, 607 pairs of subjects treated and non-treated remained. A total of 489 fractures were reported, 414 at the osteoporosis registry entry. The 5-year cumulative incidence of fracture and death events were 34.5% vs 50.4% and 13.6% vs 21.3% in the treated versus non-treated patients. The risk of fracture and death were HR=0.67 (0.55-0.81) and HR= 065 (0.48-0.88) respectively.

Conclusions: Our findings suggest that anti-resorptive agents reduce osteoporotic fractures and mortality among obese patients, offering valuable insights for treatment strategies in this vulnerable population.

P1494

CORRELATION OF LIPIDS LEVEL AND OSTEOPOROSIS IN RHEUMATOID ARTHRITIS

V. Salko[1], A. Zoto[1], T. Backa[1], E. Rapushi[1], S. Florenc[1]

[1]UHC"Mother Teresa", Tirana, Albania

Objectives

Rheumatoid Arthritis (RA) is recognized as a contributory factor for osteoporosis (OP) development and also it is acknowledged as a risk factor for cardiovascular disease. Although patients with RA commonly exhibit abnormal lipid metabolism, the underlying mechanisms remain elusive. To date, few studies have focused into the interrelation between lipids, RA, and OP. The aim of this study is to investigate the relationship between lipid levels and OP risk in RA patients.

Methods

It is a retrospective study which enrolled 100 patients with RA, all have been hospitalized at Rheumatology Service of UHC from January 2023-January 2024. Their diagnosis was established according to ACR/EULAR 2010 criteria. Reason for hospitalization vary from diagnosis determination, disease flare ups, current therapy failure ect. Disease activity was evaluated with Clinical Disease Activity Index (CDAI). For each patient was made a correlation of disease activity and lipid panel. DEXA scan was performed in all patients.

Results

Out of 100 patients, 84 were female (84%) and 16 male (16%). Mean age of patients was 39±11 y.o. In total 58 patients (58%) resulted with lipid panel abnormalities, 43 patients resulted with lower levels of HDL (43 %). It resulted a significant statistical association between high disease activity and higher total cholesterol. (p-value < 0.01). Also a significant correlation between disease activity and lower HDL level was observed (p-value < 0.01). From 100 patients,67 patients resulted with T-score below -2.5(defined as osteoporosis).35 out of 67 patients have been in treatment for osteoporosis before this hospitalisation.51 out of 67 patients belongs to the group of 58 patients with lipid panel abnormalities.

Conclusions

This study shows clearly an association of disease activity and lipid panel changes in RA patients.Also it is notable that lipid levels may be indicators of OP occurrence in RA patients.

P1495

EFFICACY OF COMBINED UNDENATURED TYPE II COLLAGEN AND HYDROLYSED COLLAGEN SUPPLEMENTATION IN KNEE OSTEOARTHRITIS: A RANDOMISED CONTROLLED TRIAL

V. Yuenyongviwat[1], C. Anusitviwat[1], K. Iamthanaporn[1], P. Tuntarattanapong[1], T. Hongnaparak[1]

[1]Department of Orthopedics, Faculty of Medicine, Prince of Songkla University, Hatyai, Thailand

Background: Collagen supplements have gained significant market popularity, with numerous products claiming to improve knee osteoarthritis symptoms. Previous clinical studies have primarily evaluated individual collagen formulations, with most being industry-sponsored, which raises potential bias concerns. This study aimed to evaluate the efficacy of combined undenatured type II collagen (UC-II) and hydrolysed collagen supplementation in patients with knee osteoarthritis.

Methods: In this randomised, double-blind, placebo-controlled trial, 68 patients with knee osteoarthritis were divided into two groups: one receiving collagen supplements (tablets containing hydrolysed collagen and UC-II) and the other receiving a placebo. Clinical outcomes, including pain intensity (Verbal Numerical Rat-

ing Scale), functional outcomes (Knee Injury and Osteoarthritis Outcome Score [KOOS]), rescue medication consumption, and patient satisfaction, were assessed at baseline, 2, 6, and 12 weeks. Results: Baseline demographic characteristics were comparable between the collagen and placebo groups. Both groups showed significant improvements in pain intensity ($p<0.001$) and KOOS scores over time. However, no significant differences were observed between the groups in terms of pain intensity, functional outcomes, rescue medication consumption, or patient satisfaction ($p>0.05$). No adverse effects were reported in either group. Conclusion: Combined UC-II and hydrolysed collagen supplementation over 12 weeks did not demonstrate superior efficacy compared with that of the placebo in managing knee osteoarthritis symptoms. Further research is required to explore the potential long-term benefits of combined collagen supplementation.

P1496

COMPARISON OF OUTCOMES FOLLOWING BIPOLAR HEMIARTHROPLASTY FOR DISPLACED FEMORAL NECK FRACTURES VERSUS UNSTABLE INTERTROCHANTERIC FRACTURES: A RETROSPECTIVE PROPENSITY-MATCHED STUDY

V. Yuenyongviwat[1], S. Taosuwan[1], K. Iamthanaporn[1], T. Hongnaparak[1]

[1]Department of Orthopedics, Faculty of Medicine, Prince of Songkla University, Hatyai, Thailand

Objective: Bipolar hemiarthroplasty (BHA) is a well-established treatment for displaced femoral neck fractures, but its use for unstable intertrochanteric fractures remains less common. This study aims to compare the outcomes of BHA in these two distinct fracture types, focusing on operative parameters, complications, and recovery profiles.
Material and Methods: We conducted a retrospective analysis of 40 patients with unstable intertrochanteric fractures and 319 patients with displaced femoral neck fractures who underwent BHA at our institution. Propensity score matching was applied to account for baseline differences, resulting in 38 intertrochanteric fracture patients matched to 152 femoral neck fracture patients. The primary outcomes evaluated included operation time, blood loss, transfusion requirements, hospital length of stay, and postoperative complications.
Results: Patients in the intertrochanteric fracture group had significantly longer operation times, higher intraoperative blood loss, and greater transfusion requirements compared to those in the femoral neck fracture group. Additionally, the intertrochanteric group had longer hospital stays and a significantly higher incidence of medical complications, particularly cardiovascular events (13.2% vs. 1.3%, $p=0.007$). Surgical complications, including dislocation and infection, were comparable between the two groups.
Conclusions: Although BHA for unstable intertrochanteric fractures is associated with longer operation times and a higher risk of medical complications, particularly cardiovascular events, the incidence of surgical complications such as dislocation and infection is similar to that seen in femoral neck fractures.

P1497

PRIMARY HYPERPARATHYROIDISM: THE INFLUENCE OF VISCERAL ADIPOSE TISSUE ON BONE QUALITY

V. Zikan[1], J. Hrdlička[2], J. Klímová[3], J. R. Raška[1], A. Bocán[2], M. Wágnerová[2], D. Michalská[1], J. R. Hána[1], R. Vlasáková[1], P. Libansky[4], L. Lambert[5]

[1]Department of Internal Medicine III, General University Hospital, 1st Faculty of Medicine, Charles University, Prague, Czechia, [2]Department of radiology, General University Hospital, 1stFaculty of Medicine, Charles University, Prague, Czechia, [3]Department of Internal Medicine, Military University Hospital, 1stFaculty of Medicine, Charles University, Prague, Czechia, [4]Department of Surgery III, Motol University hospital, 2nd Faculty of Medicine, Charles University, Prague, Czechia, [5]Department of imaging Methods, Motol University Hospital, 1stFaculty of Medicine, Charles University, Prague, Czechia

Obesity, namely visceral adiposity (VAT) associated with insulin resistance is responsible for other metabolic comorbidities including bone fractures. However, the influence of adipose tissue on bone metabolism has been scarcely evaluated in patients with primary hyperparathyroidism (PHPT). Objectives: To investigate the effect of adipose tissue (e.g. VAT and total fat mass FM) on trabecular bone score (TBS) and bone mineral density (BMD) in subjects with PHPT at baseline and through 12 months after parathyroidectomy (PTX). Moreover, relationships between body composition and calcium-phosphate, lipid and bone metabolism (e.g. plasma osteocalcin) were evaluated. Methods: 112 subjects with PHPT were included in cross-sectional study and subset of 40 postmenopausal women was followed prospectively. Dual X-ray absorptiometry (DXA) was compared with magnetic resonance imaging (MRI) for estimating VAT in prospective study. The results showed that VAT measurement by DXA is well-correlated with MRI in subjects with PHPT. TBS was positively associated with BMD ($p<0.001$) and negatively associated with VAT and FM/height^2 ($p < 0.001$). Plasma osteocalcin levels negatively associated with VAT and FM /height^2 ($p<0.01$). There was a significant increase in BMD (both in lumbar spine and hip) and serum 25(OH) vitamin D after PTX ($P < 0.001$). Although our results demonstrated a mild increase in FM/height^2 and VAT after PTX no significant change in TBS was observed. Our results suggest that the increment of VAT in PHPT may contribute to bone deterioration, as suggested by lower TBS and lower plasma osteocalcin. However, further studies are needed to investigate the underlying mechanisms.
This study was supported by the project GIP -23-SL-07-203 (General University Hospital in Prague) and MH CZ—DRO (General University Hospital in Prague—00064165)

BONE MINERAL DENSITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS CORRELATION WITH DISEASE ACTIVITY

V. Živković[1], B. Stamenković[1], S. Stojanović[1]

[1]Institute for Treatment and Rehabilitation "Niška Banja"-Niš; University of Niš, Faculty of Medicine, Serbia, Niš, Serbia

Objective: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease of unknown etiology, characterized by a very heterogeneous clinical picture. Osteoporosis and osteoporotic fractures are common in patients with SLE, they contribute significantly to morbidity and mortality, and they are primarily the result of systemic inflammation and treatment with glucocorticoids. The objective is to examine bone mineral density (BMD) in patients with SLE and its correlation with disease activity.
Methods: The retrospective study included 81 patients with SLE, hospitalized in the Clinic for Rheumatology, Institute "Niška Banja", who were diagnosed based on the revised ACR criteria from 1997. In addition to the clinical examination, BMD was measured at the level of the lumbar vertebrae L1-L4 and the hip using the method of dual-energy X-ray absorptiometry (DEXA) on a Hologic brand device. Osteoporosis and osteopenia are determined according to the definition of the World Health Organization. The level of disease activity was assessed by the prescribing physician for all patients using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI).
Results: The examined group consisted of 73 women (91.9%) and 8 men (9.9%), average age 46.3±9.6 years. The average duration of the disease of the examined group was 10.5±8.5 years. The results of the study showed that normal BMD was registered in 27 (33.3%) patients, osteopenia in 42 (51.9%), while osteoporosis was recorded in 12 patients (14.8%). The average value of the SLEDAI index in the examined group was 11.6±7.5 (median 9, minimum 0, maximum 36). In the subgroup with normal BMD values, the average SLEDAI values were 11.8±7.9, in patients with osteopenia 10.7±7.4, and in patients with osteoporosis 13.9±7.1. The mean value of the SLEDAI index was higher in the subgroup with osteoporosis compared to the group of patients with normal BMD and osteopenia, but the difference was not statistically significant. Spearman's correlation analysis indicates that there is no statistically significant correlation between the SLEDAI score and the bone mineral density of the spine (r=-0.065) and hip (r=0.035), expressed in g/cm^2.
Conclusion: Our results showed that osteopenia and osteoporosis are present in two thirds of patients with SLE, and that only one third of patients have normal BMD values. Patients with osteoporosis have higher disease activity compared to the group of patients with normal BMD and osteopenia, but the difference is not statistically significant. By examining the correlation of bone mineral density at the spine and hip with disease activity, it was shown that there is no association between disease activity and bone mineral density in patients with systemic lupus erythematosus.

P1499

SARCOPENIA ,THE GATEWAY FOR ELDERLY SUFFERING

W. A. Almalik[1]

[1]king abdulaziz medical city, RIYADH , Saudi Arabia

Sarcopenia is a geriatric syndrome characterized by a progressive and generalized loss of skeletal muscle mass and strength, resulting in reduced physical function and increased risk of adverse health outcomes in older adults. Skeletal muscle mass naturally declines with age, but sarcopenia represents an accelerated loss beyond the typical aging process. The etiology of sarcopenia is multifactorial, involving a complex interplay of age-related changes in anabolism, catabolism, inflammation, oxidative stress, and neuromuscular function. Additionally, various lifestyle factors, comorbidities, and genetic predispositions can contribute to the development and progression of sarcopenia. Sarcopenia is associated with a range of adverse health consequences, including increased risk of falls, fractures, disability, frailty, and mortality. It significantly impacts an individual's quality of life, independence, and overall health status. Early identification and intervention are crucial for mitigating the negative effects of sarcopenia and improving the health and well-being of older adults. Several strategies can help prevent and manage sarcopenia, including regular physical activity, particularly resistance training, adequate nutrition with sufficient protein intake, and addressing underlying medical conditions. Healthcare providers play a vital role in screening for sarcopenia, educating older adults about risk factors and preventive measures, and implementing appropriate interventions to optimize muscle health and function.

ONE-YEAR ADHERENCE OF ANTI-OSTEOPOROSIS MEDICATIONS AFTER HIP AND VERTEBRAL FRACTURE ON LONG-TERM MORTALITY: A REAL-WORLD EVIDENCE STUDY

W. C.-H. Wu[1], L. C.-C. Li[2], C. Y.-F. Chang[3], T. T.-W. Tai[4]

[1]Institute of Gerontology, Medical College, National Cheng Kung University, Tainan, Taiwan, [2]Institute of Allied Health Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan, [3]Department of Family Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, [4]Department of Orthopedics, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Objective
There exists a range of anti-osteoporosis medications designed to mitigate fracture risks and even mortality. Poor adherence to osteoporosis medications resulted in an approximately 50% reduction in the potential benefit observed in clinical trials. This real-world evidence study investigates the impact of adherence to anti-osteoporosis medicines for one year on long-term mortality.

Material and Methods
The study focused on individuals diagnosed with osteoporosis, having experienced significant fractures leading to hospitalization, as identified in Taiwan's National Health Insurance Research Database spanning from 2008 to 2021. Subjects with osteoporotic fracture who had used anti-osteoporotic medication (AOMs) within only one-year timeframe were selected and compared with the non-users. All subjects were followed as long as the mortality recorded or survival kept. Survival outcomes were analyzed using Cox proportional regression adjusted by Time-Dependent and inverse probability of treatment weighting (propensity score).
Results
A total of 164,527 subjects (10,945 AOMs users and 153,582 non-users) were enrolled with a mean follow-up period of 5.99±3.76 years. Most patients were women (72.5%), with a mean age of 71.84±11.92 years. Female subjects showed lower mortality than males. The older subjects and higher Charlson co-morbidity index showed higher mortality. Compared to non-users, one-year AOMs users with either hip fracture (HR 0.68, 95% CI: 0.67–0.70) or vertebral fracture (HR 0.65, 95% CI: 0.63-0.68) had significantly lower long-term mortality.
Conclusions
In conclusion, one year of anti-osteoporosis medication used for post-fracture treatment can significantly reduce long-term mortality in both hip and vertebral fracture.

COMPREHENSIVE INVENTORY OF BIOMARKERS ASSAYS: ANALYTICAL CAPABILITIES AND ADVANCED TECHNOLOGIES AT THE CHU OF LIÈGE

W. Determe[1], C. Wojtaszek[1], J.-Y. Reginster[2], M. Alokail[3], E. Cavalier[4]

[1]Department of Clinical Chemistry, CHU of Liège, Liège, Belgium, [2]CARES (Centre Académique de Recherche et d'Expérimentation en Santé) sprl, Liège, Belgium, [3]Biochemistry Department, College of Science, King Saud University, Riyadh, Saudi Arabia, [4]Department of Clinical Chemistry, CHU of Liège and CIRM, University of Liège, Liège, Belgium

To present a structured summary of the analytical capabilities and biomarker profiling performed in the Clinical Chemistry department of the CHU of Liège, particularly the Bone and Cartilage Marker Laboratory (BCML) in partnership with CARES sprl, a former spin-off of the University of Liege. This document provides a comprehensive inventory of more than 150 assays, detailing their clinical relevance and the advanced technologies employed to support diagnostic and research needs.
Material and Methods
The inventory was developed by reviewing over 10 years of laboratory records. The list was curated and regularly updated to retain only assays currently available in the laboratory. Each assay's description was based on peer-reviewed literature, ensuring accurate and standardized information on biological and clinical relevance. Biomarkers were grouped by their clinical applications, such as autoimmune diseases, metabolic disorders, and neurodegeneration. Key details, including analytical platforms (e.g., ELISA, LC-MS/MS, SIMOA, CLIA), detection principles, and clinical utilities, were systematically documented following international guidelines.
Results
The inventory includes biomarkers such as inflammatory cytokines (e.g., IL-6, TNF-α), neurodegenerative markers (e.g., tau proteins, neurofilament light chain), and metabolic indicators (e.g., vitamin D metabolites, leptin). The BCML leverages cutting-edge technologies, including ultra-sensitive SIMOA for single-molecule detection, high-precision LC-MS/MS for small molecules, and automated systems like Roche Cobas and Fujirebio Lumipulse for high-throughput immunoassays. Each entry provides a complete overview of the biomarker's clinical applications and analytical methods.
Conclusions
This document highlights the BCML and CARES extensive diagnostic and research capabilities, offering insights into its advanced technologies and expertise. It underscores the laboratory's role in supporting precision medicine and translational research, serving as a valuable resource for clinicians and researchers seeking high-quality biomarker analyses.

P1502

THE IMPACT OF THE PRESENCE OF RHEUMATOID ARTHRITIS ON TOTAL KNEE ARTHROPLASTY IN PATIENTS WITH OSTEOARTHRITIS

W. Jeong[1], J. Kim[1]

[1]Jeju National University School of medicine, Jeju, South Korea

Background
According to the results of previous studies, it has been reported that rheumatoid arthritis (RA) patients receive total knee arthroplasty (TKA) at a younger age than osteoarthritis (OA) patients. However, studies on the effect of RA on TKA are still insufficient.
Objectives
We conducted this study to find out how RA affects primary TKA and revision arthroplasty.
Methods
The data of OA and RA patients who underwent primary TKA and revision at Jeju National University Hospital between March 2003 and December 2022 were retrospectively analyzed. To exclude the effect of other connective tissue diseases, patients with SLE, Sjogren's syndrome, polymyalgia rheumatica, mixed connective tissue disease, undifferentiated connective tissue disease, Behcet's disease, systemic sclerosis, and vasculitis were excluded.
Results
A total of 5245 TKAs were performed, and the average age at primary TKA was 72.4 ± 6.4 years, and 2292 (85.7%) were female. When they were divided into OA group and RA group, RA knees were 159 (3.1%). The age at primary TKA in the RA group was significantly smaller (69.6 ± 6.8 vs 72.5 ± 6.4, p<0.001), and the female ratio was higher (91.9% vs 85.5%, P=0.031). Although the rate of revision surgery was not statistically significant, the RA

group had more (5.6% vs 3.1%, p=0.111), and the period to revision tended to be shorter in the RA group (33.8 ± 49.2 months vs 67.7 ± 56.1 months). month, p=0.078). The cause of reoperation was not significantly different between the two groups, but the rate of infection was higher in the RA group (55.6% vs 43.7), and reoperation due to loosening was more common in the OA group (46.2% vs 22.2%). There was no difference in other test values at the time of surgery, but in the RA group, ESR (43.8 ± 31.7 mm/h vs. 26.6 ± 22.6 mm/h, P<0.001), CRP (1.8 ± 2.3 mg/dL vs. 0.8 ± 2.1 mg/dL, p<0.001) was significantly higher.
The incidence of TKA was higher in the RA patients than OA patients (1436.2 per 100,000 Person-Years vs 1379.7 per 100,000 Person-Years). When comparing the risk of patients undergoing primary TKA during their lifetime by adjusting for gender, it was found that RA patients started receiving primary TKA at a younger age and had a significantly higher risk of undergoing TKA (HR 1.48, 95% CI 1.263–1.733, P<0.001).
As a result of logistic regression analysis, the increase in ESR (OR 10.2, 95% CI 1.01-1.03, P=0.001) and CRP (OR 1.09, 95% CI 1.01-1.17, P=0.021) at the time of primary TKA increase risk of revision arthroplasty, but RA did not.
Conclusion
Patients with RA have a higher risk of primary TKA and start primary TKA at a younger age, and the increased inflammation level at the time of primary TKA increase risk of revision arthroplasty, so it is recommended to perform primary TKA after inflammation is controlled.

WHOLE-BODY VIBRATION TRAINING IN COMBINATION WITH VITAMIN D FOR ENHANCING OSTEO-SARCOPENIA: A CLINICAL STUDY

W. Li[1], Z. Li[2], F. Wang[2], Y. Li[1], Y. Zhong[1], F. Yang[1]

[1]Shaanxi University of Chinese Medicine, Xianyang, China, [2]Affiliated Hospital of Shaanxi University of Chinese Medicine, Xianyang, China

ABSTRACT: This research endeavors to probe into the impacts of whole-body vibration training (WBVT) in conjunction with vitamin D (Vit. D) supplementation on muscle quality and bone density among elderly individuals suffering from osteo-sarcopenia (OS). OS is a widespread geriatric syndrome that markedly compromises the quality of life in the elderly populace; however, research on its mechanisms and targeted pharmacological interferences is currently constrained. Muscles and bones interact via mechanical and chemical processes, and elucidating these interactions can contribute to the prevention and treatment of musculoskeletal disorders. In this investigation, we propose to quantify the levels of myokines irisin and myostatin (MSTN) in the serum of clinical subjects, while implementing WBVT combined with Vit. D supplementation as an intervention for OS patients. Dual-energy X-ray absorptiometry (DXA) will be employed to assess bone mineral density and muscle mass, while grip strength meter and 5-time chair stand test will be utilized to evaluate muscle strength. Additionally, 6-meter walk speed, Short Physical Performance Battery, and Timed Up and Go test will be used to assess physical function. The study will analyze the correlation between irisin/MSTN and OS, as well as the clinical efficacy and mechanism of action of WBVT combined with Vit. D in alleviating OS. The objective is to enhance the clinical diagnosis rate of OS, prevent OS complications at an early stage, facilitate the development of targeted pharmacological interventions for OS, provide a scientific basis for clinical diagnosis and treatment, improve the quality of life of the elderly, reduce the societal medical and economic burden, and make a substantial contribution to advancing medical and health technology in China.
KEYWORDS: Whole body vibration training; Vitamin D; Sarcopenia; Osteoporosis; Osteo-sarcopenia

Funding: This trial was funded by the Program of National Natural Science Foundation of China (82474543 to FY), the Program of Shaanxi Province Natural Science Foundation (2023-YBSF-210 to FY & 2023-JC-QN-0978 to WL), the Program of Shaanxi Administration Bureau of Traditional Chinese Medicine (2021-01-22-009 to FY &2022-QCYZH-029 to WL), Youth Innovation Team in Shaanxi universities, and the Program of Health Commission of Shaanxi Province (2022B002 to WL).

A NATIONAL SURVEY OF DXA QUALITY CONTROL PRACTICES AT TAIWAN TRAINING CENTERS

W. P. Chan[1], Y.-C. Lu[2], R. O. Kosik[3]

[1]Department of Radiology, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan, [2]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, Taiwan, [3]Department of Radiology, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan

Objective: We implemented a series of strategies to promote the accurate diagnosis of osteoporosis in Taiwan, including the use of NHANES III data as a standard reference, performance of BMD measurements at two or more skeletal sites, and initiation of DXA training programs since 2015. The aim of this report is to determine whether DXA quality measures at Taiwan's training centers comply with international practice guidelines.
Material and methods: All Taiwan Radiology Resident Training Centers were invited to complete a questionnaire regarding current DXA QA practices, especially in terms of skeletal sites scanned and reference databases used. Responders were DXA related leaders or responsible radiologists.
Results: All 37 and 39 centers were invited to participate in two time slots, in May 2018, and July 2020, respectively, with a 100% response rate. When comparing centers that responded in 2020 to those that responded in 2018, 82.1% and 76.3% respectively used the Asian reference database for Z-score tabulation; 84.6% and 65.8% respectively used the NHANES III reference database for T-score tabulation; and 89.7% and 86.9% respectively performed BMD measurements at 3 skeletal sites. The self-reported reasons for these improvements were related to DXA training

courses (n=3), following radiological guidelines (n=5), both (n=3), and manufacturers' changes in settings (n=2). The reasons why institutes did not comply with the guidelines regarding the use of the Asian reference database for Z-score tabulation and the NHANES III reference database for T-score tabulation, included an unwillingness to change examination procedures (n=2, n=1, respectively), no supporting software (n=1, n=2, respectively), and manufacturers' settings (n=3, n=3, respectively). The reasons why institutes did not follow the guidelines regarding measuring multiple skeletal sites (i.e. the spine and at least one hip) included national insurance reimbursement of one site only (n=1) and lack of operating procedure support (n=2). However, all centers had a comprehensive QC protocol and schedule.

Conclusion: This study provides a useful reference for centers to benchmark their DXA practices with national and international standards. These results also reflect the effectiveness of efforts to comply with international standards in Taiwan in terms of improving osteoporosis diagnostic accuracy.

P1505

EPIDEMIOLOGY AND MANAGEMENT OF OLECRANON FRACTURES: A NATIONWIDE REGISTER-BASED ANALYSIS OF 27,780 CASES IN DENMARK FROM 1999 TO 2018

W. Z. Zeyghami[1], D. K. Karimi[1], P. G. Gundtoft[2], B. V. Viberg[3], T. M. Maleitzke[1]

[1]Hvidovre Hospital, Copenhagen, Denmark, [2]Lillebaelt Hospital, Kolding, Denmark, [3]Odense University Hospital, Odense, Denmark

Objective

Olecranon fractures (OFs) account for approximately 20% of proximal forearm fractures [1, 2]. While OF management is well-studied, there is limited epidemiological data [1, 3]. This study investigates OF incidence rates (IRs), and treatment trends in Denmark over a 20-year period from 1999 to 2018.

Material and Methods

This study is a population-based register study on OFs in adult patients from 1999 to 2018 in Denmark. Patients ≥20 years diagnosed with an OF (ICD-10: DS520) were included. Next to age and sex, treatment was recorded. Treatment was classified as surgical if relevant surgical procedure codes were recorded within 21 days of OF diagnosis. IRs were calculated per 100,000 person-years using population data from Statistics Denmark.

Results

A total of 27,780 OF cases (61% female) were identified between 1999 and 2018. The overall mean IR was 33/100,000/year, increasing from 31 in 1999 to 41 in 2018. Females and males had similar IRs between ages 20–49 and ≥50 females had markedly higher IRs than males. Non-surgical treatment was predominant (67%, range: 64–72%). Surgical treatment was more frequent in females (36%, range: 30–42%) than in males (28%, range: 25–34%) and more frequent in patients ≥50 years (37%, range: 32-41%) than in patients <50 years (24%, range: 22-26). Over time, plate fixation (PF) use increased from 7% in 1999 to 45% in 2028. Tension band wiring (TBW) declined from 89% in 1999 to 46% in 2018.

Conclusion

The incidence of OFs increased by 29% over the 20-year study period, with increasing IRs seen mainly in females ≥50. Non-surgical treatment was predominant across all ages but increased markedly in older patients since 2013. Over the assessed two decades, PF increased and TBW decreased in popularity for surgically managed OFs. Future research should aim to identify which patients benefit most from surgical versus non-surgical treatment by incorporating patient-specific factors such as age, activity level, and comorbidities, thereby refining decision-making and optimizing outcomes.

NUTRITION AND METABOLIC REGULATION: REVEALING NON-EXERCISE PATHWAYS LINKING HANDGRIP STRENGTH AND MORTALITY RISK

W. Zhangxin[1], C. Rong[2], L. Xinpeng[1], L. Hong[1], S. Zhifeng[1]

[1]Central south university, Zhuzhou, China, [2]jishuitan hospital, Beijing, China

Objectives : Handgrip strength (HGS) has emerged as a simple biomarker for evaluating muscle function and predicting mortality. Previous studies have shown that physical activity is associated with improved HGS, but there is limited research on the association between protein intake, insulin resistance and HCS. Therefore, this study investigates the novel role of nutrition and metabolic regulation, specifically protein intake and insulin resistance, as mediators in the relationship between HGS and mortality using NHANES 2001-2018 data.

Methods : This study enrolled 10362 participants from NHANES 2001-2018, with HGS categorized into low and normal groups. Mortality risk was analyzed across age, sex, and BMI subgroups. Mediation analyses were performed to evaluate the role of protein intake and insulin resistance in improving HGS and its subsequent impact on mortality. Adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated.

Results : During 6.75 years of follow-up, a total of 840 all-cause deaths were recorded. Low HGS was significantly associated with increased mortality risk across all age, sex, and BMI groups. The association was most prominent in individuals aged ≥40 years, where HGS decline accelerated significantly. Mediation analysis revealed that 50% of the effect of protein intake on HGS improvement was mediated through reduced insulin resistance, highlighting a critical metabolic pathway. Surprisingly, the relationship between HGS and mortality was not mediated by physical activity,

suggesting that HGS may influence mortality through non-exercise pathways such as nutrition and metabolic regulation.

Conclusions : This study reveals the significant role of protein intake and insulin resistance in the relationship between HGS and mortality, independent of physical activity. HGS, as a simple clinical biomarker, can be effectively used for early screening marker. Interventions focusing on protein intake and metabolic regulation may provide novel strategies for improving population health and promoting healthy aging.

NEW INSIGHTS INTO THE ASSOCIATION BETWEEN TYPE 2 DIABETES AND OSTEOPOROSIS: THE IMPACT OF HEMOGLOBIN GLYCATION INDEX (HGI) ON OSTEOCLASTIC ACTIVITY

W. Zhangxin[1], L. Xinpeng[1], J. Wanlin[2], S. Zhifeng[1], L. Hong[1]

[1]Central south university, Zhuzhou, China, [2]Central south university, Changsha, China

Background

Osteoporosis is characterized by reduced bone mineral density (BMD) and deteriorated bone microarchitecture, leading to increased fracture risk. The hemoglobin glycation index (HGI), defined as the difference between observed and predicted HbA1c based on mean blood glucose, reflects advanced glycation end-product (AGEs) accumulation. HGI is emerging as a biomarker in diabetes and its complications. This study explores the association of HGI with BMD and its impact on osteoclast and osteoblast activities.

Methods

We enrolled 412 hospitalized patients with type 2 diabetes mellitus (T2DM). BMD was measured using dual-energy X-ray absorptiometry (DXA), and vertebral fractures were assessed via thoracolumbar radiography. HbA1c, blood glucose, and bone turnover markers (PINP, β-CTX, and OC) were analyzed. Correlations between HGI, BMD, and bone cell activity markers were examined. Mediation analysis was performed to determine whether osteoclastic activity mediates the HGI-BMD relationship.

Results

HGI was significantly higher in the vertebral fracture group compared to the non-fracture group (0.8 ± 2.1 vs. 0.3 ± 2.1, $p<0.05$). HGI negatively correlated with BMD ($r = -0.140$, $p = 0.005$) and positively correlated with β-CTX ($r = 0.15$, $p = 0.03$), but showed no significant association with P1NP ($r = 0.022$, $p = 0.755$). Mediation analysis revealed that osteoclastic activity explained 28.88% of the HGI-BMD relationship. Subgroup analysis by age showed a stronger correlation between HGI and BMD in patients ≥65 years compared to younger patients.

Conclusion

HGI is a potential contributor to bone loss in T2DM through its influence on osteoclastic activity, highlighting a novel link between diabetes and osteoporosis. While its effect on osteoblastic activity remains unclear, these findings suggest HGI as a target for future interventions to prevent osteoporosis and fractures in diabetic patients.

EFFICACY OF TRADITIONAL CHINESE MEDICINE IN REDUCING FRACTURE INCIDENCE AND PROLONGING FRACTURE-FREE SURVIVAL IN BONE DISEASE PATIENTS

W.-L. Chen[1], Y.-L. Deng[1], C.-Y. Hsu[1]

[1]Taichung Veterans General Hospital, Taiching, Taiwan

Objective

Osteoporosis represents a major public health issue, significantly affecting human health and quality of life. In Taiwan, a considerable number of patients seek Traditional Chinese Medicine (TCM) as a complementary treatment. This study aims to compare the risk of fracture and fracture-free survival time between osteopenia and osteoporosis patients treated with specific TCM and western medicine (WM).

Material and Methods

A retrospective cohort study was performed using data from Taichung Veterans General Hospital, Taiwan. The cumulative dose criteria of TCM were set at 12g or more for single-herb medicines and 80g or more for formulas. A total of 420 patients were included, with 84 patients in the TCM group and 336 in the WM group. Propensity score matching was applied at a 1:4 ratio to balance baseline characteristics between the two groups, including age, gender, and T-score. Statistical tests such as Chi-Square test, Mann-Whitney U test, and Cox proportional hazards model were used to analyze the differences in fracture incidence and fracture-free survival time.

Results

The incidence of fractures was significantly lower in the TCM group (51.2%) compared to the WM group (94.6%) ($p<0.001$). The median fracture-free survival time was 2.2 years for the TCM group, while it was only 0.2 years for the WM group ($p<0.001$). The hazard ratio (HR) for fractures in the TCM group compared to the WM group was 0.38 (95% CI: 0.26-0.55). Additionally, TCM treatment was associated with a lower mortality rate compared to WM (19% vs. 6.3%, $p<0.001$).

Conclusion

This study demonstrates that the use of specific traditional Chinese medicine in osteopenia and osteoporosis patients is associated with a significantly lower risk of fractures and longer fracture-free survival time compared to western medicine. These findings suggest that TCM may provide an effective alternative treatment for reducing fracture risk in this patient population.

Objective: Osteoporosis, though common, is often underdiagnosed due to limited access to dual-energy X-ray absorptiometry (DXA) scans and reluctance to undergo screening among the public. A deep learning model, PROS CXR: OSTEO, has been developed to close these gaps using the chest radiograph (a cost-effective and widely accessible tool) in the South Korean population. Here, we aimed to externally validate PROS CXR: OSTEO in an urban, multi-ethnic population in Malaysia.

Materials and Method: We recruited participants aged ≥50 years and osteoporotic treatment-naïve from Universiti Malaya Medical Centre, Kuala Lumpur, Malaysia from September 2024 to January 2025. We excluded those with either chest implants or active lung diseases. Eligible participants underwent chest radiographs (posteroanterior erect) and DXA with the bone mineral density (BMD) for lumbar spine and femur measured. We classified them into 1) osteoporosis (BMD T-score ≤ -2.5) or 2) non-osteoporosis (T-score > -2.5) using the lowest measured T-score on DXA. We evaluated the correlation between PROS CXR: OSTEO model predictions and actual BMD-derived categories for differentiating osteoporosis and non-osteoporosis. We also examined for sensitivity, specificity, and area under the curve (AUC) using a binary classification decision threshold of 0.2. Subgroup analyses by ethnicity were also conducted.

Results: This interim analysis involved 100 participants (44% Malays, 38% Chinese, and 18% Indians). On DXA, 35% of the participants were classified as having osteoporosis, 49% with osteopenia, and 16% with normal BMD. The sensitivity of PROS CXR: OSTEO was 70.6%, with a specificity of 81.8% and an AUC of 0.850. When stratified by ethnicity, the AUCs were 0.890, 0.812, and 0.850 for Malays, Chinese, and Indians, respectively.

Conclusion: The PROS CXR: OSTEO deep learning model shows broad applicability across diverse populations for early screening of osteoporosis.

HOW DO RHEUMATOLOGISTS OF CREER GROUP MANAGE LEVEL 2 ANALGESICS

X. Grapton[1], P. Lemesle[2], L. Poulain[3], N. Bouhedja[3]

[1]Hopital Suisse de Paris, ISSY LES MOULINEAUX, France, [2]Rives de Seine, Courbevoie, France, [3]Private Practice, La Garenne Colombes, France

Objectives:

Study the use of Level 2 analgesics by private practice rheumatologists (Rh) among the 7 most common diseases.

Investigate the perceived effectiveness and possible drug dependence of patients on some of these medications.

Material and Methods :

- 130 patients.
- W 71 %, with an average age of 67 years (women W = 70, men M = 59).
- Rheumatoid arthritis RA (7%), Ankylosing spondylitis AS (11%), Psoriatic arthritis PsoA(4%), Osteoarthritis OA (44%), Lower back pain LBP (26%), Radiculopathy (17%), and Fibromyalgia (3%).

Results:

Current Treatment (cur tt): Opium OP (33-57%), tramadol TR (30-40%), codeine C (13-25%), Nefopam and morphine at 7% (excluded). For both inflammatory or not conditions, the hierarchy is OP, TR, and C, except for AS.

1st tt: In both inflammatory or not, the order : TR = OP (30-42%), C (7-28%)

By conditions :

- Inflammation: A shift from equal use of OP and TR to greater reliance on OP in cur tt
- OA : OP = TR = C used initially but shifted to more OP in cur tt
- LBP : TR (30%) initially, OP = C (25%), shifting to TR (41%), OP (33%), and C (22%).
- Radiculopathy: 1st treatment was 42% OP, 29% TR, and 24% C, moving to 33% OP, 30% TR, 20% C.
- AS : Unique pattern with 1sr tt of 42% TR = OP, 17% C, shifting to 50% C, 21% TR = OP.
- Gender : M used OP, TR, C equally (30%), W used OP (49%), TR (38%), C (8%).
- Duration: The average duration of Level 2 analgesic use was 3.5 years regardless of the tt.

Effectiveness :

- In 1s^{t} tt, perceived effectiveness was for : OP 6/10, C 5.8/10, TR 5.5/10, often leading to tt changes. If effectiveness score = 7/10, changes were due to intolerance 22%, at 4.4/10, changes were due to ineffectiveness 56%.
- For cur tt, perceived effectiveness ratings were for : C 6,9/10, OP 6.6/10, TR 6.4/10.
- Frequency of daily doses decreased from 1st to cur tt, while weekly frequency increased, indicating improved effectiveness with changes.

Prescriptions:

- Initial treatment was initiated by Rh = general practitioners (Gp) (50%), with renewals by Rh.

- Cur tt was initiated by Rh 70% renewed by them 67%, Gp initiated 19% renewed 31%.
- 23% of patients modified doses in 1st tt..
- Cur tt, 27,3% reduced doses (W 71.4%); OP : 40%, TR :27%, C : 20%. 29% had LBP, 21% RA, 21% OA, 15% radiculopathy.
- 56% felt unable to stop their tt: 71% W, average age 63, 46% had OA, 45% used OP, 29% TR, 21% C, with daily use 84%. 15% believed they could reduce the dose, 11% would increase it.

Conclusion :
OP is the most prescribed Level 2 analgesic for both 1st and 2d tt, especially among W. An exception is AS : C = 50%. Product switches appear effective as usage frequency declines in 2d tt. Level 2 analgesics are extensively used in rheumatology, likely due to their effectiveness and tolerance over the long term. This study did not highlight addiction to these tt.

P1511

ROMOSOZUMAB INCREASED VERTEBRAL AND PROXIMAL FEMORAL STRENGTH IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS IN REAL-WORLD CLINICAL PRACTICE

K. Ishikawa[1], T. Keaveny[2], X. Li[3], S. Tani[4], T. Towatari[4], Y. Shi[3], B. Elder[5], P. Passias[1], M. Oates[3]

[1]Duke University, Durham, United States, [2]University of California Berkely, Berkeley, United States, [3]Amgen Inc., Thousand Oaks, United States, [4]Showa University, Tokyo, Japan, [5]Mayo Clinic, Rochester, United States

Objectives: Bone strength reflects the ability of bone to resist fracture. Limited data is available on the effect of romosozumab or other osteoporosis therapies on bone strength in real-world clinical practice. This study evaluated the real-world effectiveness of romosozumab (Romo) or teriparatide (TPTD) on vertebral and proximal femoral strength in Japanese postmenopausal women with osteoporosis using biomechanical computed tomography (BCT; VirtuOst®), an FDA-cleared diagnostic test.
Materials and Methods: In this retrospective observational study, 91 Japanese postmenopausal women with osteoporosis received Romo (n=57) or TPTD (n=34) for 12 months. None of them received osteoporosis treatment within 3 years of the index date. Vertebral strength, vertebral cortical and trabecular compartment strength, and proximal femoral strength were assessed before and after treatment, using BCT on a patient's routine clinical CT scan. BCT analyses were performed blinded to treatment status. The primary endpoint was percent change from baseline in vertebral strength at 12 months. Secondary endpoints included change in vertebral compartment and proximal femoral strength.
Results: At baseline, vertebral (including cortical and trabecular compartment strength) and proximal femoral strength were similar between Romo and TPTD groups. After 12 months of treatment, percent change in vertebral strength was 41.1% for Romo and 23.3% for TPTD (Figure). Percent change in vertebral cortical compartment strength was 38.4% for Romo and 15.9% for TPTD. Percent change in vertebral trabecular compartment strength was 40.3% for Romo and 30.9% for TPTD. These trends suggest that the treatment difference in overall vertebral strength was largely derived from the cortical compartment. Percent change in proximal femoral strength was 5.9% for Romo and 3.1% for TPTD (Figure).
Conclusion: Romo and TPTD increased vertebral strength in postmenopausal women with osteoporosis in real-world clinical practice, and the increase trended larger with Romo. Proximal femoral strength significantly increased with Romo, but not with TPTD after 12 months of treatment.

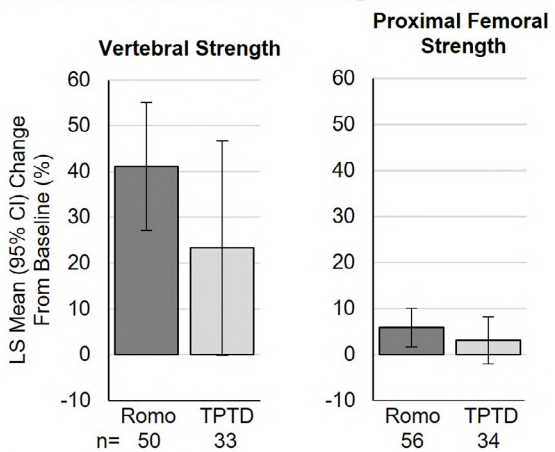
Figure: Percent Change from Baseline in Vertebral and Proximal Femoral Strength at Month 12



LS mean percent change was determined using generalized linear models adjusted for the patient's age at the index date, baseline value of the parameter, and fracture history. *CI, confidence interval; LS, least squares; Romo, romosozumab; TPTD, teriparatide.*

P1512

PREOPERATIVE OSTEOPOROSIS IN JOINT ARTHROPLASTY PATIENTS: A CALL FOR ROUTINE SCREENING AND MANAGEMENT IN CHINA

X. X. Wu[1], X. Z. Mao[1]

[1]second xiangya hospital, Changsha, China

Background: Osteoporosis is a leading contributor to periprosthetic fractures and elevated rates of long-term revision in joint replacement patients. Despite the significant global burden of osteoporosis, there is a lack of systematic studies investigating its prevalence among individuals undergoing joint replacement surgery, particularly in China, where the number of osteoporosis cas-

es is the highest worldwide. This study aimed to determine the prevalence of preoperative osteoporosis and the rate of osteoporosis treatment in patients undergoing joint replacement surgery.
Methods: We retrospectively analyzed patients aged 50 years or older who underwent total knee arthroplasty (TKA), unicompartmental knee arthroplasty (UKA), total hip arthroplasty (THA), or hemiarthroplasty (HA) at the Department of Orthopedics, the Second Xiangya Hospital, Central South University, between 2021 and 2023. Data on preoperative osteoporosis and related clinical aspects were collected and analyzed.
Results: A total of 1,736 patients were included in the study, comprising 811 TKA, 169 UKA, 697 THA, and 86 HA cases. Among these, 1,122 patients (64.6%) underwent dual-energy X-ray absorptiometry (DXA) testing prior to surgery. The prevalence of osteoporosis was 60.6% in TKA patients, 52.7% in UKA patients, 62.5% in THA patients, and 100% in HA patients. Notably, 75% of patients with comorbid arrhythmia, heart failure, or valve disease had osteoporosis, compared to 60.7% in those without these conditions. The overall treatment rate for osteoporosis was 68.6%, with most patients opting for denosumab over teriparatide or other oral medications. In terms of age distribution, the majority of patients (41.0%) were between 60 and 69 years old, and 54.5% of this age group were diagnosed with osteoporosis.
Conclusion: Osteoporosis is highly prevalent among joint replacement patients, particularly in HA, TKA, and THA cases, highlighting the need for routine DXA screening and targeted management.

RELATIONSHIP BETWEEN SERUM CHEMERIN LEVELS AND INFLAMMATORY MARKERS IN PATIENTS WITH OSTEOPOROSIS IN THE BACKGROUND OF RHEUMATOID ARTHRITIS

Y. Akhverdyan[1], B. Zavodovsky[1], E. Papichev[1], L. Seewordova[1], J. Polyakova[1]

[1]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A. B. Zborovsky», Volgograd, Russia

Introduction
Numerous studies have shown that adipokines are actively involved in inflammation and immune responses in rheumatoid arthritis (RA) [1]. One of the relatively new representatives of adipokines is chemerin. The latter belongs to the cathelicidin/cystatin protein family, consisting of antibacterial proteins cathelicidins and cysteine protease inhibitors [2]. Chemerin is known to play both pro-inflammatory and anti-inflammatory roles, and higher levels of chemerin have been found in inflamed tissues and body fluids in various inflammatory diseases [3]. Data have been obtained that suggest that elevated systemic chemerin levels in RA patients may be associated with systemic inflammation [4]. Chemerin is involved in the initiation and resolution of inflammation and may be a useful biomarker in some inflammatory diseases, such as psoriasis and inflammatory bowel disease.
Objective: to investigate the possible relationship between serum chemerin levels in patients with osteoporosis in the background rheumatoid arthritis (RA) and classical markers of inflammation and disease activity

Material and methods.
We examined 110 patients diagnosed with osteoporosis (OP) against the background of RA, the age of the examined subjects ranged from 18 to 75 years. The duration of the disease was 8.9 years [3.1-15.4]. The early clinical stage of the disease was observed in 19 (17.3%) patients, advanced stage – in 43 (39.1%), and late stage – in 48 (43.6%) patients. Bone density was determined using Dual Energy X-ray Absorptiometry (DXA). The serum chemerin level was determined using the commercial Human Chemerin ELISA kit (BioVendor, Cat. No.: RD191136200R).
Results.
We studied the relationship between the chemerin level in the blood serum of patients with OP and RA and markers reflecting the activity and rate of disease progression. Moderate correlations were found between the chemerin level and the following inflammatory markers: CRP ($r=0.2728$, $p<0.05$), ESR ($r=0.3193$, $p<0.05$). A relationship was also found between the serum chemerin concentration and disease activity according to DAS28 ($r=0.2198$, $p<0.05$). Thus, the level of chemerin in patients with OP against the background of RA is associated with RA activity.
Conclusions.
These results confirm our assumption that chemerin is an important element of autoimmune processes in the body of patients with OP against the background of RA.

CHEMERIN AS A LABORATORY MARKER FOR THE DEVELOPMENT OF ARTERIAL HYPERTENSION IN PATIENTS WITH OSTEOPOROSIS IN THE BACKGROUND OF RHEUMATOID ARTHRITIS

Y. Akhverdyan[1], B. Zavodovsky[1], E. Papichev[1], J. Polyakova[1], L. Seewordova[1]

[1]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A. B. Zborovsky», Volgograd, Russia

Introduction
There are epidemiological data confirming the important role of chemerin in the development of cardiovascular pathology. In particular, there is a positive correlation between the concentration

of chemerin protein in serum and diseases such as atherosclerosis, hypertension and atrial fibrillation. It is believed that in heart failure, the level of chemerin can serve as a new prognostic indicator.
Objective:
to study the relationship between the level of chemerin in the blood serum of patients with osteoporosis in the background of rheumatoid arthritis (RA) and blood pressure levels.
Material and methods.
We observed 110 patients with osteoporosis (OP) against the background of RA a diagnosis of RA corresponding to the 2010 ACR/EULAB diagnostic criteria. The age of the patients ranged from 18 to 75 years, of which 93% were women and 7% were men. Bone density was determined using Dual Energy X-ray Absorptiometry (DXA). The serum chemerin level was determined using the commercial Human Chemerin ELISA kit (BioVendor, Cat. No.: RD191136200R).
Results.
We assessed the chemerin level in a group of healthy donors and patients with RA. The normal chemerin level in healthy individuals (calculated as M±2σ) ranged from 142.5 μg/ml to 257.3 ng/ml. The average chemerin level in RA patients was 495.6±168.49 ng/ml, which was significantly higher than the healthy donor levels — 178.6±45.81 ng/ml (t=-10.15; p<0.0001). The chemerin level was subject to normal distribution (K-S d=0.10621, p>0.2).
When conducting a correlation analysis of chemerin with blood pressure indicators, a connection was found with the level of SBP (systolic blood pressure) - (Spearman - R = -0.408491, p = 0.000805) and DBP (diastolic blood pressure) - (Spearman - R = -0.274877, p = 0.027935), which is completely consistent with the literature data on the negative correlation of chemerin levels and blood pressure. Next, we studied the diagnostic value of determining the level of chemerin for detecting arterial hypertension in patients with RA using the ROC analysis method. Based on the ROC curve analysis, it can be concluded that the level of chemerin, equal to 368.5 ng/ml, has 73.1% sensitivity and 26% specificity for detecting arterial hypertension in patients with OP and RA.
Conclusions.
Thus, a decrease in the concentration of chemerin in the blood serum can be used to identify patients with OP in the background of RA at risk of developing arterial hypertension.

P1515

PREVALENCE OF FALLING STATUS BASED ON WORK RELATED PHYSICAL ACTIVITY AMONG THE POPULATION IN IRAN: A NATIONWIDE STUDY

Y. Azizpour[1], S. Sarrafzadeh[2], A. Golestani[1], S. Akbarpour[1], S. Salehi[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: This study aimed to investigate the prevalence of falls based on the amount of work-related physical activity among the adult population in Iran.
Material and Methods: Data from 2021 STEPwise Approach to Non-Communicable Disease Risk Factor Surveillance (STEPS) survey were analyzed, focusing on participants aged 18 years and older. To assess the work-related physical activity, individuals were asked about their moderate and vigorous work-related activity that lasted at least 10 minutes per week. The first group consisted of individuals who reported no physical activity, and remining participants were divided into two groups according to the median value of activity: group 2 (≥10 to <660 minutes/week) and group3 (≥660 minutes/week). Prevalence estimates were adjusted according to the sampling design, and percentages with 95% confidence intervals (CIs) were reported for the overall population and by sex. A non-parametric trend test was used to evaluate the trend of an ordinal variable across another group.

Table 1. Prevalence of Falling Based on Work Related Physical Activity Among Iranian Population

Variables	Group 1 No physical activity (n=397)	Group 2 Physical Activity at Work ≥10 to <660 minutes/week (n= 131)	Group 3 Physical Activity at Work ≥660 minutes/week (n=135)	p value-trend
Total	2.20 [1.96,2.46]	3.01 [2.51,3.64]	3.10 [2.58,3.72]	<0.001
Sex				
Female	2.23 [1.94,2.57]	3.47 [2.74,4.40]	3.31 [2.41,4.53]	0.003
Male	2.15 [1.78,2.58]	2.47 [1.83,3.32]	3.01 [2.40,3.76]	0.025

Summary statistics are weighted according to sex, age, and residence (urban/rural) based on the 2016 Iranian census
Results are reported as percentages along with 95% confidence intervals (CIs) for categorical variables

Results: Out of 27,560 participants, 663 individuals reported a history of falls in last 12 months. The mean age [standard error: SE] of individuals who experienced falls was 51.4 years [SE = 0.72]. Additionally, 56.5% [95% CI: 52.2,60.8] of these individuals were females. The highest prevalence of falls was observed in the entire population and specifically among males who engaged in 660 minutes or more of physical activity per week, with prevalence rates of 3.10 [95% CI: 2.58,3.72] and 3.01 [95% CI: 2.40,3.76], respectively. In the overall population, as well as among both males and females, the prevalence of falls increased with higher levels of physical activity, and this trend was statistically significant (P<0.05).
Conclusion: The findings indicate that the prevalence of falls increases with higher levels of physical activity. It is recommended that future observational-analytical studies investigate the causes of falls during physical activity.

P1516

IN WHAT WAYS DOES THE SITE OF OSTEOARTHRITIS AFFECT THE QUALITY OF LIFE?

Y. Ben Slama[1], R. Grassa[1], N. Ben Chekaya[1], R. Bouazra[1], M. Ghali[1], M. Bekey[1], A. Chaabani[2], M. Jguirim[1], S. Zrour[1], I. Bejia[1]

[1]Department of Rheumatology, Fattouma Bourguiba University Hospital, Monastir, Tunisia, [2]department of Physical medicine and rehabilitation , Fattouma Bourguiba University Hospital, Monastir, Tunisia

Introduction :
Osteoarthritis (OA) is a common and progressive joint disorder characterized by the degeneration of cartilage . It affects any joint, but it most commonly impacts the knees and hands. It can lead to physical and mental fatigue .
Objectives :
The aim of the study was to describe the quality of life in patients with osteoarthritis, and to predict the impact of its location on both physical and mental aspects .
Methods :
This was a cross-sectional study consecutively including patients followed in the Rheumatology department for osteoarthritis. We used the short form SF-12 questionnaire to assess the quality of life. The statistical analysis was done by SPSS software.
Results :
A total of 72 patients were included in the study (77,8% women and 22,2% men) with a mean age of 68 ± 8.79 years [50-91]. Most common comorbidities were hypertension(59,7%),diabetes (33,3%) , cardiac disorders (23,6%) , osteoporosis (27,8%) and rheumatoid arthritis (13,9%).
The average BMI was 35.17 ± 5,21 [26- 39] Knee osteoarthritis was isolated in 44 patients (61,1%) .Osteoarthritis of the hand was isolated in 20 patients (27,7%) .
The average mental quality of life (MCS) score in Knee osteoarthritis was 48,43 ± 13,12, the average physical quality of life (PCS) score was 40 ± 14,3. Both were below the average health status.
Therefore, in osteoarthritis of the hand ,The average mental quality of life score was 48,13 ± 15,12, while the average physical quality of life score was 36 ± 14,3. Both were below the average health status.
No matter the location , the physical impact of osteoarthritis was remarkably more important than the mental impact .
Therefore PCS was more altered in patients with osteoarthritis of the hand .
Conclusion :
The quality of life of individuals with osteoarthritis is deeply influenced by the location of the affected joints. Osteoarthritis of the hand can significantly impair an one's independence, especially when fine motor skills are required.

PROFILE OF PATIENTS WITH COXOPATHIES: A CROSS-SECTIONAL STUDY OF 40 PATIENTS

Y. Ben Slama[1], R. Grassa[1], N. Ben Chekaya[1], R. Bouazra[1], M. Ghali[1], M. Bekey[1], M. Jguirim[1], S. Zrour[1], I. Bejia[1]

[1]Department of Rheumatology, Fattouma Bourguiba University Hospital, Monastir, Tunisia

Introduction :
The hip joint is a crucial component for the body's mobility and stability . Understanding its diverse disorders , their etiologies and manifestations is crucial for early diagnosis and effective management.

Objectives :
This aim of this study was to explore the spectrum of hip joint anomalies, their clinical presentation, diagnostic approaches, and treatment strategies to provide a comprehensive overview for improving patient outcomes.

Methods :
This was a cross-sectional study conducted over a period of two years [2022-2024], including patients with coxopathies who were followed at the Rheumatology Department of Fattouma Bourguiba Hospital in Monastir.

Results :
Our study included 40 patients (27 men and 13 women).Sex ratio (M/F) was 2.07 . The mean age was 44.42 ± 2.95 years. The most common comorbidities among our patients were hypertension, diabetes, and dyslipidemia in 25%, 10%, and 6% of cases, respectively. Metabolic syndrome was noted in 10 patients. The most frequent clinical manifestations were, in descending order of frequency: groin pain, hip limitation, and morning stiffness, reported in 100%, 97.5%, and 82.5% of cases, respectively. Bilateral involvement was noted in only 5% of cases. An inflammatory biological syndrome was present in 47.5% of patients. Standard radiographs showed hip joint involvement, frequently represented by joint space narrowing, geodes, osteophytosis, and femoral head flattening in 65.5%, 27.5%, 10%, and 5% of cases, respectively. A pelvic MRI was requested for 21 patients (52.5%). The most common etiologies, in order of frequency, were inflammatory coxitis, coxarthrosis, avascular necrosis of the femoral head, and septic coxitis, in 62.5%, 12.5%, 10%, and 5% of cases, respectively. Bone tumors, chondrocalcinosis, and Paget's disease were noted in only one patient each. Sixty-seven percent of patients (67%) were treated medically with good symptom improvement. Two patients received ultrasound-guided hip infiltration. Synoviorthesis was indicated in 22.5% of cases. Surgery was required for only 2 patients (5%).

Conclusion :
Early and accurate diagnosis is critical for tailoring appropriate treatment approaches, which can significantly alleviate symptoms and prevent long-term complications.

UNITING THE DICHOTOMY BETWEEN PRIMARY AND SECONDARY PREVENTION OF OSTEOPOROSIS – BONE AND MUSCLE HEALTH RELATED CHARACTERISTICS IN CARE HOME RESIDENTS IN EGYPT: A COMMUNITY- BASED INTERVENTION BY THE EGYPTIAN ACADEMY OF BONE AND MUSCLE HEALTH

Y. El Miedany[1], N. Gadallah[2], M. Sarhan[3], M. Elgaafary[2], W. Hassan[4], N. El Gharbawy[2], S. Moussa[2], S. Fathi[2], N. Fouda[2], D. El Mikkawy[2], O. Saboony[2], A. Safar[2], W. Elwakil[5], S. Mahran[6], M. Elkaramany[7], A. Samir[3], N. Ahmed[3], M. Mahgoub[4]

[1]Canterbury Christ Church University, Meopham, Gravesend, United Kingdom, [2]Ain Shams University, Cairo, Egypt, [3]Egyptian Food Bank, Cairo, Egypt, [4]Benha University, Benha, Egypt, [5]Alexandria University, Alexandria, Egypt, [6]Assiut University, Assiut, Egypt, [7]American university Cairo, Cairo, Egypt

Background:
The care home population represent a population at potentially high risk of fracture, who may benefit from targeted bone and muscle health screening and prevention strategy. However, the characteristics of care home populations, with respect to fracture risk and subsequent care, have not been well-defined in Egypt. In concordance with the ground-breaking collaboration between the WHO with ESCEO / IOF for the prioritization of osteoporosis and fragility fracture prevention within global healthcare policy, a project has been launched to lay the groundwork for a national approach for promoting bone and muscle health as well as prevention of osteoporosis and fragility fractures in Egypt.
Objective: To describe the bone and muscle health characteristics and risk factors among care home residents, including fracture, sarcopenia and falls risk factors, fracture rates, nutritional and psychological status as well as functional abilities.
Methods:
Design: A prospective cohort study of care home residents aged ≥50 years in Egypt
Methodology: This is a national quality improvement program that adopts "Plan, Do, Study, Act
(PDSA) cycle methodology". The project is a joint activity provided by the Egyptian Food bank
and the Egyptian Academy of Bone and Muscle Health in collaboration with the ministry of
Social Solidarity. All adults/older adults living in care homes in greater Cairo, Egypt, aged 50-years and above have been invited to join this project of primary prevention of osteoporosis. Every participant completed a questionnaire to assess for Fracture risk (FRAX-Egypt), Falls risk (FRAS), Sarcopenia Risk (SARC-F), functional disability (HAQ), as well as comorbidities and past history/ current medications intake. Assessment of bone mineral density (DXA scan) was carried out for every subject. Exercise program has been provided by local physio teams under supervision of the Rehab physicians to reduce sarcopenia and fall risk. Patient education and counselling program have been provided by the treating doctors. Blood tests for Vitamin D serum levels and bone profile were carried out for all subjects. Assessment of the nutritional status (Mini Nutritional Assessment), psychological status (GHQ-30 questionnaire) as well as mental status (Mini Mental State Examination (MMSE) were carried out for every subject. Osteoporosis therapy as well as calcium and vitamin D supplementation were provided for those participants diagnosed to have osteoporosis or at high/very high fracture risk.
Results:
357 subjects were included in this work. 37% of the care home residents were men (mean age 71.3 whereas 63% were women (mean age 72.7-years). 91% were non-smokers whereas 9% were smokers. 25% were diabetics. 81% were vitamin D deficient, 9% were insufficient, whereas 10% were sufficient. 65% had high sarcopenia risk, whereas 47% had high falls risk. There was severe physical disability in 17% of the subjects included, 30% were moderate to severe, whereas 53% had mild to moderate disability. The prevalence of depression was 60% whereas 38.4% were found to have cognitive impairment. 23% had past history of fragility fractures, whereas 77% did not. 31% of the females had high 10-year probability of hip fracture, in contrast to 16% of the men. DXA revealed 47.2% were osteoporotic. Adding the osteoporotic subjects to those who have high or very high fracture risk, mounted to 63.8% require osteoporosis therapy which was commenced accordingly.
Conclusion: The characteristics of care home populations with respect to bone and muscle risk factors have not been well-studied, and limited information is available from Egypt. This study revealed that care home residents have fracture, sarcopenia and falls risk factors which are comparable to the national figures. There is an opportunity for clinicians to reduce the gap in osteoporosis diagnosis and treatment.

P1519

FIXED INTERVENTION THRESHOLDS VS AGE-DEPENDENT FRAX-BASED ASSESSMENT FOR THERAPEUTIC DECISION MAKING IN OSTEOPOROSIS. BY THE EGYPTIAN ACADEMY OF BONE AND MUSCLE HEALTH

Y. El Miedany[1], M. Elgaafary[2], A. Samir[3], W. Elwakil[4]

[1]Canterbury Christ Church University, Meopham, Gravesend, United Kingdom, [2]Ain Shams University Community and Public Health, Cairo, Egypt, [3]Egyptian Food Bank, Cairo, Egypt, [4]Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt

Background: The use of FRAX (fixed or age-dependent thresholds) as the gateway to assessment identifies individuals at high risk has been reported to be more effectively than the use of BMD. Whilst fixed intervention thresholds for osteoporosis management are set at a specific percentages, age-dependent thresholds (developed based on the probability of a major osteoporotic fracture) are based on the idea that if a person with a certain fracture probability is eligible for treatment, then anyone with the same

probability should be eligible. Fixed thresholds can help avoid overtreating young patients, who are less likely to fracture. On the other hand, age-dependent thresholds can lead to undertreating older patients, who may still require intervention due to other risk factors. More recently a hybrid threshold has been adopted. Hybrid thresholds are a combination of age-specific thresholds up to age 70 and a fixed threshold for older ages. For men and women under 70, the threshold is set at the same risk as a woman of the same age who has had a previous fracture. For people 70 and older, fixed thresholds are used. This model is used to reduce inequalities in treatment, which can occur when younger people are overtreated and older people without a history of fractures are undertreated.

Objective: To compare the fixed intervention thresholds (Its) to the age-dependent intervention thresholds applied to the Fracture Risk Assessment (FRAX) tool in therapeutic decision making for both post-menopausal women and men with osteoporosis.

Methods: Data were collated from treatment-naïve 169-postmenopausal women and 51-men aged 40-85 years who sustained osteoporotic fragility fracture. Pre-fracture FRAX was calculated to assess the probability of developing a low trauma fracture. Both Fixed intervention threshold and age-dependent ITs, for both major osteoporotic fracture (MOF) and hip fracture (HF), were calculated considering a woman with a BMI of 25 kg/m2, aged between 40 and 85years, with a prior fragility fracture, without other clinical risk factors. The best cut-points were determined considering the optimum sensitivity and specificity using receiver operating characteristic analysis [1]. Those with fracture probabilities equal to or above upper assessment thresholds (UATs) were considered to have high fracture risk. Those below the lower assessment thresholds (LATs) were considered to have low fracture risk.

Results:

For post-menopausal women, there was discrepancy between Fixed ITs and age dependent Its in 16% of the patients which was equally distributed in both ITs. The mean age of the Fixed ITs cohort was 75.4 years whereas for the age dependent was 53.8 years. 38.5% of the age dependent post-menopausal cohort had oophorectomy/ early menopause whereas 30.8% had secondary causes (Diabetes, hypertension, asthma). In the Fixed ITs cohort, 61.5% had secondary causes whereas 15.4% had early menopause ($p< 0.01$). Whilst age-dependent ITs performed better in younger patients, it lead to undertreatment of older patients.

For the men group, there was significant discrepancy between Fixed ITs and age dependent. Fixed ITs performed significantly ($P<0.001$) better than the age-dependent ITs in identifying the fracture probability. Age-dependent ITs (developed based on its values in women) underestimated the fracture risk in men at all age groups. 35.3% had secondary causes (Diabetes, hypertension, asthma) in the men's cohort which was not significantly different from the women cohort.

Conclusion:

Fixed ITs performed better as a screening tool for the fracture risk probability, particularly for men. FRAX-plus is of value to facilitate the inclusion of risk factors in the final fracture risk assessment. FRAX-based intervention thresholds should be developed specific for men with osteoporosis. Country specific intervention thresholds are needed

P1520

VITAMIN D MANAGEMENT UPDATE: EVIDENCE-BASED GUIDELINES FOR VITAMIN D OPTIMIZATION. BY THE EGYPTIAN SOCIETY FOR BONE AND MUSCLE HEALTH

Y. El Miedany[1], M. Toth[2], M. Elgaafary[3], S. Mahran[4], W. Hassan[5], M. Abu-Zaid[6], W. Elwakil[7], W. Selim[8], E. Sultan[9], G. Saber[10], S. Galal[11]

[1]Canterbury Christ Church University, Meopham, Gravesend, United Kingdom, [2]King's college London, London, United Kingdom, [3]Ain Shams University Community and Public Health, Cairo, Egypt, [4]Assiut University, Rheumatology, Physical Medicine and Rehabilitation, Assiut, Egypt, [5]Benha University, Rheumatology, Physical Medicine and Rehabilitation, Benha, Egypt, [6]Tanta University, Rheumatology, Physical Medicine and Rehabilitation, Tanta, Egypt, [7]Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt, [8]Ain Shams University, clinical Pathology, Cairo, Egypt, [9]National Nutrition Institute, Cairo, Egypt, [10]Egyptian Railway Medical Center, Cairo, Egypt, [11]Ain Shams University, Rheumatology, Physical Medicine and Rehabilitation, Cairo, Egypt

Background Vitamin D plays a crucial role in bone health, calcium homeostasis, and prevention of chronic diseases. Deficiency and insufficiency of vitamin D poses a global health concern, particularly in specific populations such as the elderly, individuals with limited sun exposure, and those with dietary restrictions. The Egyptian Academy for bone and muscle health is issuing an updated guideline influenced by a substantial body of research conducted in recent years. for the diagnosis, prevention, and management of vitamin D deficiency.

Objective: To establish clear, evidence-based guidelines for healthcare professionals and the public on the why, how and when to recommend vitamin D supplementation with objectives to optimize vitamin D levels, prevent deficiency, minimize adverse effects, and inform public health policies.

Methodology The guideline development conformed to the Meta-Analyses guidelines and Preferred Reporting Items for Systematic Reviews. It synthesizes evidence from clinical studies and expert consensus on vitamin D requirements across different age groups and health conditions. 32 key clinical questions were identified using the Patient/Population, Intervention, Comparison, and Outcomes (PICO) framework. Review of the literature review was carried out to evaluate the benefits and risks of available pharmacologic and nonpharmacologic therapies for vitamin D insufficiency and deficiency. The level of evidence was assessed adopting the Oxford Centre for Evidence-based Medicine (CEBM) system. Based on this evidence, recommendations were developed, with A 3-round online Delphi process involving 10 experts was carried out to achieve consensus on the direction and strength of the recommendations.

Results Recommendations include daily intake guidelines, test-

ing protocols, management of deficiency, and public health interventions. The role of empirical vitamin D dosing in high-risk individuals was emphasized. Key considerations include age, body weight, lifestyle, dietary habits, individual health risks as well as comorbidities. Testing is recommended for symptomatic individuals or those with specific conditions such as osteoporosis or renal impairment. The guideline highlights the role of FGF23 in high dosing of vitamin D, relation between vitamin D deficiency and fall risk, it encourages oral over intramuscular administration and discourages routine population-wide screening.

Conclusion Effective management of vitamin D levels involves tailored supplementation strategies based on individual needs and risk factors. Maintenance of serum 25(OH)D levels above 30 ng/mL is advised for optimal health outcomes. Public health efforts should focus on lifestyle modifications, safe sun exposure, and dietary education, alongside targeted supplementation for at-risk groups.

P1521

LONGITUDINAL PATTERNS OF PHYSICAL ACTIVITY, SEDENTARY BEHAVIOUR AND SLEEP LIFESTYLE IN A REPRESENTATIVE SAMPLE OF EGYPTIAN POPULATION 50-YEARS AND OLDER: A CROSS-SECTIONAL STUDY

Y. El Miedany[1], I. Qutob[2], N. Elkastawy[2], H. Abdelaziz[2], I. Hanafy[2], A. Elkhouly[3], G. Hany[2], A. Maan[2], H. Ghorab[2], W. Elwakil[4]

[1]Canterbury Christ Church University, Meopham, Gravesend, United Kingdom, [2]Alexandria University, Alexandria, Egypt, [3]Modern University for Technology and Information, Cairo, Egypt, [4]Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt

Background:
In 2018, the World Health Assembly (WHA) approved a new Global Action Plan on Physical Activity (GAPPA) 2018–2023 and endorsed a global target to reduce global levels of physical inactivity in adults and adolescents by 15% by 2030. Egyptian older adults, similar to those in industrial countries, have also reported a lack of physical activity. Earlier data revealed that less than 10% of the older Egyptian population practice regular exercises; of them, the most inactive population were those over the age of 60 years old [1]. Providing clinicians with a tool that enables them to assess their patients for their level of physical activity as well as sedentary and sleep behaviour would have a positive impact on their strategy of management.

Objective:
1. Assess the pattern of physical activity, sedentary behaviour, and sleep behaviour among the Egyptian men and women older than 50 years old using the self-reported sedentary, physical activity, and sleep quality self-assessment questionnaire (SASA);
2. Evaluate the prevalence of non-communicable diseases in this cohort of the population and its relation to the physical activity level.

Methods:
Design: a prospective community bases study.
Participants:
Inclusion criteria: Self mobilized Egyptian men and women aged 50 years and older.
Exclusion criteria: Dementia patients, users of assistive devices that greatly affect physical activity (wheelchair lifestyle and limb prosthesis), patients taking medications that affect their sleep or physical activity, and non-Egyptians have been excluded from this work.
Methodology:
Every subject was invited to complete the self-reported sedentary, physical activity, and sleep quality self-assessment questionnaire (SASA). The questionnaire is composed of 14 questions stratified into 3 domains, namely, to assess: 1. Sedentary activity (4 questions), 2. Physical activity (4 questions), 3. Sleep behaviour (6 questions). The 14-item questionnaire ranges from a sedentary lifestyle to regular and strenuous physical activity and from strength training to flexibility-enhancing exercises. The instructions for completing the questionnaire are based on a brief description with illustrations of the three levels of physical activity (light, medium, and intense) to help judge the type of activities in each category. It takes a maximum of 5 min to complete it. For every question, there are 3 response options, with scores ranging from 0-2. The score obtained by the respondent can be classified into one of the following three levels: (1) Sedentary lifestyle: 0-<4: sedentary, 4-6 borderline, & >6: non-sedentary; (2) Physical activity: 0-2: inactive, >2-4: less than active, & >4: active; (3) Sleep: 0-3: poor sleep quality, 3-9: fair sleep quality, 9-12: good sleep quality. The presence of comorbidities, namely obesity, type II diabetes mellitus, hyperlipidaemia, hypertension, coronary artery disease, stroke, and cancer, has been recorded.
Results:
679 participants 50-years and older were included in this work: 276 males (40.65%) and 403 females (59.35%), mean age: 58.3 ± 6.71 years. The mean BMI was 30.32 ± 6.62 and was significantly higher among the female' participants (31.2 ± 8.7 compared to 27.3 ± 5.8 in male patients; $p < 0.001$). About 27% of the participants were illiterate, while the remaining individuals had varying educational levels, with 6.63% having completed postgraduate studies.
The prevalence of the 3 main components of the questionnaire are shown in table (1).
The most common comorbidity among the participants was arthritis, followed by hypertension and type 2 DM (41%, 39.32%, and 23%, respectively). Arthritis was significantly higher among females ($p < 0.001$).
Results of multivariate regression analysis showed that age, female sex, and high BMI were predictors of low PA score. Women were 1.2 times more likely to be physically inactive; moreover, those with poor sleep quality were more likely to be physically inactive (95% CI=0.09, P=0.0042).

Table (1): Prevalence of the 3 main components of the SASA questionnaire in Egyptian men and women

		Gender		
Term	**Overall N (%)**	**Male N (%) (n=276)**	**Female N (%) (n=403)**	**p-value**
Sedentary (category)				0.925
Sedentary	63 (9.28)	27 (9.8)	36 (8.9)	
Borderline	366 (53.9)	147 (53.3)	219 (54.3)	
Active	250 (36.82)	102 (37)	148 (36.7)	
PA (category)				**< 0.001*** **
Inactive	388 (57.14)	127 (46)	261 (64.8)	
Borderline	83 (12.22)	27 (9.8)	56 (13.9)	
Active	208 (30.63)	122 (44.2)	86 (21.3)	
Sleep quality (category)				0.126
Poor	20 (2.95)	8 (2.9)	12 (3)	
Fair	452 (66.57)	172 (62.3)	280 (69.5)	
Good	207 (30.49)	96 (34.8)	111 (27.5)	
α = 0.05. p < 0.05*, p < 0.01, p < 0.001*** **				
P-values obtained from Fisher's exact test				
		Gender		
Term	**Overall**	**Male**	**Female**	**p-value**
Sedentary	Med (IQR) 6 (2)	6 (2)	6 (2)	U: 0.6628
PA	Med (IQR) 0 (5)	4 (6)	0 (4)	**U: <0.001*** **
Sleep quality	Med (IQR) 7 (3)	8 (3)	7 (3)	**U: 0.0030****
α = 0.05. p < 0.05*, p < 0.01, p < 0.001*** **				
P-values obtained from two-sample t-test (t) or Mann-Whitney test (U)				

Conclusion: Worldwide, growing number of adults are not doing the recommended physical activity, which in turn is expected to increase the number of people living with non-communicable diseases (NCDs). it is recommended that Egyptians should consider doing physical activities as part of their standard routine. Older adults should do varied multicomponent physical activity at moderate or greater intensity on 3 or more days a week in order to enhance functional capacity, prevent falls and ensure high quality sleep.

P1522

FRAX-BASED INTERVENTION THRESHOLDS FOR OSTEOPOROSIS MANAGEMENT IN 6-ARABIC COUNTRIES: IMPACT ON PATIENTS' MANAGEMENT

Y. El Miedany[1], M. Elgaafary[2], S. Mahran[3], W. Elwakil[4]

[1]Canterbury Christ Church University, Meopham, Gravesend, United Kingdom, [2]Ain Shams University Community and Public Health, Cairo, Egypt, [3]Assiut University, Rheumatology, Physical Medicine and Rehabilitation, Assiut, Egypt, [4]Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt

Background: Currently, country-specific, age-dependent FRAX is available in ten of the fourteen Middle Eastern countries, including the United Arab Emirates, Egypt, Iran, Jordan, Kuwait, Lebanon, Palestine, Qatar, Saudi Arabia, and Syria. The FRAX® models have been adjusted for the various countries by incorporating country-specific fracture and mortality rates taken from national or regional sources.

Objective: This study aimed to compare the outcome of implementing age-specific intervention thresholds for both major osteoporotic fractures as well as hip fracture in some of the Middle Eastern countries where FRAX models are available.

Methods: The 10-year probability of both major osteoporotic fracture as well as hip fractures were assessed for 237 patients (51 Males and 186 Females) who sustained osteoporotic fractures. The risk was calculated using their risk factors prior to the occurrence of the index fracture. The age-specific 10-year probabilities of a major osteoporotic fracture (MOF) as well as hip for a woman with a BMI of 25.0 kg/ m2, without BMD were calculated as intervention Threshold (IT). The sensitivity of the fracture risks were compared using Kappa statistics amongst Egypt, Emirates, Jordan, Lebanon, Saudi Arabia and Qatar.

Results: The sensitivity of the different age-specific intervention thresholds for major osteoporotic fractures ranged from 24% to 51.9% among women below 70-years old, whereas it ranged between 24.3% to 62.6% for women over 70-years old. For hip fractures, the sensitivity ranged from 36% to 76% in women under 70-years old and 80.2% to 90% in women over 70-years old. In men, under 70-years old, the sensitivity ranged from 27.3% to 54%, whereas over 70-years the sensitivity ranged from 62.1% to 72.4%. Kappa agreement of risk of fractures using major fracture FRAX revealed significant relation between all the Arab countries in both men and women ($p < 0.001$). Similar significant relation was noted at the hip fracture side.

Conclusion: Inspite of the heterogeneity of the intervention thresholds among individuals of different ages in the studied Arabic countries, there was a significant relation amongst all those countries in identifying those at risk of developing osteoporotic fractures. These intervention thresholds provide valuable insights to make informed decisions regarding osteoporosis management. Development of country-specific fixed interventional thresholds might be an approach to improve the sensitivity of the cut-off thresholds for osteoporosis management and to facilitate screening and management of the patients according to the national clinical guidelines.

P1523

THE ASSOCIATIONS BETWEEN MEETING 24-HOUR MOVEMENT GUIDELINES (24-HMG) AND SELF-RATED PHYSICAL HEALTH IN ADULTS AND OLDER ADULTS—CROSS SECTIONAL EVIDENCE FROM EGYPT. BY THE EGYPTIAN ACADEMY OF BONE AND MUSCLE HEALTH

Y. El Miedany[1], I. Qutob[2], N. Elkastawy[2], H. Abdelaziz[2], I. Hanafy[2], A. Elkhouly[3], G. Hany[2], A. Maan[2], H. Ghorab[2], W. Elwakil[4]

[1]Canterbury Christ Church University, Meopham, Gravesend, United Kingdom, [2]Alexandria University, Alexandria, Egypt, [3]Modern University for Technology and Information, Cairo, Egypt, [4]Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt

Background: The 24-HMG recognize that physical activity, sedentary behavior, and sleep are interconnected behaviors that influence health. These guidelines emphasize the importance of a balanced approach to movement throughout the day. Meeting the 24-hour movement guidelines is expected to match the self-rated physical health in adults and older adults. This way, the more 24-HMG guidelines met, the better the self-rated physical health in both adults and older adults.

Objectives: This study determined the prevalence of adults and older adults (aged 50-years and
older) meeting the Egyptian 24-hour movement guidelines alone and in combination, and their
association with the self-rated physical activity.

Methods: Participants included were Egyptian men and women aged 50-years and older (age, 67.37 ± 0.08 years; 46.87% male). Physical health scores were obtained for every subject who was asked to complete a copy of the self-Assessment (SASA) questionnaires. The criteria for meeting the 24-hour movement guidelines were: physical activity time ≥ 150 min/week, sedentary time ≤ 480 min/day, screen time ≤ 180 min/day, sleep time 7-9 hours. The questionnaire is composed of 14 questions stratified into 3 domains, namely, to assess: 1. Sedentary activity (4 questions), 2. Physical activity (4 questions), 3. Sleep behaviour (6 questions). For every question, there are 3 response options, with scores ranging from 0-2. The score obtained by the respondent can be classified into one of the following three levels: (1) Sedentary lifestyle: 0-<4: sedentary, 4-6 borderline, & >6: non-sedentary; (2) Physical activity: 0-2: inactive, >2-4: borderline, & >4: active; (3) Sleep: 0-3: poor sleep quality, 3-7: fair sleep quality, 7-9: good sleep quality.

Results: The proportion of older people meeting three of the Egyptian 24-hour movement guidelines
was 4.16%, the proportion meeting two guidelines was 28.19% and the proportion meeting one
guideline was 39.14%. The number of people meeting 24-hour movement guidelines was closely
related to the self-rated physical health in both adults (50-60 years old) and older adults (60-years
old and higher) Egyptians.

Table: The prevalence of the different patterns of behaviour among Egyptian adults and older adults

Variable	N (%)
Weekly Physical Activity-time	
<150 minutes	492 (72.46%)
150 minutes or more	187 (27.54%)
Daily sedentary time	-
>480 minutes	429 (63.18%)
480 minutes or less	250 (36.82%)
Screen-time	-
>180 minutes	403 (59.35%)
180 minutes or less	276 (40.65%)
Sleep duration	-
7-9 hours	243 (35.79%)
Otherwise	436 (64.21%)

Conclusion: A relatively small proportion of older people met all the 24-HMG recommendations, highlighting the need to promote and support the adherence to these movement behaviours. To improve self-rated physical health, it is essential to encourage individuals to adopt healthy lifestyle habits that align with the 24-HMG. This can be achieved through: education and awareness campaigns, creating supportive environments (promoting active transportation, providing access to safe and accessible recreational spaces, and creating workplace wellness programs) and tailored interventions.

P1524

TARGETING THE MUSCLE–BRAIN AXIS: THE RECIPROCAL RELATIONSHIP BETWEEN COGNITIVE IMPAIRMENT AND SARCOPENIA- DOES IT REPRESENT A NEW PARADIGM IN SARCOPENIA?

Y. El Miedany[1], N. Gadallah[2], M. Sarhan[3], M. Elgaafary[4], W. Hassan[5], N. El Gharbawy[2], S. Moussa[2], S. Fathi[2], N. Fouda[2], D. El Mikkawy[2], O. Saboony[2], A. Safar[2], W. Elwakil[6], S. Mahran[7], M. Elkaramany[8], N. M. Ahmed[3], M. Y. Mahgoub[5], A. Samir[3]

[1]Canterbury Christ Church University, Meopham, Gravesend, United Kingdom, [2]Ain Shams University, Rheumatology, Physical Medicine and Rehabilitation, Cairo, Egypt, [3]Egyptian Food Bank, Cairo, Egypt, [4]Ain Shams University Community and Public Health, Cairo, Egypt, [5]Benha University, Rheumatology, Physical Medicine and Rehabilitation, Benha, Egypt, [6]Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt, [7]Assiut University, Rheumatology, Physical Medicine and Rehabilitation, Assiut, Egypt, [8]American university Cairo, Cairo, Egypt

Background: Cognitive impairment and sarcopenia are increasingly linked, with research showing that individuals experiencing muscle loss and weakness associated with sarcopenia are also more likely to exhibit cognitive decline, particularly in areas like

processing speed and executive function; this connection suggests a potential shared underlying mechanism between muscle health and brain function, although the exact pathways are still being investigated. This work was carried out by the Egyptian Academy of Bone and Muscle health in collaboration with the Food Bank Egypt.
Objective: To evaluate the bidirectional association between sarcopenia and cognitive impairment in a community based assessment.
Methods: This was a cross-sectional study carried out to assess sarcopenia and cognitive function amongst adults (over 50-years old) and older adults (176-subjects, 115 females and 61 males) living at care homes in Egypt. Assessment for risk of sarcopenia in cognitive impaired patients was carried out using SARC-F questionnaire. To quantitatively assess for sarcopenia, every subject was evaluated for: 1. Muscle strength: this included: measurement of the Handgrip strength; 2. Dynamic strength tests: including chair stands or timed up-and-go tests as well as, 3. Muscle function: Gait speed: Measures walking speed over a 4-meter distance. Cognitive impairment assessment was carried out using the Mini-Mental State Examination (MMSE) tool. Falls risk assessment was assessed by using the Falls Risk Assessment Scale (FRAS). Statistical analysis was carried out to analyse the relationship between sarcopenia and cognitive impairment.
Results: There was significant association ($p< 0.01$) between sarcopenia measures and cognitive decline. 66% of the patients with cognitive impairment had high SARC-F score. Assessment of muscle strength in subjects with cognitive impairment revealed that the prevalence of weak hand grip was 86%, whereas assessment of dynamic strength tests revealed chair stand test was impaired in 81.4% and time-up-and-go was impaired in 53.5%. Similar significant association ($p< 0.01$) was reported on assessment of outcome of muscle function which revealed impaired gait speed in 95.3% in subjects with cognitive impairment. Patients with cognitive impairment were at high risk of falls with mean Falls risk score of 4.84 ± 0.6 ($P<0.5$) in comparison to subjects without cognitive impairment.
Conclusion: Sarcopenia is significantly associated with an increased risk of cognitive impairment. This raises the possible role for muscle-derived mediators (myokines) in mediating muscle–brain crosstalk and highlights the importance of promoting muscle health through exercise and nutrition as a potential strategy for preventing cognitive decline in older adults.

P1525

PREVALENCE OF FALLS IN THE OLDER ADULTS: RESULTS OF A NATIONWIDE REPRESENTATIVE STUDY

Y. Farzi[1], M. Mirzad[1], S. Naderian[1], O. Tabatabaei-Malazy[2]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: This study investigates the prevalence of falls among Iranian individuals aged 50 and above, while also identifying specific populations at increased risk.
Methods: Data from 10,883 Iranian participants in the STEPS survey (STEPwise approach to non-communicable disease risk factor surveillance) were analyzed. The weighted prevalence of falls was reported in different categories of sex, employment status, residence, marital status, and body mass index. All statistical analyses for the study were performed using R. Software version 4.4.1.
Results: The prevalence of falls in the total participants was 3.43% (95%CI: 3.0, 3.8%). However, it was 4.0% (95%CI: 3.4, 4.6%) and 2.8% (95%CI: 2.3, 3.4%), respectively among women and men. Falls were most frequently occurred among individuals with body mass index of greater than 35 kg/m^2 (2.9% (95%CI: 2.5, 3.4)). Moreover, the frequency of falls was higher in single participants 2.8% (95%CI: 2.4, 3.3%) than in married individuals 2.3% (95%CI: 2.1, 2.6%). Rural residents had a higher frequency of falls than urban residents (2.5% (95%CI: 2.2, 2.9%) vs. 2.4% (95%CI: 2.2, 2.7%). The prevalence of falls among unemployed and employed participants was 2.8% (95%CI: 2.2, 2.6%) and 2.6% (95%CI: 2.3, 3.1%), respectively. However, all of the above prevalence rates were statistically non-significant between groups.
Conclusion: Certain demographic groups of individuals aged 50 and above exhibited a higher prevalence of falls, including females, individuals living in rural areas, those without employment, and morbid obese population. Health authorities should prioritize fall prevention strategies that focus on these high-risk segments of the population. These results highlight the importance of taking proactive steps to mitigate fall-related risk factors specific to the population aged 50 and above in Iran.
Keywords: Fall, Elderly, Iran
Conflict of Interest: All authors declare that they have no conflicts of interest.

P1526

THE CORRELATION BETWEEN POSTURAL ALIGNMENT AND MANDIBULAR DEVIATION

Y. G. Choi[1], F. F. Li[1], I. Y. Moon[2], C. H. Yi[3]

[1]Yonsei University, Graduate School, Department of Physical Therapy, Wonju, South Korea, [2]Wonju Severance Christian Hospital, Wonju, South Korea, [3]Yonsei University, College of Software and Digital Healthcare Convergence, Department of Physical Therapy, Wonju, South Korea

O: Abnormal changes in temporomandibular joint (TMJ)-associated connective tissues can alter mandibular position and function, with muscle imbalances potentially causing mandibular lateral deviation (MLD), prompting our investigation into its correlation with global posture, related regions, and underlying causal relationships.
M: The study included 110 healthy adults aged 19–39 years, with

exclusion criteria for factors affecting mandibular stability. Posture analysis was conducted using a virtual reconstruction device (MotiPhysio Pro), and maximal mouth opening (MMO) and MLD were analyzed with Kinovea software. Measurements were taken three times, and mean values were used.
R: The most interesting result is that the more the knee flexed, the more the mandible moved to the right (ρ = 0.390, $p < 0.001$). A multiple linear regression analysis was conducted to examine whether knee flexion angles (KFA) influence MLD. The analysis showed that the regression model was significant ($F = 19.616$, $p < 0.001$), indicating its appropriateness. The adjusted R^2 was 0.146, explaining 14.6% of the variance. It was found that for each 1° increase in KFA, the MLD shifted 0.339 mm to the right. Additionally, when MLD exceeded 2 mm, the change slightly increased, with the mandible moving 0.407 mm for each degree of KFA. The adjusted R^2 for this case was 0.159, explaining 15.9% of the variance. Furthermore, a multiple regression analysis was conducted to examine whether other postural variables influence MMO. The analysis revealed that round shoulder, head posture, and the right hip-knee-ankle angle formed a valid regression equation ($F = 4.838$, $p = 0.003$). As the fascia connects the entire body, tension or issues in one area can be transmitted to another. This interconnectedness might explain why the observed impact was distributed across various tissues and joints through which the fascia passes between the TMJ and the knee. Such distribution could have diluted the overall effect, resulting in a lower observed impact.
C: This study found that KFA influences MLD and that round shoulder and other postural variables are associated with MMO. These findings may provide clinical evidence supporting the prevention and treatment of TMJ disorder through posture correction, as well as contributing to improved overall postural stability.

P1527

CORTISTATIN PREVENTS GLUCOCORTICOID-ASSOCIATED OSTEONECROSIS OF THE FEMORAL HEAD VIA THE GHSR1A/AKT PATHWAY

Y. Gao[1], L. Li[1], L. Li[1], Z. Zhao[1]

[1]Qilu Hospital of Shandong University, Jinan, China

Objective: Long-term use of glucocorticoids (GCs) is known to be a predominant cause of osteonecrosis of the femoral head (ONFH). Moreover, GCs can mediate apoptosis of various cell types by exaggerating oxidative stress. The objectives of this research were to elucidate the potential function and underlying mechanisms of CST in the ONFH process.
Material and Methods: In this study, we detected that the CST expression levels were diminished in patients with ONFH compared with femoral neck fracture (FNF). In addition, a GC-induced rat ONFH model was established, which impaired bone quality in the femoral head. Then, administration of CST attenuated these ONFH phenotypes. Furthermore, osteoblast and endothelial cells were cultured and stimulated with dexamethasone (Dex) in the presence or absence of recombinant CST.
Results: Dex induced impaired anabolic metabolism of osteoblasts and suppressed tubeformation endothelial cells, while additional treatment with CST reversed this damage to the cells. Moreover, blocking GHSR1a, a well-accepted receptor of CST, or blocking the AKT signaling pathway largely abolished the protective function of CST in Dex-induced disorder of the cells.
Conclusion: We indicate that CST has the capability to prevent GC-induced apoptosis and metabolic disorder of osteoblasts in the pathogenesis of ONFH via the GHSR1a/AKT signaling pathway.

EFFICACY AND SAFETY OF COMBINATION DENOSUMAB WITH ELDECALCITOL FOR POSTMENOPAUSAL OSTEOPOROSIS: AN OPEN-LABEL, RANDOMIZED, PARALLEL-CONTROLLED TRIAL

Y. H. Zeng[1], Q. H. Tang[1], Q. M. Li[1], L. Yang[1], B. Zhang[1], M. Yang[1], M. H. Che[1], Y. H. Peng[1]

[1]Honghui Hospital, Xi'an, China

Objective
This study aims to compare the efficacy and safety of denosumab combined with eldecalcitol in postmenopausal osteoporosis.

Material and Methods

This open-label, randomized, positive-controlled trial was conducted at Honghui Hospital, Xi'an Jiaotong University. Eligible patients were postmenopausal women with osteoporosis (BMD T-score ≤ -2.5) or low bone mass (T-score between -2.5 and -1.0) with a fragility fracture. Participants were randomly assigned (1:1) to receive denosumab 60 mg every 6 months via subcutaneous injection for 12 months, with either oral eldecalcitol (0.75 μg daily) or vitamin D (800 IU daily) and calcium supplementation (600 mg daily). The primary outcome was the percentage change from baseline in lumbar spine BMD (L1-L4) at 12 months. Safety outcomes included adverse events and abnormal laboratory data over 12 months.

Results

Between Aug 24, 2023, and Mar 26, 2024, 112 postmenopausal women were assessed for eligibility, and 100 were randomly assigned to the eldecalcitol group (n=50) or the vitamin D group (n=50) (Figure 1). Baseline characteristics were well balanced. At baseline, all randomized participants were non-smokers and non-drinkers, and none had a history of fragility fractures. Both groups had been postmenopausal for over 10 years (11.3±6.7 vs. 11.0±7.1 years). Baseline serum 25(OH)D levels were 15.7 ng/mL and 16.8 ng/mL in the eldecalcitol and vitamin D groups, respectively. Serum calcium levels were 2.4±0.1 mmol/L in both groups. Serum phosphorus levels were both 1.2±0.1 mmol/L, serum β-CTX were both 0.6 ng/ml, and serum PINP were 64.7±18.8 ng/ml in the eldecalcitol group and 62.9±23.1 ng/ml in the vitamin D group.

Conclusion

This trial compared denosumab combined with eldecalcitol to that with vitamin D and calcium supplements, providing insights into the treatment of postmenopausal osteoporosis.

INCREASED RISK OF MEDICATION-RELATED OSTEONECROSIS OF THE JAW IN RHEUMATOLOGIC PATIENTS TREATED WITH DENOSUMAB FOLLOWING INTRAVENOUS BISPHOSPHONATE THERAPY

Y. J. Jung[1], C. H. Heo[2], Y. D. Kwon[2], S. J. Jeong[3], S. J. Hong[1], J. W. Hwang[1], Y. A. Lee[1]

[1]Division of Rheumatology, Department of Internal Medicine, Kyung Hee University Hospital, Seoul, Republic of Korea, Seoul, South Korea, [2]Oral and Maxillofacial Surgery, College of Dentistry, Kyung Hee University Hospital, Seoul, Republic of Korea, Seoul, South Korea, [3]Department of Statistics Support Part, Medical Science Research Institute, Kyung Hee University Medical Center, Seoul, Republic of Korea, Seoul, South Korea

[Objectives]

Given the lifelong nature of rheumatic diseases, investigating the long-term safety and efficacy of osteoporosis treatments, including treatment sequences, is crucial. Denosumab offers advantages in reducing drug burden and simplifying administration, but MRONJ risk factors, especially in those switching from bisphosphonates, remain unclear. This study examines MRONJ prevalence and risk factors in rheumatic patients treated with denosumab, focusing on prior osteoporosis treatments.

[Methods]

We retrospectively reviewed 310 patients with rheumatic diseases who received denosumab therapy from 2005 to 2022 at Kyung Hee University Hospital. The cohort included rheumatoid arthritis (RA), osteoarthritis (OA), and other connective tissue diseases. Patients were categorized based on prior osteoporosis treatment. T-score changes and MRONJ incidence were assessed, and regression analysis was conducted to identify MRONJ risk factors.

[Results]

Of the patients, 64.2% were aged 65 or older, and 89.4% were female. 43.5% had no prior osteoporosis treatment, while 29.3% had used oral bisphosphonates (BP), 22.9% intravenous BP, and 4.2% selective estrogen receptor modulators (SERM). The oral BP to denosumab sequence group showed significant T-score improvement ($p < 0.0376$) (Figure1). MRONJ occurred in 9 patients (2.9%), all aged 65 or older. Six MRONJ cases were in the IV BP to denosumab group, and two in the oral BP group (Table1). Cox regression identified glucocorticoid use (OR=18.15), RA (OR=9.54), IV BP (OR=24.88), dental disease (OR=4.64), and alveolar bone surgery (OR=18.27) as significant risk factors for MRONJ (Table2).

[Conclusion]

This study underscores the need for clear guidelines on transitioning from bisphosphonates to denosumab, as increased MRONJ risk was observed in rheumatic patients following IV BP. Those with risk factors like advanced age, IV BP use, long-term glucocorticoid therapy, RA, dental conditions, or prior surgeries need careful management.

IMPROVING FRACTURE RISK PREDICTION WITH A DEEP LEARNING CHEST RADIOGRAPHY MODEL COMBINED WITH FRAX

Y. Kim[1], S. H. Kong[2], C. M. Park[1]

[1]Seoul National University Hospital, Seoul, South Korea, [2]Seoul National University Bundang Hospital, Seoul, South Korea

Objective

FRAX is a widely used tool for predicting fracture risk but is limited by its reliance on dual-energy X-ray absorptiometry (DXA) and inability to assess short-term fracture risk. This study aimed to develop a deep learning (DL)-based model using chest radiography (CXR) and combine it with FRAX to enhance predictive performance.

Materials and Methods

This multicenter study included 42,014 patients from Institution A (2008–2019) for DL model development and 10,523 patients from Institution B (2003–2022) for external test. CXRs were preprocessed using localized energy-based normalization, and convolutional neural network-based DL models were trained separately for original and normalized images. Ensemble outputs of DL and FRAX (DL-FRAX) were used for final predictions. A logistic hazard loss function was employed to directly estimate survival functions. Performance was assessed using C-index and area under the receiver-operator curves (AUROCs) in internal (5,000 cases) and external (10,523 cases) test sets, comparing DL, DL-FRAX, and FRAX.

Results

Mean ages were 59.3, 61.4 years, and 79.8%, 67.9% were female in development and external test sets, respectively. In predicting major osteoporotic fractures, the DL model achieved a C-index of 0.867 and 2-, 3-, and 5-year AUROCs of 0.878, 0.887, and 0.886, outperforming FRAX (C-index: 0.800; AUROCs: 0.805, 0.804, and 0.805, all $P<0.001$) in the internal test set. The DL-FRAX ensemble model showed a C-index of 0.847 and AUROCs of 0.858, 0.873, and 0.868, which were also significantly higher than the performances of FRAX model (all $P<0.001$). Similarly, in the external validation set, C-index values were 0.763 and 0.752 for DL and DL-FRAX models, respectively, which showed significantly higher performances than that of FRAX (C-index of 0.737, both $P<0.001$). In terms of vertebral, nonvertebral, and hip fractures, DL model's performances showed C-indices of 0.871, 0.852, and 0.923, respectively. Corresponding 2-, 3-, and 5-year AUROCs were 0.873, 0.886, and 0.888 for vertebral; 0.934, 0.907, and 0.874 for non-vertebral; and 0.931, 0.928, and 0.936 for hip fractures.

Conclusion

Combining a DL-based model using CXR with FRAX significantly improved fracture risk prediction compared to FRAX alone. This approach may provide a more accessible, effective tool for clinical fracture risk assessment.

P1531

ISORHYNCHOPHYLLINE MITIGATES BONE LOSS IN OVX MICE BY MODULATING INFLAMMATORY RESPONSES, OXIDATIVE STRESS, GUT MICROBIOTA COMPOSITION AND SCFA PRODUCTION

Y. Lei[1], Y. Liu[1], L. Hu[1], Y. Zhang[1], S. Li[1], Y. Zhou[1], Q. Dong[1], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou, China

Background: Osteoporosis (OP) is a systemic skeletal disorder characterized by reduced bone mass and deteriorated bone architecture, leading to an increased fracture risk. Isorhynchophylline (IRN), an active alkaloid derived from *Uncaria rhynchophylla*, is known for its significant anti-inflammatory and antioxidant properties. However, its potential role in mitigating bone loss has not been thoroughly investigated. This study examines the protective

effects of IRN against bone loss in ovariectomized (OVX) mice, with a focus on its regulation of inflammatory responses, oxidative stress, gut microbiota composition, and the production of short-chain fatty acids (SCFAs).
Methods: The potential core targets and mechanisms of action of IRN in the treatment of OP were investigated through network pharmacology and molecular docking, following by in vivo validation on OVX mice treated with 8-week IRN. The study included Micro-CT analysis to assess bone microstructure, measurement of serum biomarkers for inflammation and oxidative stress, immunohistochemical analysis of tight junction proteins, SCFAs quantification, and gut microbiome profiling via 16S rRNA sequencing.
Results: Network pharmacology analysis identified 50 intersecting targets between IRN and OP, with molecular docking demonstrating strong binding affinities of IRN to EGFR and GSK3B. GO and KEGG enrichment analyses revealed that IRN is involved in many key pathways related to cell survival, inflammation, and oxidative stress, with the PI3K-Akt signaling pathway being notably prominent. *In vivo* assessment showed that IRN treatment reduced serum levels of the pro-inflammatory cytokines, such as tumor necrosis factor-alpha (TNF-α), interleukin-1 beta (IL-1β) and interleukin-6 (IL-6), while increasing serum levels of the anti-inflammatory cytokine interleukin-10 (IL-10) in OVX mice and reversed the excessive bone loss caused by estrogen deficiency. IRN also effectively managed the oxidative stress in OVX model, characterized by lowered serum levels of nitric oxide (NO), inducible nitric oxide synthase (iNOS) and reactive oxygen species (ROS). Immunohistochemical analysis indicate that IRN repaired the compromised intestinal barrier in OVX mice by upregulating the expression of tight junction proteins, including Zonula Occludens-1(ZO-1), Claudin-1 and Occludin. Additionally, IRN modulated the gut microbiota composition, reducing the abundance of *Helicobacter* and increasing the level of butanoic acid, a type of SCFAs.
Conclusions: IRN effectively alleviates OVX-induced bone loss through its anti-inflammatory and antioxidant properties, modulation of gut microbiota composition, and enhancement of short-chain fatty acid (SCFA) production.

ASSESSMENT OF BONE HEALTH AND BISPHOSPHONATE TREATMENT IN GIRLS WITH RETT SYNDROME: RESULTS FROM A NATIONAL CENTER

Y. Levy-Shraga[1], S. Goldmann[2], N. Gruber[1], L. Tripto-Shkolnik[3], D. Modan-Moses[1], U. Givon[4], B. Ben-Zeev[5]

[1]Pediatric Endocrinology and Diabetes Unit, The Edmond and Lily Safra Children's Hospital, Ramat Gan, Israel, [2]Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv , Israel, [3]Division of Endocrinology, Diabetes and Metabolism, Sheba Medical Center, Ramat Gan, Israel, [4]Pediatric Orthopedics Unit, The Edmond and Lily Safra Children's Hospital, Ramat Gan, Israel, [5]Division of Pediatric Neurology, The Edmond and Lily Safra Children's Hospital, Ramat Gan, Israel

Background: A common non-neurological morbidity of Rett syndrome (RTT) is impaired bone health and increased fracture risk. Our aim was to assess lumbar bone mineral density (BMD) and trabecular bone score (TBS) of girls with RTT and evaluate the efficacy bisphosphonates treatment.
Methods: This retrospective study included 40 females with RTT aged 5-22 years who performed dual energy x-ray absorptiometry (DXA) scan between 2019-2024 at a national center for RTT. Data retrieved included: medical treatment, anthropometric measurements, mobility score (GMFCS), blood test results and fracture history.
Results: The median age at the first DXA scan was 10.8 years. Mean L1-4 BMD Z-score was -2.1±1.4, and mean TBS Z-score was -0.4±1.3. L1-4 BMD Z-score showed significant correlations with height Z-score (r=0.407, p=0.009), weight Z-score (r=0.551, p<0.001), and BMI Z-score (r=0.644, p<0.001). TBS Z-score was correlated with height Z-score (r=0.753, p<0.001), weight Z-score (r=0.652, p=0.003), and with L1-4 BMD Z-score (r=0.594, p=0.009). poor L1-4 BMD Z-score was associated with poor mobility score (p=0.05), and valproic acid treatment (p=0.016). Nine girls (23%) were treated with zoledronate. The mean age at zoledronate initiation was 9.7±2.3 years (range 6.5-12.3 years), and the mean duration of treatment was 2.0±0.5 years. Four of them completed two DXA scans (prior to the initiation of zoledronate treatment, and 2.0 ± 0.2 after treatment). The mean L1-L4 BMD Z-score was -2.2 ± 0.9 at the first scan and -1.4 ± 0.9 at the second scan
Conclusions: Girls with Rett syndrome (RTT) demonstrated reduced lumbar BMD, which was significantly correlated with anthropometric parameters, TBS, mobility, and valproate treatment. Zoledronate treatment may be considered in selected cases.

P1533

RECOMBINANT HUMAN BONE MORPHOGENETIC PROTEIN ENHANCES FRACTURE HEALING AND BONE REGENERATION IN CEMENT PERFUSION BLIND ZONES: A PROSPECTIVE COHORT STUDY OF OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES

Y. Li[1], C. Zhang[1], P. Xia[1], C. Liu[1], K. Wang[1]

[1]Peking University People's Hospital, Beijing, China

BACKGROUND CONTEXT: Vertebroplasty alleviates pain, restores vertebral height, and enhances spinal stability through the injection of polymethylmethacrylate (PMMA). However, in cases of severe osteoporosis and extensive trabecular destruction within the fractured vertebra, the distribution of PMMA may become uneven, resulting in perfusion blind spots. These blind spots can increase the risk of delayed or poor vertebral fracture healing. At present, research on PMMA perfusion blind spots remains limited, with a notable lack of clinical evidence from comparative prospective studies.
PURPOSE: This study aims to test the hypothesis that recombinant human bone morphogenetic protein (rh-BMP) combined

with bone cement augmentation in osteoporotic vertebral compression fractures can enhance bone repair in the blind areas of bone cement perfusion and significantly promote fracture healing at the 3-month postoperative follow-up. Additionally, it seeks to report and compare radiographic outcomes and patient-reported clinical improvements at the 12-month postoperative follow-up.
DESIGN: Prospective, Single-center, observational cohort study.
PATIENT SAMPLE: Patients with osteoporotic vertebral compression fractures undergoing 1 or 2-level percutaneous vertebroplasty.
OUTCOME MEASURES: Eligible patients were consecutively recruited from outpatient clinics and emergency departments. Vertebroplasty was performed based on clinical judgment by surgeons with extensive experience in the procedure, with rh-BMP implanted in the experimental group. Baseline characteristics, surgery-related factors, and laboratory test results were collected and analyzed to assess potential baseline differences between the two groups. Repeated measures ANOVA was conducted to compare changes in CT values of the non-perfused areas in the surgical segments between the groups. Independent sample t-tests were used to evaluate changes in CT values of the non-perfused areas at various postoperative time points. Additionally, propensity scores were introduced as covariates, and an additional analysis of covariance (ANCOVA) was performed to validate the reliability and robustness of the initial intergroup comparison results.
RESULTS: Patients who underwent vertebroplasty with rh-BMP implantation (n=48) compared to those who underwent standard vertebroplasty (n=50) were similar in age (71.4±21.6 vs 68.1±19.9 years, p=0.433), gender distribution (female: 70.8% vs 72.0%, p=0.898), BMI (23.6±3.41 vs 22.9±4.07, p=0.359), and smoking status (35.4% vs 40.0%, p=0.640). There were no statistically significant differences between the groups in baseline pain scores, fracture severity, or duration of symptoms prior to treatment. At 1-month follow-up, patients in the rh-BMP group demonstrated greater improvement in pain scores compared to the control group (VAS: 4.3±1.2 vs 3.5±0.6, p<0.001), and a higher rate of radiographic evidence of fracture healing in 3-month follow-up (98.3% vs 88.3%, p=0.028). By 12-month follow-up, the rh-BMP group continued to show superior outcomes in bone density CT value improving rates (47.1±18.6 vs 15.8±5.2, p<0.001) and structural stability (96.7% vs 85.0%, p=0.007), while no clinically meaningful differences were observed between the groups in functional disability scores (ODI: 21.4±9.6 vs 22.1±8.7, p=0.706) or quality of life measures. No significant differences in complication rates were noted between the two groups.
CONCLUSIONS: Patients with osteoporotic vertebral compression fractures who underwent vertebroplasty augmented with rh-BMP exhibited statistically significant and clinically meaningful improvements in fracture healing and pain alleviation during the follow-up period. Notably, rh-BMP demonstrated a unique ability to enhance bone regeneration in areas beyond the direct reach of bone cement, effectively improving bone quality in the cement perfusion blind zones. This property contributed to enhanced osteogenesis and improved structural stability, underscoring the potential of rh-BMP as a valuable adjunctive strategy for promoting fracture repair and functional recovery in patients with osteoporosis.

TARAXASTEROL AMELIORATES OVX MICE BONE LOSS BY SUPPRESSINGNLRP3 INFLAMMASOME AND MODULATING GUT MICROBIOTA

Y. Liu[1], Y. Lei[1], L. Hu[1], Y. Zhang[1], S. Li[1], Y. Zhou[1], Q. Dong[1], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou, China

Aims: Postmenopausal osteoporosis (PMOP) is a prevalent skeletal disorder associated with menopause-related estrogen withdrawal. Taraxasterol (Tara), a pentacyclic-triterpene isolated from Taraxacum officinale, has been shown to have anti-inflammatory and anti-rheumatic effects. However, its efficacy against PMOP remains unclear. The purpose of this research is to investigate Tara's anti-osteoporotic effects.
Main methods: In this study, the ovariectomized (OVX) mouse model is a well-established surrogate for PMOP, recapitulating the bone loss observed in humans following menopause. After 8 weeks of intervention, the mice were euthanized, and samples from their femur, serum, colon and feces were collected, then bone microstructure parameter, NLRP3 inflammasome, inflammatory cytokines, intestinal barrier and gut microbiota (GM) were assessed. Network pharmacology and molecular docking approach to predict and validate its anti-osteoporosis-related molecular targets and pathways.
Key findings: The results revealed that Tara lowered proinflammatory cytokine levels (IL-6, TNF-α), suppressing NLRP3 inflammasome (caspase-1, IL-1β and IL-18) and affected adipokines content (decrease leptin and visfatin, increases adiponectin), which enhances bone strength and prevents OVX-induced bone loss. Moreover, it restored the abundance of GM and increased the expression of Occludin and ZO-1 protein in the colon. Network pharmacology identified a total of 75 core anti-osteoporosis targets. Of these, ALB, PPARG, IGF1, EGFR, ESR1, CASP3, HSP90AA1, SRC, GSK3B, MMP2 were successfully docked with the Tara and showed excellent binding ability.
Significance: The present study suggests that Tara alleviated inflammatory cytokines, NLRP3 inflammasome andintervened GM, representing Tara is a novel, promising therapeutic candidate for PMOP.
Keywords: Taraxasterol; Osteoporosis; NLRP3 inflammasome; Gut microbiota

THE PERCEPTION AND CHALLENGES OF PRACTITIONERS IN THE MANAGEMENT OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Y. Makhlouf[1], F. Ben Massoud[1], H. Boussaa[1], S. Miladi[1], K. Ben Abdelghani[1], A. Fazaa[1], A. Laatar[1]

[1]Department of rheumatology, Mongi Slim Hospital, Tunis, Tunisia

Objectives

Sjögren's Syndrome (SSj) is a systemic disease whose management is sometimes critical and requires various healthcare practitioners' collaboration [1].

Our study aimed to assess the perception of practitioners when dealing with a patient with SSj.

Material and Methods

We conducted a cross-sectional study involving physicians treating SSj patients. They were invited to answer a self-administered questionnaire via Google Forms. The questions included sociodemographic data, data related to the doctors' perception of patients with SSj as well as their confidence in the management of the disease using a Likert scale. We identified factors associated with an overall better perception. The level of significance was fixed at p≤0.05.

Results

Our study included 96 practitioners with a male-to-female ratio of 0.2. The participants were rheumatologists (38%), internists (20%), nephrologists (10%), family physicians (23%), ophthalmologists (6%), pulmonologists (1%), anesthetists (1%) and physical medicine specialists (1%). The average age of the participants was 30.9 years [25-60], and the average years of practice were 4.95 [1-58]. The mean number of SSj patients per monthly consultation was less than 5 (65%), between 5 and 10 (27%) and more than 10 (8%). During the consultation, half of the physicians (50%) were indifferent; others felt empathy (37%), anxiety (8%), and annoyance (5%). More importantly, 69% of the respondents felt apprehensive during consultations, due to disease manifestations (43%), the risk of degeneration (41%), the limited therapeutic arsenal (57%), the lack of effectiveness of treatments in certain manifestations (54%), and a lack of knowledge about the pathology (1%). Sixty-three percent of the doctors believed that patients would be more complainant compared to other chronic inflammatory rheumatic diseases. This complaint was justified in 87% of the cases and attributed to: various clinical manifestations of the disease (62%), the risk of lymphomatous transformation (10%), fibromyalgia (21%), dry syndrome (21%), anxiety (1%), and the lack of improvement (1%). About 42% of the respondents were not confident and satisfied with managing SSj patients. This was attributed to the limited treatments in most of the cases (96%). Proposed solutions included encouraging medical research (48%), optimizing consultation time (10%), establishing a SSj calendar with patient-recorded complaints to discuss during consultations (15%), and improving access to care (1%). There was no association between physicians' satisfaction and their specialty (p=0.869) nor the years of practice (p=0.19). However, the degree of satisfaction in the management of SSj was significantly lower in practitioners who expressed apprehension (p=0.031).

Conclusion

This study highlighted the challenges faced by practitioners when managing patients with SSj. The limited therapeutic options were the most frequently reported cause. This underscores the importance of promoting research to ensure optimal care for these patients.

INTEREST OF THE NEUTROPHIL/LYMPHOCYTE RATIO (NLR) AND PLATELET/LYMPHOCYTE RATIO (PLR) IN PRIMARY SJÖGREN'S SYNDROME: RELATIONS WITH CLINICAL AND BIOLOGICAL MANIFESTATIONS

Y. Makhlouf[1], F. Ben Massoud[1], S. Miladi[1], A. El Ouni[2], H. Boussaa[1], A. Fazaa[1], S. Toujani[2], K. Bouslema[2], K. Ben Abdelghani[1], S. Hamzaoui[2], A. Laatar[1]

[1]Department of rheumatology, Mongi Slim Hospital, Tunis, Tunisia, [2]Department of internal medicine, Mongi Slim Hospital, Tunis, Tunisia

Objectives Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease characterized by both glandular and extra-glandular involvement. Its activity is assessed using established clinical and biological scores [1]. Inflammatory markers such as the NLR (neutrophil/lymphocyte ratio) and PLR (platelet/lymphocyte ratio) have been associated with the activity of other chronic inflammatory rheumatic diseases, such as rheumatoid arthritis [2].

This study aimed to explore the associations between these markers and the clinical, biological, and immunological features of primary Sjögren's syndrome.

Material and methods We conducted a cross-sectional study that included female patients followed for pSS. Clinical, biological, immunological, and therapeutic data were recorded. Disease activity was assessed using the ESSDAI score. The NLR and PLR were calculated for all patients. An association between these ratios and clinical and biological parameters, as well as disease activity, was sought. A significance threshold was set at p<0.05.

Results Our study included 31 women. The mean age of the patients was 57.8 years [32-75], and the mean age at diagnosis was 52.9 years [32-70]. The average duration of disease was 11.3 years [1-32]. The distribution of manifestations was as follows: joint involvement (87.1%), pulmonary involvement (22.6%), renal involvement (3.2%), hematological involvement (12.9%), neurological involvement (16.1%), xerophthalmia (93.5%), and xerostomia (54.8%). The mean ESSDAI score was 5.3±5.1 [0-17]. The mean ESSPRI score was 5.9±1.9 [1-8.3]. The mean ESR and CRP levels were 39.4±27.6 [5-100] and 8.3±13.8 [0-5.59], respectively. The mean NLR was 1.9±1 [0.7-5.1]. The mean PLR was 149.4±77.5

[58.2-400]. A statistically significant association was found between NLR and renal involvement (p=0.026) and mean corpuscular volume (MCV) (p=0.051). Similarly, PLR was significantly associated with disease duration (p=0.051), joint involvement (p=0.001), CRP (p=0.018), and the positivity of anti-SSB antibodies (p=0.055). However, there was no association between PLR and ESSDAI (p=0.734) nor between NLR and ESSDAI (p=0.978).

Conclusion Our study showed that PLR is significantly associated with disease duration and CRP, while NLR is mainly related to renal involvement and MCV. These results suggest that PLR may be useful for monitoring pSS, although NLR is not a reliable indicator of the overall activity of the disease or its other manifestations. Further studies are needed to refine these associations.

ASSESSMENT OF OSTEOPOROSIS KNOWLEDGE AMONG NURSES: GAPS AND INFLUENCING FACTORS

Y. Makhlouf[1], S. Loukil[1], H. Boussaa[1], S. Miladi[1], K. Ben Abdelghani[1], A. Fazaa[1], A. Laatar[1]

[1]Department of rheumatology, Mongi Slim Hospital, Tunis, Tunisia

Objective

Osteoporosis (OP) is a common skeletal disorder characterized by reduced bone mineral density, leading to an increased risk of fractures. Nurses, as one of the primary healthcare providers, play a critical role in the detection, prevention, and management of osteoporosis. However, despite their vital contribution, limited research has explored nurses' knowledge and understanding of osteoporosis.

The objective of this study was to assess nurses' knowledge of OP and factors associated with better awareness.

Material and methods

We conducted a cross-sectional survey involving nurses from various specialties, across three healthcare settings. Data were collected using a self-administered questionnaire developed through Google Forms. The survey included the Osteoporosis Knowledge Assessment Test (OKAT), a validated tool to evaluate osteoporosis-related knowledge [1]. The questionnaire consisted of 20 questions addressing key topics such as risk factors, diagnostic methods, prevention strategies, and treatment options. OKAT scores ranged from 0 to 20, with knowledge levels categorized as follows: scores of 0–7 indicated poor knowledge, 8–13 indicated good knowledge, and scores of 14 or higher indicated excellent knowledge.

Results:

The study included 50 participants, with a female predominance (sex ratio M/F=0.35).

The mean age of the participants was 33 (9) years [24-60]. The mean duration of practice was 8 (8) years [1-42]. Regarding workplace distribution, 71% of participants worked in medical specialties, while 29% were in surgical specialties. Additionally, 96% of participants worked in urban healthcare settings, with only 4% based in rural areas. Most participants (92%) were employed in public institutions, while only 8% worked in private settings. In terms of prior training, 26% of participants reported having received education on osteoporosis. The mean OKAT score was 10(3) [0–16]. Based on the scoring categories, 18% of participants demonstrated poor knowledge, 76% exhibited good knowledge, and 6% achieved excellent knowledge. Among the OKAT questions, Question 1 (focusing on fracture risk) had the highest percentage of correct answers (94%), whereas Question 18 (addressing the statement: "There is a small amount of bone loss during the ten years following the onset of menopause") had the lowest percentage of correct responses (14%). OKAT scores were significantly higher among females and participants with prior training on osteoporosis (p=0.025 and p=0.003 respectively). Participants from medical specialties scored significantly better on risk factor-related questions compared to those in surgical specialties (P=0.014).

Additionally, Participants with more years of clinical experience demonstrated significantly better responses to prevention-related questions, suggesting that professional experience contributes to a stronger understanding of prevention strategies (P=0.04).

Conclusion:

Our study revealed low to good levels of OP knowledge among nurses, highlighting the need for targeted education to raise osteoporosis awareness among healthcare providers, and improve patient outcomes.

OSTEOPOROSIS IN RHEUMATOID ARTHRITIS PATIENTS: FACTORS INFLUENCING ADHERENCE TO BISPHOSPHONATE THERAPY

Y. Makhlouf[1], J. Souaa[1], H. Boussaa[1], S. Miladi[1], K. Ben Abdelghani[1], A. Fazaa[1], A. Laatar[1]

[1]Department of rheumatology, Mongi Slim Hospital, Tunis, Tunisia

Objectives

Osteoporosis (OP) represents a significant socio-economic burden due to its most severe complication, fractures, which are particularly prevalent in cases of poor treatment adherence [1]. While most studies on bisphosphonate (BP) compliance have

focused on postmenopausal osteoporosis, limited attention has been given to patients with rheumatoid arthritis (RA), a population at heightened risk for both OP and fractures [1].
The aim of this study was to assess the frequency of BP use in OP patients with RA and identify factors associated with poor adherence to treatment.

Material and methods:

This cross-sectional study, included patients diagnosed with RA according to the ACR/EULAR 2010 criteria and osteoporosis, recruited from the rheumatology department of Mongi Slim Hospital, La marsa [1]. Sociodemographic data, comorbidities, disease-related characteristics as well as data related to OP management were collected. Bone mineral density (BMD) was assessed using dual-energy X-ray absorptiometry (DXA) at the lumbar spine and femoral neck. Good compliance with BP treatment was defined as a renewal of treatment for a minimum of 3 years.

Results :

The study included 54 women with RA, of whom 94.4% were postmenopausal. The mean age was 62 ± 11 years, and the mean disease duration was 111 ± 109 months. More than half of the patients (55.6%) were illiterate, and 72.2% were covered by the national health insurance fund. Comorbidities included arterial hypertension (42.6%), diabetes (25.9%), and dyslipidemia (5.6%). The mean body mass index (BMI) was 25±5 kg/m² [13.2-36.8], with 14% categorized as lean. Disease activity was high in over 50% of participants, with a mean DAS28ESR score of 5 ± 1.4. The mean BMD at the vertebral and femoral sites was -2.8±0.9 SD [-4.4; -0.2] and -2.9±0.7 SD [-4.8; -1.5] respectively. Calcium supplementation was prescribed in 83.3% of cases, at an average dose of 550±255 mg/d, and Vitamin D in 90.7% of cases at an average dose of 932±351 IU/d. A history of fracture was noted in 22.2% of cases, with 9.3% experiencing femoral fractures, 9.3% vertebral fractures, and 3.7% wrist fractures. BP intake was noted in 31.5% of patients, with the majority (81.8%) using the oral route. The average duration of BP treatment was 3.2±1.1 years [1-5] with over 88% having good compliance. There was a significant association between good BP compliance and social security coverage (p=0.008), as well as high disease activity (p=0.03). There was no statistically significant association between good adherence to BP and age (p=0.28), level of education (p=0.8), geographical origin (p=0.77), length of RA (p=0.44) or history of fracture (p=0.07).

Conclusion :

Our study highlighted the suboptimal prescription of BP among osteoporotic RA patients in real-life practice, which limits the overall effectiveness of osteoporosis management. Over 88% of patients demonstrated good compliance with treatment. Social security coverage and high disease activity were identified as significant factors associated with adherence.

P1539

IMPACT OF ORAL HYGIENE ON THE WELL-BEING OF PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Makhlouf[1], S. Loukil[1], S. Miladi[1], H. Boussaa[1], K. Ben Abdelghani[1], A. Fazaa[1], A. Laatar[1]

[1]Department of rheumatology, Mongi Slim Hospital, Tunis, Tunisia

Objectives

Patients with rheumatoid arthritis (RA) suffer more frequently from periodontitis than the rest of the population [1]. Although this causal relationship has been demonstrated, few studies have assessed the impact of oral hygiene on RA patients
The objective of this study was to assess the impact of dental abnormalities on the quality of life and disease activity of patients with RA.

Material and methods

We conducted a cross-sectional study that included patients with RA recruited from the rheumatology department of Mongi Slim Hospital. Sociodemographic data as well as those related to RA were transcribed. All patients underwent an oral examination and a dental panoramic. The impact of oral conditions on the patients' well-being and their quality of life was measured using the Oral Health Impact Profile-14 (OHIP-14) scale [2]. The questionnaire covers 7 areas: functional limitations, physical pain, psychological discomfort, physical disability, psychological disability, social disability and disability. The total score ranges from 1 to 7, where a high score reflects a significant discomfort. We investigated the profile of RA associated with a poorer oral health. The significance threshold was set at $p<0.05$.

Results

In total, 50 patients were included. The mean age was 56 (10) years [30-75 years]. There was a female predominance (sex ratio 8:1). The mean disease duration was 9 (6) years [1-23]. RA was immunopositive and erosive in the majority of cases (92% and 82%, respectively). Regarding treatment modalities, the prescription was as follows: Methotrexate (76%), Salazopyrine (14%), Leflunomide (12%), b-DMARDs (24), and ts-DMARDs (6%). The mean erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were 48 (30) mm [3-107] and 25 (30) mg/L [1-119], respectively. The mean Disease Activity Score (DAS28-ESR) was 4.3 (1.53) [2.02-7.9] with the majority of the patients having a moderate activity (44%).The dental examination was abnormal in most cases (82%). The most common abnormalities were carious lesions (78%), dental abscesses (26%) and periodontitis (8%). About 36% of the patients had more than one abnormality. The mean OHIP-14 score was 0.6 [0-1.6]. Among the subscores obtained for the different domains, the highest was for physical pain (0.2). There was no significant association between oral hygiene and the number of painful joints (p=0.3), swollen joints (p=0.567), ESR (p=0.59), CRP (p=0.505), and DAS28 ESR (p=0.6). However, younger RA patients with oral abnormalities had a better quality of life according to the OHIP-14 (p=0.026).

Conclusion

Our study emphasizes the high prevalence of oral involvement in

RA. The main factors associated with a poorer well-being were age particularly in the domain of physical pain. This highlights the need for a better screening and targeting of these abnormalities as part of a holistic approach.

PARITY AND LOW HAND GRIP STRENGTH IN POSTMENOPAUSAL WOMEN

Y. S. Chung[1], J. K. Baek[1], E. Choi[1], H. Kim[1], S. K. Seo[1]

[1]Yonsei University College of Medicine, Seoul, South Korea

Objective: Given the high prevalence of sarcopenia among postmenopausal women, identifying predictive parameters is crucial. Since hand grip strength (HGS) is one of key parameter in diagnosing sarcopenia and parity affects estrogen exposure, this study aims to examine the association between parity and HGS. Material and Methods: Data from the Korean National Health and Nutrition Examination Survey (KNHANES) from 2014 to 2019 were analyzed and 4,102 postmenopausal women aged 45-65 years were involved. Participants were categorized into two groups: HGS<18kg and HGS≥18kg. Logistic regression analysis was used to assess the association between parity and HGS. Results: Among participants, 17.8% had HGS<18kg, indicating possible sarcopenia. Mean HGS were 20.33kg for nulliparous women, 21.65kg for primiparous women, and 21.88kg for those with three or more parities (p<0.001). The risk of low HGS increased by 5% with age (OR: 1.05, p<0.001), and decreased by 6% with each year increase in age at menopause (OR:0.94, p<0.001). Women with parities had a lower risk of low HGS compared to nulliparous women (OR=0.52, p=0.004). Among women with parities, those with more than two births had reduced risk of low HGS (OR=0.68, p=0.021). Conclusion: Increased parity is significantly associated with higher mean grip strength. In postmenopausal women, multiparity is linked to a reduced risk of “possible sarcopenia". Advanced age, early menopause, and dyslipidemia also contribute to low HGS in this population.

P1541

FREQUENCY OF PROPABLE SARCOPENIA IN PATIENTS AGED 60 AND OLDER WITH KNEE OSTEOARTHRITHIS AND ITS ASSOCIATION WITH GERIATRIC SYNDROMES

Y. Safonova[1], D. Zaparina[1], D. Dyachkova-Gertseva[1]

[1]North-Western State Medical University named after I.I. Mechnikov, St. Petersburg, Russia

Objective: To evaluate the frequency of probable sarcopenia in patients with knee osteoarthritis after 60 years of age and to identify the relationship with geriatric syndromes by comprehensive geriatric assessment.

Methods: Cross-sectional, single-center study was included 46 patients (median age 77 [70;81]) with confirmed knee osteoarthritis according to the 2019 ACR criteria. Sarcopenia was diagnosed according to the criteria European Working Group on Sarcopenia (EWGSOP2). Skeletal muscle strength was determined by grip strength using a dynamometer. Low muscle strength was defined as values less < 16 kg for women and < 26 kg for men. Low physical performance was defined as a decrease in the total score Short physical performance battery (SPPB) < 9 points. Geriatric assessment included: screening of frailty using «Age is not a blocking» questionnaire, Mini Nutritional Assessment, orthostatic test, Barthel Index for Activities of Daily Living, Lawton Instrumental Activities of Daily Living Scale, fracture risk assessment tool, Visual Analog Scale, Geriatric Depression Scale-15, The Mini Mental State Examination. Physical activity was assessed using International Physical Activity Questionnaire, comorbidity by Charlson Comorbidity Index.

Results of the study: probable sarcopenia was diagnosed among 28,3% of patients with knee osteoarthritis, 69,2% were women and 30,9% men. There were no differences in education level, residential status, disability group and number of chronic comorbidities between sarcopenic patients and non-sarcopenic patients. Patients aged 60-74 years and women were more in both groups (p>0.05). Sarcopenic patients were more likely to have orthostatic hypotension (p=0.027), urinary incontinence (p=0.030), low physical activity (p=0.03) and had a higher need for personal care (p= 0.075) than non-sarcopenic patients. Chronic pain syndrome by VAS 40 mm and more, falls and high fracture risk occurred in patients with similar frequency in both groups. Moderate and severe comorbidity did not differ between sarcopenic and non-sarcopenic patients (p>0.05).

Conclusion: geriatric syndromes like orthostatic hypotension, urinary incontinence, and low physical activity were more frequent in sarcopenic patients with knee osteoarthritis. Patients with probable sarcopenia were more in need of personal care and a complex of physical exercises.

P1542

FREQUENCY AND RELATIONSHIP OF SARCOPENIA WITH LATE DEBUT OF RHEUMATOID ARTHRITIS IN ELDERLY PATIENTS

Y. Safonova[1], Y. Garova[1], O. Inamova[1]

[1]North-Western State Medical University named after I.I. Mechnikov, St. Petersburg, Russia

Objective: to evaluate the frequency of sarcopenia in patients with rheumatoid arthritis (RA) with the onset of the disease at the age of 60 years and older and to identify the relationship with demographic indicators and disease activity.
Methods: The study included 46 patients (mean age 71.8±6.5 years) with confirmed RA corresponding to the 2010 ACR/EULAR classification criteria. RA activity was assessed by the DAS28. Sarcopenia was diagnosed according to the criteria European Working Group on Sarcopenia (EWGSOP2). Low muscle strength was defined as values less < 16 kg for women and < 26 kg for men. Skeletal muscle mass was calculated by Appendicular skeletal muscle mass (ASMM) by Dual-energy X-ray absorptiometry (DXA). Low muscle mass was defined as values less < 5.5 kg in women and < 7 kg in men. Low physical performance was defined as a decrease in the total score Short physical performance battery (SPPB) <9 points.
Results of the study: Sarcopenia was detected in 18% of patients with late onset RA (75% of women and 25% of men). There were no differences in the mean values of muscle strength (p = 0.09) and muscle mass (p=0.3) in this groups. However, gender differences in the components of sarcopenia have been revealed. Thus, women aged 60-74 years muscle strength (p=0.04) and muscle mass (p=0.0001) were significantly lower than in men. In age group 75-84 years the values of muscle strength (p=0.04), muscle mass (p=0.005) and physical performance (p=0.04) women were significantly lower than in men. There was no association between the diagnostic components of sarcopenia and RA activity. Muscle mass in women with high RA activity was significantly lower than women with low activity (p=0.0001) and men (p=0.0001), regardless of the DAS28 (p=0.06). Patients on combination treatment (methotrexate and glucocorticoids) had significantly lower muscle strength (p=0.01), muscle mass (p=0.01) and physical performance (p=0.04) compare to the patients receiving methotrexate monotherapy or other DMARD regardless of glucocorticoids intake (p=0.06).
Conclusion: In women, muscle strength, muscle mass, and physical performance decreased with age and were significantly lower than in men. Sarcopenia was more common in women with high RA activity and was associated with low muscle mass. Glucocorticoid use was associated with low values of muscle strength, muscle mass, and physical performance.

P1543

INVESTIGATING THE LINK BETWEEN URINARY ALBUMIN EXCRETION AND OSTEOPOROSIS IN HOSPITAL AND COMMUNITY COHORTS

Y. T. Lin[1], Y. S. Chuang[1], C. T. Cheng[2], P. H. Wu[2], C. Y. Lee[1]

[1]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, Kaohsiung, Taiwan, [2]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, Kaohsiung, Taiwan

Objective: Chronic kidney disease (CKD) is increasingly recognized as a complex condition with potential implications for bone health. The relationship between urinary albumin-to-creatinine ratio (UACR) and osteoporosis remains incompletely understood, particularly across different kidney disease stages.
Material and Methods: We conducted a crossectional analysis across hospital-based and community-based cohorts from four distinct populations, including TAKO (TAiwan Kidney Outcome Study, N=25,626), KHNHANES (Korea National Health and Nutrition Examination Survey, N=1,868), US NHANES (United State National Health and Nutrition Examination Survey, N=3,298), and TWBB (Taiwan BioBank, N=9,844). Baseline characteristics, including age, sex, hypertension, diabetes, body mass index (BMI), estimated glomerular filtration rate (eGFR), and UACR were compared. Logistic regression models were employed to investigate the association between UACR and osteoporosis, with adjustments for key confounding variables. Stratified analyses were performed by sex and CKD stages.
Results: UACR was positively associated with osteoporosis in individual meta-analysis of four cohorts, particular in the TAKO and TWBB cohorts. Although US NHANES and KHANES datasets demonstrated a similar positive association, these cohorts lacked statistical power. Notably, sex-specific analyses revealed a distinct pattern: among female participants with CKD stages 1-3, UACR showed a positive association with osteoporosis, whereas this relationship was absent in stages 4-5. In contrast, male participants did not exhibit such a stage-specific pattern.
Conclusion: This study elucidates the relationship between UACR and bone health across hospital-based and community-based population. UACR showed a positive association with osteoporosis, particularly in females and the early stage of CKD.

P1544

FIBROBLAST GROWTH FACTOR (FGF)-21 AND ITS CORRELATIONS WITH DISEASE CHARACTERISTICS IN RHEUMATOID ARTHRITIS

Y. U. Polyakova[1], E. Rozhkova[2], E. Papichev[1], L. Seewordova[1], Y. U. Akhverdyan[1], B. Zavodovsky[1]

[1]Research institute of clinical and experimental rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Volgograd State Medical University, Volgograd, Russia

Fibroblast growth factors (FGFs) are a family of cell signaling proteins produced by macrophages. FGF21 is secreted primarily by the liver, regulating simple sugar consumption and preference for sweet foods. Increased FGF21 is associated with energy deficiency.
Objective: to study FGF21 levels in patients with rheumatoid arthritis (RA).
Materials and methods. The study assessed 88 women with RA. The average age was 54.2±12.0 (51.7-56.7) years, BMI - 28.5 [24.1-32.3], disease duration - 10 [4.5-17.0]. Laboratory examination was standard, FGF21 level - by enzyme immunoassay using HUMAN FIBROBLAST GROWTH FACTOR 21 (FGF-21) ELISA KIT. The obtained results were analyzed by STATISTICA 10.
Results: No correlation was found between the FGF21 level and RF, ACPA, CRP, DAS 28, clinical and X-ray stage of the disease, or functional class of the disease.

A negative correlation was found between FGF-21 and the duration of the disease (ρ= -0.22; p=0.041), and a positive correlation was found with ESR (ρ=0.35; p=0.0023). High levels of FGF-21 were observed in patients taking GC at the time of the study (Z=3.25; p=0.001; 983 [556-179.9]) versus patients not taking GC (398 [239-936]).
Discussion: FGF21 improves tissue sensitivity to insulin, helps to reduce serum glucose levels and reduce body weight. Short-term high FGF21 is observed during fasting and overeating. Increased FGF-21 levels in RA patients taking glucocorticoids (GC) at the time of the study are likely due to the effect of GC on carbohydrate and fat metabolism. GC interference in all levels of carbohydrate metabolism leads to energy metabolism disorder, contributing to an increase in FGF21. With prolonged energy metabolism disorder, there is a redistribution of the mass fraction of fat and muscle tissue, a decrease in the percentage of the latter. Probably, a decrease in active muscle mass as a result of a long-term illness leads to a decrease in the body's need to release fast energy fuel - glucose and, as a consequence, to a decrease in the FGF21 level in long-term RA patients.
The correlation between ESR and FGF21 levels is more difficult to explain, since we did not find other associations of FGF21 with RA activity. Probably, FGF21 is indirectly associated with frequent use of GC with high ESR.

P1545

TYPICAL OSTEOPOROTIC FRACTURES IN THE BACKGROUND OF OSTEOPENIA

V. A. Beloglazov[1], Y. U. V. Usachenko[1], V. B. Kaliberdenko[1], A. A. Zayaeva[1], A. V. Klimchuk[1], N. G. Nikolashina[1], E. M. Dolya[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: Densitometry (DXA) is the most widely used method and the gold standard for the diagnosis and treatment of osteoporosis. Low-energy fracture is a typical complication of osteoporosis.
According to the definition of the World Health Organization, osteopenia is determined by bone densitometry as a T index from -1 to -2.5.
Trabecular bone index (TBI) provides an indirect idea of the state of bone tissue microarchitecture during routine dual-energy X-ray osteodensitometry and has prognostic properties for low-traumatic fractures.
Trabecular bone score (TBS) is one of the most widely used assessments of bone tissue quality. Previous studies have shown that TBC predicts fractures independently of BMD.
Methods: 142 patients with a history of fractures were observed (44 men and 98 women, aged 40 to 70 years, average age 56.3±1.1 years). Moreover, these fractures were significantly more common among women than men (p<0.001). All patients underwent a 10-year fracture risk calculation (https://www.sheffield.ac.uk/FRAX/tool.aspx?lang=rs). The obtained result was compared with the threshold of therapeutic intervention developed for the Russian Federation. All patients also underwent densitometry (DXA).
Results: Vertebral fractures were detected in 62 (44%) of the examined patients, 39 (27%) fractures of the proximal femur, 25 (18%) fractures of the radius and 16 (11%) proximal humerus. According to the results of densitometry (DXA), no decrease in bone mineral density (BMD) in the lumbar vertebrae and femoral neck was detected. However, a low TBS of L1–L4 was noted, associated with a high risk of new low-trauma fractures.
Conclusion: According to the study, low TBS is associated with a high risk of typical fractures against the background of osteopenia. Determining the TBS score to FRAX and/or BMD improves prediction of fracture risk not only in osteoporosis, but also in osteopenia, which contributes to the correct decision-making on treatment methods and monitoring.

P1546

FREQUENCY OF ATYPICAL FRACTURES DURING ANTI-OSTEOPOROSIS THERAPY

Y. U. V. Usachenko[1], V. B. Kaliberdenko[1], A. A. Zayaeva[1], E. M. Dolya[1], N. G. Nikolashina[1], S. Kulanthaivel[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: Bisphosphonates are first-line drugs for the prevention of osteoporosis and fracture prevention. Their findings include a selective effect on bone tissue, which has a powerful ability to increase bone mineral density (BMD) among all known antiresorptive agents and a low frequency of exposure, the risk of which is lower compared to the benefits of the drugs. However, in recent years, the number of cases of atypical femoral fractures (AFF) has increased during long-term treatment with bisphosphonates.
Methods: We observed 96 women who took bisphosphonates and had a history of atypical femoral fracture. The mean age of patients is 63.5±2.8 years, the average duration of bisphosphonate use is 6.6 years. Data on risk factors, including the use of bisphosphonates, were obtained using medical records. Fractures were confirmed radiologically. The studied patients underwent clinical and radiological examination, as well as densitometry.
Results: When examining patients by densitometry, osteoporosis was detected in 54 patients (56%), osteopenia - in 42 patients (44%). As a result of the obtained data, typical radiological signs of atypical fracture were accidentally observed more often in patients who entailed treatment with bisphosphonates compared to patients who did not use them as treatment ($p < 0.001$).
Conclusion: The researchers concluded that atypical changes may be a manifestation of the influence of bisphosphonates.

P1547

ASSESSMENT OF CELLULAR AND HUMORAL IMMUNITY INDICATORS IN THE DEVELOPMENT OF JUVENILE IDIOPATHIC ARTHRITIS IN CHILDREN

Y. V. Usachenko[1], O. P. Galkina[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1], E. M. Dolya[1], E. R. Kulieva[1], S. Kulanthaivel[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: Juvenile idiopathic arthritis (JIA) is the most severe and disabling form of chronic pathology in children and adolescents. Early diagnosis and treatment of idiopathic arthritis in children is one of the most pressing problems in pediatrics. Currently, and throughout the world, there is a tendency towards a steady increase in the prevalence of rheumatic diseases in both the general and pediatric populations.
Methods: The study included 84 children with a confirmed diagnosis of juvenile arthritis. The role of the cellular and humoral components of the immune system in the development and formation of juvenile idiopathic arthritis was assessed, in particular the CD3 and CD8 indices.
Results: The analyzing the immunological parameters of the cellular and humoral components of the immune system in children with juvenile rheumatoid arthritis, the CD3 - T lymphocytes parameters had significant differences from the norm and, depending on the form of the disease, tended to increase (N - 50.25±4.59%; polyarticular form of JIA - 61.00±2.09%; systemic form of JIA - 68.97±5.115%), which confirmed the hyperactivity of the immune system and the immunoproliferative nature of the disease. The CD3- T lymphocytes and CD8- cytotoxic lymphocytes parameters in children with JIA were significantly higher ($P<0.05$) than the normal level.
Conclusion: The results of the study indicate that other immunological markers, CD3 T lymphocytes and CD8 cytotoxic lymphocytes, are also detected with equal or greater frequency in children with early JIA. The frequency of increase and concentration levels of these indicators were higher than in healthy children.

P1548

ANALYSIS OF THE QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLOARTHRITIS AND NSAID-GASTROPATHY RECEIVING COMBINED GASTROPROTECTIVE THERAPY

Y. V. Usachenko[1], V. B. Kaliberdenko[1], E. R. Kulieva[1], N. G. Nikolashina[1], S. A. Khamidova[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Non-steroidal anti-inflammatory drugs (NSAIDs) occupy one of the leading positions in terms of the volume of use as therapy for ankylosing spondylitis (AS). Despite a number of positive aspects from taking NSAIDs, at the same time, this group of drugs is characterized by the development of class-specific side effects from the cardiovascular system (CVS), gastrointestinal tract (GIT), kidneys, liver, which also leads to a deterioration in the quality of life of patients.
Methods: We examined (according to the SF-36 questionnaire) in 90 patients with AS aged 34-49 years. The average age was 39.8±2.4 years. The control group consisted of 45 practically healthy volunteers (36 men and 9 women); both groups were comparable by gender and age. For 6 months, all patients with AS received NSAIDs, for the purpose of gastroprotection 30 (33%) patients received PPI (Omeprazole), 27 (30%) – PPI (Omeprazole) and Rebamipide, 15 (17%) – Rebamipide, 18 (20%) patients did not systematically take gastroprotective drugs.
Results: In patients with AS, compared to the control group, physical and psychological indicators the quality of life (QOL) are reduced ($p<0.001$). QOL of patients with AS worsens with increasing inflammatory activity of the disease, functional limitations, joint manifestations and enthesitis. Coxitis, detected in 76.7% of patients, has an adverse effect on the scale of role physical functioning. QOL indicators were higher in patients taking PPI (Omeprazole) + Rebamipide. When assessing the impact of drug therapy on QOL in patients taking monotherapy with only Proton

pump inhibitors (PPI) like Omeprazole and Rebamipide, compared to the control group, statistically significantly worse indicators were noted on all scales of the SF-36 questionnaire (p<0.001). In patients who took only PPI for gastroprotection, QOL indicators were also worse than in the control group (p<0.001). In patients receiving PPI (Omeprazole) + Rebamipide, a number of QOL parameters according to the SF-36 questionnaire were comparable with the corresponding QOL indicators in the group of practically healthy people.

Conclusion: Patients with AS have significantly lower physical and psychological QOL indicators than healthy people. Deterioration in QOL is noted as the inflammatory activity of AS and functional limitations increase. No effect of socio-demographic factors on the QOL of patients with AS was found. Therapy with PPI (Omeprazole) and Rebamipide provided a higher QOL in patients with AS than other types of treatment.

P1549

MACHINE LEARNING MODELS FOR CLASSIFYING NECK-SHOULDER PAIN BASED ON SMARTPHONE USAGE CHARACTERISTICS

Y. X. Wang[1], U. J. Hwang[1], H. S. Jeon[1]

[1]Department of Physical Therapy, Yonsei University, Wonju, South Korea

Objective(s):
The widespread use of smartphones has increased musculoskeletal discomfort, particularly neck-shoulder pain (NSP). This study aimed to develop machine learning models to classify NSP based on smartphone usage characteristics and personal traits.

Material and Methods:
A total of 188 non-NSP and 160 NSP participants aged 20-50 years participated. Participants with NSP were eligible if they reported their neck-shoulder pain on the Cornell Musculoskeletal Discomfort Questionnaire (CMDQ). 18 Features included demographics (sex, age, BMI, job, vision status) and smartphone usage variables (usage time, smartphone sizes, weight, body postures, neck postures, hand postures, and usage purposes such as video watching, social media, and others). The complete dataset (n = 348) was split into a training set (80%, n = 278, NSP = 128, non-NSP = 150) and a test set (20%, n = 70, NSP = 32, NSP-free = 38) for external validation. Four machine learning models—Random Forest, SVM, Logistic Regression, KNN—were trained and evaluated using AUC, Accuracy, and F1-Score. Random Forest performance was further interpreted using SHapley Additive Explanations (SHAP).

Results:
The Random Forest model performed best (AUC: 0.721, Accuracy:0.693, F1: 0.691) in classified smartphone users with and without neck-shoulder pain. Smartphone usage time and neck posture were identified as the most critical predictors. SHAP analysis showed that moderate smartphone use (1-4 h/day) reduced the likelihood of neck-shoulder pain, whereas prolonged use (7-10 h/day) increased the risk. Similarly, neck posture (reduced neck flexion) and upright body posture (sitting) significantly reduced the likelihood of discomfort, while non-optimal postures increased it. Additional insights indicated that avoiding video watching, maintaining normal vision, and listening to music while using smartphones were associated with a lower risk of neck-shoulder pain.

Conclusion(s):
This study highlights the importance of smartphone usage time, posture, and other factors in predicting neck-shoulder discomfort. Machine learning models, particularly Random Forest combined with SHAP analysis, provide valuable insights for identifying high-risk behaviors and guiding interventions to reduce musculoskeletal pain.

P1550

A SHORT-TERM CLINICAL EFFICACY ANALYSIS OF MR-GUIDED VERTEBROPLASTY FOR THE THORACOLUMBAR SPINE

Y. Xie[1]

[1]Department of Orthopedics, General Hospital of Northern Theater Command, Shenyang, China

抽象：
目的：比较 MR 引导下 PVP 手术技术与常规透视辅助单侧穿刺椎体成形术 （PVP） 治疗老年骨质疏松性椎体压缩骨折 （OVCFs） 患者的短期临床疗效。方法：共有 100 名 OVCF 受试者 （从 2022 年 3 月至 2024 年 1 月） 在北方战区总医院骨科接受了单节段经皮椎体成形术，并在本回顾性研究中进行了测试。将这些受试者随机分为 MR 指导组（MR 引导的 PVP 手术组）和对照组（常规透视组），共 50 例受试者（MR 指导组：23 名男性和 27 名女性受试者，年龄 72.72 ± 8.38 岁;对照组：25 名男性和 25 名女性受试者，年龄 72.66 ± 6.05 岁），以及两组间透视次数指标， 评估不同时间点的疼痛评分、骨水泥用量、骨水泥渗漏率和术后并发症。结果： MR 引导组透视次数 （14.00 倍 [13.00， 15.00]） 低于对照组 （20.50 倍 [19.00， 21.00] P<0.001）。MR 引导组的 VAS 评分在穿刺定位 （p<0.001）、术后即刻 （p<0.001） 和术后第 1 天 （p<0.001） 方面均显著低于对照组。与对照组相比，MR 指导组骨水泥用量 （6.00 [6.00， 6.00]，P<0.001） 大于对照组 （5.00 ml [5.00， 5.00]）。MR 引导组骨水泥渗漏率 （2%） 大于对照组 （8%），但差异无统计学意义 （P>0.05）。两组并发症发生率也无统计学意义 （P>0.05）。结论：与传统透视手术相比，MR 引导的 PVP 手术可显着减少荧光计的数量、额外的辐射风险和即时疼痛，并可改善骨水泥对 OVCF 患者的弥散量。

P1552

VITAMIN D STATUS OF GUANGZHOU SUBJECTS AGED≥40 YEARS IN SUMMER

Y. Zhang[1], L. Hu[1], N. Liu[1], Q. Dong[1], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou, China

Objective: We aimed to describe the vitamin D status of Guangzhou subjects aged ≥40 years in summer. **Method:** In the present study, serum 25-hydroxyvitamin D (25(OH)D) and serum calcium were examined of 590 subjects aged ≥ 40 years from 1 May to 31 Oct. Results: We had to exclude 238 males with average level of 25(OH)D was (57.09±24.06) nmol/L, and 352 females with average level of 25(OH)D was (53.71±22.63) nmol/L. Among our subjects, the normal vitamin D status accounted was 24.79%, vitamin D deficiency was 33.19%, insufficiency was 34.45%, serious vitamin D deficiency was 7.56% in group Male. The normal vitamin D status accounted was 15.63%, vitamin D deficiency was 40.63%, insufficiency was 37.22%, serious vitamin D deficiency was 6.53% in group Female. Vitamin D inadequacy existed generally in subjects aged ≥ 40 years. There was statistic difference between males and females subjects aged ≥ 80 years (P= 0.026, P= 0.043).

Conclusion: Vitamin D deficiency and insufficiency is very common in subjects aged ≥ 40 years living in Guangzhou in summer. In subjects aged ≥ 80 years, Male group was significantly higher than Female group. Vitamin D intakes should be taken into account.

Key words: Vitamin D; 25-hydroxyvitamin D; Vitamin D insufficiency; Vitamin D deficiency

P1553

SMART WALKER IMPLEMENTATION IN POSTOPERATIVE HIP FRACTURE REHABILITATION: FEASIBILITY AND IN-HOSPITAL OUTCOMES

Y.-J. Kuo[1], Y.-P. Chen[1]

[1]Department of Orthopedics, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan, Taipei, Taiwan

Introduction Achieving independent mobility after hip fracture surgery is vital for enhancing quality of life (QoL) and lowering the likelihood of complications. The use of advanced technology in mobility aids represents a growing trend aimed at improving patient recovery. This study investigates the impact of a smart walker compared to a standard walker in aiding postoperative walking rehabilitation for hip fracture patients.

Materials and Methods A prospective cohort design was employed, involving patients treated surgically for hip fractures at our institution between August 2023 and June 2024. Participants were grouped based on their preference and familiarity with either a traditional or smart walker. Evaluations were conducted pre- and post-rehabilitation, focusing on walking ability, mental health, independence in daily activities, QoL, hip range of motion (ROM), muscle strength, gait patterns, and a 10-meter walking test.

Results Thirty-two participants (mean age: 81.7 years; 19 females, 13 males) were included, equally split between the two walker groups. Both devices proved effective for recovery, but the smart walker group exhibited notable advantages in hip ROM, mobility, walking speed, and physical functionality. Although overall rehabilitation outcomes between the two groups were comparable, the smart walker showed superior benefits in specific areas.

Conclusion The findings suggest that walking aids significantly support recovery after hip fracture surgery, with the smart walker offering enhanced rehabilitation outcomes in targeted metrics. While the follow-up period was brief, extended use of smart walkers may yield further improvements in mobility, recovery speed, and autonomy in daily activities.

Keywords: smart walker, traditional walker, hip fracture recovery, mobility aids, postoperative rehabilitation, quality of life

P1554

USING QUALITY MONITORING TOOLS TO IMPROVE THE ENROLLMENT RATE OF OSTEOPOROSIS PATIENTS

C.-H. Liang[1], Y.-L. Huang[1]

[1]Tungs' Taichung MetroHarbor Hospital, Taichung, Taiwan

Objective

Osteoporosis is a global health issue, particularly with a high incidence and risk of complications among the elderly. However, many osteoporosis patients fail to receive timely diagnosis, education, and treatment, leading to fractures and worsening health conditions. It is hoped that through the use of quality monitoring tools, the enrollment rate of osteoporosis patients can be improved, especially by conducting FRAX fracture risk assessments for patients with non-traumatic fractures to promote early diagnosis and intervention measures.

Methods

- Research Design and Scope

Time Frame: January 1, 2024, to December 31, 2024.

Subjects: Hospitalized and outpatient patients aged ≥50 years who have been diagnosed with non-traumatic fractures.

- Quality Monitoring Indicators

Name: Rate of FRAX Fracture Risk Assessment Completion Within 8 Weeks for Patients with Non-Traumatic Fractures.

Formula:

$$\text{FRAX Assessment Rate}(\%) = \left(\frac{\text{Number of eligible patients who completed FRAX assessment within 8 weeks}}{\text{Total number of eligible patients with non-traumatic fractures}}\right) \times 100$$

Threshold Setting: ≥50%

- Implementation Measures

1. Develop Standard Operating Procedures (SOPs):

Establish comprehensive SOPs that cover the roles of physicians, nursing staff, and patient education processes for managing osteoporosis patients.

2. Regular Training and Awareness Programs:

Conduct periodic training sessions and awareness campaigns to emphasize the importance of enrolling osteoporosis patients,

especially those with non-traumatic fractures, into monitoring programs.
3. Host Osteoporosis-related Educational Programs:
Organize educational courses to raise public awareness about osteoporosis, its risks, and provide initial screening for the disease.
- Data Collection and Analysis

1. Monthly Statistics on FRAX Risk Assessment Completion:
Track and calculate the percentage of non-traumatic fracture patients who complete the FRAX risk assessment each month.
2. Quarterly Team Meetings for Review and Improvement:
During each quarterly team meeting, review the reasons for not meeting the target and propose strategies for improvement.

Results
- Monthly Evaluation Results

1. Average Completion Rate from January to December 2024:
The average completion rate is 61.79%, which meets the set threshold.
2. Quarterly Completion Rate Trends:
The completion rate fluctuated significantly in the first quarter, but from the second quarter onward, it showed a steady improvement, reaching a peak of 77.50%.
- Key Findings

1. Significant Improvement in FRAX Risk Assessment Completion Rate:
After implementing quality monitoring, the completion rate of the FRAX risk assessment showed a significant increase.
2. Higher Proportion of Successfully Enrolled Patients:
The proportion of successfully enrolled patients increased, effectively promoting the diagnosis of osteoporosis and the initiation of related interventions.

Conclusion
This study shows that through quality monitoring tools, the enrollment rate of osteoporosis patients can be significantly improved, particularly for those with non-traumatic fractures. Establishing clear indicators and standardized intervention measures can enhance assessment efficiency and execution outcomes. Future research should further explore the effectiveness of this approach in the long-term prevention of fracture risks.

P1555

A DECADE OF EXPOSURE: LONG-TERM AIR POLLUTION AND ITS ASSOCIATION WITH OSTEOARTHRITIS RISK - A NATIONWIDE COHORT STUDY IN TAIWAN

Y.-P. Chen[1], Y.-J. Kuo[1], Y.-C. Chan[2], S.-H. Chuang[3]

[1]Department of Orthopedics, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan, Taipei, Taiwan, [2]School of Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan, Taipei, Taiwan, [3]Division of General Practice, Department of Medical Education, Changhua Christian Hospital, Changhua, Taiwan, Taipei, Taiwan

Objective: This research examines the effects of prolonged exposure to air pollution on the risk of developing osteoarthritis (OA) in Taiwan. The study evaluates ten years of exposure to multiple pollutants, including sulfur dioxide (SO_2), carbon monoxide (CO), particulate matter (PM10 and PM2.5), nitrogen oxides (NOx), nitrogen monoxide (NO), nitrogen dioxide (NO_2), total hydrocarbons (THC), non-methane hydrocarbons (NMHC), and methane (CH_4).
Design: A retrospective cohort analysis was conducted using data from Taiwan's National Health Insurance Research Database (NHIRD) linked with air quality measurements from 76 environmental monitoring sites. The study followed 526,630 individuals without a prior OA diagnosis over a decade. Daily cumulative averages of pollutant levels were calculated, and the association with OA onset was analyzed using Cox proportional hazards models, with adjustments for demographic and clinical variables.
Results: Long-term exposure to air pollutants was significantly associated with increased OA risk. Hazard ratios (HRs) for each standard deviation increase in pollutant levels were as follows: SO_2 (1.40), CO (1.83), PM10 (1.58), PM2.5 (1.53), NOx (1.59), NO (1.45), NO_2 (1.62), THC (1.75), NMHC (1.23), and CH_4 (2.76). Among these, CH_4 exhibited the strongest correlation, with a 176% rise in OA risk per standard deviation.
Conclusions: This study establishes a clear link between chronic air pollution exposure and a higher likelihood of developing OA. The findings emphasize the necessity of effective air quality management to reduce the public health burden of OA. These insights provide valuable evidence for identifying environmental risk factors and guiding preventive strategies.
Keywords: Osteoarthritis, Air pollution, Chronic exposure, Particulate matter, Gaseous pollutants, Public health policy.

P1556

ADVANCEMENTS IN REGENERATIVE MEDICINE IN TAIWAN: EVALUATING THE EFFICACY OF PERIPHERAL BLOOD MONONUCLEAR CELL PURIFICATION (PCP) THERAPY FOR OSTEOARTHRITIS

Y.-T. Guo[1], Y.-C. Cheng[1], S.-N. Cheng[1]

[1]Tungs' Taichung MetroHarbor Hospital, Taichung, Taiwan

Objective
Osteoarthritis (OA) is a prevalent degenerative joint disease that affects approximately 54 million people in the United States, according to CDC data in 2023. In Taiwan, over 3.5 million people are afflicted with OA, and treatment options vary based on the severity of joint degeneration. Total Knee Arthroplasty may be necessary in advanced stages. Peripheral Blood Cell Purification (PCP) utilizes the differentiation of monocytes into M2 macrophages, which exhibit anti-inflammatory properties and immunomodulatory functions. This report presents the outcomes of PCP in reducing pain, improving joint mobility, and delaying cartilage degeneration.
Material and Methods
Autologous peripheral blood (100–120 mL) was collected including 2.5 hours of cell separation and purification, followed by

the culture of 1–2×10^8 PCP in 4 mL, with knee joint injection performed on the same day. Pain levels were assessed by using the Defense and Veterans Pain Rating Scale (DVPRS) and the Knee Injury and Osteoarthritis Outcome Score (KOOS) both pre- and post-treatment. Radiographic imaging follow-up was conducted six months after treatment.

Results

The DVPRS scores for Case 1 and Case 2 decreased from 9 and 8 to 0, respectively. The KOOS scores demonstrated a significant enhancement in joint mobility six months following treatment, with Case 1 improving from 45 to 84 and Case 2 from 35 to 100. Imaging follow-up at the six-month mark revealed a notable widening of the joint space (Figure 1), contributing to a reduction in knee joint wear and tear. The decline in pain correlated with increased mobility for both cases (Figure 2).

Figure 1:X-ray image before(A) and post(B) 6 months PCP treatment

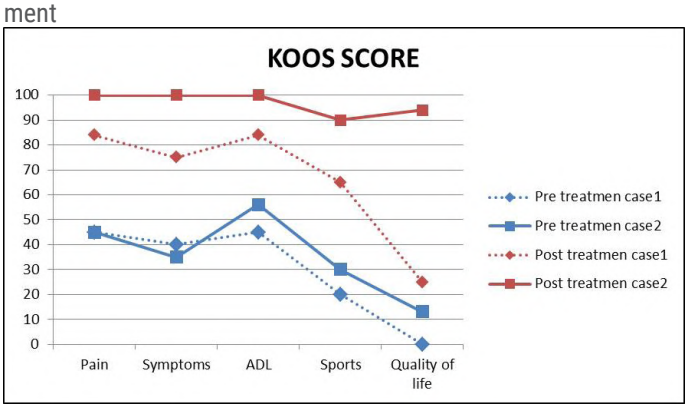

Figure 2 : Knee Injury and Osteoarthritis Outcome Score

Conclusions

PCP effectively suppresses inflammatory responses. This therapy demonstrated the significant efficacy in treating osteoarthritis (OA) by reducing joint pain, improving motor function, and enhancing quality of life, making it a fast, safe, and effective new treatment option.

P1557

PREDICTORS OF MORTALITY IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE REAL LIFE STUDY

Z. Apostolova[1], T. Shivacheva[1], T. Georgiev[1]

[1]MEDICAL UNIVERSITY "PROF. DR. P. STOYANOV" - VARNA, Varna, Bulgaria

Objective:

To identify key predictors of mortality in patients with rheumatoid arthritis (RA)

Material and methods:

In a retrospective cohort study, an administrative database from the Rheumatology Clinic of the IMHAT "St. Marina", Varna, Bulgaria, of RA patients was analyzed. Study period -from the start of biologic til Oct. 2024 or death. Demographic characteristics (age, smoking, BMI), disease-related factors (duration of RA, time to bDMARD, functional stage), and treatment (methotrexate and methylprednisolone use) as well comorbidities were assessing. Cox regression was applied to assess the risks of mortality.

Results

190 patients treated with biologics for a period of 4 to 19 years (mean = 9.33, SD = 2.35). The mean age of the patients was 64.1 years (25-86), 14.7% were women, mean duration of RA was 17.8 years (8-50), mean duration of treatment (years) was 9.32 (4-15). The analysis period included 1772 years of treatment.

Patients were treated with TNF and IL-6 inhibitors (55.3% vs. 44.7%, p>0.05). 65.8% and 45.8% of them were in radiographic stage III or IV and functional stage II or III (p <0.001 and p >0.05, respectively). A significant proportion were taking steroids and were on combination with methotrexate (p=0.042 and <0.01, respectively). 58.9% of patients had HTN, 12.1%- IHD, 9.5%- CVD, 7.4%- pulmonary, 8.4%- renal disease and 15.3%- diabetes mellitus.

The average mortality rate was 112,9 for the 1772 treatment years.

More advanced functional disability leads to an increased risk of mortality (HR = 9.127, 95% CI 2.185–38.132, p = 0.002), longer time from diagnosis to initiation of biological therapy significantly increases the risk of mortality (HR = 6.240, 95% CI 3.306–11.775, p < 0.001). Interestingly, the duration of RA was associated with protection against the risk of mortality (HR = 0.152, 95% CI 0.079–0.295, p < 0.001). Age, sex, BMI, smoking, comorbidities, did not show a statistically significant relationship with mortality rates.

Conclusion

The results highlight the importance of functional status and time to initiation of biologic therapy as key risk factors for mortality in RA. Early and adequate treatment, such as with ts/bDMARDs, could prevent invalidation and thus contribute to improving long-term outcomes.

P1558

TYROSINEMIA TYPE 1 MANIFESTING AS HYPOPHOSPHATEMIC OSTEOMALACIA IN A YOUNG ADULT

E. Mamedova[1], M. Berlovich[1], K. Smirnov[1], R. Salakhov[1], R. Khusainova[1], Z. Belaya[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective: We present a clinical case of HT-1 in a young adult, which manifested as hypophosphatemic osteomalacia. Tyrosinemia type 1 (hepatorenal tyrosinemia, HT-1) is a rare autosomal recessive disorder caused by mutations in *FAH* gene encoding fumarylacetoacetate hydrolase. This genetic alteration leads to the accumulation of tyrosine and its metabolites, which exert cytotoxic effects on cells. HT-1 can cause progressive damage to the liver and kidneys, as well as severe neurological complications. Clinically, HT-1 can present from the early neonatal period (characterized by its most aggressive form) to adolescence (manifesting as a slowly progressive disease).
Materials and methods: Whole-exome sequencing was performed on G400 (BGI, China).
Results: A female patient noticed pain in the costosternal joints, pelvic bones, hip joints, knee joints, and feet, without clinically significant improvement despite analgesic treatment at the age of 19. At the age of 24, hypophosphatemia and fractures of proximal femoral metaphyses and metatarsals of both feet were revealed for the first time. The patient's height is 150 cm, weight 46kg. Medical history reveals early closure of the anterior fontanelle and delayed eruption of deciduous teeth with otherwise normal development. During admission to our center at the age of 24, she had complaints of muscle weakness, waddling gait, bone and joint pain. Hypophosphatemia (0.54 mmol/L (0.74-1.52)) and hyperphosphaturia (TRP 54%) were identified alongside with elevated alkaline phosphatase (176 IU/L (40-150)), hypouricemia, glucosuria and proteinuria. Imaging revealed multiple vertebral compression fractures (Th1,4,5-10,L5). FGF23-producing tumor was excluded by ^{99m}Tc-Tectrotide scintigraphy. Therapy with alfacalcidol and phosphate was initiated. Due to suspected Fanconi syndrome, whole-exome sequencing was performed, which revealed a compound heterozygous mutation in the *FAH* gene (NM_000137.4, c.374C>T/c.192G>T (p.Thr125Ile/p.Gln64His)), confirming the diagnosis of HT-1. Further examination showed signs of macro-nodular cirrhosis and a focal lesion in segment 8 of the liver, with no evidence of hepatocellular carcinoma. The patient has been prescribed therapy with nitisinone and low-tyrosine diet.
Conclusion: HT-1 necessitates early diagnosis to prevent the development of severe complications. Newborn screening for tyrosinemia is not implemented worldwide, though it is crucial for a timely diagnosis and medical intervention. Our case shows that HT-1 can manifest in young adults as hypophosphatemic osteomalacia.

P1559

TRANSITION OF HYPOPHOSPHATASIA TREATMENT WITH ASFOTASE ALFA FROM CHILDHOOD TO ADULTHOOD.

N. Kalinchenko[1], E. Kaletnik[1], V. Peterkova[1], A. Tiulpakov[1], O. Bezlepkina[1], G. Melnichenko[1], Z. Belaya[1]

[1]Endocrinology Research Center, Moscow, Russia

Hypophosphatasia (HPP) is genetic disease characterized by impaired mineralization and systemic disabling complications due to alkaline phosphatase (ALP) deficiency which is treated by enzyme replacement therapy with asfotase alfa.
We report two cases of hypophosphatasia with successful continuity of asfotase alfa treatment from childhood to adulthood.
Clinical case 1: a girl with signs of rickets and growth retardation starting at age 3 months, X-ray signs of severe rickets, along with consistently very low ALP (5-20 IU/l), elevated phosphate and genetic confirmation TNSALP (p.T85P and p.E191K). The premature loss of deciduous teeth started at age 1. She suffered from keeled chest deformity, scoliosis, bone and joint pain and poor physical performance. Asfotase alfa was started at age 10 (SDS height:-1,93, BMI SDS:-3,13) at a dose of 2 mg/kg 3 times/week subcutaneously. This patient was transferred to adult department at age 18 at the height 164 cm, (SDS: 0,64, midparental height 166,5 cm SDS: 0,75 vs normal), weight 50 kg, BMI: 18.4 kg/m^2), scoliosis, but no other visual bone deformities. Her physical performance (6 min walking test, 10 second chair rise test and grip strength) were as expected for a healthy adult. She has continued receiving treatment with asfotase alfa with the only side effect of skin reaction.
Clinical case 2: a boy with signs of rickets and growth retardation starting at age 3 months, delayed motor development without the ability to walk independently until 2.5 years old. He had a left shin facture at age 3 and sacrum fracture at age 5. At age 15 multiple bone deformities were detected, movement limited to a few meters with crutches. At 17 years (SDS height:-3.24) hypophosphatasia was confirmed based on repeatedly low ALP levels, hyperphosphatemia and genetic confirmation ALPL c.302A>G/c.571G>A; asfotase alfa was prescribed at of 2 mg/kg 3 times/week subcutaneously. Currently he has received asfotase alfa for 6 years. The patient is able to walk independently with 6 min walking test, chair rise test and grip strength corresponding to the normal for a young adult. He had to undergo surgery to correct valgus deformities. However, his height is 155 cm (SDS: -2.96).
Both patients are able to study/work and lead an active lifestyle.
Conclusion: asfotase alfa is effective at preventing fragility fractures, further bone deformities and maintaining normal physical activity in transition from childhood to adulthood with better outcomes when started from a younger age.

P1560

TWO YEAR OUTCOMES OF BUROSUMAB TREATMENT VERSUS SURGERY IN TUMOR-INDUCED OSTEOMALACIA

Z. Belaya[1], S. Gronskaia[1], Y. Buklemishev[2], L. Rozhinskaya[1], S. Rodionova[2], I. Uljanova[1], G. Melnichenko[1]

[1]Endocrinology Research Center, Moscow, Russia, [2]National Medical Research Center of Traumatology and Orthopedics named after. N.N. Priorov, Moscow, Russia

This study compares the effectiveness of burosumab treatment and surgical resection in patients with tumor-induced osteomalacia (TIO).

Methods: We evaluated TIO patients (July 2018 - December 2024), who either received burosumab treatment or underwent surgery leading to remission and were followed-up for 24 months. iFGF23 levels were measured using the Biomedica ELISA Kit (BI-20700), with healthy controls -14.8 [3.8; 25.0] pg/mL. Phosphate (0.74-1.52 mmol/L), alkaline phosphatase (40-150 IU/L), parathyroid hormone (15-65 ng/mL) were measured by routine methods. Tubular reabsorption of phosphate (TRP) was calculated via the Scymed website. Pain was assessed on a scale from 0 (no pain) to 10 (extreme pain). Bone Mineral Density (BMD) was assessed by iDXA, GE.

Results: We enrolled 31 patients with TIO: 26 (7 female, 26.9%; mean age 52 ± 8 years, weight 75 ± 18.4 kg) who underwent successful surgery and 7 who received burosumab because surgery was not possible or was not effective (2 female, 28.6%; mean age 47 ± 9 years, weight 81 ± 22.2 kg). Burosumab was started at a dose of 0.5 mg/kg with maximum dose escalation to 2 mg/kg. Biochemical values at baseline were similar between burosumab vs surgery patients: serum phosphorus 0.46 ± 0.1 vs 0.52 ± 0.3 mmol/L, PTH 82 ± 44 vs 87 ± 33 ng/mL, intact FGF-23 789 ± 500 vs 856 ± 257 pg/mL, TRP 57 ± 17 vs 62 ± 14 %, ALP 223 ± 76 vs 254 ± 65 IU/L. At diagnosis, all patients had multiple fractures and a mean height reduction of 18±7cm.

After 24 months, BMD increase at the total hip (TH) of 18 ± 14% and femoral neck (FN) 20 ± 27% in the burosumab group and surgery group TH 21 ± 11% and FN 19 ± 15% . No new fractures were registered in either group. Prior to treatment, pain scores 8 ± 1 in the burosumab group and 7 ± 2 in the surgery group, and post-treatment scores dropped to 2 ± 1 for both groups. In the burosumab group, phosphate normalized (0.9 ± 0.3 mmol/L) in 6 out of 7 subjects, with burosumab mean dose of 1.2 ± 0.6 mg/kg every 4 weeks. In the surgery group, phosphate normalized (1.5 ± 0.2 mmol/L) in all subjects.Burosumab was well tolerated, no side effects were registered. In one case the response was partial most likely due to insufficient dose as this was the largest tumor volume (unresectable 40mm sacral tumor) and the highest FGF-23 (4588.3 pg/mL).

Conclusion: Burosumab is a promising alternative to surgery for inoperable or occult FGF23-producing tumors, effectively normalizing phosphate levels, increasing BMD, preventing fractures, and relieving pain. Initial FGF-23 levels may influence the required burosumab dose for recovery.

P1561

FILLING GAPS IN TELEREHABILITATION: ASSESSING RELIABILITY OF REMOTE PERFORMANCE-BASED OUTCOME ASSESSMENT

Z. Boos[1], K. Mullen[1], M. K. Alshahrani[1], L. Muhammad[2], D. Pinto[1]

[1]Marquette University, Milwaukee, United States, [2]Northwestern University, Evanston, United States

Objective: The purpose of this study was to evaluate the reliability of three widely utilized performance-based outcome measures—the Timed Up and Go (TUG), Four-Meter Walk (4MW), and Five-Repetition Sit-to-Stand (5XSTS)—across two remote assessment modalities: synchronous and asynchronous, with participants serving as their own timers in both scenarios.

Materials and Methods: A total of 58 participants were randomized into six groups, completing assessments in different sequences for in-person, remote synchronous, and remote asynchronous. Participants performed the 4MW and TUG at normal walking speeds, while the 5XSTS was completed as rapidly as possible. In the synchronous and in-person mode, participants timed themselves under real-time supervision by a trained researcher; while in the asynchronous mode, participants timed themselves and relied solely on instructional videos and written guidance. Reliability was assessed using the second trial to mitigate potential biases related to learning effects, with Intraclass Correlation Coefficients (ICCs) serving as the primary metric for cross-mode consistency.

Results: Participants were on average 40 years old (range 19–86), confident using technology (97%), managed a medical condition (40%), and managed at least one active pain complaint (12%). The 4MW exhibited good reliability (ICC = 0.76, $p < 0.001$, 95% CI [0.53, 0.88]), the TUG showed good reliability (ICC = 0.884, $p < 0.001$, 95% CI [0.778, 0.942]), and the 5XSTS demonstrated excellent reliability (ICC = 0.94, $p < 0.001$, 95% CI [0.88, 0.97]). Greater variability was observed among older adults, particularly in comparisons of synchronous and asynchronous modalities.

Conclusions: Telerehabilitation is a viable management approach, but barriers exist to its implementation, including the challenges with physical examinations. These findings indicate that performance-based outcome measures can be reliably self-administered with or without real-time assistance from trained staff. This supports the potential for broader implementation of remote self-assessments in clinical and community-based settings. However, further research is warranted to better understand sources of variability, particularly in older adult populations, and to optimize these tools for widespread application.

P1562

NOMOGRAM FOR PREDICTING CEMENTED VERTEBRAL REFRACTURE AFTER PERCUTANEOUS KYPHOPLASTY IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES

W. Yonghao[1], Z. Chenfei[1], W. Kaifeng[1]

[1]Department of spinal surgery, Peking University People's Hospital, Beijing, China

Background: Cemented vertebral refractures (CVFs) are a common complication following percutaneous kyphoplasty (PKP) in patients with osteoporotic vertebral compression fractures (OVCFs). This study aims to develop a nomogram model for predicting CVFs in postmenopausal women, providing guidance for clinical practice to reduce the incidence of such occurrences.
Methods: The hospitalization records and outpatient follow-up data of 406 patients with OVCFs who underwent unilateral single-segment PKP at Department of Spine Surgery, Peking University People's Hospital, from May 2016 to July 2022, were collected. We utilized univariate analysis and binary logistic regression to identify the risk factors associated with CVF, select relevant variables, and develop a nomogram model. The predictive performance of the nomogram was evaluated using the Receiver Operating Characteristic (ROC) curves, calibration curves, Decision Curve Analysis (DCA), Clinical Impact Curves (CIC) and internal validation through bootstrap with 1000 resamples.
Results: 127 patients were involved, with the CVFs incidence rate of 13.39% (17/127). low CT value, preoperative IVC, high restoration of vertebral height, low postoperative Cobb angle, high restoration of Cobb angle, low bone-cement distribution score and absence of postoperative anti-osteoporosis treatment ($p < 0.05$) were possible risk factors of CVFs after PKP in postmenopausal women. The high restoration of the Cobb angle ($p< 0.001$, OR 1.088, 95%CI 1.043~1.134) and postoperative anti-osteoporosis treatment (p 0.017, OR 0.039, 95% CI 0.003~0.565) are closely related to CVFs. The ROC curves indicate that the Nomogram exhibits a high level of accuracy, with the AUC for both the nomogram and the bootstrap-validated nomogram being 0.966 and 0.753, respectively. The calibration curves, DCA, and CIC demonstrated that the nomogram exhibits favorable predictive capabilities and clinical utility.
Conclusion: The high restoration of Cobb angle and absence of anti-osteoporosis treatment in postmenopausal women with OVCFs increase the risk of CVFs after PKP. The nomogram model developed in this study serves as an effective instrument for predicting CVFs in postmenopausal women.

P1563

ESTABLISHMENT AND VALIDATION OF A NOMOGRAM TO PREDICT INTRADISCAL CEMENT LEAKAGE AFTER PERCUTANEOUS KYPHOPLASTY

W. Yonghao[1], Z. Chenfei[1], W. Kaifeng[1]

[1]Department of spinal surgery, Peking University People's Hospital, Beijing, China

Background: Bone cement leakage is reported to be the most frequent following vertebroplasty. Among these, intradiscal cement leakage is closely associated with disc degeneration and adjacent vertebral body refractures. Therefore, investigating the risk factors associated with intradiscal cement leakage after percutaneous kyphoplasty (PKP) in osteoporotic vertebral compression fractures (OVCFs) and constructing a nomogram prediction model is crucial for assisting spinal surgeons in clinical practice to prevent such occurrences.
Methods: A total of 452 patients with single-segment OVCFs who underwent single-entry PKP at Department of Spinal Surgery, Peking University People's Hospital, from July 2016 to July 2022 were included for inpatient and outpatient follow-up data collection. We utilized univariate analysis and binary logistic regression to identify the risk factors associated with intradiscal cement leakage and developed a nomogram model. The predictive performance of the nomogram was evaluated using the Receiver Operating Characteristic (ROC) curves, calibration curves, Decision Curve Analysis (DCA), Clinical Impact Curves (CIC) and internal validation through bootstrap with 1000 resamples.
Results: 138 patients were included in this study, among which 15 patients suffered from intradiscal cement leakage. The endplate defects ($p<0.001$), low vertebral anterior edge height recovery rate ($p<0.001$), low distance from bone cement to endplate(p 0.020) and contact between bone cement and endplates (p 0.004) are possible risk factors for intradiscal cement leakage following PKP. The endplate defects ($p<0.001$, OR 25.427) and low vertebral anterior edge height recovery rate (p 0.023, OR 0.841) are independent risk factors for intradiscal cement leakage. The ROC curves indicate that the Nomogram exhibits a high level of accuracy, with the AUC for both the nomogram and the bootstrap-validated nomogram being 0.896 and 0.721, respectively. The calibration curves, DCA, and CIC demonstrated that the nomogram exhibits favorable predictive capabilities and clinical utility.
Conclusion: The nomogram model developed in this study serves as an effective instrument for predicting intradiscal cement leakage in OVCFs.

P1564

MOLECULAR AND CLINICAL CHARACTERISTICS OF OSTEOGENESIS IMPERFECTA TYPE VI ASSOCIATED WITH VARIANTS IN THE SERPINF1 GENE

E. S. Merkuryeva[1], T. V. Markova[1], T. S. Nagornova[2], V. M. Kenis[3], Z. E. Belaya[4], S. Deviataikina[2]

[1]Research Centre for Medical Genetics/Research and Counseling Department, Moscow, Russia, [2]Research Centre for Medical Genetics, Moscow, Russia, [3]H. Turner National Medical Research Center for Children's Orthopedics and Trauma Surgery, Saint Petersburg, Russia, [4]Endocrinology Research Centre, Moscow, Russia

Background/Objectives: *SERPINF1* gene encodes pigment epithelium-derived factor, which inhibits osteoclastogenesis by regulating osteoprotegerin expression and blocking RANKL-mediated proliferation and differentiation of osteoclast precursors. Homozygous and compound heterozygous mutations in the *SERPINF1* gene lead to the rare Osteogenesis Imperfecta (OI) Type VI. This study aims to investigate the molecular and clinical-radiological features of four patients with OI Type VI caused by pathogenic *SERPINF1* gene variants.

Methods: Data from four OI patients with clinical-radiological symptoms were examined using various methods, including genealogical analysis, clinical examination, radiography, whole exome sequencing, and Sanger sequencing, RT-PCR analysis of fibroblast skin total RNA for diagnosis refinement. Additionally, 801 newborn dried blood spots were evaluated to estimate the frequency of the mutation (c.261_265dup (p.Leu89fs)) in the general population.

Results: In three patients from two unrelated families with severe OI, whole exome sequencing revealed a homozygous variant c.261_265dup (p.Leu89fs) in the *SERPINF1* gene. Given their Tuvinian origin, it was hypothesized that this pathogenic variant might be prevalent in the Tuvan population. Screening of newborns confirmed this hypothesis, showing a carrier frequency of 0.00876 (95% CI: 0.0044872-0.0130328) or 1:114 (95% CI: 1:222-1:77). The fourth patient had previously undescribed variants c.185G>T (p.Gly62Val) and c.992-993insCA (p.Glu33Asnfs) in a compound heterozygous state. To evaluate the impact of the c.992_993insCA variant on protein function, total RNA from the patient's skin fibroblasts underwent RT-PCR analysis and deep sequencing of PCR products. The analysis showed that the c.992_993insCA insertion leads to an 86-amino acid truncation of the protein (p.Glu331Asnfs Ter3), associated with a severe disease progression.

Conclusion: This study elucidates Osteogenesis Imperfecta (OI) Type VI's genetic underpinnings, emphasizing *SERPINF1* gene mutations' impact. Found in Tuvinians, variant c.261_265dup (p.Leu89fs) heavily influences disease prevalence. Unveiling novel *SERPINF1* variants enhances our comprehension of the mutational spectrum, providing valuable insights for future genotype-phenotype correlation studies in Osteogenesis Imperfecta.

P1565

CLINICAL AND GENETIC CHARACTERISTICS OF PATIENTS WITH MONOGENIC FORMS OF OSTEOPOROSIS

E. S. Merkuryeva[1], T. V. Markova[1], V. M. Kenis[2], Z. E. Belaya[3]

[1]Research Centre for Medical Genetics, Moscow, Russia, [2]H. Turner National Medical Research Center for Children's Orthopedics and Trauma Surgery, Saint Petersburg, Russia, [3]Endocrinology Research Centre, Moscow, Russia

Osteoporosis and low-trauma fractures occurring in childhood without an apparent cause are indicative of the need to search for an inherited skeletal disease. This study examines the molecular and clinical-radiological features of patients with early-onset osteoporosis and spontaneous fractures due to pathogenic variants in *SGMS2*, *FKBP10, PLOD2*, and *GORAB* genes.

Data from 27 patients were analyzed using genealogical, clinical, neurological examinations, radiography, and dual-energy X-ray absorptiometry, complemented by next-generation sequencing (gene panel, whole exome, whole genome).

A heterozygous recurrent *SGMS2* variant: c.148C>T (p.Arg50Ter) was found in 11 individuals from three unrelated families with Calvarial doughnut lesions (CDL) and bone fragility. CT scans detected sclerotic skull lesions in 10 patients, and some experienced recurrent facial nerve paralysis. These findings reveal significant inter- and intrafamilial phenotypic variability.

Bruck syndrome (BS) - 1 and SB-2 were confirmed in 10 and 3 patients, respectively. Eleven nucleotide variants in *FKBP10* and *PLOD2* were identified, with six being novel. The existence of inter- and intrafamilial polymorphism in the severity and course of clinical manifestations among patients.

3 patients with Osteodysplastic gerodermia had new *GORAB* gene variants in a compound heterozygous state: c.170C>G (p.Ser57Ter) and c.790G>C (p.Ala264Pro); c.295C>T (p.Gln99Ter) plus a heterozygous deletion on chromosome 1 affecting the 1st and 2nd exons; c.15G>C (p.Trp5Cys) and a similar deletion. The primary clinical manifestations of the syndrome were wrinkled skin, sagging cheeks, muscle hypotonia, and joint hypermobility. Radiological signs included congenital bilateral hip dislocation, compressive vertebral body fractures. Disruption of the continuity of the epiphyseal growth plate of the distal femur and proximal tibia in the form of an "insertion" was diagnosed in 2 patients.

Genetic factors are a significant cause of recurrent low-trauma fractures occurring in childhood, necessitating the search for such factors in all patients with early-onset osteoporosis.

P1566

IMPROVING INPATIENT MANAGEMENT OF HIP FRACTURES IN OLDER ADULTS: IMPLEMENTATION OF ORTHOGERIATRIC CARE IN TÜRKIYE

Z. Fetullahoglu[1], D. Seyithanoglu[1], N. M. Catikkas[2], B. Ozulu Turkmen[3], G. Bahat[1]

[1]Istanbul University Faculty of Medicine, Department of Geriatric Medicine/Istanbul Musculoskeletal Health Consortium, Istanbul, Turkiye, [2]Sancaktepe Prof. Dr. Ilhan Varank Training and Research Hospital, Istanbul, Turkiye, [3]Sisli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkiye

Background/Objectives: Hip fractures in older adults pose significant challenges due to their high morbidity, mortality, and association with frailty and multi-morbidity. Orthogeriatric care integrates geriatrics and orthopedics to optimize outcomes by addressing these complexities through a multidisciplinary approach. This study evaluates the implementation of an orthogeriatric care model and identifies key areas for intervention to improve outcomes in Türkiye.
Methods: An orthogeriatric care model was established in 2018 through a comprehensive review of evidence-based practices, consultation with international experts, and adaptation of protocols to local healthcare resources. Standardized assessments were applied to the hip fracture patients, emphasizing early intervention, prevention of complications, and tailored follow-up care. Data on demographics and clinical characteristics were collected and analyzed for patients managed under this model through June 2024.
Results: The cohort included 156 patients with a mean age of 81.5 ± 7.9 years; 67.1% were female. Patients had an average of 3 chronic diseases and used 5 regular medications. Frailty (79.7%) and malnutrition (50.5%) were highly prevalent. Polypharmacy (≥4 medications) was observed in 54.5%. Only 16.0% had received osteoporosis treatment prior to their current hip fracture. Previous fragility fractures were reported in 22.4%, and of those, only 21.7% had received osteoporosis treatment. Recommendations were made to align with orthogeriatric care principles and improve inpatient outcomes.
Conclusion: The orthogeriatric care model in our clinic has worked to address addresses the unique challenges of managing hip fractures in older adults. Findings highlight critical areas for intervention, emphasizing enhanced interdisciplinary collaboration and proactive management of geriatric syndromes to improve short- and long-term outcomes.

P1567

TURKISH-SPECIFIC MID-UPPER ARM CIRCUMFERENCE THRESHOLDS: INSIGHTS FROM A YOUNG ADULT REFERENCE POPULATION

T. Erdogan[1], Z. Fetullahoglu[1], C. Kilic[1], S. Ozkok[1], M. Karan[1], G. Bahat Ozturk[1]

[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Geriatrics, Istanbul, Turkiye

Background: Mid-upper arm circumference (MUAC) is a widely recognized anthropometric tool, appreciated for its practicality, cost-effectiveness, and diagnostic accuracy in assessing nutritional deficiencies, muscle mass and body composition. In this study, we aimed to establish sex-specific MUAC cut-off values for the Turkish population to define optimal thresholds.
Material and methods: We included healthy young participants aged between 18 and 39 years and without chronic diseases or chronic drug use. MUAC was measured at the midpoint between the tip of the elbow (olecranon process) and the tip of the scapula (acromion process). MUAC cut-off points were calculated as two SDs below in each sex.
Results: There were 301 participants (187 male, 114 female; mean age: 26.5±4.6 years). Mean MUAC was 29.14±2.76 cm and 24.23±2.27 cm in males and females, respectively. The rounded cut-off values were calculated as 24 cm for males and 19 cm for females.
Conclusion: Our study reported MUAC cut offs derived from the Turkish reference group which can be used as a tool for the mussle mass assessment and nutrition status. However , these cut-off values need to be validated with further studies to prove their adequacy.
Keywords: mid upper arm circumference, cut-off, reference, thresholds

P1568

THE IMPACT OF OCCUPATIONAL ACTIVITY ON LUMBAR DISC DEGENERATION

Z. Gassara[1], R. Drira[2], Y. Hentati[2], H. Fourati[1], S. Baklouti[1]

[1]Rheumatology Department, Hedi Chaker Hospital, Sfax, Tunisia, Sfax, Tunisia, [2]Radiology Department, Hedi Chaker Hospital, Sfax, Tunisia, Sfax, Tunisia

Introduction : Low back pain is a significant socio-professional health problem, responsible for 30 % of prolonged work absences in Europe **(1)**. Moreover, occupational activity plays a considerable role in the onset and progression of disc degeneration through mechanical overload associated with work, poor postures, inappropriate ergonomics, and microtrauma.
Objective : The aim of our study was to assess the relationship between occupational activity and the severity of disc degeneration on MRI in patients suffering from chronic low back pain.
Patients and Methods : We conducted a cross-sectional and analytical study over an 17-month period (December 2022-April

2024), including patients with low back pain lasting more than 3 months with degenerative disc disease on MRI. Sociodemographic, clinical, and radiological data were collected. The Oswestry Disability Index was used to assess functional impairment. The Pfirrmann classification was performed to categorize the severity of disc degeneration into three levels: mild (grades 1 and 2), moderate (grade 3), and severe (grades 4 and 5). A p-value < 0.05 was considered statistically significant.

Results : A total of 150 patients were included, with a median age of 48 years [24-71] and a sex ratio of 0.39 (48 males / 102 females). The mean pain Visual Analog Scale (VAS) score was 6 ± 1. The majority of patients had a middle socio-economic level (70.6%) and had attained either a university (52.7%) or secondary (37.3%) level of education. Workers represented 49.3% of the cases, while non-workers represented 42%, and retirees made up 8.7% of the cases. Among workers, 73% performed sedentary work, while 27% had manual labor jobs. Prolonged sitting posture was observed in 74% of cases, and prolonged standing posture in 36.4% of cases. Job dissatisfaction and/or stress was reported by 82% of workers. According to the Pfirrmann scale, being a worker was significantly correlated with the level of disc degeneration on MRI: the prevalence of severe degeneration (Pfirrmann > 3) was significantly higher among workers compared to non-workers (57.4% vs 42.6%, p = 0.02). The Oswestry Disability Index score was also significantly higher in workers (p < 0.01).

Discussion : In our study, occupational activity was significantly associated with the severity of disc degeneration on MRI and the degree of functional disability. In the literature, manual work requiring physical effort and the lifting of heavy loads, generating repeated microtrauma, has been identified as a factor contributing to the acceleration of degenerative damage to the lumbar spine **(2)**. However, studies have also shown that sedentary work is an important occupational factor implicated in the onset and aggravation of common low back pain **(3)**. In our series, patients with sedentary jobs represented the predominant category.

Conclusion : Our study demonstrated the significant impact of occupational activity on the progression and aggravation of lumbar disc degeneration. Professional assessment and patient education in the workplace should be part of the management strategy of these patients.

METABOLIC SYNDROME IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES

Z. Gassara[1], C. Abid[1], A. Feki[1], S. Ben Jemaa[1], M. H. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker Hospital, Sfax, Tunisia, Sfax, Tunisia

Background : Rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) can promote the development of metabolic syndrome **(MetS)**, mainly through systemic inflammation, but also through commonly used drugs such as corticosteroids and non-steroidal anti-inflammatory drugs. **MetS** is defined by the presence of at least three of the following five criteria: abdominal obesity, hypertriglyceridaemia (≥ 1.7 mmol/L), low HDL cholesterol (< 1 mmol/L in men and < 1.3 mmol/L in women), arterial hypertension (≥ 130/85) and hyperglycaemia (> 5.6 mmol/L). It represents a major risk factor for cardiovascular events.

Objective : To assess the prevalence of **MetS** in inflammatory rheumatic diseases and to determine the factors associated with its occurrence.

Patients and Methods : We conducted a descriptive and analytical cross-sectional study including patients with chronic inflammatory rheumatic disease (RA, AS or PsA). Demographic data and clinico-biological characteristics of the disease were collected. RA activity was assessed by the DAS28 score. AS and PsA activity was assessed by the ASDAS score. All patients had measurements of weight, height, waist circumference, diastolic and systolic blood pressure, fasting blood glucose, cholesterol (total, HDL-C) and triglycerides.

Results : We included 150 patients in the study (105 RA, 45 AS, 40 PsA) with a mean age of 49.5 ± 9.7 years and a sex-ratio M/F of 0.62. The mean duration of disease was 22 months [3 months, 60 months]. RA was destructive and erosive in 71.4% and seropositive in 61.7% of cases. For AS, it was a strictly axial form in 63.6% and a mixed (axial and peripheral) form in 36.4% of cases. For PsA, the form was strictly peripheral in 57.5% and mixed (axial and peripheral) in 42.5% of cases. Coxitis was noted in 26.7% of cases. A biological inflammatory syndrome was noted in 62% of cases, with mean values for ESR (erythrocyte sedimentation rate) and CRP (C-reactive protein) of 51.5 ± 10.25 mm and 19.75 ± 7.25 mg/L, respectively. The mean DAS28 value in RA patients was 3.25 ± 1.55 with active disease in 78.7% of cases. The mean ASDAS value for AS and PsA patients was 3.11 ± 1.14, with active disease in 79.15% of cases. The mean BMI (body mass index) was 28.76 ± 6.8 kg/m2. The prevalence of **MetS** elements was as follows : abdominal obesity (35.3%, n=53), hyperglycemia (30.6%, n=46), hypertriglyceridemia (24%, n=36), low HDL-cholesterol (18.7%, n=28), arterial hypertension (38.6%, n=150). **MetS** (at least 3 out of 5 criteria) was reported in 32% (n=48). Smoking was reported in 23.3% (n=35) and alcohol in 13.3% (n=18). Hyperuricemia was noted in 24% (n=36). Liver ultrasound was performed in 32% of patients (n=48), and hepatic steatosis was found in 18.7% (n=9). A history of cardiovascular disease (myocardial infarction, embolic stroke etc.) was reported in 18% (n=27). The presence of

MetS was significantly associated with advanced age (p=0.04) and a longer duration of disease (p=0.42). No significant correlation was found with indices of disease activity or with levels of biological markers of inflammation.
Conclusion : Our study shows the high prevalence of **MetS**, hyperuricemia and cardiovascular risk in patients with inflammatory rheumatic diseases. Although previous studies have shown that **MetS** is mainly related to the systemic inflammation generated by these pathologies, our work has not documented a significant link between **MetS** and activity indices or with biological markers of inflammation.

P1570

ASSESSMENT OF EFFECTS OF HORMONAL AND BIOCHEMICAL CHANGES ON ONE YEAR BMD CHANGES IN THALASSEMIA MAJOR PATIENTS

Z. Hamidi[1], F. Mohseni[2], A. S. Alemzadeh[1], F. Abbaszadeh Marzbali[1], M. R. Mohajeri Tehrani[2], B. Larijani[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objectives:
Low bone density is a known problem in thalassemia major patients. Disorders of thyroid, liver, glucose and ca metabolism that are also common in these patients, affect bone density changes. In this project we measured correlation between changes of these parameters in one year interval.
Material and methods:
In this study, 20 patients with thalassemia major were enrolled in the project. Bone density measurements were performed in the spine and femur twice, a year apart, using a densitometer device (Norland, XR-46). The results of TSH, fasting blood sugar, calcium, phosphorus, SGOT, SGPT tests at the times around these measurements were collected. The mean age of the participants was 17.3 ± 5 years (8-25 years). The ratio of male to female participants was 6/14. Bivariate correlation analysis was used to find correlation between changes in bone density and changes in laboratory variables. The correlation coefficient was used to examine the correlation between variables with normal distribution was Pearson and Spearman coefficient was used to examine correlation between variables that did not have a normal distribution. The variables were examined for normal distribution by Kolmogorov-Smirnova test.
Results:
Mean of changes of BMD in spine and femur was 0.0341 ± 0.056 and 0.005 ± 0.070, respectively. We found mean of changes of TSH, calcium, phosphorus, fasting blood sugar, SGOT, SGOT as -0.36 ± 1.50, -0.23 ± 1.37, 5.84 ± 14.60, -3.94 ± 10.63, -2.10 ± 13.09, respectively. No correlation observed between BMD changes and changes of laboratory results.
Conclusion:
It seems one year is not enough time to see the effects of hormonal, metabolic and hepatic parameters such as TSH, calcium, phosphorus, FBS, SGOT, SGOT changes on bone mineral density alterations.

QUANTITATIVE EVALUATION OF MAGNETIC RESONANCE IMAGING IN THE EARLY DETECTION OF OSTEOPOROSIS

Ľ. Mikulová[1], Z. Lörinczová[2], D. Gičová[3], T. Špakovská[4], S. Kalafutová[5], N. Vaňová[6], M. Mydlárová Blaščáková[7]

[1]Dept. of Medical and Technical Disciplines in Health Care, Faculty of Health Care, University of Prešov in Prešov, Prešov, Slovakia, [2]Department of Internal Medicine, Safarik University and Agel Hospital Košice-Šaca, Košice-Šaca, Slovakia, [3]Dept. of Radiology, Faculty Hospital Trnava, Trnava, Slovakia, [4]Dept. of Radiology, Safarik University ang Agel Hospital Košice-Šaca, Košice-Šaca, Slovakia, [5]Dept. of Medical and Technical Disciplines in Health Care, Faculty of Health Care, University of Prešov, Prešov, Slovakia, [6]Department od Internal Medicine, Safarik University and Agel Hospital Košice-Šaca, Košice-Šaca, Slovakia, [7]Dept. of Biology, Faculty of Humanities and Natural Sciences, University of Prešov in Prešov, Prešov, Slovakia

Objectives: Osteoporosis is an asymptomatic disease, therefore, many patients, despite the need for body mass density (BMD) testing, do not undergo timely dual-energy X-ray absorptiometry (DEXA), examination and remain undiagnosed, while they may undergo magnetic resonance imaging (MRI) due to lumbar spine pain and osteoporosis-related complications. In addition to parameters from DEXA, we aimed to assess the use of quantitative M-score from MRI for early detection of osteoporosis and preliminary investigate the correlation between signal-to-noise ratio (SNR) and M-score from MRI versus TBS from DEXA.
Material and Methods: Five newly diagnosed osteoporotic women underwent densitometry examination using the *Hologic Discovery A (S/N 84182)* device to determine BMD, T-score and trabecular bone score (TBS) in the lumbar spine and subsequently MRI examination of the lumbar spine using a *Hitachi Oasis 1.2T MRI Scanner* to obtain SNR values from T1-weighted images for calculating a quantitative M-score. The reference group consisted of five young non-osteoporotic women.
Results: Spearman's Rho correlation calculator was preferred for evaluating correlations. Both SNR and M-score were negatively correlated with BMD [r = -0.300, p = 0.68] and with T-score [r = -0.36, p = 0.55]. A positive correlation was found between SNR/M-score versus TBS [r = 0.82, p = 0.089]. This only approached statistical significance, probably due to the fewer probands.
Conclusion: High-resolution MRI allows doctors to assess the quality of trabecular bone, providing insight into the disease's se-

verity. The study's interaction of imaging methods suggests that MRI could become a non-invasive opportunistic screening technique in the diagnosis and early treatment of osteoporosis.

OFF-TARGET EFFECTS OF TYROSINE-KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Z. S. Szili-Janicsek[1], I. Istenes[1], J. Demeter[1], B. Szili[1]

[1]Semmelweis University - Department of Internal Medicine and Oncology, Budapest, Hungary

Introduction: Thanks to modern tyrosine kinase inhibitors (TKIs), the survival rate of patients with chronic myeloid leukemia (CML) does not differ from the general population. Several off-target effects of these drugs, unrelated to their indications, have been described. Objective: We aimed to investigate the changes in bone metabolism, metabolic parameters, and body composition over the course of one year in CML patients undergoing TKI treatment. **Methods:** We investigated patients who were treated at our tertiary referral center for hematology in the Department of Internal Medicine and Oncology, Semmelweis University. In addition to collecting medical and treatment history, laboratory tests (metabolic parameters, calcium and bone metabolism parameters, hormone levels) were performed at baseline, and after 6 and 12 months. Osteodensitometry and total body composition measurements (GE Lunar Prodigy) were performed at the start of the study and one year later. **Results:** Data from 53 patients were analyzed (34 men, 19 women), with a mean age of 53±16 years. Almost half of the patients were on imatinib (49%), 19% on dasatinib, 17% on nilotinib, and 14% were receiving other treatments. At enrollment, 3/53 patients had osteoporosis, and 4/53 had osteopenia. During the one-year follow-up period, there was no significant change in spinal bone mineral density (BMD) (1.281±0.221 vs. 1.271±0.250 g/cm^2; p>0.1). However, femoral neck BMD decreased by 4.5% (1.044±0.133 vs. 0.997±0.172 g/cm^2; p=0.010), and total hip BMD decreased by 3.2% (1.095±0.143 vs. 1.060±0.143 g/cm^2; p=0.019). At the time of the baseline visit, the patients were obese (BMI: 30.9±7 kg/m^2), and this did not change significantly during the observation period. The average vitamin-D level of the patients at screening was close to the adequate range (29.6±12.3 ng/dl), although 47% had vitamin D deficiency, which was corrected in all cases. The albumin-corrected serum calcium level was 2.26±0.08 mmol/l, with mild hypocalcemia frequently observed. There were no manifest disturbances in carbohydrate metabolism, although atherogenic dyslipidemia was common. **Discussion:** In CML patients treated with tyrosine kinase inhibitors, the off-target effects of the drugs must also be monitored. During the observation period, there was no change in BMD at the spine, but decreases were observed at the total hip and femoral neck. Further follow-up of the patients is planned, and comparisons will be made to determine which effects may be attributed to the TKIs.

P1573

WEARABLE-BASED ACCELEROMETRY FEATURES AS A POTENTIAL DIGITAL BIOMARKER FOR IDENTIFYING FIBROMYALGIA PATIENTS THROUGH GAIT ASSESSMENT IN DUAL-TASK CONDITIONS

Z. Veličković[1], N. Trajković[2], M. Novičić[2], N. Šuljagić[2], M. Janković[2], G. Radunović[3]

[1]Institute of Rheumatology, Belgrade, Serbia, [2]School of Electrical Engineering, University of Belgrade, Belgrade, Serbia, [3]Institute of Rheumatology, School of Medicine, University of Belgrade, Belgrade, Serbia

Objective: To find the potential digital biomarker through accelerometry-based assessment of dinamic balance and gait in dual-task settings in FM patients.
Material and Methods: The 27 non-treated primary fibromyalgia (FM) patients (3 M, 24 F, 46,8±8.75 y) and 27 healthy age and gender matched subjects (HC) were recruited for this cross-sectional study. All participants were wearing 4 tri-axial accelerometers (X, Y, and Z axis): one over the L4-L5 junction (spine), over the right anterior superior iliac spine (hip) and both ankles. Patients' dinamic balance characteristics were assessed using a gait analysis accross four conditions (basic gait, with motor task, with mental task, with both). Raw data was sent through the Wi-Fi connection from accelerometers to the tablet and then to the central server for further analysis. After signal processing, time –, frequency – and step – domain features (Figure 1.) were analyzed and used for discrimination between FM and HC subjects. **Results:** Thirty different features are significant in distinguishing fibromyalgia (FM) from healthy controls (HC). Among these, most frequent were time-domain features: minRES (significant for all four sensors in three conditions), stdRES (four sensors and three conditions) and stdY (four sensors and four conditions), stdX and minmaxY (two sensors in two and three conditions). The other were frequency-domain feature hr3Z (significant for three sensors in three conditions) and stepdomain feature mean_amplitude (two sensors in three conditions). In terms of sensor placement, the key features were primarily captured by ankle and hip sensors. Dual-task conditions showed that the gait combined with either a mental or motor task (but not both) provided the most valuable information, while basic gait alone was less informative. **Conclusion:** The results indicate that the selected features could serve as potential digital biomarkers for identifying fibromyalgia patients during gait analysis. It appears that sensors placed on the feet and hip are more effective for data collection, with a clear advantage to using time-domain features. Regarding dual-task conditions, the findings showed that the optimal condition for analysis is adding a mental or motor task while walking to reveal any balance impairments. By combining foot-mounted sensors, the selected features, and dual-task conditions, this methodology could provide a fast and cost-effective way to assess the motor abilities of FM patients, potentially influencing diagnostic and therapeutic decisions while reducing the frequency of falls.

Figures:

Time – Domain Features	Calculation
SMA (signal mangitude area)	$SMA = \frac{1}{N}\sum_{i=1}^{N}(\lvert X_i\rvert + \lvert Y_i\rvert + \lvert Z_i\rvert)$
meanRES (mean value of resultant acceleration)	$meanRES = \frac{1}{N}\sum_{i=1}^{N}\sqrt{X_i^2 + Y_i^2 + Z_i^2}$
stdRES (standard deviation of resultant acceleration):	$stdRES = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}\left(\sqrt{X_i^2 + Y_i^2 + Z_i^2} - meanRES\right)^2}$
minmaxRES (difference between max and min of resultant acceleration):	$minmaxRES = \max(\sqrt{X_i^2 + Y_i^2 + Z_i^2}) - \min(\sqrt{X_i^2 + Y_i^2 + Z_i^2})$
stdX, stdY, stdZ (standard deviation in the X, Y and Z axis)	$stdX = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(X_i - \overline{X})^2}$ analogues for Y and Z
minmaxX, minmaxY, minmaxZ (difference between max and min in the X, Y and Z axis	$minmaxX = \max(X_i) - \min(X_i)$ analogues for Y and Z
Frequency – Domain Features	**Calculation**
harmonicsratioX, harmonicsratioY, harmonicsratioZ, harmonicsratioRES (ratio between first 4 harmonics and total spectrum in X, Y, and Z axis and resultant acceleration)	$harmonicsratioX = \frac{\sum_{k=1}^{4}\lvert H_k\rvert}{\sum_{k=1}^{N}\lvert H_k\rvert}$ analogues for Y , Z and RES
hr1X, hr2X, hr3X, hr4X; hr1Y, hr2Y, hr3Y, hr4Y; hr1Z, hr2Z, hr3Z, hr4Z; hr1RES, hr2RES, hr3RES, hr4RES (part of each harmonics (from 1 to 4) in total spectrum and resultant acceleration)	$hr1X = \frac{\lvert H_1\rvert}{\sum_{k=1}^{N}\lvert H_k\rvert}$ analogues for other harmonics and axis
Step – Domain Features	**Calculation**
mean_step_time (mean step time)	$mean\_step\_time = \frac{1}{N-1}\sum_{i=1}^{N-1}(t_{i+1} - t_i)$
std_step_time (standard deviation of step time)	$std\_step\_time = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N-1}((t_{i+1} - t_i) - mean\_step\_time)^2}$
asymmetry1 (assymetry of step time):	$asymmetry1 = \frac{\sum_{i=1}^{N-1}\lvert(t_{i+1} - t_i) - (t_i - t_{i-1})\rvert}{N-1}$
mean_amplitude (mean amplitude of step)	$mean\_amplitude = \frac{1}{N}\sum_{i=1}^{N}(A_{max} - A_{min})$
std_amplitudes (standard deviation of step amplitudes	$std\_amplitudes = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}((A_{max} - A_{min}) - mean\_amplitude)^2}$
asymmetry2 (assymetry of step amplitude):	$asymmetry2 = \frac{\sum_{i=1}^{N-1}\lvert(A_{max_{i+1}} - A_{min_{i+1}}) - (A_{max_i} - A_{min_i})\rvert}{N-1}$

SURGICAL CORRECTION OF THE LIMB LENGTH DISCREPANCY AND SOME CLINICAL AND DUPLEX ANGIOSCANNING DEPENDENCIES IN CONGENITAL VASCULAR MALFORMATIONS

Z. Zyma[1], C. Chernuha[1], V. Vyderko[1], C. Cheverda[1], F. Filipchuk[1], K.-P. Kincha-Policschuk[1], S. Skuratov[1], S. Stewart[2], H. Herzenberg[3], D. Demyan[1], P. Mcclure[3]

[1]1 Institute of Traumatology and Orthopedics,, Kiev, Ukraine, [2]4 Children's Bone And Spine Surgery, Las Vegas, United States, Las Vegas, United States, [3]International Center for Limb Lengthening, Baltimore, United States, Baltimore, United States

Summary: Congenital vascular malformations (CVM) are the cause of the limb length discrepancy (LLD) and geodynamic disorders in children, which requires correction Methods. We observed 10 children with CVM who undergo surgical treatment: 6 patients with arteriovenous (AVM); 2 – with venosum form (VM); 2 - with kapilar fom (KM). The average age of patients was 9.8±2.5 years. Lengthening of the affected limb was noted in 8 patients; in 2 patients - shortening. Performed: long standing X-rays of the lower legs to assess LLD; color duplex angioscanning (CDA) of arteries lower extremities and to establish their influence on the formation LLD in pediatric patients with CVM. indication for surgical treatment was LLD over 2 cm. In 8 patients with lengthening of the affected limb, epiphisiodesis of the distal femur and proximal tibia was performed: in 7 - with eight plates; one has screws. Results. The existence of a statistically significant relationship between the increase in the linear velocity of blood circulation of the femur and the LLD of the femur was established - r=0.975; the inverse relationship between the increase in resistance of the femur and the resistance of the posterior tibial artery and the increase in LLD of the tibia, r=-0.898 and r=-0.900 (Spearman's rank correlation coefficient). According to color duplex angioscanning (CDA) results the presence of a conglomerate of vessels in soft tissues with a diameter of more than 2.0 mm; the linear speed of blood flow in vessels over 0.2 m/s was considered a contraindication to surgical treatment. The average total LLD before treatment was 4.4±2.2 cm, after - 1.5±1.3 cm, LLD correction was 2.6±1.7 cm (p=0.011), which indicates a significant reduction of LLD . Changes in LLD of the femur and tibia were also statistically significant. Reduction of LLD for the tibia- 1.5±1.0 cm, p=0.017 (from 2.8±1.6 to 1.3±1.1 cm). The dynamics of the femur LLD - 1.1±0.8 cm, p=0.012 (from 1.3±0.8 to 0.4±0.4 cm). The average rate of recovery was 1.6±0.7 cm per year. Surgical intervention did not cause progression in any case. The duration of treatment and observation was 18+7.9 months. Conclusions. Some reliable correlations were established between hemodynamic disturbance of the affected limb and its elongation; the effectiveness of theepiphisiodesis of the distal femur and proximal tibia to correct LLD in patients with CVM has been proven. The degree of hemodynamic disturbances is the main factor to determining the possibility to perform surgical correction LLD in patients with CVM.

P1575

CONTRIBUTION OF MINERAL-BONE DISORDERS OF CHRONIC KIDNEY DISEASE TO JAW BONE FRAGILITY OF INDIVIDUALS WITH HIGH-EXCHANGE OSTEOPOROSIS ON OUTPATIENT HEMODIALYSIS

Г. Парфенюк[1], А. Лепилин[1]

[1]СГМУ, Саратов, Russia

Parfenyuk [1], G.V. Lepilin [1],

[1]A.V. Department of Stomatology Surgical and Maxillofacial Surgery. Medical University, Saratov, Russia

Objectives: To evaluate the severity of osteoporosis (OP) with high bone metabolism in patients with terminal stage of chronic kidney disease (CKD) on outpatient hemodialysis. Bone strength is known to be determined by bone quantity and quality. The latter encompasses factors affecting the structural and material properties of bone, both of which are mainly dependent on bone tissue renewal. All these components are controlled by remodeling and any modification of one of them leads to bone fragility. In OP, the volume of resorbed bone increases. An imbalance in the volume of resorbed and formed bone jeopardizes bone structure. The most informative biochemical parameters of bone tissue repair monitoring - markers of osteogenesis - were studied.

Materials and Methods: Thirty-five mature women who had already suffered from idiopathic OD at the time of referral to an implantologist for dental implant surgery were examined. The marker of bone formation - ostase in venous blood and the marker of resorption - deoxypyridinoline/creatinine (DP/Cr) in morning urine of patients at the G2 stage of CHD were studied twice with an interval from 3 to 4 weeks for the purpose of laboratory diagnostics of osteoporotic changes. Similar values were obtained in 12 patients with chronic kidney disease-mineral-bone disorders (CKD-MKN) and OP, with minor traumatic fractures at stage G5g of CKD (received outpatient hemodialysis 3 times a week). Low exchange variants of renal osteodystrophy in those on hemodialysis were excluded by high parathyroid hormone and bone alkaline phosphatase values.

Results: The incremental rate of ostase in patients at stage G2 of CKD was virtually indistinguishable from that in patients at stage G 5 of CKD. The rate of DP\Kr increment in stage G5 CKD, was not significantly higher than in stage G2 CKD, (p 0.05). The contribution of mineral-bone abnormalities of CBP to bone fragility in patients with prior renal disease idiopathic OP and diagnosed OP with high metabolism was not significant.

Conclusion: Bone metabolism is one of the determinants of bone quality. A better knowledge of the importance of different factors determining bone quality (intrinsic properties of bone matrix, bone architecture, etc.) will improve the understanding of the pathogenesis of brittle bone in patients with pre-existing renal disease and diagnosed OP.

P1576

BONE TURNOVER IN POSTMENOPAUSAL WOMEN: EVALUATING THE IMPACT OF ESTETROL (E4) FROM A RANDOMIZED PLACEBO-CONTROLLED PHASE 3 TRIAL

J. Douxfils[1], A. Black[2], M. Taziaux[3], U. Gaspard[4], E. Kapoor[5], R. A. Lobo[6], W. H. Utian[7], J.-M. Foidart[4]

[1]University of Namur, Namur, Belgium, [2]University of Ottawa, Ottawa, Canada, [3]Estetra SRL, a wholly owned company of Gedeon Richter PLC, Liège, Belgium, [4]University of Liège, Liège, Belgium, [5]Mayo Clinic, Rochester, Minnesota, United States, [6]Department of Obstetrics and Gynecology, Columbia University, New York City, United States, [7]Case Western Reserve University School of Medicine, Cleveland, United States

Objective

Estetrol (E4) is a naturally occuring estrogen effective in reducing menopausal vasomotor symptoms (VMS) with minimal impact on hemostasis and potential metabolic benefits. Estrogen therapy alleviates moderate to severe VMS and helps counteract menopause-related bone turnover acceleration. A Phase 2 study previously showed E4 15 mg reduces bone turnover biomarkers, suggesting a beneficial effect. This Phase 3 study assesses E4 impact on these markers after 12 and 52 weeks in postmenopausal (PM) women.

Design

E4Comfort II (NCT04090957) was a double-blind, placebo-controlled, multicenter trial conducted at 122 US and Canadian sites to evaluate E4 efficacy and safety for treating moderate-to-severe VMS in PM women aged 40–65. A total of 579 participants received E4 15 mg (n=192), E4 20 mg (n=193), or placebo (n=194) once daily for 52 weeks. Blood samples were collected at baseline, week 12 (W12), and week 52 (W52) for CTX-1, P1NP, calcium, and vitamin D analysis. Mixed Model Repeated Measures was used for statistical comparisons ($p<0.05$ significant).

Results

CTX-1 significantly decreased with E4 vs. placebo at W12 and W52 (all $p<0.0001$). P1NP levels also declined significantly at W12 ($p=0.0220$ for 15 mg; $p<0.0001$ for 20 mg) and W52 (all $p<0.0001$). Calcium decreased significantly vs. placebo at W12 ($p=0.0004$ for 15 mg; $p<0.0001$ for 20 mg) and at W52 for 20 mg ($p<0.0001$). No significant vitamin D changes were observed.

Conclusion

E4 reduces CTX-1 and P1NP, indicating lower bone turnover, suggesting a beneficial role in maintaining bone strength and potentially preventing osteoporosis in postmenopausal women.

EARLY CLINICAL DEVELOPMENT OF COMBINATION DRUG CANDIDATE RJX-01 FOR THE TREATMENT OF SARCOPENIA

J. Aerssens[1], E. Mercken[1], L. Meuleners[1], L. Haazen[1], D. Kanters[1], S. Corveleyn[1], D. Bwirire[1], A. Beliën[1]

[1]Rejuvenate Biomed nv, Diepenbeek, Belgium

Objective

The novel combination drug candidate RJx-01 was shown to exert beneficial synergistic effects on muscle strength and physical performance in preclinical studies. It was proposed to evaluate the potential of RJx-01 in human clinical trials as a therapeutic intervention for sarcopenia.

Material and Methods

A Phase 1 study was conducted in 42 healthy men (65-75 years old) during and after 2 weeks of muscle inactivity (immobilization by leg casting) to assess the tolerability, safety and effect on muscle strength of 6 weeks daily treatment with RJx-01.

Results

In healthy elderly volunteers, 6 weeks of RJx-01 treatment was safe and well tolerated. Compared to placebo-treated subjects (n=21), RJx-01 treatment (n=21) induced faster and better recovery of muscle strength in the leg after 2 weeks of immobilization (isometric analysis). During isokinetic measurements, RJx-01 treatment showed significantly improved muscle function (rate of velocity development) and resistance to muscle fatigue in the casted leg.

We then designed a Phase 2 study to evaluate the safety and effects of longer term (6 months) treatment with RJx-01 on muscle integrity in elderly COPD patients. Unplanned hospitalization for severe acute exacerbation is a major event for COPD patients and the associated disability can lead to significant functional decline. The skeletal muscle dysfunction seen in COPD is part of the spectrum seen in sarcopenia. We hypothesize that RJx-01 treatment may have beneficial effects on functional performance of these patients.

Conclusion

Following a Phase 1 study showing initial evidence of safety and efficacy of RJx-01 in an acute sarcopenia model, a Phase 2 program was initiated. A first study will assess the longer-term response to RJx-01 treatment in COPD patients at risk of developing chronic sarcopenia. Additional Phase 2 studies in other patient populations where sarcopenia has a significant impact on disease burden are being considered.

The UK National Osteoporosis Guideline Group published updated guidance for the Prevention and Treatment of Osteoporosis in 2021. The guideline aims to provide clinically appropriate recommendations by integrating available evidence on clinical efficacy, effectiveness and safety. It is intended for use by all healthcare professionals involved in the prevention and treatment of osteoporosis and fragility fractures, including primary care practitioners, allied health professionals and relevant specialists in secondary care. The guideline is provided in full on the NOGG website (https://www.nogg.org.uk/) which permits audit of online access to the website by users. We aimed to audit website views and users over the period 1st January-31st December 2024.

In 2024, the NOGG website had a total of 936,217 views, a single view being a page on the website being seen by a visitor. Of these views, the majority (625,498, 66.8%) were views arising after calculated FRAX 10-year probabilities, with the user being sent directly from the UK FRAX website to the NOGG Guideline website. Most of these FRAX-based views (62.0%) were calculations conducted without femoral neck BMD input, suggesting FRAX was being used to determine the need for DXA assessment and/or treatment. Of the other pages viewed, the NOGG home page was the most viewed (70,426 times) followed by the Full Guideline page (46,857 views). Views showed a classical 5-day working week pattern, with an average of 3,601 views per working day (Figure-1). Over the year, a total of 781,643 users accessed the website; as expected, most users were based in the UK (685,427, 87.7%), but users were also documented in at least 57 other countries, with the top 3 countries being Ireland (2.3% of users), Brazil (1.7%) and the USA (1.3%).

This audit demonstrates very active use of the NOGG website. The use is largely driven by the direct link between the FRAX UK tool and the NOGG website, a facility that only exists for a small number of countries currently but can easily be set-up for other countries. The NOGG website and guideline has very good international visibility and engagement; it provides a suitable guideline template that other countries could contextually adapt.

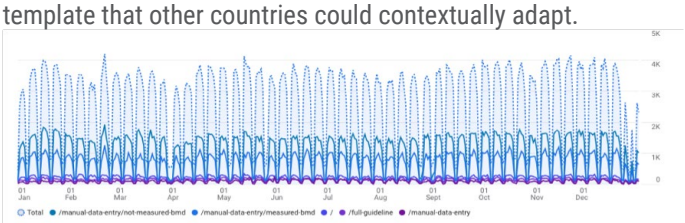

Figure 1 Views by page path and screen class over time. Total views in 2024 = 936,217

GLP-1 RECEPTOR AGONISTS AND RISK OF BONE FRACTURES IN ELDERLY PEOPLE WITH TYPE 2 DIABETES

M. Kasher Meron[1,2], T. Hornik-Lurie[3], G. Twig[4,5,6], P. Rotman-Pikielny[1,2]

[1]Department of Endocrinology, Meir Medical Center, Kfar-Saba, Israel, [2]School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel, [3]Research Department, Meir Medical Center, Kfar Saba, Israel, [4]Division of Endocrinology, Diabetes and Metabolism, Sheba Medical Center, Ramat Gan, Israel, [5]Department of Preventive Medicine, School of Public Health, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv , Israel, [6]The Gertner Institute for Epidemiology and Health Policy Research, Sheba Medical Center, Ramat Gan, Israel

Objective: To assess the risk of fractures associated with glucagon-like peptide 1 receptor agonists (GLP-1 RA) therapy compared to sodium-glucose cotransporter-2 inhibitors (SGLT-2i) or dipeptidyl peptidase-4 inhibitors (DPP-4i) therapy in elderly people with type 2 diabetes.

Methods: This nationwide, population-based, cohort study included individuals with type 2 diabetes, ≥ 65 years, who initiated GLP-1 RA therapy or one of the comparators during January 2018–October 2022. The primary outcome was the first incident of vertebral, hip, pelvic, humerus, forearm or rib fracture. Anthropometric and clinical characteristics of patients, including osteoporosis and risk factors for fractures, were extracted from the electronic database. People were followed until fracture, death, or March 2024. After adjusting for propensity score, hazard ratios (HRs) with 95% confidence interval (CI) were estimated using stepwise Cox models, and the Fine-Gray model for competing risks. Subgroup analyses by age, sex, ethnicity, BMI, and osteoporosis were performed.

Results: Among 45,222 people, 73.0±6.4 years, 50% female, 66.5% were 65-75 years and 31.3% ≥75 years. During a median follow up of 35.3 (interquartile range 24.7-48.0) months, 3,618 (8.0%) had an incident fracture. Among 11,061 new users of GLP-1 RA and 34,161 of the comparator drugs, the overall incidence of fractures was comparable between groups ((2.82 (95%CI 2.63-3.02) vs. 2.75 (95%CI 2.65-2.85)), p=0.53, respectively, per 100 person years. In multivariate analysis for osteoporotic fractures (adjusted for multiple risk factors), initiating GLP-1 RA was associated with a 12% increased risk for bone fractures compared to the control group (HR 1.12, 95%CI 1.03-1.23, p=0.006). Repeating the analysis for competing risks, along with conducting various subgroup and sensitivity analyses, yielded results consistent with those of the main analysis.

Conclusions: Initiation of GLP-1 RA therapy was associated with an increased risk of incident fractures compared to SGLT-2i and DPP-4i, among elderly individuals with type 2 diabetes.

RESTORING BONE STRENGTH: IT TAKES TWO TO DANCE A TANGO

S. Ferrari[1], B. Leder[2], S. Minisola[3]

[1]Division of Bone Diseases, Geneva University Hospital, Geneva, Switzerland, [2]Department of Medicine, Endocrine Unit, Massachusetts General Hospital, Boston, United States, [3]Department of Clinical, Internal, Anaesthesiologic and Cardiovascular Sciences, "Sapienza" University of Rome, Rome, Italy

Restoring optimal bone strength requires a coordinated approach on both components of bone fragility, i.e. stopping the accelerated decay of bone mass and structure and rebuilding new bone—much like a well-executed tango. This symposium, co-chaired by esteemed experts Dr. Serge Ferrari (Geneva University Hospital, Geneva, Switzerland) and Dr. Salvatore Minisola (Sapienza Rome University, Italy), will explore the harmonious interplay between anabolic and anti-resorptive therapies in managing bone fragility. Dr. Serge Ferrari will set the stage by examining the roles of bone modelling and remodelling in both healthy bone and osteoporosis, highlighting their critical contributions to bone health and the mechanisms underlying bone fragility. He will then explore how anti-resorptives and bone-forming agents influence both bone modelling and remodelling, and bone microstructure.

Building on this, Dr. Benjamin Leder (Massachusetts General Hospital, United States) will draw from his extensive hands-on experience, having conducted some of the key studies on sequential and combination therapies. He will demonstrate how these therapeutic approaches translate into clinical benefits, offering a dynamic strategy for optimising patient outcomes. He will assess the comparative efficacy of various anabolic/anti-resorptive combination approaches in treating postmenopausal osteoporosis and highlight the unique properties of specific sequential treatment regimens, detailing their effects on bone mineral density, microarchitecture, and strength.

This session offers a unique opportunity to uncover the dynamic partnership between these therapeutic approaches, providing attendees with valuable insights into advancing osteoporosis care.

This satellite symposium is funded and organised by Gedeon Richter Plc. and is intended for Healthcare Professionals only.

SY2

UCB-SPONSORED SATELLITE SYMPOSIUM

U. C. B. Ucb[1]

[1]UCB, Brussels, Belgium

Romosozumab: Right Patient, Right Time

The introduction of anabolic therapies has represented a shift in osteoporosis care, transforming the potential of early and effective treatment in fracture risk reduction[1,2]

Despite being highly prevalent, osteoporosis remains significantly undertreated, particularly in postmenopausal patients at very high fracture risk (VHFR).[3] Following an initial fracture, these patients may feel robbed of their independence, fearful of another fracture.[3,4] Approximately half of all subsequent fractures occur within 2 years of a major osteoporotic fracture – a universal criterion for VHFR – underscoring the urgent need for rapid bone formation in this population.[2,5]

In this interactive session, leading experts will uncover how, through its ability to build bone rapidly, romosozumab can reduce fracture risk amongst postmenopausal patients at VHFR.[1,5–7] They will also explore how efficient and timely intervention can help to optimise romosozumab's use in clinical practice.[1,2,6]

A Defining Era in Osteoporosis Management

Professor Salvatore Minisola (Sapienza University of Rome, Italy)

Opening the symposium, Professor Salvatore Minisola will reflect on the pioneering advancements within postmenopausal osteoporosis (PMO) care over the past decade, highlighting the established shift in guidelines towards prioritising bone formation in patients at VHFR.[1,2]

Rethinking Bone Building with Romosozumab

Dr Lothar Seefried (University Hospital at the Julius-Maximilians-University Würzburg, Germany)

Dr Lothar Seefried will begin by providing a visual summary of the mechanistic differences among current osteoporosis therapies. Considering outcomes beyond bone density is important when selecting a treatment, as structural weakening and increased porosity of the bone independently contribute to fracture risk, even with improved bone mass.[3,7,8]

Dr Seefried will demonstrate how romosozumab, through its action on sclerostin, rapidly increases bone formation whilst decreasing bone resorption, concluding by describing how this dual-effect mechanism translates into positive effects on bone structure and strength at both the trabecular and cortical level.[1,7]

Optimising Outcomes with Romosozumab First

Professor Kassim Javaid (University of Oxford, UK)

Professor Kassim Javaid will examine the wealth of evidence supporting the use of romosozumab as a valuable and effective treatment option for women with PMO at VHFR.[1,2,6] Utilising key clinical data, Professor Javaid will provide insights into romosozumab's clinical profile, focusing on crucial aspects of efficacy and tolerability.[1,6] He will also explore how first-line use of romosozumab can help to enhance outcomes for patients who have recently suffered a fracture.[2,5,6]

Recognising the Opportunity with Romosozumab

Professor Bente Langdahl (Aarhus University Hospital, Denmark)

Professor Bente Langdahl will lead a case-based presentation focusing on the practical application of romosozumab in clinical practice. She will describe the key characteristics that can help identify patients who may benefit from romosozumab, offering strategies to augment clinical decision-making and deliver optimal care for VHFR patients.[2]

Drawing on real-world insights gathered since romosozumab's launch in 2019, [9] Professor Langdahl will showcase the clinical reality of the outcomes seen following romosozumab treatment, touching on the importance of continued follow-on antiresorptive therapy and discussing how to effectively assess and manage cardiovascular risk.[1]

Looking to a Stronger Future

Following a stimulating Q&A, Professor Minisola will close the symposium by looking ahead to the future, considering the steps to take to ensure that the right patient receives the right care at the right time.

SY3

RISING OA INCIDENCE: EARLY INTERVENTION AND SYSADOAS FOR EFFECTIVE MANAGEMENT

N. Fuggle[1]

[1]Associate Professor of Rheumatology at the MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Osteoarthritis (OA) is a growing global concern, with over 595 million individuals affected worldwide in 2020. The early stages of osteoarthritis provide a potential window of opportunity to change the disease trajectory and improve quality of life. For this reason, early diagnosis allows timely disease management and burden reduction.
Dr. Fuggle's presentation will focus on the role of symptomatic slow-acting drugs for osteoarthritis (SYSADOAs) as an effective and safe therapy for improved management of knee OA. Attention will be paid to the key efficacy and safety data for these treatments, which form an important part of the ESCEO guidelines for the management of osteoarthritis.

SY4

FROM PAIN TO PRECISION: CHOOSING AN NSAID FOR OSTEOARTHRITIS MANAGEMENT

E. Choy[1]

[1]Head of Rheumatology and Translational Research at the Division of Infection and Immunity and Director of the Cardiff Regional Experimental Arthritis Treatment and Evaluation (CREATE) Centre at Cardiff University School of Medicine, Cardiff, Wales, United Kingdom

Non-steroidal anti-inflammatory drugs (NSAIDs) are among the most frequently prescribed drugs, and broadly recommended by international guidelines as a pharmacological option for the symptomatic relief of osteoarthritis. Medicines in this drug class are divided into two groups: COX-2 selective agents and non-selective agents that inhibit both the COX-2 and COX-1 isoforms. Professor Choy's presentation will focus on an update on the management of osteoarthritis and inflammation, overview of international guidelines and the role of COX-2 inhibitors in treating pain effectively with a consideration on safety data highlighting the PRECISION outcomes. PRECISION was the first study to look at long-term CV safety of NSAIDs in over 24,000 OA patients at high CV risk.

SY5

INTEGRATING MULTIMODAL APPROACHES FOR COMPREHENSIVE OA MANAGEMENT

J. J. Lichauco[1]

[1]Section Chief of Rheumatology at St. Luke's Medical Center and Past President of Philippine Rheumatology Association, Manila, Philippines

Osteoarthritis (OA) is generally a progressive degenerative condition, with different stages of severity, whose management requires long-term pharmacological and non-pharmacological options. OA related pain has a detrimental effect, impacting overall quality of life, from sleep disturbance to reduction of social and leisure activities. In advanced stages, with moderate to severe pain, a single therapeutical option may not be enough to reduce symptoms and improve wellbeing.
Dr Lichauco's presentation will focus on multimodal, multicomponent, multidisciplinary approaches, as the best solution at present to manage osteoarthritis disease. He will analyze the current pharmacological options with a focus on the

standardized care protocols adopted in the Philippines such as the shared decision-making process, a key component of patient-centered multidisciplinary approach, where clinical evidence and the patient's preference are considered.
A further project adopted in St Luke's Medical center is the rheumatology skilled nurse program. In the actual clinical practice nurses play an important role within the rheumatology multidisciplinary team. Nurses are providers of self-care support, patient education and assessment, treatment and disease monitoring with follow-up care, enhancing OA care and treatment consistency.

SY6

INTRODUCTION OF A CHEST X-RAY BASED OPPORTUNISTIC OSTEOPOROSIS SCREENING AI SOLUTION

D. Sunghyun Jung[1]

[1]Promedius Inc., Seoul, South Korea

The early diagnosis of osteoporosis has become a globally significant concern, particularly in the context of promoting healthy aging. This presentation introduces an advanced artificial intelligence (AI) solution developed for enhanced osteoporosis screening, leveraging chest X-ray imaging. We will outline the development process of this AI solution and present the results of its performance validation using both domestic and international datasets. Furthermore, we will discuss ongoing initiatives and notable achievements aimed at facilitating the successful market adoption of this innovative technology.

SY7

COST-EFFECTIVENESS ANALYSIS OF OPPORTUNISTIC OSTEOPOROSIS SCREENING USING CHEST X-RAY

M. Hiligsmann[1]

[1]Maastricht University, Maastricht, Netherlands

Recent advances have demonstrated that deep learning models applied to chest radiographs can effectively support opportunistic osteoporosis screening, offering a novel approach to identifying individuals at risk of fractures. However, the costs associated with implementing this strategy underscore the importance of assessing its cost-effectiveness. This lecture presents the results of unpublished economic evaluations comparing opportunistic screening via chest radiographs with deep learning, followed by treatment, versus no screening and treatment.
These studies were conducted in three countries with diverse healthcare settings and osteoporosis guidelines: the United States, Germany, and Japan. In each country, national clinical experts were integral to the study process, providing input on data collection and validating assumptions to ensure the relevance and accuracy of the analyses. Across all settings, the incremental cost-effectiveness ratio for screening women aged 50 years and over was consistently below established cost-effectiveness thresholds, demonstrating the economic viability of this strategy. Scenario analyses revealed that cost-effectiveness could be further improved, and even lead to dominance (lower costs for better health outcomes), by optimizing follow-up pathways and improving medication adherence, making these critical priorities in policy decision-making. Drug costs, treatment efficacy and fracture incidence also emerged as important drivers of cost-effectiveness. Additionally, sensitivity analyses showed that even after adjusting key parameters, the results remained favorable and demonstrated robustness.
These findings indicate that opportunistic osteoporosis screening via chest radiographs with deep learning represents a highly cost-effective intervention across diverse healthcare systems. By complementing existing osteoporosis management strategies, this innovative approach could play a pivotal role in reducing fracture rates, improving health outcomes, and mitigating the societal burden of osteoporosis.

SY8

JOURNEY TO FIND OPTIMAL FRACTURE RISK PREDICTION MODEL BASED ON CHEST X-RAYS

S. H. Kong[1]

[1]Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seoul, South Korea

Fragility fractures are a growing healthcare concern, particularly in aging societies. Current tools like DXA (dual-energy X-ray absorptiometry), have limitations in accessibility and predictive accuracy. To address these challenges, we propose an innovative approach leveraging artificial intelligence (AI) to predict fracture risk using standard chest radiographs (Chest PA), which are widely available in routine clinical settings.
The series of studies that I would like to introduce today aimed to develop and validate an AI model capable of estimating fracture risk with enhanced accessibility and comparable predictive performance compared to conventional methods. We utilized a comprehensive dataset of over 72,000 patients who underwent both DXA and chest radiography at three major medical centers. Our approach incorporates clinical data, such as fracture history, surgical records, and imaging outcomes, alongside chest PA to train and evaluate the model.
Key methodologies include preprocessing techniques, ensemble modeling, and survival curve analysis to predict fracture-free intervals. Preliminary results demonstrate that our AI model achieves superior predictive performance when added to FRAX, with the additional benefit of utilizing widely performed imaging modalities.
This study highlights the potential of integrating AI with conventional imaging to enable opportunistic screening, reduce healthcare costs, and improve patient outcomes. By harnessing additional information beyond bone density, this AI-based model bridges the gap in fracture risk prediction, offering a scalable and accessible solution for early intervention in high-risk populations. Our findings emphasize the transformative potential of AI in

reshaping osteoporosis care and fracture prevention strategies. We invite you all for discussions on the clinical implications and opportunities for broader adoption of this innovative approach.

SY9

REMS IN THE FRACTURE SETTING

A. Kurth[1]

[1]Orthopaedic Institute Dr. Baron&Colleagues and Goethe University Frankfurt, Frankfurt/Main, Germany

In clinical practice, REMS (Radiofrequency Echographic Multi Spectrometry) has potential applicability in secondary fracture prevention, particularly within the frameworks of Fracture Liaison Services (FLS) or Orthogeriatric services. The portable nature of REMS makes it particularly suitable for frail inpatients who may struggle to position themselves appropriately for DXA scans of the spine or hip. REMS can be conducted at the bedside, enabling rapid assessment of bone mineral density (BMD) in the immediate post-fracture period. This capability allows for timely, BMD-informed decisions regarding optimal orthopedic interventions and risk stratification, which can guide the prescription of anti-osteoporosis treatments (both anti-resorptive and bone-forming agents). Furthermore, REMS may play a crucial role in assessing BMD during initial fracture presentations in the Emergency Department, thereby facilitating more efficient Fracture Liaison Service management and addressing a critical gap in fracture prevention strategies.

SY10

REMS SUITABILITY IN SECONDARY OSTEOPOROSIS

G. Adami[1]

[1]Rheumatology Unit, University of Verona, Policlinico GB Rossi, Piazzale A. Scuro, Verona, Italy

Objective(s):
Secondary osteoporosis is a significant clinical challenge, often associated with chronic diseases or treatments that affect bone health. Notably, secondary osteoporosis affects 66% of older men, over 50% of premenopausal women and 30% of postmenopausal women. Secondary osteoporosis predisposes patients to fragility fractures, which can further worsen their condition. In this context, effective and safe diagnostic tools are essential for managing various patient populations, including those who cannot undergo radiation-based assessments. This study aims to evaluate the suitability of Radiofrequency Echographic Multi Spectrometry (REMS) in secondary osteoporosis diagnosis and monitoring, highlighting its advantages over conventional imaging techniques.
Material and Methods:
A systematic literature review was conducted to evaluate the clinical performance of REMS in assessing bone health in patients affected by secondary osteoporosis. Relevant studies were identified through searches in peer-reviewed databases, focusing on comparisons between REMS and standard diagnostic methods such as dual-energy X-ray absorptiometry (DXA).
Results:
Different disorders negatively impact bone health. Pregnancy and certain therapies can also cause secondary osteoporosis and increase fracture risk. REMS technology provides a radiation-free, non-invasive method to assess bone health via lumbar spine and femoral ultrasound scans. By measuring key parameters such as Bone Mineral Density (BMD), T-Score, and Fragility Score, REMS offers valuable insights into bone health and fragility. Recently published clinical studies have shown REMS's diagnostic accuracy in secondary osteoporosis. For instance, in patients undergoing peritoneal dialysis, REMS is not influenced by aortic calcification artifacts that artificially elevate lumbar BMD in DXA scans. Furthermore, in kidney transplant recipients, REMS demonstrates superior performance to DXA in the early detection of osteoporosis. Notably, in patients with type 2 diabetes—who exhibit a 'paradoxical situation' with normal BMD values but an increased fracture risk due to microarchitectural deterioration—REMS accurately revealed their true bone health status.
Conclusion(s):
REMS technology represents a significant advancement in the diagnosis and monitoring of secondary osteoporosis, offering a radiation-free, non-invasive alternative to traditional methods like DXA. Its demonstrated diagnostic accuracy across several conditions, including metabolic, renal, and nutritional disorders, as well as its ability to detect microarchitectural deterioration inchallenging cases like type 2 diabetes mellitus, underscores its potential as a valuable tool for improving bone health assessment and patient management.

SY11

BONE HEALTH MANAGEMENT IN PREGNANCY

M. L. Brandi[1]

[1]Osservatorio Fratture da Fragilità Italia (OFF Italia), Florence, Italy

Objective(s):
Pregnancy induces significant physiological changes in maternal bone metabolism to meet the calcium demands of the developing fetus. The development of the fetal skeleton requires a substantial transfer of calcium from the mother to the fetus throughout pregnancy, with 80% of this transfer occurring during the third trimester. These changes, while typically reversible after breastfeeding weaning, can lead to complications such as bone loss or fractures, including pregnancy-associated osteoporosis. This study aims to evaluate the efficacy of Radiofrequency Echographic Multi Spectrometry (REMS) as a safe and effective tool for assessing and managing bone health during pregnancy, focusing on femoral neck assessments and addressing the limitations of conventional methods.
Material and Methods:
A systematic review of current literature was conducted to analyse the usefulness of REMS technology in monitoring bone health during pregnancy. The review focused on published studies evaluating REMS-derived parameters, such as bone mineral density (BMD) measured at the femoral neck, during pregnancy.

Results:
The maternal skeleton acts as the primary calcium reservoir for the developing fetus, potentially leading to maternal bone deterioration. Monitoring bone health during pregnancy is critical. Traditional methods, such as DXA, assess bone density but involve ionizing radiation, making them unsuitable during pregnancy. Typically, DXA evaluations are conducted before or after pregnancy, limiting early diagnostics and intervention. In contrast, REMS technology, using ultrasound, offers a radiation-free, non-invasive alternative with no negative effects on the fetus. Thanks to ts high precision, REMS allows continuous monitoring during pregnancy. An important REMS study allowed, for the first time, the identification of BMD changes between the first and third trimesters, revealing an average 2.0% decrease. Additionally, by using REMS for the assessment of BMD in the third trimester, an 8.1% decrease compared to non-pregnant women was found.
Conclusion(s):
REMS offers a safe and non-invasive approach for measuring bone mineral density during pregnancy, overcoming the limitations of conventional techniques like DXA. The technology enables continuous monitoring of maternal bone health, crucial for early detecting pregnancy-related bone loss without posing risks to the fetus.

SY12
ECONOMIC BENEFITS OF REMS

M. Hiligsmann[1]

[1]Maastricht University, Maastricht, Netherlands

Radiofrequency Echographic Multi-Spectrometry (REMS) is an innovative, non-ionizing diagnostic technique that has demonstrated high accuracy and precision, positioning it as a promising alternative to DXA for osteoporosis diagnosis in clinical settings. Given the growing emphasis on economic considerations in healthcare decisions, it is important to discuss the cost- effectiveness and economic benefits of REMS as a diagnostic tool for osteoporosis. During this lecture, we will introduce the rationale and significance of economic assessments in healthcare decision-making, review and discuss existing studies on the economic benefits of REMS and finally examine the generalizability of these findings.
Economic evaluations play a crucial role in healthcare, guiding policymakers and clinicians in the efficient allocation of resources while ensuring optimal patient outcomes. The cost-effectiveness of diagnostic tools such as REMS is therefore essential in determining their value in routine clinical practice. A recent study by Reginster et al. (JBMR Plus. 2025) evaluated the cost-effectiveness of REMS in the United States, revealing that REMS followed by treatment leads to improved health outcomes, including increased quality-adjusted life years (QALYs) and a reduction in fractures, while also lowering fracture-related costs compared to scenarios without diagnosis and treatment. For example, utilizing REMS to achieve a 5% increase in diagnosing and treating women over 50 years old who are at high or very high risk of fractures is estimated to result in approximately 30,000 life years gained, 43,500 QALYs, and the prevention of 100,000 fractures over a lifetime, assuming real-world medication adherence. The incremental cost-effectiveness ratio (ICER) of REMS was estimated at $33,891 and $49,198 per QALY gained under full adherence and real-world adherence scenarios, respectively, both well below the US cost-effectiveness threshold of $100,000 per QALY. Beyond the US context, assessing the broader applicability of these findings is essential, as factors such as healthcare system structures, treatment protocols and costs, and population demographics may influence the economic benefits of REMS in other regions. This lecture will therefore also explore the transferability of the economic benefits of REMS to different healthcare settings, assessing its potential as a cost-effective approach to osteoporosis diagnosis and management.

SY13
REMS: BONE DENSITY ASSESSMENT WITHOUT IONISING RADIATION - AN ALTERNATIVE TO DXA?

N. Fuggle[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Dual-energy X-ray Absorptiometry (DXA), introduced in the 1980s, remains the standard technique for assessing bone mineral density (BMD) and diagnosing osteoporosis. However, DXA is limited by its reliance on ionising radiation, lack of portability, and susceptibility to artefactual BMD elevation, particularly in patients with spinal osteoarthritis.
Radiofrequency Echographic Multi Spectrometry (REMS) is an emerging ultrasound-based technology that addresses these limitations. REMS is radiation-free, making it suitable also for vulnerable populations such as pregnant women, children, and those requiring frequent monitoring. Its portability also enables use in immobile or house-bound patients.
Notably, REMS applies spectral analysis to differentiate true bone signal from artefact, potentially improving diagnostic accuracy in patients with spinal osteoarthritis (which is a known limitation of DXA). Recent clinical studies have demonstrated the validity of REMS in such contexts, showing strong correlation with DXA measurements while avoiding common artefacts.
In conclusion, REMS represents a promising alternative for BMD assessment, particularly in clinical scenarios where DXA is contraindicated, inaccessible, impractical or limited by artefact.

SY14

IS A TREAT TO TARGET (T2T) APPROACH REALISTIC IN OSTEOPOROSIS PATIENTS AT HIGH FRACTURE RISK?

W. F. Lems[1], B. Langdahl[2], S. Ferrari[3]

[1]Department of Rheumatology, Amsterdam University Medical Center, Amsterdam, Netherlands, [2]Department of Endocrinology, Aarhus University Hospital and Aarhus University, Aarhus, Denmark, [3]Service and Laboratory of Bone Diseases, Geneva University hospital and Faculty of Medicine, Geneva, Switzerland

For about 20 years, treat to target (T2T) has been a commonly used strategy in the treatment of inflammatory rheumatic diseases. Early data have shown that T2T therapy is superior to usual care. Optimal T2T is possible when:

- there is consensus on the target;
- the target can be measured reliably and easily;
- the target reflects the current disease activity and is sensitive to change;
- the target is associated with a favorable long-term outcome;
- both the rheumatogist and the patient support this strategy;
- when the target cannot be reached, several other drugs are available.

In the lecture, the BEST-study in rheumatoid arthritis will be discussed in detail, as one of the best examples for T2T. Rheumatologists also treat patients with SLE, spondyloarthropathies and gout with a T2T strategy, which is not yet as successfull as in RA. Nevertheless, rheumatologists and their patients are used to T2T treatment, aiming at clinical remission or low disease activity in all patients. Therefore, this lecture can be an attractive start in a symposium in which the clinical relevance of T2T in osteoporosis as the preferred strategy will be discussed.

T2T in current task forces/guidelines – where are we now
B. LANGDAHL

The goal of osteoporosis management is to prevent fractures. All approved treatments reduce fracture risk, however, a T2T approach for the management of fracture risk helps ensure that the most appropriate initial treatment and treatment sequence is selected for the individual patient. A T2T approach for osteoporosis management has been described in the position statement of the ASBMR/BHOF Task Force on Goal-Directed Osteoporosis Treatment (Cosman et al.[1]). The T2T approach requires a decision about the target, which requires assessment of clinical fracture history, vertebral fracture identification, measurement of bone mineral density and consideration of other major clinical risk factors. Treatment targets should be decided based on the individual risk profile, including recency of fracture, number and severity of prior fractures, and BMD levels at the hip and spine. The choice of initial treatment should focus on reducing fracture risk rapidly for patients at very high and imminent risk and consider the probability that a BMD treatment target can be attained within a reasonable period of time. For patients at high and imminent risk of fracture and/or with very low BMD, bone anabolic treatment should be considered as the initial treatment followed by antiresorptive treatment. For patients at moderate risk of fracture, antiresorptive treatment may be appropriate. The T2T approach is also discussed in the most recent guideline on postmenopausal osteoporosis from the Endocrine Society (Eastell et al.[2]).

Can we achieve a long-term goal in osteoporosis with current drugs?
S. FERRARI

The mere concept of a treatment goal (or target) in osteoporosis is now more than 10 yrs old, yet no clear consensus has been achieved on what this goal should be. Nevertheless, BMD T-score is emerging as a most practical target, since it is not only the base for osteoporosis definition, but also directly correlated to fracture risk with as well as without therapy. A recent update from the ASBMR task force indicates a BMD T-score > -2.5 as a general goal, but a T-score above -2.0 in high-risk patients; alternatively, for those high-risk patients starting with a hip BMD T-score above -2, a minimal BMD gain of 3-5%. For many years, we have resisted the concept of treat-to-target in osteoporosis because of the limited BMD gains achieved with BPs, i.e. typically 3-5%. Denosumab demonstrated long-term gains greater than 10% at spine and 5% at hip over 10 yrs of exposure. Yet subgroup analyses of the FREEDOM Extension trial clearly showed that "target" BMD T-scores could not be achieved even with 10 yrs of treatment in those starting with very low hip BMD T-scores. In contrast, treatment sequences beginning with bone forming agents followed by an antiresorptive have allowed substantial BMD gains in lesser time. In particular, the sequence of romosozumab for one year followed by denosumab has led to BMD gains of more than 1 T-score at spine and more than 0.5 T-score at hip in just three years. For those patients with T-scores below -2.5, and even more so for those with T-score < -3.0, the probability to achieve a T-score > -2.5 was greater with the romosozumab-denosumab sequence than with romosozumab-alendronate and a fortiori than alendronate alone. In addition, in patients previously on alendronate who switched to romosozumab or teriparatide (TPT), 45% of those switched to romosozumab achieved at least 3% BMD gain at both spine and hip, whereas only 15% of those switched to TPT achieved this goal. In conclusion, achieving long-term, and in some cases even short-term, treatment goals in osteoporosis appears now more feasible than it was, thanks to the optimal use of bone forming agents and anti-resorptives' sequences. Yet for optimal long-term protection against bone fragility, sequences of biologic drugs must finally be consolidated with a bisphosphonate.

COULD IT BE HYPOPHOSPHATASIA (HPP)? A CONVERSATION WITH EXPERTS

M. L. Brandi[1], L. Seefried[2]

[1]University of Florence, Florence, Italy, [2]Julius Maximilian University of Würzburg, Würzburg, Germany

This Meet-the-Expert session will explore key challenges in diagnosing and managing hypophosphatasia (HPP) in adults, focusing on practical, case-based insights and interactive discussions.
Prof Brandi will present patient cases that illustrate the diverse clinical manifestations of HPP, emphasizing the diagnostic complexity. She will discuss ways to increase awareness of HPP and symptoms that should raise suspicion, highlighting the current criteria for early recognition and accurate diagnosis and their continuing evolution.

Dr Seefried will present patient cases that highlight the systemic nature of HPP, extending beyond skeletal symptoms to emphasize broader clinical impacts. He will discuss the importance of a multidisciplinary approach to managing HPP and share insights into treatment strategies, outcome measures, and the impact on quality of life.

Both speakers will actively engage with those present through interactive discussions and Q&A sessions, encouraging participants to share challenges and experiences related to diagnosing and managing HPP.

muscles

an Open Access Journal by MDPI

Editor-in-Chief

Prof. Dr. Corrado Angelini
Department of Neurosciences,
University of Padova, Italy

Message from the Editor-in-Chief

Muscles is a publishing platform that promotes discoveries related to the realm of neuromuscular disorders (genetic and acquired neuromuscular disorders in man) and relevant cell and animal models. The journal aims to be a publishing venue that disseminates scientific papers with emphasis on multidisciplinary approaches to understand the complexities and interactions occurring on a variety of metabolic, endocrinological and neurogenic disorders. Papers on sarcopenia, exercise and atrophy/hypertrophy of muscles will be given space and attention, as will clinical trials and possible pharmacological interventions.

A rapid turnaround time and full open access provide the opportunity to make research results immediately available to scientific communities and the general public.

Author Benefits

- **Open Access** Unlimited and free access for readers
- **No Copyright Constraints** Retain copyright of your work and free use of your paper
- **Thorough Peer - Review**
- **Rapid Publication** First decisions in 16 days; acceptance to publication in 5.8 days (median values for MDPI journals in the second half of 2023)
- **No Space Constraints, No Extra Space or Color Charges** No restriction on the maximum length of the papers, number of figures, or colors
