Fundamentals of Osteoporosis

Enhancing Clinical Excellence

APPLY TO ORGANIZE A COURSE OR FIND A COURSE NEAR YOU!

An IOF on-site/hybrid course that provides up-to-date knowledge on diagnosing and managing osteoporosis, equipping participants with the theoretical and practical skills to enhance their clinical practice.

ADVANCE CLINICAL KNOWLEDGE WITH FUNDAMENTALS OF OSTEOPOROSIS

- **BRAND NEW CURRICULUM**
- **2 MODELS AVAILABLE:** HYBRID AND ON-SITE
- **APPLY TO BE A LOCAL HOST**
- **INCLUDES ONLINE POST-COURSE EXAMINATION**
- **ATTESTATION OF ACHIEVEMENT PROVIDED**

ABOUT ESCEO

The European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) is a not-for-profit organization, dedicated to a close interaction between clinical scientists dealing with bone, joint and muscle disorder, pharmaceutical industry developing new compounds in this field, regulators responsible for the registration of such drugs and health policy makers, to integrate the management of Osteoporosis and Osteoarthritis within the comprehensive perspective of health resources utilization.

The objective of ESCEO is to provide practitioners with the latest clinical and economic information, allowing them to organize their daily practice, in an evidence-based medicine perspective, with a cost-conscious perception.

www.esceo.org

ABOUT IOF

The International Osteoporosis Foundation (IOF) is a non-profit, non-governmental organization dedicated to the worldwide fight against osteoporosis, the disease known as "the silent epidemic". IOF's members – committees of scientific researchers, patient, medical and research societies and industry representatives from around the world – share a common vision of a world without osteoporotic fractures. IOF now represents 343 societies in 152 locations around the world.

www.osteoporosis.foundation

Mission

- Increase awareness and understanding of osteoporosis.
- Motivate people to take action to prevent, diagnose and treat osteoporosis.
- Support national osteoporosis societies in order to maximize their effectiveness

DEAR COLLEAGUES,

It is with great pleasure that we welcome you the 2025 IOF-ESCEO World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases in Rome.

The Congress' scientific programme has been developed by a team comprising members of the Committee of Scientific Advisors of the International Osteoporosis Foundation (IOF) and the Scientific Advisory Board of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO). We would like to thank the respective Scientific Chairs, Professors Nicholas C. Harvey, Eugene McCloskey and René Rizzoli, for taking the lead in setting up an exciting and comprehensive programme that brings together the world's best in the field of musculoskeletal health and disease and takes advantage of the synergies and combined expertise of our two organisations.

We are all meeting with a common aim - to gather new knowledge, skills and tools in the prevention and treatment of osteoporosis and osteoarthritis, the two most disabling conditions in elderly people. An important addition is a focus on sarcopenia because of its intimate relation to bone and joint disease. It is our hope that this Congress will move the field one step forward on all fronts - from new understanding of bone metabolism and pathology to new strategies and options in prevention, diagnosis and treatment.

The core scientific programme consists of **10** plenary lectures by renowned speakers and **40** oral communications selected from the very best of hundreds of submitted abstracts, and **20** oral presentations of selected posters. In addition, participants can choose among **12** different Meet-The-Expert sessions and a large number special sessions and symposia on issues of clinical importance. We also encourage you to visit many of the scheduled poster sessions and industry sponsored satellite symposia and to visit the large commercial exhibition presented by the leading companies in the bone field. Visit also the 'CNS village' where you can meet some of IOF's member societies.

The past few years has been a difficult time for scientific communication. Our World Congresses have weathered the storm of Covid-19 and successfully rebounded to the face-to-face format of previous times. Indeed, each year we break new records for attendance and abstract submissions. We are especially thankful for your continued support and participation. We will do our best to ensure that this meeting is a memorable, enriching experience for all. Welcome to Rome, a great world city far more than just the capital of Italy. Rome is bustling, vibrant, multicultural and cosmopolitan. We look forward to meeting in person with the undoubted advantages of direct rather than virtual contact.

PRE-COMPETITIVE CONSORTIUM ON OSTEOPOROSIS AND BONE HEALTH

An initiative from ESCEO and IOF to support the five-year partnership signed between ESCEO and the World Health Organization to improve the management of osteoporosis

ESCEO and IOF are very proud to announce the creation of the Pre-Competitive Consortium on Osteoporosis and Bone Health (PRECCO). This Consortium, created to support the five-year partnership signed between ESCEO and the **World Health Organization** to improve the management of osteoporosis, involves a diverse range of stakeholders, who place the osteoporotic patients at the center of their priorities, independently of their immediate strategy, in terms of content and timeline. The stakeholders supporting the PRECCO are listed below.

WORLD CONGRESS ON OSTEOPOROSIS, OSTEOARTHRITIS AND MUSCULOSKELETAL DISEASES

WCO IOF-ESCEO

2026 PRAGUE

April 16-19, 2026

Prague | Czech Republic

O_2 universum Prague

WORLD'S LEADING CLINICAL CONFERENCE ON BONE, JOINT AND MUSCLE HEALTH

Congress Organizer Sinklar Congress Management B.V.

Congress Secretariat www.humacom.com

www.**WCO-IOF-ESCEO**.org

13:00 - 16:00 - Auditorium A

SYMPOSIUM: OSTEOPOROSIS & CHRONIC KIDNEY DISEASES – METABOLIC BONE DISEASES UNDER THE SAME UMBRELLA

Chairpersons: David Dempster, Nicholas C. Harvey

13:00 **Introduction - Osteoporosis vs Renal Osteodystrophy**
Pieter Evenepoel

13:20 **Bone Histology - Osteoporosis vs Renal Osteodystrophy**
David Dempster

13:40 **Diagnosis: Biochemistry, Imaging - Osteoporosis vs Renal Osteodystrophy**
Thomas L. Nickolas

14:00 **Discussion**

14:20 **Courtesy Break**

14:40 **Vascular Calcification in Chronic Kidney Diseases - Metabolic Bone Diseases & associated Osteoporosis**
Ziad Massy

15:00 **Current Therapeutic Options - Osteoporosis & Renal Osteodystrophy**
Sandro Mazzaferro

15:20 **Intermittent PTH Administration in the Management of Chronic Kidney Diseases - Metabolic Bone Diseases**
Michael Pazianas

15:40 **Discussion**

16:30 - 19:10 - Auditorium A

WCO-IOF-ESCEO - OPENING CEREMONY

Chairpersons: René Rizzoli, Nicholas C. Harvey

16:30 **Best clinical papers published in 2024**
René Rizzoli

17:10 **Opening of the congress**
René Rizzoli, Nicholas C. Harvey

17:15 **Two years of partnership between WHO and ESCEO: Achievements and perspectives**
Doctor Jotheeswaran Amuthavalli Thiyagarajan (WHO-Geneva)

17:25 **Presentation of the Islene Araujo de Carvalho-ESCEO 2025 Prize**
Doctor Jotheeswaran Amuthavalli Thiyagarajan (WHO-Geneva), Jean-Yves Reginster

17:30 **Partnering for Progress: Global Drug Development and Scientific Societies**
Bruno Sepodes

17:40 **Presentation of the ESCEO-IOF Pierre Delmas Medal**
Jean-Yves Reginster

17:45 **Revival of the European Medicines Agency activities oriented towards older people**
Francesca Cerreta

17:55 **Presentation of the IOF President›s Award**
Nicholas C. Harvey

18:00 **New Perspectives in the management of patients with osteoporosis**
Willard Dere

18:30 **Presentation of the 2025 ESCEO Medal of Excellence**
René Rizzoli

18:35 **Highlights of the Galleria Borghese**
Francesca Cappelletti

19:05 **Closure of the Opening Ceremony Session and Opening of the Cocktail**
Jean-Yves Reginster

19:10 - 20:10

SPONSORED WELCOME COCKTAIL

See details on the Sponsored Sessions Section

08:00
OPENING OF THE CONGRESS & COMMERCIAL EXHIBITION

08:00 - 09:00 - Auditorium B
SPONSORED BREAKFAST SYMPOSIUM
See details on the Sponsored Sessions Section

08:00 - 09:00
NON-SPONSORED SYMPOSIA

MR1 **Management of osteoporotic vertebral fractures - Risk factor - Guidelines - Technology**
Chairpersons: Andreas Kurth, Chistopher Niedhardt
- Risk factor vertebral fractures Peyman Hadji
- German Guidelines for the Treatment of vertebral osteoporotic fractures Andreas Kurth
- 30 Years of Vertebro- and Kyphoplasty Robert Pflugmacher

MR2 **Update in Low Back Pain: Diagnosis, Guidelines and Management**
Chairpersons: Fitnat Dincer, Andreas Winkelmann
- Approach of physiatrists to Low Back Pain in Europe, results of a research and WHO guideline Fitnat Dincer
- Update in Diagnosis and Management of Low Back Pain Andreas Winkelmann

MR3 **Empowering Patients: Integrating Preferences and Perspectives into Osteoporosis Care and Policy Development**
Chairperson: Angie Botto-van Bemden
- What Do We Know About Preferences of Patients at Risk for Fractures? Lakshmi Nagendra
- Integrating Patients Preferences and Perspectives into Osteoporosis Care and Policy Development: An Academic Perspective Mickael Hiligsmann
- Integrating Patient Preferences and Perspectives into Osteoporosis Care and Policy Development: The Patient Perspective Angie Botto-van Bemden

MR4 **Muscle And Bone: A Multifaceted Connection**
Chairperson: Osvaldo Daniel Messina
- A message from the bone: how bone-secreted factors affect muscle growth and function Gustavo Duque
- The role of fat in muscle/bone crosstalk: an additional complex player Tiffany Kim
- A message from the muscle: how muscle-secreted factors affect bone metabolism and function Osvaldo Daniel Messina

MR6 **Optimization of bone health in orthopaedic surgical patients**
Chairperson: P. Dean Cummings
- Underlying Bone Health: Is it Important to Surgical Outcomes? P. Dean Cummings
- Orthopaedic Surgeries Affected by Compromised Bone Health Nikos Koumontzis
- Development of Pre- and Post-operative Bone Health Programs for Orthopedic Surgical Patients Isabella Esposito

MR7 **Hyponatremia and Bone**
Chairpersons: Maria Luisa Brandi, Alessandro Peri
- What did basic research tell us? Alessandro Peri
- Hyponatremia and bone density Laura Potasso
- Hyponatremia, falls and fractures Ploutarchos Tzoulis
- Discussion and Conclusion

MR8 **Discovery, validation and implementation of endophenotyping for patient stratification in osteoarthritis clinical trials**
Chairperson: Ali Mobasheri
- Advancing osteoarthritis trials and therapeutic development through clinical phenotyping and molecular endotyping Ali Mobasheri
- Endotyping osteoarthritis by interrogating the pathobiological bioactivity present in osteoarthritic synovial fluid Tim J. M. Welting
- Insights into OA endophenotypes from recent clinical trials Philip Conaghan
- Obesity shapes the inflammatory molecular endotypes of synovial fibroblasts in osteoarthritis Simon W. Jones
- Clinical application of longitudinally stable molecular endotypes in osteoarthritis: pathways to precision medicine Anne-Christine Bay-Jensen

MR10 **The skeleton in the Closet: A historical look at osteoporosis**
Chairperson: Bruno Muzzi Camargos
- Osteoporosis in Ancient History
  Geraldine Altamar
- Osteoporosis in Art Andres Coy
- History of Osteoporosis pharmacological treatment Michael McClung

08:00 - 09:00 - MR5
ESCEO SYMPOSIUM
Recommendations for an optimal use of Bone Forming Agents in osteoporosis
Chairpersons: Bernard Cortet, Nicola Veronese
- Which patients should benefit from a Bone Forming Agent? Elizabeth M. Curtis
- Comparative efficacy and safety of currently available Bone Forming Agents René Rizzoli
- Discussion Leader Peter R. Ebeling

09:00 - 10:30 - Auditorium A
SCIENTIFIC SESSION I
Chairpersons: Elaine M. Dennison, Salvatore Minisola

09:00 **Plenary Lecture**
Hormone therapy for fracture prevention - a sex stratified approach Michael McClung

09:30 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

09:30 **OC1** AGA2118, A BISPECIFIC MONOCLONAL ANTIBODY NEUTRALIZING BOTH SCLEROSTIN AND DKK1, INCREASED BONE FORMATION, DECREASED BONE RESORPTION, AND LED TO RAPID BMD GAINS IN A FIRST IN HUMAN, SINGLE- AND MULTIPLE- DOSE, PLACEBO-CONTROLLED, RANDOMIZED STUDY
Presenting author: B. Langdahl
Authors: M. T. Drake, Y. L. Zhang, J. Z. Ke, Y. F. Li, M. Lankachandra, A. C. Zovein, H. Z. Ke, W. H. Dere & R. E. Dent

09:40 **OC2** WEEKLY VITAMIN D AND DAILY CALCIUM CARBONATE OVER 48-WEEKS INCREASES BONE DENSITY IN ADOLESCENTS WITH HIV AND 25(OH)D <75NMOL/L: A PLACEBO-CONTROLLED TRIAL IN SOUTHERN AFRICA
Presenting author: C. Gregson
Authors: T. Madanhire, N. V. Dzavakwa, L. Kasonka, H. Banda-Mabuda, T. Bandason, M. Chisenga, S. Filteau, K. Kranzer, H. Mujuru, U. E. Schaible, S. L. Rowland-Jones, V. Simms & R. A. Ferrand

09:50 **OC3** PTH1 RECEPTOR AGONISTS FOR FRACTURE RISK: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS
Presenting author: C. Beaudart
Authors: N. Veronese, J. Douxfils, J. Amuthavalli Thiyagarajan, F. Bolzetta, P. Albanese, G. Voltan, M. Alokail, N. C. Harvey, N. R. Fuggle, R. Rizzoli & J.-Y. Reginster

10:00 **OC4** EFFECTS OF EB613 TABLETS [ORAL PTH(1-34)] ON TRABECULAR AND CORTICAL BONE USING 3D-DXA: POST-HOC RESULTS FROM PHASE 2 STUDY
Presenting author: R. Wagman
Authors: G. Burshtein, C. Itin, H. Galitzer, M. Kushnir, M. Toledano, L. Humbert, R. Boyce, S. L. Ferrari & F. Cosman

10:10 **OC5** SUSTAINED REDUCTION IN FRACTURE RATE IN PATIENTS WITH OI TREATED WITH SETRUSUMAB: FOURTEEN MONTH DATA FROM PHASE 2 OF THE PHASE 2/3 ORBIT STUDY
Presenting author: J. Nowicki
Authors: S. Gottesman, O. Carpenter, D. Velasco, M. Wallace, P. Smith, A. Imel, D. Luca, M. Byers, S. Krolczyk & E. M. Lewiecki

10:20 **OC6** PROGRESSIVE DECREASES IN FRACTURE INCIDENCE WITH ZOLEDRONATE USE >3 YEARS
Presenting author: I. Reid
Authors: A. M. Horne, B. Mihov & G. D. Gamble

10:30 - 12:10 - Auditorium A
SCIENTIFIC SESSION II
Chairpersons: Jean-Marc Kaufman, Maria Luisa Brandi

10:30 **Presentation of the 2025 IOF CSA Medal of Achievement**
Eugene McCloskey

10:40 **Plenary Lecture**
Anti-resorptives: series or parallel ?
Eugene McCloskey

11:10 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

11:10 **OC7** COMPREHENSIVE COMPARATIVE ANALYSIS OF INFRAPATELLAR FAT PAD MORPHOLOGIES IN A LONGITUDINAL KNEE OSTEOARTHRITIS STUDY: NEW INSIGHTS INTO ITS ROLE AS A PROGNOSTIC MARKER
Presenting author: J.-P. Pelletier
Authors: P. Paiement, F. Abram, M. Dorais, J.-P. Raynauld & J. Martel-Pelletier

11:20 **OC8** RESULTS FROM A RANDOMISED CONTROLLED PHASE II TRIAL WITH LEVI-04, A NOVEL NEUROTROPHIN-3 INHIBITOR, DEMONSTRATE SUBSTANTIALLY IMPROVED PAIN AND FUNCTION WITHOUT DELETERIOUS EFFECTS ON JOINT STRUCTURE IN PEOPLE WITH KNEE OSTEOARTHRITIS
Presenting author: P. Conaghan
Authors: A. Guermazi, N. Katz, A. Bihlet, R. Dror, M. Perkins, B. Hughes, C. Herholdt, I. Bombelka & S. Westbrook

11:30 **OC9** A PHASE 1B RANDOMIZED CONTROLLED TRIAL EVALUATING SAFETY AND PHARMACODYNAMICS OF A NOVEL IL-1RA GENE THERAPY (GNSC-001) INJECTION IN KNEE OA: 6-MONTH INTERIM RESULTS
Presenting author: J. Tambiah
Authors: S. Jackson, M. Concepcion, S. Vijay, T. W. Chalberg, A. Annahita & P. G. Conaghan

11:40 **OC10** EFFECTIVENESS OF CELECOXIB IN REDUCING OSTEOARTHRITIS (OA) PAIN IN PATIENTS WITH MODERATE AND SEVERE PAIN: ONCE-DAILY VS TWICE-DAILY DOSING
Presenting author: E. Choy
Authors: C. Walker, R. Chiaese, E. Biesheuvel & S. Suresh Kumbhar

11:50 **OC11** 10-YEAR FOLLOW-UP AFTER INTRA-ARTICULAR INJECTIONS OF 2.5 % POLYACRYLAMIDE HYDROGEL FOR KNEE OSTEOARTHRITIS
Presenting author: H. Bliddal
Authors: A. Hartkopp, P. Conaghan & M. Henriksen

12:00 **OC12** EFFECTS OF INTRA-ARTICULAR HYALURONIC ACID INJECTIONS ON PAIN AND FUNCTION IN KNEE OSTEOARTHRITIS PATIENTS: AN UMBRELLA REVIEW OF SYSTEMATIC REVIEWS AND META-ANALYSES OF RANDOMIZED PLACEBO-CONTROLLED TRIALS
Presenting author: O. Bruyère
Authors: M. Alokail, N. Al-Daghri, J.-Y. Reginster & S. Sabico

12:15 - 13:45 - Auditorium A
SPONSORED LUNCH SYMPOSIUM
See details on the Sponsored Sessions Section

12:15 - 13:45 - Auditorium B
SPONSORED LUNCH SYMPOSIUM
See details on the Sponsored Sessions Section

14:00 - 15:00 - Podium
ORAL PRESENTATIONS OF SELECTED POSTERS
Chairperson: Fanny Buckinx

14:00 **OP1 - P815** OBESITY IS RELATED TO POORER FUNCTIONAL OUTCOMES AMONG INDIVIDUALS WITH RADIOGRAPHIC KNEE OSTEOARTHRITIS: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY
Presenting author: L.D. Westbury
Authors: F. Laskou, F. Kirkham-Wilson, G. Bevilacqua, N. R. Fuggle & E. M. Dennison

14:06 **OP2 - P700** DRIVING KNEE OSTEOARTHRITIS STRUCTURAL PROGRESSOR PROGNOSIS INTO THE NEXT GENERATION: LEVERAGING MACHINE/DEEP LEARNING, MICRORNA AND MAGNETIC RESONANCE IMAGING
Presenting author: J. Martel-Pelletier
Authors: A. Jamshidi, O. Espin-Garcia, T. G. Wilson, I. Loveless, J.-P. Pellletier & S. A. Ali

14:12 **OP3 - P686** EFFECTIVENESS OF PRESCRIPTION GLUCOSAMINE SULFATE (PGS) IN A COHORT OF FILIPINO PATIENTS WITH MILD-MODERATE KNEE OSTEOARTHRITIS (OA)
Presenting author: J.J. Lichauco
Authors: C. Walker, R. Chiaese, H. Scott & S. Venugopal

14:18 **OP4 - P1138** SAFETY OF ANTI-OSTEOARTHRITIS MEDICATIONS: OUTCOMES OF A SYSTEMATIC LITERATURE REVIEW OF POST-MARKETING SURVEILLANCE STUDIES
Presenting author: O. Bruyère
Authors: G. Honvo, L. Lengelé, M. Alokail, N. Al-Daghri, J.-Y. Reginster

14:24 **OP5 - P553** EFFECT OF TIBOLONE ON CORTICAL AND TRABECULAR BONE IN POSTMENOPAUSAL WOMEN COMPARED WITH ESTROGEN THERAPY
Presenting author: G.A. Cruz Priego
Authors: P. Clark, M.-A. Guagnelli, L. Humbert, S. Ortiz-Santiago, L. Castrejón-Delgado & M. A. Sánchez-Rodriguez

14:30 **OP6 - P817** VERTEBRAL FRACTURES IDENTIFIED ON LATERAL DXA IMAGES USING DEEP NEURAL NETWORKS PREDICT INCIDENT FRACTURES IN OLDER WOMEN
Presenting author: L. Johansson
Authors: V. Wåhlstrand, J. Alvén, I. Häggström & M. Lorentzon

14:36 **OP7 - P381** MACHINE LEARNING FOR THE PREDICTION OF FRAGILITY FRACTURES BY BONE AND BODY COMPOSITION PARAMETERS: FINDINGS FROM THE OSTEOLAUS 10 YEARS POPULATIONAL COHORT
Presenting author: C. Vendrami
Authors: G. Gatineau, E. Gonzalez Rodriguez, O. Lamy, D. Hans & E. Shevroja

14:42 **OP8 - P485** REMS TECHNOLOGY FOR FRACTURE RISK ASSESSMENT IN KIDNEY TRANSPLANT PATIENTS
Presenting author: F.A. Lombardi
Authors: P. Pisani, F. Conversano, C. Stomaci, F. R. Contaldo, E. Casciaro, G. Peluso, A. C. Stetco, R. Franchini, M. Di Paola & S. Casciaro

14:48 **OP9 - P940** IMPACT OF AI-ENABLED VERTEBRAL FRACTURE (VF) IDENTIFICATION ON FRACTURE LIAISON SERVICE (FLS) KEY PERFORMANCE INDICATORS (KPIS) AND TREATMENT RECOMMENDATIONS VARIES BY FLS
Presenting author: K. Javaid
Authors: F. A. A. Clemeno, D. Chappell, J. Connor, J. Threlkeld, C. Chisholm, K. E. S. Poole, J. Boylan, J. Turton, M. Stone, C. Toogood, T. Santos, M. Sampson, M. Baxter, E. Curtis, R. Eckert, O. Sahota, Y. Kimmel & R. Pinedo-Villanueva

14:54 **OP10 - P724** TRENDS IN HIP FRACTURE INCIDENCE IN ENGLAND BEFORE, DURING, AND AFTER THE COVID-19 PANDEMIC (2014-2023)
Presenting author: J. Webster
Author: R. Goldacre

14:00 - 15:00
POSTER VIEWING SESSION I

14:00 - 15:00
MEET-THE-EXPERT SESSION

MR1 **Influences of parental health on the next generation bone**
Elizabeth M. Curtis, Rebecca Moon

MR2 **Paget's disease of bone: management lessons from pivotal studies**
Elaine M. Dennison

MR3 **Fracture risk in cancer survivors: bone fragility beyond metastases**
Cyrille Confavreux

MR4 **Advances in management of osteogenesis imperfecta**
Maria Luisa Brandi

14:00 - 15:00 - MR5
SPONSORED SESSION
See details on the Sponsored Sessions Section

14:00 - 15:00 - MR8
EDUCATIONAL LECTURE
Lessons from interventional studies conducted in sarcopenia: are we close to a treatment?
Francesco Landi

14:00 - 15:00 - MR6
ESCEO SYMPOSIUM
Impact of central nervous system dysfunctions (Dementia and Mild Cognitive Impairment) on bone health in older people
Chairpersons: René Rizzoli, Andrea Ticinesi
- Relation between cognitive impairment and bone health Mario Miguel Coelho Da Silva Rosa
- Drugs used in cognitive impairment and bone health Ewa Balkowiec-Iskra
- Discussion leader Maria Concepcion Prieto Yerro

14:00 - 15:00 - MR7
ESCEO-IOF-IFCC SYMPOSIUM
Update on the role of Bone Turnover Markers in the diagnosis and management of osteoporosis
Chairpersons: Andrea Laslop, Etienne Cavalier
- Why and how should we test biochemical markers of bone turnover in 2025?
  Harjit Pal Bhattoa
- What do bone turnover markers bring to the clinician, in the screening, diagnosis and monitoring of osteoporosis in 2025?
  Stuart L. Silverman
- What is the role of bone turnover markers in Chronic Kidney Disease-related osteoporosis?
  Mathias Loberg Haarhaus
- Discussion leader Etienne Cavalier

15:00 - 17:00 - Auditorium A
SCIENTIFIC SESSION III
Chairpersons: Bess Dawson-Hughes, Leith Zakraoui

15:00 **Plenary Lecture**
Osteoanabolics: to lump or to split?
Jean-Yves Reginster

15:30 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

15:30 **OC13** ASSESSING BONE MINERAL DENSITY: A COMPARATIVE STUDY OF DXA AND RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY (REMS) IN ASIAN POPULATION
Presenting author: Y. Yoshino
Authors: Y. Asada, E. Tomatsu, S. Sekiguchi-Ueda, S. Shibata, T. Takayanagi, Y. Seino, Y. Sasaki, H. Takai, H. Ito, H. Sasaki & A. Suzuki

15:40 **OC14** RAPID BONE MICROARCHITECTURE DECLINE, BUT NOT HIGHER FRACTURE RISK, IN MEN WITH ELEVATED FGF23 CONCENTRATION – THE STRAMBO STUDY
Presenting author: P. Szulc
Authors: D. Whittier, S. K. Boyd, L. C. Hofbauer & R. Chapurlat

15:50 **OC15** NUMBER OF FRACTURES AND FRACTURE INCIDENCE IN RELATION TO BONE MINERAL DENSITY: AN INTERNATIONAL META-ANALYSIS
Presenting author: H. Johansson
Authors: N. C. Harvey, E. McCloskey, E. Liu, L. Vandenput, M. Lorentzon, W. D. Leslie, J. A. Kanis & Frax Meta-Analysis Cohort Group

16:00 **OC16** TYPE I DIABETES MELLITUS IS ASSOCIATED WITH INCREASED FRACTURE RISK INDEPENDENT OF BONE MINERAL DENSITY: AN INTERNATIONAL META-ANALYSIS
Presenting author: N. C. Harvey
Authors: E. M. Curtis, H. Johansson, E. V. McCloskey, E. Liu, L. Vandenput, M. Lorentzon, W. D. Leslie, J. A. Kanis & Frax Meta-Analysis Cohort Group

16:10 **OC17** EXTERNAL VALIDATION OF AN AI-DRIVEN RADIOGRAPHIC TOOL FOR OPPORTUNISTIC DETECTION OF HIGH BONE FRAGILITY RISK IN DIVERSE INTERNATIONAL COHORTS
Presenting author: G. Gatineau
Authors: M. De Gruttola, K. Hind, M- Davies, M. Kužma, J. Payer, G. Guglielmi, A. Fahrleitner-Pammer, KJ. Chun, K. Jones, D. Krueger, N. Binkley & D. Hans

16:20 **OC18** COST-EFFECTIVENESS OF OPPORTUNISTIC OSTEOPOROSIS SCREENING USING CHEST RADIOGRAPHS WITH DEEP LEARNING IN GERMANY
Presenting author: M. Hiligsmann
Author: J.-Y. Reginster

16:30 **Plenary Lecture**
Obesity stratification in personalised osteoporosis management Peter R. Ebeling

15:00 - 16:45 - MR5

COMMITTEE OF NATIONAL SOCIETIES SPECIAL PLENARY SESSION: FRAGILITY FRACTURE MANAGEMENT – CHALLENGES AND SOLUTIONS

Chairpersons: Famida Jiwa, Şansin Tüzün

15:10 **OCs1** TARGETING THE MUSCLE–BRAIN AXIS: THE RECIPROCAL RELATIONSHIP BETWEEN COGNITIVE IMPAIRMENT AND SARCOPENIA- DOES IT REPRESENT A NEW PARADIGM IN SARCOPENIA?
Presenting author: Y. El Miedany
Authors: N. Gadallah, M. Sarhan, M. Elgaafary, W. Hassan, N. El Gharbawy, S. Moussa, S. Fathi, N. Fouda, D. El Mikkawy, O. Saboony, A. Safar, W. Elwakil, S. Mahran, M. Elkaramany, N. M. Ahmed, M. Y. Mahgoub & A. Samir

15:18 **OCs2** EVIDENCE-BASED JOINT STATEMENT POSITION OF PERIOPERATIVE BONE OPTIMIZATION IN THE ARTHROPLASTY CANDIDATE, FROM 7 NATIONAL SOCIETIES
Presenting author: R.E. Lopez Cervantes
Authors: F. Torres-Naranjo, I. Etxebarria-Foronda, C. Ojeda-Thies, F. Linares-Restrepo, M. A. González-Reyes, J. R. Caeiro-Rey & D. E. Garin-Zertuche

15:26 **OCs3** ACCURACY OF ARTIFICIAL INTELLIGENCE FOR VERTEBRAL FRACTURE ASSESSMENT BY DXA SCAN
Presenting author: O. Phruetthiphat
Authors: P. Sinlapavilawan & K. Homsapaya

15:34 **OCs4** GLP-1 RECEPTOR AGONISTS AND RISK OF BONE FRACTURES IN ELDERLY PEOPLE WITH TYPE 2 DIABETES
Presenting author: P. Rotman-Pikielny
Authors: M. Kasher Meron, T. Hornik-Lurie & G. Twig

15:42 **OCs5** SARCOPENIA AND ELECTROCARDIOGRAPHIC MARKERS OF ARRHYTHMIA RISK IN OLDER ADULTS
Presenting author: D. Seyithanoglu
Authors: O. Erdogan, T. Erdogan, Z. Fetullahoglu, D. Erbas Sacar, O. Kumet, S. Ozkok, M. A. Karan & G. Bahat

15:50 **Presentation of the IOF Committee of National Societies Medal**
Famida Jiwa, Şansin Tüzün

16:00 **OCs6** AN ARTIFICIAL INTELLIGENCE ALGORITHM TO IMPROVE DIAGNOSIS OF VERTEBRAL FRACTURES EMBEDDED IN FRACTURE LIAISON SERVICES CAN REDUCE FRACTURES AND REDUCE COSTS
Presenting author: R. Pinedo-Villanueva
Authors: G. Fabiano, F. Clemeno & M. K. Javaid

16:08 **OCs7** HIGH-DOSE VITAMIN D THERAPY (300,000 IU MONTHLY): IMPLICATIONS FOR OSTEOARTHRITIS, OSTEOPOROSIS AND ARTERIAL STIFFNESS IN VITAMIN-D DEFICIENT PATIENTS
Presenting author: S. Sokolovic
Author: I. Sokolovic-Tahtovic

16:16 **OCs8** DESTRESSING MINDS. STRENGTHENING MUSCLES. YOGA AND ITS EFFECT ON MUSCLE STRENGTH IN HEALTHY INDIVIDUALS. A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS
Presenting author: P. Bajaj
Authors: L. Nagendra, M. Samuel & M. Chandran

16:24 **OCs9** HIGH-THROUGHPUT SEQUENCING OF BONE METABOLISM GENES AND THEIR ASSOCIATION WITH OSTEOPOROSIS RISK
Presenting author: P. Marozik
Authors: A. Rudenka, V. Samokhovec, K. Kobets & E. Rudenka

16:32 **OCs10** SARCOPENIA AND BONE HEALTH PARAMETERS IN POSTMENOPAUSAL WOMEN WITH DIFFERENT TYPES OF OSTEOPOROTIC FRACTURES
Presenting author: N. Grygorieva
Authors: A. Musiienko, D. Kurylo & A. Iniushina

17:00 - 18:30 - Auditorium A
SPONSORED SATELLITE SYMPOSIUM
See details on the Sponsored Sessions Section

18:30 - 19:30
NON-SPONSORED SYMPOSIA

MR1 **Sedentary Behaviour: Understanding and measuring its importance in muscle-bone health**
Chairperson: Mylène Aubertin-Leheudre
- Assessing sedentary behaviours using the Patient Reported Outcome Measures (PROMS) Charlotte Beaudart
- The Impact of Sedentary Behaviour on Physical Capacity across lifetime Mylène Aubertin-Leheudre
- The Impact of Sedentary Behaviour Versus Physical Activity on Bone Health Olivier Bruyère

MR2 **Potential benefits of art, music and dance on bone and muscle health**
Chairpersons: Jorge Luis Alberto Morales Torres, Osvaldo Daniel Messina
- Introduction: Art, Music, Dancing and Health Osvaldo Daniel Messina
- Artists and activism Jorge Luis Alberto Morales Torres
- Potential mechanisms for Argentinian Tango and fracture reduction Kassim Javaid
- Health professionals and art: For fun only? Jorge Luis Alberto Morales Torres
- Conclusions

MR3 **Multiple sclerosis and osteoporosis**
Chairperson: Ifigenia Kostoglou-Athanassiou
- Multiple sclerosis. An autoimmune disease Ifigenia Kostoglou-Athanassiou
- Osteoporosis in the context of multiple sclerosis Lambros Athanassiou
- Treatment of osteoporosis in the context of multiple sclerosis Panagiotis Athanassiou
- Falls and prevention in multiple sclerosis Yannis Dionyssiotis

MR4 **Vertebral compression fractures: From care to augmentation**
Chairpersons: Şansin Tüzün, Ülkü Akarirmak
- The Impact of Vertebral Compression Fractures Ülkü Akarirmak
- Key Rehabilitation Principles in Vertebral Fractures Şansin Tüzün
- Bracing in Vertebral Fractures: Myths and Facts Rana Terlemez
- Vertebral Augmentation: Who and When? Çağatay Öztürk

MR6 **Not a cartilage, not a bone, osteoarthritis is a nerve-related condition**
Chairpersons: Johanne Martel-Pelletier, Jean-Pierre Pelletier

- What do we know about osteoarthritis: Does it translate between affected species? Eric Troncy
- Somatosensorial and neurological alterations in feline and canine osteoarthritis Aliénor Delsart
- Evidence-based efficacy in managing osteoarthritis in companion animals Eric Troncy

MR7 **Treatment of moving targets: from guidelines into practice**
Chairperson: Bruno Muzzi Camargos

- Guidelines addressing imminent risk strategies Andrès Felipe Coy Barrera
- Treatment discontinuation and intermittent use of bisphosphonates Geraldine Altamar
- Sequential and combination therapies mostly supported or avoided Bruno Muzzi Camargos

MR8 **Bone health in patients with prostate cancer on androgen deprivation therapy**
Chairpersons: Jean-Jacques Body, René Rizzoli

- Bone health in patients with non-metastatic prostate cancer on androgen deprivation therapy (ADT) – an Overview Nicola Napoli
- Summary of the evidence on bone agents in patients with prostate cancer on ADT Marlene Chakhtoura
- Recommendations for the management of patients with prostate cancer on ADT David Kendler

MR10 **Implementing and maintaining FLS services: (painful) Lessons learned from working with resource constraints and attempting to overcome hurdles**
Chairperson: Maria Luisa Brandi

- Opening Remarks Maria Luisa Brandi
- Lessons learned from implementing and maintaining FLS in Singapore Manju Chandran
- Lessons learned from mentorship in Switzerland Thierry Chevalley
- Navigating Challenges in the Fight For Fracture Liaison Services in South Africa Teréza Hough
- Panel Discussion and Closing Remarks

08:00 - 09:00 - Auditorium B

SPONSORED BREAKFAST SYMPOSIUM

See details on the Sponsored Sessions Section

08:00 - 09:00

NON-SPONSORED SYMPOSIA

MR1 Comprehensive Care for Pediatric Bone Fragility

Chairperson: Leith Zakraoui

- Bone fragility and osteoporosis in children and adolescents: when and how to diagnose it? Yasmine Makhlouf
- Bone fragility and osteoporosis in children and adolescents: when and how to treat it? Saoussen Miladi
- Discussion / Q&A

MR2 Osteoporosis and Complex Regional Pain Syndrome (CRPS)

Chairperson: Ayşe A. Küçükdeveci

- A significant problem following osteoporotic fractures: Complex Regional Pain Syndrome Yeşim Gökçe-Kutsal
- Can we treat CRPS by pharmacological agents? Yeşim Kirazlı
- The role of non-pharmacological approaches in the management of CRPS Ayşe A. Küçükdeveci

MR3 The evolution of post fracture care services in LATAM pre and post CTF mentorship programme

Chairpersons: Osvaldo Daniel Messina, Willem Lems

- Qualitative and quantitative change in FLS/PFC in LATAM. An overview J. Francisco Torres Naranjo
- Key Performance Indicators of PFC/FLS in LATAM. Expected outcomes based on BC in Mexico and Colombia Adriana Medina
- Successful country specific strategies to improve and increase the number of FLS Edgar Castro Osorio
- Challenges ahead. Gathering key data for monitoring performance and improving quality of PFC/FLS. Country specific dataset. Experience of the Argentine Hip Fracture Registry: Pasos® Program Maria Diehl

MR4 Patient-centred approach to Sarcopenia: from standard of care to digital technologies

Chairpersons: Maria Luisa Brandi, Giovanni Iolascon

- The global burden of Sarcopenia Francesca Gimigliano
- Multimodal exercise and nutrition: the pillars of Sarcopenia treatment Giovanni Iolascon
- Digital Technologies in Sarcopenia Treatment: the right therapy for the right patient Antimo Moretti
- Closing remarks

MR8 Pregnancy and lactation, a challenge for the Bone and Muscle Health

Chairperson: Yasser El Miedany

- Pregnancy, and lactation a challenge for the skeleton Naglaa Ali
- Movement recommendations for Pregnant and lactating women Mohamed Hassan Abu-Zaid

MR10 Abdominal aortic calcification and musculoskeletal health

Chairperson: Peter R. Ebeling

- Abdominal aortic calcification, what it is and why it is important Joshua R. Lewis
- Abdominal aortic calcification and musculoskeletal outcomes Pawel Szulc
- Abdominal aortic calcification as a novel risk factor for falls and fractures in routine clinical practice William D. Leslie
- Provision of abdominal aortic calcification results to patients John T. Schousboe

08:00 - 09:00 - MR5

ISGE-ESCEO JOINT SYMPOSIUM SESSION

The gynecologist and bone: A tale of woman›s health

Chairpersons: Andrea Riccardo Genazzani, Şansin Tüzün

- The role of sex steroids in the health of the musculoskeletal system: a lifetime journey Andrea Riccardo Genazzani
- When the ovaries fail early: protecting the bone Svetlana Vujovic
- Menopause and the bone: a matter for gynecologists Stefano Lello

08:00 - 09:00 - MR6
ESCEO SYMPOSIUM
Treatment of osteoporosis and osteoarthritis in the oldest old
Chairpersons: Andrea Laslop, René Rizzoli

- Specific considerations for the management of osteoporosis in the oldest old
  Nicholas C. Harvey
- Specific considerations for the management of osteoarthritis in the oldest old
  Philip Conaghan
- Discussion leader Carla Torre

08:00 - 09:00 - MR7
DVO-ESCEO SYMPOSIUM
Special aspects of osteoporosis
Chairpersons: Ralf Schmidmaier, Olivier Bruyère

- The role of bone anabolic treatment in the geriatric population Ralf Schmidmaier
- Management of pregnancy associated osteoporosis Peyman Hadji
- Osteonecrosis of the jaw: novel insights and current status Sven Otto, Philipp Poxleitner, Katharina Obermeier
- Dealing with atypical femur fractures
  Andreas Kurth

09:00 - 10:30 - Auditorium A
SCIENTIFIC SESSION IV
Chairpersons: Manju Chandran, Peter R. Ebeling

09:00 **Plenary Lecture**
Advances in personalized fracture risk assessment: FRAX and beyond Nicholas C. Harvey

09:30 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

09:30 **OC19** RELATIONSHIP BETWEEN COMORBIDITY, PHYSICAL ACTIVITY AND FRAILTY DIFFER ACCORDING TO EDUCATIONAL ATTAINMENT: FINDINGS FROM THE SOUTHAMPTON LONGITUDINAL STUDY OF AGEING (SALSA)
Presenting author: F. Laskou
Authors: L. D. Westbury, F. Kirkham-Wilson, G. Bevilacqua, N. R. Fuggle, E. M. Dennison, P. Aggarwal & H. P. Patel

09:40 **OC20** RELATIONSHIPS BETWEEN CHANGE IN SEX HORMONES WITH CHANGE IN MEASURES OF SARCOPENIA: A LONGITUDINAL STUDY IN COMMUNITY DWELLING OLDER MEN
Presenting author: S. Hills
Authors: T. A. Mansfield, P. Cawthon, N. E. Lane & E. S. Orwoll

09:50 **OC21** OSTEOSARCOPENIA AS A RISK FACTOR FOR DEPRESSION: LONGITUDINAL FINDINGS FROM THE SHARE STUDY
Presenting author: N. Veronese
Authors: F. S. Ragusa, S. Sabico, L. Dominguez, M. Barbagallo, G. Duque, L. Smith & N. Al-Daghri

10:00 **OC22** PSYCHOMETRIC PROPERTIES OF THE SARQOL QUESTIONNAIRE: A SYSTEMATIC REVIEW AND META-ANALYSIS
Presenting author: C. Beaudart
Authors: C. Demonceau, C. Brabant, E. Shukuru, M. Alokail, N. Al-Daghri, Y. Rolland, I. Bautmans, J. M. Bauer, A. Cherubini, A. J. Cruz-Jentoft, B. Dawson-Hughes, R. A. Fielding, N. C. Harvey, F. Landi, M. Visser, G. Duque, R. Rizzoli, J.-Y. Reginster & O. Bruyère

10:10 **OC23** BIOLOGICAL AGE-ACCELERATION ASSOCIATIONS WITH GRIP STRENGTH LEVEL AND LONGITUDINAL CHANGE: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY
Presenting author: N. Fuggle
Author: L. D. Westbury, N. Kitaba, J. W. Holloway & E. M. Dennison

10:20 **Presentation of the ESCEO-IOF Pierre Meunier Young Scientist Award** René Rizzoli

10:30 - 12:15 - Auditorium A
SCIENTIFIC SESSION V
Chairpersons: Şansin Tüzün, Ambrish Mithal

10:30 **Presentation of the IOF Olof Johnell Science Award** Nicholas C. Harvey

10:35 **Presentation of the ESCEO-IOF Young Investigator Awards** Jean-Yves Reginster, Nicholas C. Harvey

10:40 **Presentation of the 2025 ESCEO-Aging Clinical and Experimental Research Award**
Nicola Veronese, Valentina Corio, Jean-Yves Reginster

10:45 **Plenary Lecture**
MicroRNAs: novel risk predictors in musculoskeletal disease? Luigi Gennari

11:15 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

11:15 **OC24** TREATMENT-RELATED CHANGES IN TOTAL HIP BONE MINERAL DENSITY AND FRACTURE RISK REDUCTION FOR TRIALS WITH ACTIVE CONTROL AND SEQUENTIAL THERAPY: THE FNIH-ASBMR-SABRE PROJECT
Presenting author: T. Vilaca
Authors: L. Lui, M. Schini, S. Ewing, A. Thompson, E. Vittinghoff, D. C. Bauer, D. M. Black & M. L. Bouxsein

11:25 **OC25** THE PREVALENCE OF VERTEBRAL FRACTURES AND ASSOCIATED FACTORS IN THE GAMBIA, ZIMBABWE AND SOUTH AFRICA
Presenting author: K. Ward
Authors: L. Gates, C. M. Pearse, A. Burton, T. Manyanga, M. K. Jallow, B. Cassim, C. Grundy, H. Wilson, B. Mbanjwe, F. Paruk, Y. Madele, E. M. Clark, R. A. Ferrand, N. J. Crabtree & C. L. Gregson

11:35 **OC26** ENHANCING FRACTURE RISK PREDICTION: A COHORT-SPECIFIC MODEL INTEGRATING FRAXPLUS® VARIABLES FOR IMPROVED ACCURACY AND RECLASSIFICATION
Presenting author: M. Zoulakis
Authors: H. Johansson, N. C. Harvey, K. F. Axelsson, H. Litsne, L. Johansson, M. Schini, L. Vandeput, E. V. McCloskey, J. A. Kanis & M. Lorentzon

11:45 **OC27** ENGAGEMENT WITH AND TOLERABILITY OF AUGMENTED REALITY (AR) EXERGAMES AMONG OLDER WOMEN WITH OSTEOPOROSIS: RESULTS FROM A CLINICAL TRIAL
Presenting author: E. Thuilier
Authors: J. J. Carey, B. Whelan, M. Fitzgerald, J. Dingliana, M. Dempsey, S. Biggins & A. Brennan

11:55 **OC28** EFFECTS OF ANTIDIABETETIC TREATMENTS ON FRACTURE RISK
Presenting author: G. Cavati
Authors: F. Pirrotta, E. Ceccarelli, G. Dipasquale, M. Garofalo, P. Cardamone, D. Merlotti & L. Gennari

12:05 **OC29** GLP-1 RECEPTOR AGONISTS AND RISK OF BONE FRACTURES IN ELDERLY PEOPLE WITH TYPE 2 DIABETES
Presenting author: P. Rotman-Pikielny
Authors: M. Kasher Meron, T. Hornik-Lurie & G. Twig

12:15 - 13:45 - Auditorium A
SPONSORED LUNCH SYMPOSIUM
See details on the Sponsored Sessions Section

12:15 - 13:45 - Auditorium B
SPONSORED LUNCH SYMPOSIUM
See details on the Sponsored Sessions Section

14:00 - 15:00
POSTER VIEWING SESSION II

14:00 - 15:00
MEET-THE-EXPERT SESSION

MR1 **Vaccination and musculoskeletal disorders** Stefania Maggi

MR2 **Osteoporosis management in transgender patients** Jean-Marc Kaufman

MR3 **Is there a role for SYSADOAs in the management of osteoarthritis ?** Olivier Bruyère

MR4 **Biochemical markers of bone turnover: when and which?** Etienne Cavalier

14:00 - 15:00 - Podium
ORAL PRESENTATIONS OF SELECTED POSTERS
Chairperson: Elizabeth M. Curtis

14:00 **OP11 - P1425** EVALUATING THE PRAGMATISM OF SARCOPENIA CLINICAL TRIALS USING PRECIS-2: A SYSTEMATIC REVIEW
Presenting author: S. Van Heden
Authors: Z. Baoubbou, D. Sanchez-Rodriguez & C. Beaudart

14:06 **OP12 - P1387** REFINING EARLY DETECTION OF LOW BONE MINERAL DENSITY: A DEEP LEARNING MODEL FOR OSTEOPENIA SCREENING USING CHEST RADIOGRAPHS
Presenting author: S. Park
Authors: J. Park, M. Kim & H.-J. Bae

14:12 **OP13 - P147** CALCIUM ISOTOPE RATIOS IN SERUM INFORM ON SKELETAL CALCIUM BALANCE IN PATIENTS ON DIALYSIS
Presenting author: A. Eisenhauer
Authors: R. Shroff, M. Müller, A. Heuser, A. Kolevica, P. D´haese, I. Jochmans, E. Cavalier & P. Evenepoel

14:18 **OP14 - P1025** ASSOCIATIONS BETWEEN BODY COMPOSITION, EXERCISE, DIET, SHORT-CHAIN FATTY ACIDS, AND BONE LOSS IN EARLY POSTMENOPAUSAL WOMEN
Presenting author: M. Vilar Geraldi
Authors: G. Gregori, L. Johansson, U. Hjertonsson, E. Brättemark & M. Lorentzon

14:24 **OP15 - P144** CALCIUM ISOTOPES AS A NOVEL BIOMARKER FOR VASCULAR CALCIFICATION IN CKD: IMPLICATIONS FOR OSTEOPOROSIS MANAGEMENT
Presenting author: A. Dosseto
Authors: A. Fuller, A. Borst, T. Tacail, K. Lambert & H. Cheick Hassan

14:30 **OP16 - P776** FILLING GAPS IN TELEREHABILITATION: VALIDATING REMOTE SYNCHRONOUS AND ASYNCHRONOUS ASSESSMENTS OF PERFORMANCE-BASED OUTCOMES
Presenting author: Z. Boos
Authors: K. Mullen, L. Muhammad, M. K. Alshahrani & D. Pinto

14:36 **OP17 - P736** THE FIRST COMPARISON OF HIP FRACTURE INCIDENCE ACROSS 4 COUNTRIES IN AFRICA
Presenting author: K. Ward
Authors: C. L. Gregson, H. Wilson, A. Burton, M. K. Jallow, B. Trawally, L. S. Gates, T. Manyanga, J. Masters, R. A. Ferrand, M. Costa & K. Marenah

14:42 **OP18 - P498** DIFFERENTIAL ANALYSIS OF LUMBAR SPINE BONE MINERAL DENSITY AND TRABECULAR BONE SCORE IN HYPOPHOSPHATASIA PATIENTS WITH BIALLELIC VS MONOALLELIC ALPL GENOTYPE
Presenting author: F. Genest
Authors: K. Hind, M. De Gruttola, D. Hans & L. Seefried

14:48 **OP19 - P538** WHICH THRESHOLD VALUES OF CROSSLAPS TO TARGET TO PREVENT BONE LOSS AT 1 AND 2 YEARS AFTER DENOSUMAB DISCONTINUATION. THE REOLAUS STUDY
Presenting author: G. Liebich
Authors: E. Gonzalez-Rodriguez & O. Lamy

14:54 **OP20 - P1044** ABALOPARATIDE INCREASES DISTAL FEMUR BMD POST TOTAL KNEE ARTHROPLASTY
Presenting author: N. Binkley
Authors: D. Krueger, G. Borchardt, B. Nickel & P. A. Anderson

14:00 - 15:00 - MR10
EDUCATIONAL LECTURE
Osteoporosis in inflammatory rheumatic musculoskeletal diseases (iRMDs) Giovanni Adami

14:00 - 15:00 - MR5
EUGMS-ESCEO SYMPOSIUM
Fragility fractures: One size fits all?
Chairpersons: Nathalie van der Velde, Alvaro Casas Herrero

- Preventing fragility fractures in the oldest old: special considerations? Nathalie van der Velde
- Preventing fragility fractures: similarities and differences in approaches between LMICs and Europe Celia Gregson
- Integrating fall risk prevention within fracture management: practical steps to optimize implementation Tahir Masud

14:00 - 15:00 - MR6
ESCEO-OARSI JOINT SYMPOSIUM
Early knee osteoarthritis: Classification criteria for research and diagnostic criteria for clinical use
Chairpersons: Jean-Yves Reginster, Martin Englund

- Classification criteria of early-stage symptomatic knee osteoarthritis: updates of the OARSI initiative Armaghan Mahmoudian
- Diagnostic criteria for early knee osteoarthritis: Opportunities and challenges Jos Runhaar

14:00 - 15:00 - MR7
ESCEO SYMPOSIUM
Novel approaches to the stratified management of knee osteoarthritis: State of the art
Chairpersons: Ali Mobasheri, Roland Chapurlat

- The delineation of endotype and phenotype to identify the patients with knee osteoarthritis who should be treated Philip Conaghan
- The role of biomarkers (imaging, biological) to identify the patients with knee osteoarthritis who should be treated Francis Berenbaum
- Discussion leader Ali Mobasheri, Roland Chapurlat, Philip Conaghan, Francis Berenbaum

14:00 - 15:00 - MR8
EDUCATIONAL LECTURE
Biosimilars in osteoporosis management
Stuart L. Silverman

15:00 - 16:45 - MR5
COMMITTEE OF SCIENTIFIC ADVISORS SPECIAL SESSION: FUTURE OPPORTUNITIES IN THE MANAGEMENT OF OSTEOPOROSIS

Chairpersons: Eugene McCloskey, Etienne Cavalier

- Barriers and solutions for global access to osteoporosis management John A. Kanis
- Approaches to risk-based Population Screening: Insights from the ROSE study and FREM development in Denmark Katrine Rubin
- The Fact and Fiction of AI in Osteoporosis Nicholas Fuggle

15:00 - 17:00 - Auditorium A
SCIENTIFIC SESSION VI

Chairpersons: Patricia Clark, Radmila Matijevic

15:00 **Plenary Lecture**
Novel concepts: assessment of intrinsic capacity
Bess Dawson-Hughes

15:30 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

15:30 **OC30** EFFECTS OF A REMOTELY-DELIVERED FUNCTIONAL RESISTANCE AND IMPACT TRAINING PROGRAM VERSUS WALKING ON PHYSICAL FUNCTION IN OLDER ADULTS WITH OBESITY UNDERGOING CALORIC RESTRICTION: A 6-MONTH RANDOMISED CONTROLLED TRIAL
Presenting author: D. Scott
Authors: P. Jansons, C. Glavas, S. Sood, M. Hunegnaw, J. Ryan, J. Mesinovic, R. Daly, A. Zengin, E. George & P. Ebeling

15:40 **OC31** MATERNAL BONE MINERAL DENSITY AT 4 YEARS POST-DELIVERY IS NOT AFFECTED BY PREGNANCY VITAMIN D SUPPLEMENTATION
Presenting author: R. Moon
Authors: S. D'Angelo, E. M. Curtis, K. A. Ward, K. M. Godfrey, C. Cooper & N. C. Harvey

15:50 **OC32** USING PROBIOTICS TO SUPPORT BONE HEALTH IN POSTMENOPAUSAL WOMEN: A RANDOMIZED, DOUBLE-BLIND, PARALLEL, PLACEBO-CONTROLLED, MULTI-CENTRE STUDY
Presenting author: J. Yumol
Authors: S. Binda, V. Nagulesapillai & W. E. Ward

16:00 **OC33** RELATIONSHIPS BETWEEN MICRORNAS AND CORTICAL BONE IN CHRONIC KIDNEY DISEASE
Presenting author: T. L. Nickolas
Authors: C. Metzger, N. Chen, D. Mcmahon, M. Allen, R. Moyses & S. Moe

16:10 **OC34** FRAGILITY FRACTURES MANAGEMENT IN PREGNANCY BY REMS TECHNOLOGY: THE PREGNANCY OSTEOPOROSIS INITIATIVE (POI)
Presenting author: V. Degennaro
Authors: T. Bignardi, A. Bulfoni, I. Cetin, A. Cromi, G. Franzoni, F. Ghezzi, M. Ossola, H. Valensise, T. Ghi & M. L. Brandi

16:20 **OC35** INTERACTIONS BETWEEN CALCIUM AND PROTEIN INTAKES, AND OSTEOPOROSIS MEDICATIONS ON HIP BONE STRENGTH: AN OBSERVATIONAL STUDY IN OLDER WOMEN
Presenting author: M. Papageorgiou
Authors: Y. Gugler, S. Ferrari, R. Rizzoli, P. Zysset & E. Biver

16:30 **Plenary Lecture**
Osteoimmunology: a legacy discipline?
Willem Lems

17:00 - 18:00 - Auditorium B
EDUCATIONAL LECTURE

Pregnancy - and lactation-related osteoporosis
Maria Luisa Brandi

17:00 - 18:00
NON-SPONSORED SYMPOSIA

MR1 **Bone, Muscle and Fat interractions in neurodisabled persons**

Chairperson: Ifigenia Kostoglou-Athanassiou

- Introduction in bone, muscle and fat interactions Ifigenia Kostoglou-Athanassiou
- (Osteo)Sarcopenia and sarcopenic obesity in neurodisabled individuals Yannis Dionyssiotis
- Sarcopenia in Hemiplegia and Stroke Maria Papadatou
- Discussion in bone, muscle and fat interactions Ifigenia Kostoglou-Athanassiou

MR2 **From bone metastasis to osteoporosis - Joint IOF and CABS Symposium (Cancer and Bone Society)**
Chairpersons: Patricia Juarez-Camacho, Peyman Hadji

- Decoding skeletal complications in bone metastases Patricia Juarez-Camacho
- Treatment of bone metastasis – state of the art 2025 Cyrille Confavreux
- CTIBL – size of the problem and treatment options? Peyman Hadji

MR3 **The Latest in Artificial Intelligence in Osteoporosis: From Large Language Models to Computer Vision**
Chairperson: Nicholas Fuggle

- What are 'A Large Language Models' and how can they be deployed in osteoporosis? Nicholas Fuggle
- Health Equity considerations when using AI in Clinical Practice Joe Alderman
- AI for vertebral fracture screening: A UK perspective – An update from the ADOPT study Kassim Javaid

MR4 **Improving and Enhancing DXA Practices; A joint symposium with ISCD and IOF**
Chairpersons: Nicholas C. Harvey, William D. Leslie

- DXA Quality, Common Errors and Clinical Impact Neil Binkley
- The ABCs of DXA and How to Improve fractures Diane Krueger
- Expanding DXA Functionality to Enhance Clinical Care Kate Ward

MR5 **The challenge of oral health in patients with osteoporosis: A pragmatic approach**
Chairpersons: Jorge Luis Alberto Morales Torres, Osvaldo Daniel Messina

- Introduction: Oral health and bone health. A quotidian dilemma? Jorge Luis Alberto Morales Torres, Osvaldo Daniel Messina
- The overall impact of oral health in the elderly Hugo Gutiérrez Hermosillo
- Osteoporotic fractures and MRONJ: Sobering statistics Francisco Fidencio Cons Molina
- Improving oral screening: the Oral Health Assessment Tool Jorge Luis Alberto Morales Torres
- Discussion: Whose task is it to identify oral health?
- Conclusions Jorge Luis Alberto Morales Torres

MR6 **Skeletal fragility: The role of vitamin D and K in CKD patients**
Chairpersons: Maria Fusaro, Thomas L. Nickolas

- Vitamin D: from native to active form in CKD-associated osteoporosis Rosa Moyses
- Vitamin K: instructions for use in skeletal fragility Maria Fusaro
- The Statistician in detecting fraud and negligence in clinical trials Giovanni Tripepi
- Vitamin D in Skeletal Fragility: Clinical Case Hanne Jorgensen
- Discussion

MR7 **Breaking Barriers and Advancing Bone Health for People with Intellectual Disability**
Chairperson: Éilish Burke

- The Silent Epidemic of Osteoporosis among Adults with Intellectual Disabilities Éilish Burke
- Exploring Dietary Deficiencies in Adults with Intellectual Disabilities Contributing to Poor Bone Health Judy Ryan
- Sedentary Behaviour and its Implications for the Bone Health of those with Intellectual Disability Louise Lynch
- Innovative Solutions: The Echolight Rems Device for Accessible Bone Health Screening for Adults With Intellectual Disability Anne Power

MR8 **New horizons in sarcopenia: From pediatric reference values to emerging therapeutic advances**
Chairpersons: Gulistan Bahat, Radmila Matijevic

- Recognizing and managing Sarcopenia in Children: Reference muscle mass values from a European cohort Taha Kizilkurt
- Molecular Insights, Pathways and Candidates for Novel Interventions in Sarcopenia Serdar Ozkok

08:00 - 09:00

NON-SPONSORED SYMPOSIA

MR1 Update on the Study to Advance BMD as a Regulatory Endpoint (SABRE): What Might Osteoporosis Trials look like in the Future?

Chairperson: Mary Bouxsein

- Challenges of Clinical Trials for New Osteoporosis Medications Eugene McCloskey
- Evidence Supporting the Use of BMD as a Surrogate Endpoint for Fractures Richard Eastell
- Considerations for designing trials that use BMD as a Primary EndpointKyphoplasty Dennis Black

MR2 Improving Women's Bone Health Throughout the Lifespan

Chairpersons: Adriana Orcesi Pedro, Maria Celeste Osório Wender

- Opening and Welcome from FEBRASGO Maria Celeste Osório Wender
- Bone Consequences of Premature Ovarian Insufficiency (POI) Jaime Kulak Jr.
- The Role of Hormone Therapy in the Management of Postmenopausal Maria Celeste Osório Wender
- Evaluation and management of osteopenia and osteoporosis in breast cancer survivors Adriana Orcesi Pedro

MR3 Perioperative Bone Optimization in Arthroplasty Candidates with Osteoporosis

Chairperson: Rafael Jimenez-Umbarila

- Updated Joint Positions on Perioperative Bone Optimization in Arthroplasty Candidates 2024 Roberto E. Lopez Cervantes
- Current Practices, Needs, and Challenges in Periprosthetic Bone Mineral Density Assessment: Towards Standardization J. Francisco Torres Naranjo
- Current Practices and Educational Needs in Perioperative Bone Optimization for Arthroplasty Candidates: Survey Results José Máximo Gomez-Acevedo

MR4 The intimate relationship between adipose and bone tissue

Chairperson: Yannis Dionyssiotis

- Adipose and bone tissue. A close relationship Ifigenia Kostoglou-Athanassiou
- Metabolic syndrome. A paradigm of the intimate relationship between adipose and bone tissue Panagiotis Athanassiou
- Metabolic syndrome and osteoporosis Yannis Dionyssiotis

Pre-Congress Symposium Abstracts

PRE-CONGRESS1

INTRODUCTION - OSTEOPOROSIS VS RENAL OSTEODYSTROPHY

P. Evenepoel[1]

[1]Department of Medicine, Division of Nephrology University Hospital Gasthuisberg, Leuven, Belgium

In patients with chronic kidney disease (CKD), optimal control of mineral and bone disorder (MBD) is important not only to preserve cardiovascular health, but also to prevent debilitating skeletal complications. Patients with CKD experience a multifold increased fracture risk compared to age and sex matched controls and the risk of mortality following a hip fracture is substantially higher. Most cumbersome, the treatment gap, being already huge in postmenopausal women is even more pronounced in patients with CKD. Lack of evidence from randomized controlled trials, fear for complications, and incomplete understanding of the complex pathophysiology of bone fragility in CKD fuel therapeutic inertia. Participants of the 2023 Madrid CKD-MBD KDIGO Controversies Conference raised the concern that the term ROD may represent a roadblock to managing fracture risk as it fosters an overly PTH- and calcium–phosphate-centric approach to bone disease management. Therapies focusing on these pathogenic drivers, however, failed to meet expectations. Conference participants argued that treatment of renal bone disease should be re-centered to the skeleton itself and that a change in terminology might facilitate this paradigm shift. The term CKD-associated osteoporosis was proposed to acknowledge and emphasize that ROD is a disorder of bone strength that increases fracture risk in the setting CKD. Diagnostic work up and therapy will be similar to what is proposed for other osteoporosis conditions, but need to be individualised with knowledge of CKD. While CKD-MBD biochemical abnormalities cannot be dissociated from the relevant clinical outcomes of bone loss and fractures, additional efforts are needed to better understand mechanisms by which uremia, altered gut and immune systems, inflammation, and medications affect the CKD-associated osteoporosis phenotype. The bone phenotype can be assessed by bone imaging and bone biomarkers. Within the new framework, the treatment targets of PTH should be considered in the context of bone phenotype. This makes sense if we consider that a key feature of hyperparathyroidism in CKD is a reduced and variable skeletal response to PTH. The metabolic bone component of CKD-associated osteoporosis is best evaluated by a bone biopsy. However, the key parameter of bone turnover, which has implications for treatment options, can be non-invasively assessed using bone turnover markers.

PRE-CONGRESS2

BONE HISTOLOGY - OSTEOPOROSIS VS RENAL OSTEODYSTROPHY

D. W. Dempster[1]

[1]Vagelos College of Physicians and Surgeons of Columbia University, New-York, United States

Histomorphometric analysis of the iliac crest bone biopsy is one of the most powerful techniques to study bone metabolism. It owes its strength to the ability to produce, high quality undecalcified sections of bone and the use of tetracycline antibiotics to provide dynamic assessment of bone formation rate, as well as disorders of mineralization. In the 1960's through the 1980's the technique was used widely in the clinical assessment of patients with bone disease. Nowadays, with the advent of bone densitometry and biochemical markers of bone turnover, the technique is rarely used in a clinical setting, except in the management of patients with renal osteodystrophy (RD).

In this setting, biochemical markers are poor predictors of bone turnover and densitometry does not distinguish between osteomalacia and other manifestations of RD. The biopsy has taught us that RD can present in several distinct forms: high bone turnover (osteitis fibrosa), osteomalacia, low turnover (adynamic bone) and mixed bone disease, commonly referred to under the umbrella of CKD-MBD. Concomitantly, patients with CKD-MBD also frequently present with osteoporosis.

The speaker will compare the histomorphometric profile of patients with osteoporosis in the setting of CKD-MBD with that in postmenopausal and age-related osteoporosis. He will also present examples of the effects of approved osteoporosis medications on bone structure and turnover in patients with CKD-MBD, as revealed in paired bone biopsies before and after treatment.

PRE-CONGRESS3

DIAGNOSIS: BIOCHEMISTRY & IMAGING – OSTEOPOROSIS VS. RENAL OSTEODYSTROPHY

T. L. Nickolas[1]

[1]David C. and Betty Farrell Professor of Medicine Chief, Division of Bone and Mineral Diseases Washington University School of Medicine, St. Louis, United States

Distinguishing osteoporosis from renal osteodystrophy remains a major challenge in clinical practice. While both conditions lead to bone fragility and an increased risk of fractures, their underlying pathophysiology differs, necessitating distinct diagnostic and therapeutic approaches.

Imaging techniques such as dual-energy X-ray absorptiometry (DXA) are widely used for assessing bone mineral density (BMD) and diagnosing osteoporosis and monitoring treatment efficacy. However, DXA alone cannot differentiate osteoporosis from the bone disorders associated with chronic kidney disease (CKD), including disorders of turnover and mineralization.

Biochemical markers offer a more nuanced, non-invasive approach

to distinguish these conditions. Serum parathyroid hormone (PTH) and bone turnover markers, such as bone-specific alkaline phosphatase (BSAP) and tartrate-resistant acid phosphatase 5b (TRAP5b), provide insight into bone remodeling activity. In CKD, abnormalities in calcium, phosphate, fibroblast growth factor-23 (FGF-23), and vitamin D metabolism further contribute to bone pathology.

Besides DXA, advanced imaging techniques, such as high-resolution peripheral quantitative computed tomography (HR-pQCT), trabecular bone score (TBS) and hip structural analysis, may help assess cortical and trabecular microarchitecture, potentially improving the differentiation between osteoporosis and renal osteodystrophy. Serial HR-pQCT imaging and PET/CT imaging may even provide insight into bone remodeling activity. However, these methods are not yet widely implemented in routine clinical practice.

A comprehensive diagnostic approach that integrates biochemical assessment with imaging findings is essential for more accurate non-invasive identification of bone disease in patients with CKD. This distinction is critical for guiding appropriate treatment strategies, as antiresorptive and anabolic therapies commonly used for osteoporosis may be contraindicated or require caution in patients with CKD-related bone disorders.

PRE-CONGRESS4

VASCULAR CALCIFICATION IN CHRONIC KIDNEY DISEASES- METABOLIC BONE DISEASES & ASSOCIATED OSTEOPOROSIS

Z. A. Massy[1,2]

[1]AURA (Association pour l'Utilisation du Rein Artificiel), Paris, France, [2]Centre for Research in Epidemiology and Population Health (CESP), Paris-Saclay University, Versailles Saint Quentin University, INSERM U1018, Clinical Epidemiology Team, Villejuif, and FCRIN INI-CRCT, Nancy, France

Chronic Kidney Disease (CKD) affects nearly 10% of the population. Individuals at all stages of CKD have a higher risk of developing cardiovascular calcification (CVC) and bone fragility. The latter is due to the CKD-associated bone and mineral disorder (CKD-MBD), frequently and age- and sex- dependent osteoporosis.

CVC presence is correlated with higher cardiovascular and all-cause mortality risk. Clinical, epidemiological and imaging evidence links arterial and valvular calcifications to arterial stiffness, valve stenosis and/or regurgitation in patients with CKD. CVC results from complex cellular interactions involving the endothelium, vascular/valvular cells (i.e., vascular smooth muscle cells, osteoblast-like cells, valvular interstitial cells and resident fibroblasts), and monocyte-derived macrophages. CKD is associated with various metabolic dysregulations such as inflammation and accumulation of uremic toxins, favoring the genesis and the progression of CVC. CKD, which is a model of accelerated aging, is but one key factor for the development of CVC in such patients.

Bone fragility is due to reduced bone quantity, reflected by decreased bone mineral density (BMD), as well as impaired bone quality, reflected by abnormal bone turnover, mineralization, matrix composition, collagen fiber arrangement, and microarchitecture. CKD related osteoporosis is an additional mechanism predisposing to increased fracture risk, and a higher risk of fracture-associated mortality. The incidence of fractures increases with the progression of CKD, in favor of a CKD-specific bone disorder . Since the relationship between BMD and bone fracture is less marked in patients with CKD than in the general population the predictive value of low BMD for type of bone disease and fracture risk is lower in those with kidney failure. This is due to a more complex pathophysiology of bone fragility in CKD, resulting from a combination of age-related factors, disturbances of mineral and endocrine metabolism, sex-related hormonal deficiencies, uremic toxins and inflammation.

A large number of studies on CKD patients have demonstrated associations between CVC and bone pathologies. The nature of these associations is not yet completely understood. It could result from 1) a direct action of molecules secreted by bone on vascular structure and function; 2) compromised skeletal blood supply secondary to alterations of bone vessel structure and reduced blood flow; and 3) common factors acting on both bone remodeling and CVC. Uremic toxins, senescence, and inflammation are probably the principal common pathways linking bone and arterial pathologies. Some of these common risk factors are modifiable and represent potential targets for intervention.

PRE-CONGRESS5

CURRENT THERAPEUTIC OPTIONS – OSTEOPOROSIS (OP) & RENAL OSTEODYSTROPHY (ROD)

S. Mazzaferro[1]

[1]Sapienza University of Rome, Roma, Italy

In agreement with the definition of OP, ROD is now regarded as a secondary type of OP. Chronic renal failure patients (CRF) experience a long clinical history of progressive metabolic derangements in mineral and bone homeostasis, with variable degrees of bone material properties derangements and bone fragility. Importantly, the different types of substitutive therapies (hemo- or peritoneal dialysis or transplantation) can differently impact bone disease. Accordingly, the first step when evaluating OP & ROD is to aim at phenotyping the CRF patients by means of biomarkers and instrumentals. Predictably, lower glomerular filtration rates (GFR) will be associated with more severe metabolic derangements, but also with lower renal excretion of bone markers. For this reason, the diagnostic value of serum PTH, whose levels are affected by reduced renal excretion and by sub-optimal standardization of assay methods, has been challenged and suggested to reflect parathyroid hyperplasia better than bone turnover. Thus, type and severity of ROD, if not by the gold-standard bone biopsy, should be evaluated by bone biomarkers unaffected by reduced renal excretion. Namely, bone formation should be evaluated by serum levels of bone specific alkaline phosphatase (BALP) and intact procollagen type I N-terminal peptide (PINP),

while bone resorption should be estimated with tartrate resistant acid phosphatase (TRAP5b). Bone mineral density, which underestimates fracture risk in CRF, is nonetheless recommended for screening and therapeutic follow-up above the age of 50 years in males and females. Vertebral morphometry will help identifying asymptomatic fractures thus further characterizing patients. Acid base balance and concomitant drugs will complete the clinical assessment. Therapeutic strategies will first aim at controlling secondary hyperparathyroidism and then at affecting bone turnover by choosing among the different anti-osteoporotic drugs which are capable of modifying bone formation or bone resorption. For these drugs, specific pharmacokinetic considerations are necessary according to the degree of residual GFR and to the specific requirements of renal patients to avoid side effects. Importantly, other contributing elements of increased fracture risk (e.g. lifestyle, diet and drugs) should be taken into account. As a whole, tailoring therapy is the main challenge in patients with CRF associated OP.

PRE-CONGRESS6

INTERMITTENT PTH ADMINISTRATION IN THE MANAGEMENT OF CKD-MBD

M. Pazianas[1]

[1]Center for Translational Medicine and Pharmacology, Icahn Sinai School of Medicine at Mount Sinai, New York, United States

Osteoporosis and chronic kidney disease-metabolic bone disease (CKD-MBD) often coexist, particularly in the elderly. Intermittent parathyroid hormone (PTH) therapy is the standard anabolic treatment for osteoporosis and is also used to manage adynamic bone disease, a common form of renal osteodystrophy.

Phosphorus retention—a hallmark of CKD—begins early, even before hyperphosphatemia develops, followed by compensatory rises in fibroblast growth factor 23 (FGF-23) and later PTH to enhance phosphate excretion. However, phosphate retention alone does not fully explain CKD-MBD. Equally critical is the **delayed PTH response to calcium-phosphate imbalances** in driving the cascade of events leading to CKD-MBD. It is also imperative to recognize that the hyperparathyroidism seen in advanced CKD represents **secondary hyperparathyroidism (2° HPT)**—a reactive process, not a primary disorder.

The management of CKD-MBD remains a significant clinical challenge, as the effectiveness of current therapeutic regimens to prevent and treat CKD-MBD is limited. Therefore, targeting the delayed PTH response in the early stages of phosphorus retention may offer a more effective strategy for preventing disease progression.

Administering intermittent PTH in patients with early stages CKD could mitigate phosphorus retention before compensatory mechanisms are triggered. This early intervention may help limit or even avert the rise of FGF-23 and PTH, both of which are key contributors to the skeletal and cardiovascular complications associated with CKD. Several studies support this potential outcome. Additional benefits may include the anabolic effects on bone from intermittent PTH administration, contrasting with the catabolic effects observed with continuously elevated PTH concentrations, as well as the prevention of 2o HPT.

WORLD CONGRESS ON OSTEOPOROSIS, OSTEOARTHRITIS AND MUSCULOSKELETAL DISEASES

Abstract Book

Opening Ceremony Abstracts

OPENING1

REVIVAL OF THE EUROPEAN MEDICINES AGENCY ACTIVITIES ORIENTED TOWARDS OLDER PEOPLE

F. Cerreta[1]

[1]Geriatrics - HTA collaboration -Digital technologies, Evidence Generation Department, Amsterdam, Netherlands

In 2011 the EMA published its geriatric medicines strategy, and in 2018 was the first major regulatory agency worldwide to issue guidance on considering frailty rather than chronological age as a stratification factor in registration clinical trials (*Reflection paper on physical frailty: instruments for baseline characterisation of older populations in clinical trials*). Additional guidance paying specific attention to age-adapted packaging and formulation followed. The last 5 years have seen a slowing down of activity due to resource challenges due to Brexit and Covid. At the end of 2024 a new group of geriatric experts was nominated to support the EMA activities. Efficiency and targeted actions are clearly important in a resource-poor environment: how can healthcare professionals and patients support an effective implementation of the Geriatric Strategy to ensure that that medicines for older people are of high quality and appropriately researched and evaluated throughout their lifecycle?

OPENING2

NEW PERSPECTIVES IN THE MANAGEMENT OF PATIENTS WITH OSTEOPOROSIS

W. H. Dere[1]

[1]Professor Emeritus, University of Utah, Salt Lake City, United States

Osteoporosis is a bone disease affecting a growing number of individuals globally. Its underlying pathologic processes, such as estrogen deficiency or the effects of aging on the immune system, impact multiple organ systems, thus therapeutic interventions targeted for one organ system may be beneficial or detrimental to others. Furthermore, the clinical impact of aging may not be consistent across the organ systems, hence targeted interventions for osteoporosis should continue to be warranted in clinical practice since the majority of those at high risk of fracture remain untreated or inadequately treated.

Epidemiologic studies, access to large data sets like UK Biobank, and reassessment of earlier large trials give us insights into the potential value of drug targets of the past, like estrogen-based hormone replacement, calcitonin, and beta-blockers. New methods of drug delivery have or are being evaluated using currently available molecules such as oral PTH 1-34 and transdermal abaloparatide, though differences in the pharmacokinetic profiles seem to provide pharmacodynamic effects which differ from subcutaneous administration. Biosimilars such as denosumab biosimilar (CP-T41) will soon be available. These offer potentially more affordable therapies for those suffering for osteoporosis.

Clinical syndromes such as osteo-sarcopenia, and sarcopenic obesity, and the current use of gastric bypass surgery and the impact of expanded use of incretins give us insights into potential drug targets. Our greater understanding of myokines, osteokines, and adipokines provide biological plausibility to these inter-organ relationships. The strong correlation of aging to bone fragility gives us additional potential ways to increase bone formation and attenuate bone loss. Bone specific senescence-associated secretory phenotype cells (SASP) and their impact on neighboring cells will be reviewed.

Finally, the genetics revolution, with data from large population cohorts or family-based studies remain an attractive source of drug targets. Furthermore, advances in the antibody platforms to include targeting two or more offending proteins allow greater versatility and potentially improve benefit-risk profiles for molecules in development. However, at this time, the ability to identify older individuals at highest risk of fracture through polygenic risk scores or other genetic markers seems limited.

OPENING3

HIGHLIGHTS OF THE GALLERIA BORGHESE

F. Cappelletti[1]

[1]Galleria Borghese, Director, Rome, Italy

The Galleria Borghese stands as one of the most extraordinary art collections in the world, housed within a 'villa of delights' designed to showcase its prestigious holdings. Established under the patronage of Cardinal Scipione Caffarelli Borghese (1577–1633) during the papacy of Paul V Borghese (1605–1621), the collection rapidly grew to become one of the most significant of its time. Through strategic acquisitions and an ambitious architectural vision, Scipione assembled an unparalleled array of masterpieces.

The Museum today displays works by some of the most renowned artists of the Renaissance and Baroque periods, including Gian Lorenzo Bernini, Caravaggio, Raphael, Titian, and Antonio Canova, among others. It holds the most important collection of Bernini's sculptures and a remarkable selection of Caravaggio's paintings, alongside ancient sculptures, bas-reliefs, and mosaics. The collection is presented in its original setting across twenty ornately decorated rooms, offering an immersive experience that reflects its historical grandeur.

This presentation explores the unique history, artistic significance, and curatorial approach of the Galleria Borghese, shedding light on its role in preserving and celebrating a heritage of exceptional artistic value.

OP1 - P815

OBESITY IS RELATED TO POORER FUNCTIONAL OUTCOMES AMONG INDIVIDUALS WITH RADIOGRAPHIC KNEE OSTEOARTHRITIS: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], F. Laskou[1], F. Kirkham-Wilson[1], G. Bevilacqua[1], N. R. Fuggle[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objective: Osteoarthritis is the most common joint condition, with obesity an established risk factor. Although osteoarthritis patients are advised to maintain a healthy weight, this is often challenging, especially when pain limits activity. We examined relationships between obesity and functional outcomes in older community-dwelling adults with radiographic knee osteoarthritis.
Material and Methods: We studied 101 men and 115 women, aged 71-80 years, from the UK Hertfordshire Cohort Study. Participants completed a questionnaire that ascertained information on health-related quality of life (EuroQol-5D) and pain according to the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Knee radiographs were taken and classified according to Kellgren and Lawrence (K&L) criteria; analysis was restricted to individuals with radiographic knee osteoarthritis (K&L score ≥2 on either knee). Balance, walking and chair rise scores were assigned, depending on performance, and used to derive the Guralnik physical performance score. Binary and ordinal logistic regression were used to examine obesity status in relation to functional outcomes after adjustment for age and sex.
Results: Prevalence of obesity (BMI≥30kg/m^2) was 26.7% among men and 44.3% among women. Odds of having a higher Guralnik score were lower among obese participants compared to those who were not obese (p<0.001). Being obese was associated with greater odds of reporting at least some problems in the following EuroQol domains compared to those who were not obese: mobility (odds ratio [95% CI]: 4.73 [2.52, 8.85], p<0.001); self-care (3.40 [1.44, 8.02], p=0.005); usual activities (4.38 [2.31, 8.30], p<0.001); and pain (2.27 [1.24, 4.15], p=0.008). Obesity was also related to increased odds of having a WOMAC pain score > 0 (2.21 [1.24, 3.95], p=0.007).
Conclusions: These findings highlight the strong relationships between obesity and functional outcomes in community-dwelling older people with radiographic knee osteoarthritis, and reinforce the need for support to achieve appropriate weight management.

OP2 - P700

DRIVING KNEE OSTEOARTHRITIS STRUCTURAL PROGRESSOR PROGNOSIS INTO THE NEXT GENERATION: LEVERAGING MACHINE/DEEP LEARNING, MICRORNA AND MAGNETIC RESONANCE IMAGING

A. Jamshidi[1], O. Espin-Garcia[2], T. G. Wilson[3], I. Loveless[3], J.-P. Pellletier[1], S. A. Ali[4], J. Martel-Pelletier[1]

[1]Osteoarthritis Research Unit/University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada, [2]Department of Epidemiology and Biostatistics, University of Western Ontario; Dalla Lana School of Public Health and Department of Statistical Sciences, University of Toronto; Department of Biostatistics, Schroeder Arthritis Institute; Krembil Research In, Toronto, Canada, [3]Henry Ford Health + Michigan State University Health Sciences, Detroit , United States, [4]Henry Ford Health + Michigan State University Health Sciences; Center for Molecular Medicine and Genetics, Detroit , United States

Objective: Predicting knee osteoarthritis (OA) patients at risk of rapid structural progression remains challenging. Circulating micro-RNAs (miRNAs) showed promise as biomarkers for stratifying such patients. This study aimed to develop a miRNA-based prognosis model to identify knee OA structural progressors using machine/deep learning, with structural progressors defined via a methodology using MRI and X-ray data[1].
Methods: Baseline serum miRNAs from 152 Osteoarthritis Initiative (OAI) participants were isolated, sequenced, and used for model development. Dimensionality reduction was performed to identify the most informative miRNAs within the initial set of 456. Key miRNAs and OA determinants, including age, sex, BMI, and race (Caucasian and African American), were selected after a comprehensive exploration of 7 feature selection machine learning. The final model was developed after extensively exploring an array of machine/deep learning algorithms. The performance of the models was assessed using AUC, accuracy, sensibility, and specificity. Validation employed an independent cohort of 30 OAI baseline plasma samples.
Results: Feature clustering reduced the initial set to 107 miRNAs. Elastic Net was identified as the optimal feature selection model. The final prediction model utilized an Artificial Neural Network (ANN) comprised of age and four miRNAs, hsa-miR-556-3p, hsa-miR-3157-5p, hsa-miR-200a-5p, and hsa-miR-141-3p, and achieved an excellent performance (AUC, 0.94; accuracy, 0.84; sensitivity, 0.89; specificity, 0.75). The ANN model validation analysis confirmed the model's robustness (AUC, 0.81; accuracy, 0.83; sensitivity, 0.71; specificity, 0.94).
Conclusion: This study identifies, for the first time, a microRNA signature capable of predicting rapid structural progression in knee OA patients. The model demonstrated strong performance and was validated in an independent cohort, showcasing its potential for generalization. The translational potential of this prediction model is significant, as it will provide clinicians with a valuable tool for personalized and targeted treatment strategies as well as assist early identification of high-risk structural pro-

gressor patients for inclusion in trials.

EFFECTIVENESS OF PRESCRIPTION GLUCOSAMINE SULFATE (PGS) IN A COHORT OF FILIPINO PATIENTS WITH MILD-MODERATE KNEE OSTEOARTHRITIS (OA)

J. J. Lichauco[1], C. Walker[2], R. Chiaese[3], H. Scott[4], S. Venugopal[5]

[1]Department of Rheumatology at St. Luke's Medical Center, Manila, Philippines, [2]Global Medical Affairs, Viatris, United Kingdom, [3]Global Medical Affairs, Viatris, Italy, [4]Global Clinical Development, Viatris, United Kingdom, [5]Global Clinical Development, Viatris, India

Objective

To evaluate the effectiveness of pGS in reducing the severity of pain in patients with mild to moderate knee OA pain.

Materials and Methods

A multicenter, low interventional parallel-group 8-week study in Manila, Philippines recruited participants aged 50-70 years with mild to moderate knee OA(diagnosed using American College of Rheumatology criteria). All patients had baseline Western Ontario and McMaster Universities Osteoarthritis Index(WOMAC) score≥40, a BMI<29.99 and received pGS for 4 weeks. Thereafter patients either remained on monotherapy for a further 4 weeks or had their pain relief supplemented with celecoxib 200 mg OD depending on patient preference and their response to treatment with pGS at 4 weeks. This abstract focuses on the pGS monotherapy arm only. The primary end point was reduction from baseline in knee pain severity at week 8 based on the WOMAC Pain and visual analogue scale(VAS)(0 to 100mm) scores.

Results

Of 324 screened subjects, 281 treated; 244 completed 8 weeks of pGS treatment. At week 8, WOMAC pain scores showed a significant reduction (least square mean (LSM) change of -11.96,P< 0.0001)(Table 1)(Figure 1A). Similarly, VAS scores showed a significant reduction compared to baseline(LSM change of -56.36,P< 0.0001)(Table 1)(Figure 1B).

	Baseline	Week 8
	pGS(n=279)	pGS(n=244)
WOMAN pain score(SD)	13.5(2.63)	1.6(2.10)
WOMAN pain score LSM change		-11.96(95%CI;-12.26 to-11.67)
VAS score(SD)	68.4(10.89)	11.9(12.33)
VAS score LSM change		-56.36(95%CI; -58.05,-54.67)

Table.1: WOMAC pain outcomes mean value(SD) and VAS(SD) score in Full Analysis Set(FAS) population(n=279) with knee OA receiving pGS(1500 mg QD) for 8 weeks

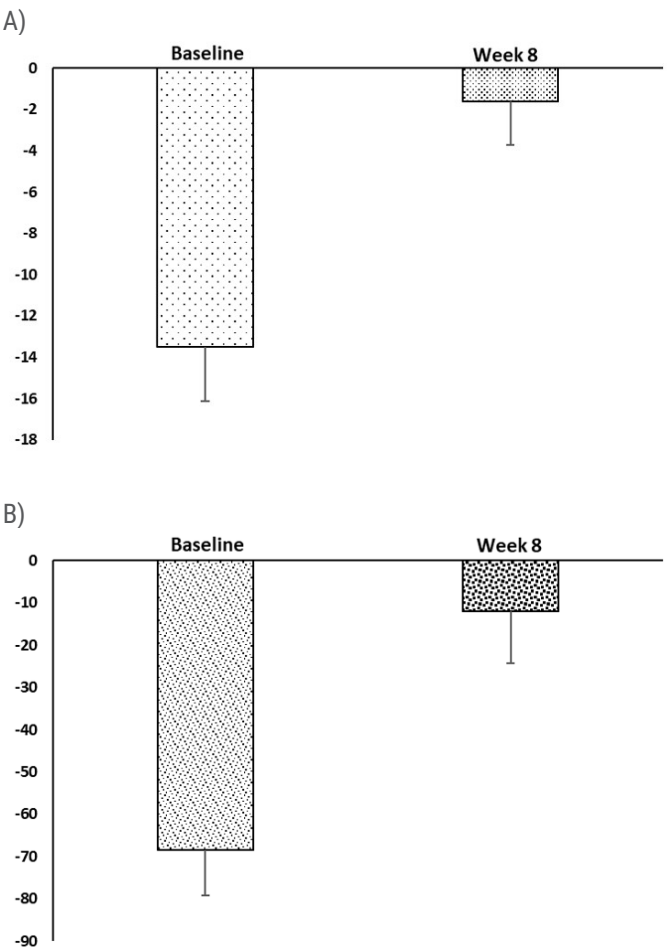

Fig.1: knee OA patients(FAS population,n=279) treated with pGS; A)WOMAC pain index at baseline and week 8(P<0.0001) in knee OA patients treated with pGS; B)VAS score at baseline and week 8(P<0.0001) .

Conclusion

Prescription Glucosamine Sulfate (pGS) demonstrated a significant reduction in knee OA pain in patients with mild to moderate osteoarthritis at the end of 8 weeks.

OP4 – P1138

SAFETY OF ANTI-OSTEOARTHRITIS MEDICATIONS: OUTCOMES OF A SYSTEMATIC LITERATURE REVIEW OF POST-MARKETING SURVEILLANCE STUDIES

G. Honvo[1], L. Lengelé[2], M. Alokail[3], N. Al-Daghri[4], J.-Y. Reginster[3], O. Bruyère[1]

[1]Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium, [2]Metabolism and Nutrition Research Group, Louvain Drug Research Institute, UCLouvain, Université catholique de Louvain, Sint-Lambrechts-Woluwe, Belgium, [3]Protein Research Chair, Biochemistry Department, College of Science, King Saud University, Riyadh, Saudi Arabia, [4]Chair for Biomarkers of Chronic Diseases, College of Science, King Saud University, Riyadh, Saudi Arabia

Objective: To identify all the published post-marketing safety surveillance (PMS) studies on anti-osteoarthritis (OA) medications, and to describe the characteristics and the main findings of these studies.

Methods: This study followed the Cochrane guideline for systematic reviews (SR) of interventions. The Medline, CENTRAL, Scopus, and TOXLINE databases were comprehensively searched from inception to November 2023, to include all PMS studies on any anti-OA medications. The outcomes of the review were any adverse events (AEs) reported in the included studies.

Results: From 16,990 records retrieved from literature search, 59 articles were included. Most studies investigated non-steroidal anti-inflammatory drugs (NSAIDs, 27 studies, 28 reports) and intra-articular hyaluronic acid (IAHA, 16 studies). Symptomatic slow-acting drugs for osteoarthritis (SYSADOAs) were assessed in 7 studies, and corticosteroid injections in 4 studies. Opioids and "herbal mixtures and other compounds" each were investigated respectively in 3 and 2 studies. Most studies were cohort studies (n = 44), others were case reports or case series (n = 12), randomized controlled trials (RCTs, 2 reports of a same trial), or case-control study (n = 1). The most commonly reported AEs with NSAIDs from cohort studies, RCTs, and case-control studies were gastrointestinal (GI) and/or cardiovascular (CV) AEs. Where comparisons between NSAIDs were made, the overall literature shows a better or similar safety profile for celecoxib (at a daily dose of 200 mg) compared to other NSAIDs in regards with the GI, CV, and renal events. Other anti-OA medications with most commonly reported AEs were: IAHA (injection site pain); diacerein (GI AEs and reddish urine); avocado–soybean unsaponifiables (GI AEs); non-pharmaceutical grade glucosamine and chondroitin (allergic reactions, GI disorders); opioids (hip fracture associated with long-term tramadol use among older adults; and GI and nervous system disorders with hydrocodone); corticosteroid injections (increased risk of OA progression); herbal mixtures and other compounds (GI AEs). There were case reports or case series of specific AEs with various anti-OA medications that require further investigations in well designed cohort studies before any definitive conclusions.

Conclusions: This SR of PMS studies confirms previous evidence on the safety of anti-OA medications from meta-analyses of phase 3 RCTs. Beyond the findings reported, the limitations of this research highlight the urgent need of a reporting guideline for PMS studies.

OP5 - P553

EFFECT OF TIBOLONE ON CORTICAL AND TRABECULAR BONE IN POSTMENOPAUSAL WOMEN COMPARED WITH ESTROGEN THERAPY

G.-A. Cruz-Priego[1], P. Clark[1], M.-A. Guagnelli[1], L. Humbert[2], S. Ortiz-Santiago[1], L. Castrejón-Delgado[3], M. A. Sánchez-Rodriguez[3]

[1]Hospital Infantil de México-Universidad Nacional Autónoma de México, Mexico City, Mexico, [2]3D-Shaper Medical, Spain, Spain, [3]Facultad de Estudios Superiores Zaragoza UNAM, Mexico City, Mexico

Objective: To evaluate the effects of 2.5 mg/day of tibolone compared to 0.625 mg/day of estrogen and placebo on cortical and trabecular bone in postmenopausal women at 6 and 12 months of treatment.

Material and Methods: A randomized controlled trial was conducted in postmenopausal women from Mexico City. Participants were divided into three groups: A) Tibolone 2.5 mg/day, B) Conjugated estrogens 0.625 mg/day with medroxyprogesterone 5 mg/10 days, and C) Placebo. Hip aBMD was assessed at 6 and 12 months. Cortical and trabecular bone measurements were obtained using 3D modeling from DXA scans (3D-SHAPER v2.10.1, Galgo Medical, Spain). Parameters included cortical vBMD, cortical thickness, cortical surface BMD, and trabecular vBMD. Comparisons between groups were performed for these measurements.

Results: There were 22 participants in the tibolone group, 27 in the estrogen group, and 22 in the placebo group. At 6 months, hip aBMD increased by 0.34% in the tibolone group but decreased by 0.47% and 0.31% in the estrogen and placebo groups, respectively. Comprehensive vBMD increased by 0.77% in the tibolone group and 0.11% in the estrogen group, while it decreased by 1.04% in the placebo group. Trabecular vBMD increased by 1.51% and 0.65% in the tibolone and estrogen groups, respectively, but decreased by 1.5% in the placebo group. Cortical thickness increased by 1.69% in the tibolone group but decreased by 2.17% and 2.75% in the estrogen and placebo groups, respectively. 3D modeling provided valuable insights into whether changes in DXA aBMD were driven by trabecular or cortical compartments, highlighting more pronounced improvements in the tibolone group.

Conclusions: Tibolone therapy demonstrated a trend toward improvement in all parameters, with increases of up to 2% at the 6-month mark. These findings suggest tibolone could be a viable alternative to hormonal therapy, offering similar BMD benefits with fewer adverse effects. Greater improvements are expected with continued treatment at 12 months.

Figure 1. Changes in cortical and trabecular bone measured with 3D DXA.

VERTEBRAL FRACTURES IDENTIFIED ON LATERAL DXA IMAGES USING DEEP NEURAL NETWORKS PREDICT INCIDENT FRACTURES IN OLDER WOMEN

L. Johansson[1], V. Wåhlstrand[2], J. Alvén[2], I. Häggström[2], M. Lorentzon[3]

[1]Sahlgrenska University Hospital, Mölndal, Sweden, [2]Chalmers University of Technology, Gothenburg, Sweden, [3]Institute of Medicine, University of Gothenburg, Mölndal, Sweden

Objective: The aim of this study was to examine if vertebral fractures (VFs) identified on lateral DXA-images, using deep neural networks [1], predict incident fractures to a comparable degree of manually annotated vertebral fracture assessments (VFAs).
Material and Methods: 2,831 women from the SUPERB study were included in this study. VFs (mild to severe) were diagnosed from DXA by VFA or by the novel deep learning method XVFA[1]. Due to image quality, manually annotation was possible for 30,589 vertebrae, while XVFA used all visible vertebrae (n=37,123). Incident fractures were x-ray verified. Cox regression models were used to assess the association between VFs and incident fractures, with adjustments for clinical risk factors and femoral neck BMD.
Results: During 8 years of follow-up 683 and 1,310 women were identified as having any VF when analyzed manually or by XVFA, respectively. Women with any VF verified by the manual method or by XVFA had 327 (47.9%) and 539 (41.1%) any fracture, respectively. With the manual annotation method women with any VF had 70% increased risk of any fracture compared to women without VF. With the XVFA method, women with any VF had 42% increased risk of any fracture, compared to women without VF. These associations remained in adjusted models in both methods (Table 1).
Conclusion: Both methods for identification of VFs, the novel XVFA and manually annotated VFAs, predicted incident fractures.

1.V Wåhlstrand Skärström, L Johansson, J Alvén, M Lorentzon, I Häggström, *Explainable vertebral fracture analysis with uncertainty estimation using differentiable rule-based classification.* https://doi.org/10.48550/arXiv.2407.02926, 2024.

Table 1. Associations between VF identified by VFA manually or by XVFA and fracture risk in older women.

	VF identified manually		VF identified by XVFA	
	No VF n=2148	Any VF n=683	No VF n=1521	Any VF n=1310
Any fracture				
No. (%)	698 (32.5)	327 (47.9)	486 (32.0)	539 (41.1)
HR (95% CI)				
Adjusted for age, height, weight	1 [Reference]	**1.70 [1.49-1.94]**	1 [Reference]	**1.42 [1.26-1.61]**
+ clinical risk factors	1 [Reference]	**1.58 [1.38-1.81]**	1 [Reference]	**1.34 [1.18-1.52]**
+ FN BMD	1 [Reference]	**1.47 [1.29-1.68]**	1 [Reference]	**1.28 [1.13-1.45]**

Associations were examined using cox regression model. Hazard Ratios (HR) and 95% confidence intervals (CI) are presented. XVFA = explainable VFA (a model developed by deep learning).

MACHINE LEARNING FOR THE PREDICTION OF FRAGILITY FRACTURES BY BONE AND BODY COMPOSITION PARAMETERS: FINDINGS FROM THE OSTEOLAUS 10 YEARS POPULATIONAL COHORT

C. Vendrami[1], G. Gatineau[1], E. Gonzalez Rodriguez[1], O. Lamy[2], D. Hans[1], E. Shevroja[1]

[1]Interdisciplinary Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital and University of Lausanne, Switzerland, Lausanne, Switzerland, [2]Department of Medicine, Internal Medicine, Lausanne University Hospital and University of Lausanne, Switzerland, Lausanne, Switzerland

Objectives: Recent reviews highlighted the potential value of artificial intelligence in improving fragility fracture prediction. However, no studies have comprehensively integrated bone and body composition metrics from Dual X-ray Absorptiometry (DXA) in fracture prediction models. We aim to analyse the prediction of fragility fractures using regional and total body DXA assessments using a machine learning pipeline.
Material and methods: 1475 Swiss post-menopausal women (age 64.5±7.6years, body mass index 25.9±4.5kg/m^2) from the Osteo-Laus cohort were followed for 10 years (2010-2022). Parameters of bone health (hip and spine DXA: 34 variables) and body composition (Whole body DXA: 65 variables) were assessed by DXA scans. Vertebral fractures were screened with lateral DXA. Other risk factors (15 variables) and fragility fractures were collected from questionnaires. These parameters were tested separately or combined (114 variables) in different datasets. All datasets were split for training (85%) and testing (15%) with a balanced fragility fractures proportion. Models were trained using logistic regression, multilayer perceptron, random forest, and XGBoost, with hyperparameters optimized through grid search and 5-fold internal cross-validation, to maximize the area under the curve (AUC).

Results: 590 to 957 participants were included in the final complete case analyses, with 237 fragility fractures. Across all models and datasets, the training AUC values ranged from 0.69 to 1.0, while the test AUC values ranged from 0.55 to 0.78. The combination of bone, body composition and fracture risks parameters in the same dataset achieved the best test AUC (0.65-0.78). Logistic regression demonstrated the best balance between performance (AUC 0.78) and generalizability (specificity 0.66, recall 0.69). Other models showed varying trade-offs between overfitting and reduced test performance (eg. XGBoost: AUC 0.72, specificity 0.82, recall 0.25).
Conclusions: These findings emphasize the value of combining DXA-derived bone and body composition parameters for fragility fracture prediction in postmenopausal women. While logistic regression produced the most promising results in this preliminary study, the other models remain at interest for further analysis in combination with image based analysis. Further studies including a comparison with FRAX®, larger sample size and external validation are needed.

OP8 - P485

REMS TECHNOLOGY FOR FRACTURE RISK ASSESSMENT IN KIDNEY TRANSPLANT PATIENTS

F. A. Lombardi[1], P. Pisani[1], F. Conversano[1], C. Stomaci[2], F. R. Contaldo[2], E. Casciaro[1], G. Peluso[3], A. C. Stetco[2], R. Franchini[1], M. Di Paola[1], S. Casciaro[1]

[1]National Research Council, Institute of Clinical Physiology, Lecce, Italy, [2]University of Salento, Department of Biological and Environmental Sciences and Technologies, Lecce, Italy, [3]University of Salento, Department of Innovation Engineering, Lecce, Italy

Objective(s): Changes in bone quantity and quality are common consequences in Kidney transplant patient (KTP), who are at a significantly increased risk of fractures. A complex interplay of factors contributes to bone damage in KTPs, including immunosuppressive therapy and alterations in the parathyroid hormone-vitamin D-fibroblast growth factor 23 axis. The high fracture risk in KTPs is associated with increased morbidity, higher healthcare costs, hospitalizations, and mortality. Therefore, due to the substantial burden of this issue, assessing fracture risk and, consequently, implementing targeted early interventions and proper patient management are crucial. The aim of this study is to evaluate the 5-year fracture risk in KTP patients by using the non-invasive Radiofrequency Echographic Multi Spectrometry (REMS) technology.
Material and Methods: The 5-year fracture risk was calculated using a REMS-based algorithm that automatically combines information on both bone quantity and quality. Specifically, by combining the REMS T-score and the Fragility score (figure 1), 7 distinct risk classes are identified, each representing a different fracture risk probability. The R1 category represents the group with the lowest fracture risk probability, which increases progressively up to R7 for the category with the highest risk (figure 2).

Combining Matrix of REMS BMD and Fragility Score

REMS FRAGILITY SCORE Classification	REMS T-SCORE classification: NORMAL	OSTEOPENIA	OSTEOPOROSIS
NORMAL	R1	R3	R5
DECREASED	R2	R4	R6
LOW	R3	R5	R7

Figure 1

Total Fracture Risk at 5 years (‰)

Risk class	Risk of major osteoporotic fracture per 1000 subjects per 5 years
R1	≤ 5
R2	[5-10]
R3	[10-20]
R4	[20-35]
R5	[35-60]
R6	[60-100]
R7	> 100

Figure 2

Results: A total of 30 patients were enrolled (50-80 y; BMI 16-23 Kg/m^2, both genders). All participants underwent a lumbar spine REMS scan (L1-L4) to assess their fracture risk class. The KTPs were all classified into the high-risk categories R5-R6, indicating a 5-year fracture risk for major fractures of more than 60 ‰.
Conclusion(s): In conclusion, REMS technology enables the identification of high-risk individuals. The prevalence of R5-R6 cases in KTPs highlights the need for improved bone health monitoring and prevention strategies to reduce fractures and enhance quality of life.

Baxter[8], E. Curtis[9], R. Eckert[10], O. Sahota[11], Y. Kimmel[12], R. Pinedo-Villanueva[1], M. K. Javaid[1]

[1]University of Oxford, NDORMS, Oxford, United Kingdom, [2]NIHR Cambridge Biomedical Research Centre, Department of Medicine, Cambridge, United Kingdom, [3]Bradford Teaching Hospitals NHS Foundation Trust, Fracture Liaison Service, Bradford, United Kingdom, [4]Bradford Teaching Hospitals NHS Foundation Trust, Radiology, Bradford, United Kingdom, [5]University Hospital Llandough, Bone Research Unit, Cardiff, United Kingdom, [6]University Hospital Southampton NHS Foundation Trust, Fracture Liaison Service, Southampton, United Kingdom, [7]University Hospital Southampton NHS Foundation Trust, Radiology, Southampton, United Kingdom, [8]University Hospital Southampton NHS Foun-

dation Trust, Medicine for Older People, Southampton, United Kingdom, [9]University of Southampton, MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom, [10]Oxford University Hospitals NHS Foundation Trust, Fracture Liaison Service, Oxford, United Kingdom, [11]Nottingham University Hospitals NHS Trust, Department of Medicine for Older People, Nottingham, United Kingdom, [12]Nanox-AI, Petah Tikva, Israel

Objectives:
To compare the KPIs of FLSs before and after the introduction of AI-enabled VF identification across FLSs in England and Wales.
Materials and Methods:
The Nanox-AI HealthVCF AI model was implemented in 3 FLSs to identify potential vertebral fractures from existing CT scans with additional funding for FLS administrators and nurses. The KPIs for identification, assessment, treatment recommendation and follow-up were compared before (Jan to Nov 2023) and after (Jan to Nov 2024) AI implementation using the FLS-Database of England and Wales. Each AI-FLS was supported to deliver patient-co-produced Quality Improvement (QI). Up to 4 control FLSs for each AI-FLS were identified, matching on spine fracture identification KPI in 2023 to account for secular changes. Differences in proportions were compared using two-proportion z-tests.
Results
While overall VF identification doubled from 25.1% (2023) to 55.4% (2024), p<0.001, there were marked differences between AI-sites (Figure). Non-AI Control sites demonstrated a smaller increment in VF identification from 28.6 to 31.3% (p=0.007) which was inconsistent across sites. The change in KPI for VF patients varied by AI-FLS. Time to assessment significantly worsened in Hosp B and C but remained stable in Hosp A. DXA within 12 weeks worsened in Hosp B (85.7% to 66.7%) and Hosp C (92.3% to 80.6%) with little change in Hosp A (96.8 to 94.9%). The proportion of patients who were recommended treatment remained unchanged except for Hosp C, where it worsened from 85.2 to 71.4% (p=0.01).
For non-vertebral fracture (NVF) patients in AI-FLSs, time to assessment worsened in Hosp A & C (p<0.03) but improved in Hosp B. DXA within 12 weeks did not significantly change except for Hosp C where it improved (91.9% to 96.6%, p=0.02). The treatment recommendation rate for NVF significantly improved in Hosp B and C (p<0.003) and was unchanged in Hosp A.
Conclusion
As expected, AI implementation significantly improved VF identification but had differential effects on the KPI for VF and NVF between the AI-FLSs despite a focus on QI. These findings highlight the importance of enhancing QI when implementing AI-enabled VF identification in the FLS setting.

OP10 - P724

TRENDS IN HIP FRACTURE INCIDENCE IN ENGLAND BEFORE, DURING, AND AFTER THE COVID-19 PANDEMIC (2014-2023)

J. Webster[1], R. Goldacre[1]

[1]Applied Health Research Unit, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom

Objective
To investigate recent trends in hip fracture incidence in England before, during, and after the COVID-19 pandemic.
Methods
An epidemiological population-based study was conducted of all first-time emergency hip fracture hospital admissions unrelated to high-energy trauma in adults aged ≥ 60 years using English national secondary care data with linked national death records from January 2014 to December 2023. Temporal trends in age-standardized incidence rates were investigated by sex using national mid-year population estimates. Joinpoint regression models with permutation tests were used to calculate monthly percent changes with 95% confidence intervals (MPCs, 95% CIs).
Results
From 2014 to 2023, there were 429,499 hip fracture admissions in women, and 187,566 in men. Age-standardised incidence rates

steadily declined from 2014 to 2020, from a mean monthly rate of 20.1 to 17.6 cases per 100,000 men, and from 33.2 to 27.7 cases per 100,000 women (MPC in men: -0.17%, 95% CI: -0.23 to -0.11; MPC in women: -0.23%, 95% CI: -0.28 to -0.18). The direction of the trend changed in February 2021 in men and women, after which rates remained relatively flat (MPC for men: 0.14, 95% CI: -0.07 to 0.35; MPC for women: 0.13%, 95% CI: -0.05 to 0.31; p for slope change < 0.01 for both). By 2023, mean monthly incidence rates were 17.7 cases per 100,000 men and 28.2 cases per 100,000 women. The incidence of hip fracture was higher in women than in men (IRR 1.62, 95% CI: 1.61 to 1.64), but temporal trends were broadly consistent in both sexes.

Conclusion

This study highlights a downward trend in hip fracture incidence rates from January 2014 to February 2021 in England, followed by a sudden plateau from February 2021 onwards in men and women. Further investigation is needed to understand the cause of this change. Continued surveillance is needed to inform planning of emergency hip fracture care services and to measure the effectiveness of prevention strategies, particularly in the context of ongoing disruption and reorganisation of healthcare services in the UK.

Figures

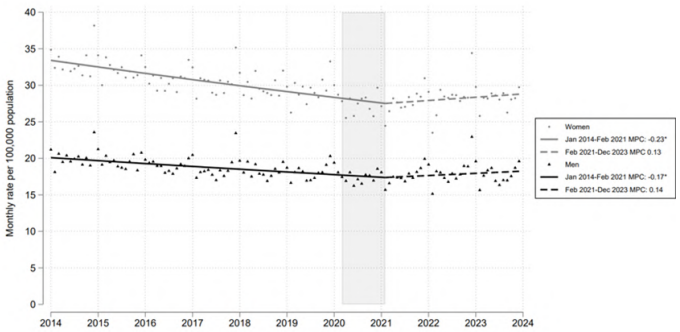

Figure 1: Age-standardised hip fracture incidence rates in England by sex, January 2014 to December 2023. *Indicates significance (p<0.05). MPC: monthly percentage change. The shaded area indicates a period of COVID-19-related public health restrictions.

EVALUATING THE PRAGMATISM OF SARCOPENIA CLINICAL TRIALS USING PRECIS-2: A SYSTEMATIC REVIEW

S. Van Heden[1], Z. Baoubbou[1], D. Sanchez-Rodriguez[2], C. Beaudart[1]

[1]Public Health Aging Research & Epidemiology PHARE Group, Research Unit in Clinical Pharmacology and Toxicology URPC, Department of Biomedical Sciences, Namur Research Institute for Life Sciences NARILIS, Faculty of Medicine, University of Namur, Namur, Belgium, [2]Geriatrics Department, Brugmann University Hospital, Université Libre de Bruxelles, 1020 Brussels, Belgium, Bruxelles, Belgium

Objectives:
This study aims to review interventional clinical trials in sarcopenia to assess their level of pragmatism and identify gaps to improve the clinical relevance and feasibility of future trials in the real world.
Material and Methods:
A systematic review was conducted using MEDLINE (via Ovid), Embase, and Cochrane Central Register of Controlled Trials (PRISMA guidelines; PROSPERO: CRD42024571027). Eligible studies included randomized controlled trials (RCTs) on sarcopenia treatment using a consensus definition. The PRECIS-2 tool was used to assess the level of pragmatism of these RCTs across nine standard domains (eligibility, recruitment, setting, organisation, flexibility of delivery, flexibility of adherence, follow-up, primary outcome, and primary analysis), with an additional "control" domain. Total PRECIS-2 scores were calculated, and subgroup analyses were conducted by intervention type, geographical location, sample size, study duration, and sarcopenia definition.
Results:
Of the 3,985 references reviewed, 58 RCTs met the inclusion criteria. The mean PRECIS-2 score across its 10 domains was 2.92 (SD 1.30), reflecting a balance of explanatory and pragmatic characteristics. Organisation, recruitment, and primary outcome were identified as the most pragmatic domains, whereas eligibility, adherence, and follow-up were the most explanatory. Subgroup analyses revealed that geographical location and sarcopenia definitions impacted significantly the overall PRECIS-2 score. More precisely, studies conducted in Asia achieved higher pragmatism scores, with significant differences in setting (p = 0.016), follow-up (p = 0.009), and control (p = 0.011). Studies using Asian sarcopenia criteria (e.g. AWGS) were also more pragmatic, particularly in the setting (p = 0.036) and control (p = 0.010).
Conclusion:
Due to the reversible nature of sarcopenia, clinical trials in this area have increased significantly in recent years. Although some methodological aspects of these RCTs follow pragmatic approaches, this systematic review highlights the need for improvements in areas such as exclusion criteria, follow-up and adherence. Specifically, there is an urgent need to design RCTs that more accurately reflect the complexity of real-world interventions in the multifaceted landscape of sarcopenia.
Disclosures: The authors have no conflicts of interest to declare.

OP12 - P1387

REFINING EARLY DETECTION OF LOW BONE MINERAL DENSITY: A DEEP LEARNING MODEL FOR OSTEOPENIA SCREENING USING CHEST RADIOGRAPHS

J. Park[1], S. Park[1], M. Kim[1], H.-J. Bae[1]

[1]Promedius Inc., Seoul, South Korea

Objective(s): We developed and validated a deep learning model to classify osteoporosis, osteopenia, and normal bone mineral density (BMD) from standard frontal chest radiographs. This framework offers finer categorization, enabling earlier identifica-

tion of osteopenic individuals and more timely DEXA referrals for those at moderate risk.

Materials and Methods: We expanded our PROS CXR:OSTEO product—which initially achieved high accuracy (AUC = 0.94 in internal validation) in classifying osteoporosis versus non-osteoporosis—to further differentiate osteopenia from normal within the non-osteoporosis category. Training data comprised 46,048 chest radiographs from Hospital A (South Korea), categorized by DXA T-scores, augmented with 16,265 unlabeled images from public datasets, totaling 62,313. For internal validation, 1,989 chest radiographs from Hospital A were used. For external validation, we collected datasets from three independent institutions spanning secondary healthcare (Hospital B), a facility serving veterans (Hospital C), and a global platform (Platform D).

Results: Our framework achieved an AUC of 0.93, sensitivity of 0.94, and specificity of 0.72 in classifying normal and osteopenia on External A (88.9% female; mean age 59.0 years), an AUC of 0.83, sensitivity of 0.78, and specificity of 0.82 on Hospital B (55.5% female; mean age 59.3 years), an AUC of 0.83, sensitivity of 0.73 and specificity of 0.67 on Hospital C (44.8% female; mean age 73.6 years), and an AUC of 0.78, sensitivity of 0.75, and specificity of 0.77 on Platform D (95.4% female; mean age 67.2 years).

Conclusion(s): Our model effectively classified osteopenia from normal BMD within the non-osteoporosis category, helping identify individuals at risk of reduced bone density and potentially enabling earlier intervention for osteopenia and osteoporosis.

Department of Abdominal Transplantation, University Hospitals Leuven, Leuven, Belgium, [6]Department of Clinical Chemistry, University of Liege, CIRM, Centre Hospitalier Universitaire de Liège, Liège, Belgium, [7]Nephrology Research Group, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium

Dysregulated mineral homeostasis in chronic kidney disease (CKD) can cause bone demineralization and an increased risk of fractures. In both healthy individuals and patients with advanced kidney failure, the ratio of naturally occurring non-radioactive calcium (Ca) isotopes 44Ca/42Ca in serum (Calcium isotope marker: CIM_Serum), serves as quantitative indicator of bone Ca balance (BCaB). Preferential incorporation of the lighter 42Ca isotope into bone elevates CIM_Serum during periods of net bone formation and reduces it when bone resorption predominates. In this study we measured the Ca isotope composition in bone biopsies (CIM_Bone) to determine the sensitivity of CIM_Serum in estimating BCaB. Nineteen patients receiving chronic dialysis (median age 60 years, time on dialysis 3.3 years) underwent Dual Energy X-ray Absorptiometry (DXA) and bone biopsies at the time of kidney transplantation. CIM_Serum and CIM_Bone was measured simultaneously in serum and bone biopsies. After adjustment of all study participants for the uptake of Ca supplements and renal impairment, we compared the results to those with a control group of ten adults with osteoporosis only. Results show that both CIM_Serum and CIM_Bone were significantly lower in the dialysis patients cohort than in the osteoporosic control. In the osteoporosis group, CIM_Serum correlated strongly with CIM_Bone ($p=0.0018$, $R^2=0.72$). A positive, albeit weaker, correlation was also observed in the dialysis group ($p=0.005$, $R^2=0.37$). CIM_Serum and CIM_Bone correlated positively with osteoblastic markers BAP and PINP, and inversely with PTH. While only 31% had DXA T-scores below -2.5 defining osteoporosis, CIM_Serum indicated severe bone mineral depletion in 89% of subjects. Histologic analysis revealed that CIM_Bone correlated positively with trabecular thickness and mineralized area, and inversely with osteoid area. Multiple regression analysis identified CIM_Bone ($\beta=0.88$, 95% CI -1.31 to -0.29, $p<0.001$), BALP ($\beta=0.63$, 95% CI 0.19 to 0.41, $p=0.008$), and osteoid area ($\beta=-0.31$, 95% CI -1.24 to -0.16, $p=0.03$) as significant predictors of CIM_Serum, collectively accounting for 87% of its variability. In conclusion, CIM_Serum is a significant and independent predictor of BCaB in dialysis patients, correlating strongly with CIM_Bone provides a comprehensive, real-time assessment of bone health, potentially enhancing the clinical evaluation of CKD-associated bone disease.

ASSOCIATIONS BETWEEN BODY COMPOSITION, EXERCISE, DIET, SHORT-CHAIN FATTY ACIDS, AND BONE LOSS IN EARLY POSTMENOPAUSAL WOMEN

M. Vilar Geraldi[1], G. Gregori[1], L. Johansson[2], U. Hjertonsson[1], E. Brättemark[1], M. Lorentzon[1]

[1]Sahlgrenska Osteoporosis Centre, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden., Mölndal, Sweden, [2]Department of Orthopaedics, Sahlgrenska University Hospital, Mölndal, Sweden, Mölndal, Sweden

Objective

The early postmenopausal period is characterized by a rapid loss in bone mineral density (BMD), which emphasizes the importance of lifestyle factors as important predictors and targets for preventive interventions. This study aimed to assess the relationship between bone characteristics and factors like nutrient intake, body composition, physical activity, and plasma SCFAs; and to identify

which of these factors predict changes in bone characteristics over 2 years in early postmenopausal women.
Material and Methods
This cross-sectional and longitudinal study involved 223 early postmenopausal Swedish women aged 50 to 60 years who participated and completed the 2-year ELBOW II clinical trial. Appendicular lean mass (ALM), fat mass (FM), and BMD were measured using dual x-ray absorptiometry (DXA), and tibia total volumetric BMD (vBMD) and microstructure by high-resolution peripheral computed tomography (HR-pQCT). Additionally, dietary intake, physical activity levels, and plasma short-chain fatty acids (SCFAs) were evaluated.
Results
In multiple linear regression analyses, weight and body mass index (BMI) were significant predictors for all bone parameters. ALM and FM were associated with BMD, with the strength of these associations varying by bone site. Over the 2-year period, the relative change (Δ) in ALM had a stronger association with bone changes than ΔFM. Women in the lowest tertile of ΔALM (ΔALM: -3.5 kg) and baseline FM (FM: 16.5 kg) experienced approximately 2.7-fold and 4.4-fold significantly greater reductions in total hip BMD and tibia total vBMD, respectively, compared to those in the highest tertiles. No consistent associations were observed for changes in neither macronutrient intake nor physical activity and the degree of bone loss. A positive relationship was found between Δisobutyric acid levels and bone loss, suggesting that gut microbiota metabolites may influence bone health.
Conclusion
Women with greater FM and maintaining/increasing ALM are linked to less development of skeletal fragility, typically seen in early postmenopausal women.

CALCIUM ISOTOPES AS A NOVEL BIOMARKER FOR VASCULAR CALCIFICATION IN CKD: IMPLICATIONS FOR OSTEOPOROSIS MANAGEMENT

A. Dosseto[1], A. Fuller[2], A. Borst[2], T. Tacail[3], K. Lambert[2], H. Cheick Hassan[4]

[1]Isochem Solutions, Wollongong, Australia, [2]University of Wollongong, Wollongong, Australia, [3]California Institute of Technology, Pasadena, United States, [4]Wollongong Hospital, Wollongong, Australia

Calcium balance is intricately linked to both bone health and vascular health. In chronic kidney disease (CKD), abnormal calcium metabolism contributes significantly to the development of vascular calcification, a major cardiovascular risk factor. While osteoporosis is a common comorbidity in CKD, the impact of vascular calcification on bone health remains an area of active investigation.
This study explored the potential of calcium isotope analysis as a non-invasive biomarker for vascular calcification in CKD patients. A cohort of 78 participants, including healthy controls, CKD patients, and those on dialysis, underwent comprehensive assessments, including vascular function tests and serum biomarker analysis.
Results demonstrated significant differences in serum calcium isotope compositions across the groups ($p<0.01$). Receiver operating characteristic (ROC) curve analysis revealed high diagnostic accuracy for serum Ca isotopes in detecting medial calcification (AUC = 0.818, $p<0.01$).
These findings have important implications for osteoporosis management in CKD patients. Accurate assessment of vascular calcification may provide valuable insights into systemic vascular health and may be a useful marker in identifying individuals with CKD at potentially increased risk for adverse health outcomes, including fractures. The use of calcium isotope analysis offers a promising approach for early detection and monitoring of vascular calcification in this vulnerable population. Further research is warranted to investigate the potential interplay between vascular calcification and bone health in CKD, and to explore the clinical utility of calcium isotope analysis in improving osteoporosis management outcomes.

FILLING GAPS IN TELEREHABILITATION: VALIDATING REMOTE SYNCHRONOUS AND ASYNCHRONOUS ASSESSMENTS OF PERFORMANCE-BASED OUTCOMES

K. Mullen[1], Z. Boos[1], L. Muhammad[2], M. K. Alshahrani[1], D. Pinto[1]

[1]Marquette University, Milwaukee, United States, [2]Northwestern University, Evanston, United States

Objective: This study assessed the agreement between three methods of performance-based outcome data collection for the 4-Meter Walk (4MW), Timed Up and Go (TUG), and Five-Repetition Sit-to-Stand (5XSTS) tests.
Materials and Methods: Fifty-eight participants were randomized into six groups, completing assessments in different sequences for in-person, remote synchronous, and remote asynchronous assessments of the 4MW, TUG and 5XSTS. In-person assessments served as the gold standard and were repeated five times to capture natural variability of the assessment; remote assessments were performed twice. Participants self-timed remote assessments. Participants were supervised in the remote synchronous assessment and were unsupervised during the remote asynchronous assessment. Agreement was analyzed using the extended Bland-Altman method accounting for repeated measurements, with limits of agreement (LOA) calculated as the mean difference ± 1.96 standard deviations.
Results: Participants were on average 40 years old (range 19–86), confident using technology (97%), held at least a bachelor's degree (83%), managed a medical condition (40%), and managed at least one active pain complaint (12%). After excluding three

statistical outliers, remote synchronous and asynchronous assessments agreed with in-person assessments across all outcomes, with no significant differences in timing. Including outliers, agreement was observed only for the 4MW. Asynchronous TUG demonstrated the largest mean bias (3.31 seconds, 95% CI [2.62, 4.01]). Agreement diminished for tasks requiring more time to complete. Notably, the three outliers were among the study's oldest participants.
Conclusion: Telerehabilitation is a viable management approach. This study shows that in-person, remote synchronous, and asynchronous methods of assessing performance-based outcomes are interchangeable for most participants but require further validation among older adults. This may have reflected the dual-task nature of the remote assessments. Our findings support the use of select performance-based assessments in virtual environments among most participants studied. This research addresses critical gaps in remote physical performance assessment as health providers transition to greater use of telehealth.

OP17 - P736

THE FIRST COMPARISON OF HIP FRACTURE INCIDENCE ACROSS 4 COUNTRIES IN AFRICA

C. L. Gregson[1], H. Wilson[1], A. Burton[1], M. K. Jallow[2], B. Trawally[3], L. S. Gates[4], T. Manyanga[5], J. Masters[6], R. A. Ferrand[5], M. Costa[6], K. Marenah[3], K. A. Ward[4]

[1]University of Bristol, Bristol, United Kingdom, [2]MRC Unit The Gambia @ London School of Hygiene and Tropical Medicine, Banjul, Gambia, [3]Department of Orthopaedics & Trauma, Edward Francis Small Teaching Hospital, Banjul, Gambia, [4]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [5]The Health Research Unit Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, [6]Oxford Trauma and Emergency Care, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Science, University of Oxford, Oxford, United Kingdom

Objectives: To determine age and sex specific hip fracture incidence rates in adults age ≥40 years in The Gambia, West Africa and compare with those from other African countries.
Methods: All hip fracture cases in adults aged ≥40 years, presenting to a hospital or traditional bone setter (TBS) in the study area over 2-years, were identified. Age- and sex- specific hip fracture incidence per 100,000 person-years were estimated using the 2024 Gambian Population census. Incidence estimates were compared between The Gambia, Zimbabwe[1], South Africa[2] and Botswana[3]. Future hip fracture numbers were estimated to 2054 using UN population projections.
Results: Over 2-years, 238 (67% female) patients, mean(SD) age 71.3(12.5) years, presented to hospital (197[82.8%]) or TBS (37[15.5%]). Most reported fragility fractures (217[91.2%]). Presentation >2 weeks after injury was common (70[29.4%]). Incidence rates in The Gambia were 28.0 and 56.2/100,000 person-years for men and women respectively. Hip fractures numbers are predicted to nearly quadruple, from 175 in 2024, to 656 in 2054.
Age-standardised hip fracture incidence rates were broadly comparable between The Gambia, Zimbabwe, Botswana, and the Black South African population (Figure-1). All countries see higher incidence in men than women until age >50 years. The highest incidence rates in women age 60-74 years were in The Gambia, and in women age >75 years in Zimbabwe.
Conclusions: These are the first hip fracture incidence data from West Africa. Fragility fractures in Gambian adults were common, indicative of age-associated osteoporosis. Across the 4 countries, hip fracture cases are predicted to at least double over coming decades; in The Gambia they will quadruple. Healthcare systems now need to pivot to provide fracture services for ageing populations.

DIFFERENTIAL ANALYSIS OF LUMBAR SPINE BONE MINERAL DENSITY AND TRABECULAR BONE SCORE IN HYPOPHOSPHATASIA PATIENTS WITH BIALLELIC VS MONOALLELIC ALPL GENOTYPE

F. Genest[1], K. Hind[2], M. De Gruttola[3], D. Hans[3], L. Seefried[1]

[1]University Hospital Wuerzburg, Wuerzburg, Germany, [2]Faculty of Health and Medicine, Lancaster + Medimaps Group, Switzerland, Lancaster, United Kingdom, [3]Medimaps Group, Lausanne, Switzerland

Objective Hypophosphatasia (HPP) is a genetic disorder marked by deficient Alkaline Phosphatase activity. Depending on genotype severity, this causes multiple extraskeletal manifestations and impaired bone mineralization. Dual-energy X-ray absorptiometry (DXA), which measures bone mineral density (BMD), has limitations in assessing bone quality in conditions like HPP, Trabecular bone score (TBS), derived from DXA images, enables an advanced evaluation of vertebral bone microarchitecture and mineralization homogeneity, to offer additional insights into bone quality in such conditions. This study aimed to compare lumbar spine BMD and TBS parameters in HPP patients with biallelic vs monoalleic ALPL variants.

Materials and Methods In this retrospective, single center, matched-pairs analysis, lumbar spine DXA scans from 90 HPP patients with biallelic (n=45) vs monoallelic (n= 45) ALPL variants an no previous enzyme replacement therapy , were analyzed. Lumbar spine (L1-L4) BMD and TBS [version 3 (body mass index- adjusted) and version 4 (tissue thickness adjusted)] were assessed.
Results Overall average values for age (49.6±14.0years), height (166.5±10.6cm), weight (74.5±17.4kg), BMI (26.9±6.0kg/m²) and tissue thickness (19.3±3.1 cm) were not significantly different between the groups.. Mean LS-BMD T-scores was normal (+0.1±2.3) but patients with biallelic variants had higher BMD (+0.88±2,22) than heterozygously affected patients (-0.70±2.06; p<0.001). Conversely, TBS T-scores were low in both cohorts 1.10 (±1.73) vs -1.48 (±1.60) for biallelic vs. monoallelic genotype, respectively (p=0.074). The more recent TBS software version 4 appeared even more sensitive to detect deterioration in both groups, with TBS T-scores of -1.40 (±1.17) vs -1.73 (±1.34) in the two groups respectively (p = 0.64).
Conclusions In line with previous findings, this study indicates that conventional DXA-BMD may appear erroneously high in HPP patients, particularly in more severe biallelic cases where elevated BMD T-scores may mask skeletal defects. Extended analysis using TBS exhibited inferior bone microarchitecture and mineralization inhomogeneity in both, biallelic and monoallelic HPP genotypes. This underscores potential added value of TBS in evaluating skeletal involvement in HPP with the newer version 4 showing greater sensitivity.

OP19 - P538

WHICH THRESHOLD VALUES OF CROSSLAPS TO TARGET TO PREVENT BONE LOSS AT 1 AND 2 YEARS AFTER DENOSUMAB DISCONTINUATION. THE REOLAUS STUDY

G. Liebich[1], E. Gonzalez-Rodriguez[2], O. Lamy[3]

[1]Faculty of Biology and Medicine, University of Lausanne and Service of Internal Medicine, Lausanne University Hospital, Lausanne, Switzerland, [2]Interdisciplinary Center for Bone Diseases, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland, [3]Interdisciplinary Center for Bone Diseases and Service of Internal Medicine, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland

Objective
After denosumab discontinuation (DD) elevated serum crosslaps (sCTX) is associated to bone mineral density (BMD) loss over a two-year period. Bisphosphonates reduce this rebound effect, especially if sCTX remain low. The objective was to define an sCTX threshold below which BMD gained on denosumab is maintained.
Material and Methods
Postmenopausal women receiving ≥2 consecutive denosumab doses and followed ≥2 years after DD with regular BMD and several sCTX measurements were included retrospectively. Lumbar spine (LS) T-score loss ≥0.2 SD defined the losers group. Linear regression analysis and ROC curves were performed to define sCTX threshold (in %ULN, upper limit of the norm; 573ng/l in our laboratory) preventing 1- and 2-year LS BMD loss.
Results
161 women received 8.0±2.9 injections; 50% were defined as losers 2 years after DD. Losers received more denosumab injections (9.0±2.8 versus 7.3±2.9, p=0.002). BMD at DD were similar at all sites in stable and losers groups. LS T-score decreased in losers after 1 (-0.38±0.40 versus -0.09±0.36 SD, p<0.001), and 2 years (-0.49±0.31 versus +0.09±0.25 SD, p<0.001). After 2 years, losers had lower LS T-score (-2.26±1.30 versus -1.75±1.10 SD, p=0.025). Two years after DD, BMD loss was highly correlated with sCTX increase during the first and during the two years on linear regression models (p<0.001). The best sCTX threshold sensitivity-specificity relationship to avoid LS BMD loss at 1 year and over 2 years was 69.3 (397.1ng/l) and 63.8 (365.6ng/l) %ULN, respectively; 32.2 (184.5ng/l) and 35.5 (203.4ng/l) %ULN respectively for a 100% sensitivity (ROC AUC 0.686 and 0.678). sCTX threshold during the first year to avoid LS BMD loss at 2 years was 49.1 (281.3ng/L) and 22.5 (128.9ng/L) %ULN for a 100% sensitivity (ROC AUC 0.674). More patients received ≥3 zoledronate infusions in the losers group (28% vs 7%, p=0.006).
Conclusions
sCTX level during the first year after DD predict 1- and 2-year BMD loss at LS. Strategy to maintain low sCTX level during this first year and regular sCTX monitoring are needed to avoid BMD loss. Maintaining sCTX below 49.1 %ULN during the first year prevent LS BMD loss at 2 years. Shorter denosumab treatments are encouraged. Despite high doses of bisphosphonates, it is not always possible to reach this target.

OP20 - P1044

ABALOPARATIDE INCREASES DISTAL FEMUR BMD POST TOTAL KNEE ARTHROPLASTY

N. Binkley[1], D. Krueger[1], G. Borchardt[1], B. Nickel[1], P. A. Anderson[1]

[1]University of Wisconsin School of Medicine and Public Health, Madison, United States

Objectives: Osteoporosis is common in total joint replacement patients and increases risk for adverse outcomes. Existing data indicate that total knee arthroplasty (TKA) leads to rapid distal femur bone loss. We hypothesized that abaloparatide (ABL) would mitigate this loss. The study's purpose was to evaluate the effect of ABL begun prior to TKA on distal femur BMD.
Materials and Methods: Female and male TKA candidates age ≥ 55 yrs were enrolled in this open-label 18-mo study. Those with clinical osteoporosis, defined as T-score ≤ -2.5 or < -1.0 if prior low-trauma fracture, received daily ABL. Subjects with osteopenia, but without fracture, comprised an untreated control (CON) group. BMD was measured by DXA at the L-spine, total hip, radius and 2 distal femur regions of interest (ROIs) placed at 15% and 25% of femur length at screening (~3 mo pre-TKA), 1-week pre-TKA, 6-mo and 15-mo post-TKA. Groups were compared at baseline by t-test. For this completers analysis (n = 21 ABL/27 CON) BMD change at all measured sites was assessed by ANOVA.
Results: At baseline (n = 58; 29 ABL/29 CON) sex, mean (SD) age

and BMI did not differ between ABL and CON groups; 3 vs. 6 male, 70.5 (7.2) vs. 68.6 (7.1) years and 31.3 (6.1) vs. 31.0 (4.7) kg/m^2 respectively. ABL group baseline BMD was lower ($p \leq 0.05$) at all sites except the L-spine. ABL was dosed for 96 (60) days prior to TKA. In the CON group, BMD declined ~1-2.5% ($p < 0.05$) at the 15% and 25% ROI by 15-mo post TKA.

Distal femur BMD increased at the 15% and 25% sites in ABL group from baseline and differed from CON ($p < 0.05$) at pre-surg, 6 and 15 mo post-surg (Table). L-spine and total hip BMD also increased by 6-mo in the ABL group (Table). BMD percent change at 15% and 25% distal femur ROIs was ~double in the surgical compared to non-surgical leg, (up to 4%; $p > 0.05$), but did not differ at the total hip.

Conclusion: In osteoporotic TKA recipients, ABL increased BMD at the distal femur, L- spine and total hip compared with osteopenic controls. Abaloparatide improves BMD in osteoporotic patients undergoing TKA. The decrease in distal femur BMD after TKA among controls was less than previously reported, thus, further study to clarify the effect of TKA on distal femur BMD is needed.

AGA2118, A BISPECIFIC MONOCLONAL ANTIBODY NEUTRALIZING BOTH SCLEROSTIN AND DKK1, INCREASED BONE FORMATION, DECREASED BONE RESORPTION, AND LED TO RAPID BMD GAINS IN A FIRST IN HUMAN, SINGLE- AND MULTIPLE- DOSE, PLACEBO-CONTROLLED, RANDOMIZED STUDY

B. L. Langdahl[1], M. T. Drake[2], Y. L. Zhang[3], J. Z. Ke[3], Y. F. Li[3], M. Lankachandra[3], A. C. Zovein[3], H. Z. Ke[3], W. H. Dere[3], R. E. Dent[3]

[1]Aarhus University Hospital, Aarhus, Denmark, [2]Hospital for Special Surgery, New York, United States, [3]Angitia Biopharmaceuticals Limited, Woodland Hills, United States

Objective: Sclerostin (Scl) and Dickkopf-1 (DKK1) are key negative regulators of Wnt signaling in bone. AGA2118 is a humanized bispecific monoclonal antibody that neutralizes both Scl and DKK1, thereby increasing bone formation. In this first-in-human study, AGA2118 was administered to men and postmenopausal women to assess safety, tolerability, pharmacokinetics (PK), and pharmacodynamic (PD) effects on biomarkers and BMD.

Methods: In this Phase 1, randomized, double-blind, placebo-controlled, single, and multiple ascending dose (SAD/MAD) study, healthy male (n=13) and female (n=77) subjects received AGA2118 or placebo (6:2) either subcutaneously (SC) or intravenously (IV). SAD cohorts received 0.3, 1, 3, 10, or 15 mg/kg SC, or 0.3 or 3 mg/kg IV, while MAD cohorts received 1, 3, 6, or 12 mg/kg SC every 4 weeks for 3 doses. Subjects were followed for 85 days (SAD) and 169 days (MAD). Eight men and 24 women were included in the MAD cohort.

Results: Dose- and exposure-dependent increases in lumbar spine (LS), total hip (TH) and femoral neck (FN) BMD were observed in both the SAD and MAD cohorts in both male and female participants. A 10.7% LS BMD increase and 4.9% TH BMD increase were observed in the 12 mg/kg MAD cohort on Day 169. LS BMD increased by 10.7% in female participants (n=4) compared to 10.6% in male participants (n=2). TH BMD increased by 5.4% in female participants compared to 3.7% in male participants. Previously reported results included a per-protocol analysis, excluding one male participant who received two doses of AGA2118. The data presented here includes all participants who received at least one dose of AGA2118. AGA2118 was safe and well-tolerated at all dose levels tested. The incidence of treatment-emergent adverse events (AEs) and drug-related AEs in the AGA2118 cohorts versus placebo were balanced. No treatment-related serious AEs were reported.

Conclusion: Single and multiple doses of AGA2118 were well-tolerated and showed robust bone building efficacy in both male and female healthy volunteers. These data support further clinical development of AGA2118 for the treatment of osteoporosis.

WEEKLY VITAMIN D AND DAILY CALCIUM CARBONATE OVER 48-WEEKS INCREASES BONE DENSITY IN ADOLESCENTS WITH HIV AND 25(OH) D <75NMOL/L: A PLACEBO-CONTROLLED TRIAL IN SOUTHERN AFRICA

C. L. Gregson[1], T. Madanhire[2], N. V. Dzavakwa[2], L. Kasonka[3], H. Banda-Mabuda[3], T. Bandason[2], M. Chisenga[3], S. Filteau[4], K. Kranzer[4], H. Mujuru[5], U. E. Schaible[6], S. L. Rowland-Jones[7], V. Simms[4], R. A. Ferrand[4]

[1]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom, [2]The Health Research Unit Zimbabwe, The Biomedical Research and Training Institute, Harare, Zimbabwe, [3]Department of Obstetrics and Gynaecology, University Teaching Hospital, Lusaka, Zambia, [4]Clinical Research Department, London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Department of Paediatrics, University of Zimbabwe, Harare, Zimbabwe, [6]Research Centre Borstel, Leibniz Lung Centre, Borstel, Germany, [7]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Objective

HIV adversely affects skeletal development despite antiretroviral therapy (ART), and vitamin D insufficiency is common. Dietary calcium intakes are low in Southern Africa. Our trial determined whether vitamin D and calcium supplementation improves bone density in adolescents with HIV, particularly those with vitamin D insufficiency.

Methods

A multi-country individually randomised, double-blinded placebo-controlled trial of weekly vitamin D (20,000IU) plus daily calcium carbonate (500mg) for 48 weeks, recruited adolescents with HIV age 11-19 years, taking ART for ≥6 months from HIV clinics in Zimbabwe and Zambia. The primary outcome was DXA-measured total body less-head bone mineral density (TBLH-BMD) Z-score using a UK reference population. The secondary outcome was lumbar spine bone mineral apparent density (LS-BMAD) Z-score. Linear regression compared arms adjusting for site and baseline Z-Score. Sub-group analyses by baseline vitamin D insufficiency (defined in this region as 25(OH)D <75nmol/l) were pre-specified.

Results

842 adolescents [53.2% female] were enrolled; most (75.9%) had 25(OH)D <75nmol/l. At 48 weeks 751 (89.2%) were available for

a DXA. Overall, there was no difference by arm in mean 48-week TBLH-BMD Z-score [-1.56 (SD 1.12) in intervention vs -1.53 (1.18) in control arm, adjusted mean difference (AMD) -0.03 (95%CI -0.08, 0.02)]. Findings were similar for LS-BMAD Z-score. However, in those with baseline 25(OH)D <75nmol/l both TBLH-BMD and LS-BMAD Z-scores were higher at 48 weeks in those randomized to supplementation (Table-1). There was no evidence of interaction by age, sex or puberty. No drug-related severe adverse events occurred.

Conclusions

Higher-dose vitamin D and lower-dose calcium, are safe and cheap interventions during adolescence, and may promote bone accrual towards maximizing peak bone mass to reduce future fracture risk in African adolescents growing up with HIV.

Baseline 25(OH)D concentration	N	Supplemented Mean (SD)	Placebo Mean (SD)	AMD (95%CI)	P-value	Interaction P-value
TBLH-BMD Z-score						
<75nmol/L	562	-1.53 (1.22)	-1.61 (1.13)	0.04 (0.00, 0.08)	0.027	0.078
≥75nmol/l	189	-1.52 (1.03)	-1.45 (1.12)	-0.05 (-0.16, 0.07)	0.44

[1]Public Health Aging Research & Epidemiology (PHARE) Group, Research Unit in Clinical, Pharmacology and Toxicology (URPC), NAmur Research Institute for LIfe Sciences (NARILIS), Faculty of Medicine, University of Namur, Namur, Belgium, [2]3Geriatric Unit, Department of Internal Medicine and Geriatrics, University of Palermo, Palermo, Italy, [3]Research Unit in Clinical Pharmacology and Toxicology (URPC), NAmur Research Institute for LIfe Sciences (NARILIS), Faculty of Medicine, University of Namur, Namur, Belgium, [4]7Ageing and Health Unit, Department of Maternal, Newborn, Child and Adolescent Health and Ageing, World Health Organization, Geneva, Switzerland, [5]Azienda ULSS (Unità Locale Socio Sanitaria) 3 "Serenissima", Venice, Italy, [6]Protein Research Chair, Biochemistry Dept, College of Science, King Saud University, Riyadh, Saudi Arabia, [7]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [8]Service of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland

Introduction: Osteoporosis, defined by reduced bone mineral density and macro- and micro-architectural degradation, leads to increased fracture risk, particularly in aging populations. While randomized controlled trials (RCTs) demonstrate that PTH1 receptor agonists, teriparatide and abaloparatide, are effective at reducing fracture risk, real-world evidence (RWE) remains sparse. This study reviews and compares the anti-fracture efficacy of these agents, against each other and against other osteoporosis treatments using both RCTs and RWE.

Methods: We systematically searched Medline, Embase, and Cochrane up to May 2024, focusing on RCTs and RWE studies reporting reduction in vertebral, non-vertebral, hip, or all fractures as primary endpoint. A network meta-analysis (NMA) was conducted, first through pairwise meta-analyses of teriparatide versus abaloparatide, then a Bayesian NMA comparing each to other treatments. Safety assessments included adverse events (AEs) classified by MedDRA, with a particular attention to hypercalcemia and cardiac events.

Results: Seventeen studies (11 RCTs, 6 RWE) met inclusion criteria. Teriparatide and abaloparatide were effective in reducing vertebral and non-vertebral fractures in all pairwise meta-analyses vs. placebo. Abaloparatide showed an advantage over teriparatide for non-vertebral fractures (OR: 0.87, 95% CI: 0.80-0.95) and hip fractures (OR: 0.81, 95%CI: 0.71-0.93).

In the NMA model, teriparatide and abaloparatide were superior to placebo, raloxifene and calcitonin in reducing vertebral fracture while teriparatide was further superior to denosumab and risedronate. For non-vertebral fracture, abaloparatide was better than any other treatment while teriparatide was only superior to alendronate or placebo. PTH1 analogs were better than placebo at reducing all fractures while no difference was observed for the risk of hip fracture.

Both abaloparatide and teriparatide demonstrate comparable safety to other osteoporosis treatments, with no increased cardiovascular risk.

Conclusion: This review highlights that PTH1 receptor agonists effectively reduce fracture risk, with abaloparatide offering enhanced benefits for non-vertebral and hip fractures compared to teriparatide. Both agents exhibit acceptable safety profiles, suggesting their valuable role in managing osteoporosis, particularly for high-risk patients.

EFFECTS OF EB613 TABLETS [ORAL PTH(1-34)] ON TRABECULAR AND CORTICAL BONE USING 3D-DXA: POST-HOC RESULTS FROM PHASE 2 STUDY

G. Burshtein[1], C. Itin[1], H. Galitzer[1], M. Kushnir[1], M. Toledano[1], L. Humbert[2], R. Boyce[3], S. L. Ferrari[4], R. B. Wagman[5], F. Cosman[6]

[1]Entera Bio Ltd., Jerusalem, Israel, [2]3D-Shaper Medical, Barcelona, Spain, [3]Beechy Ridge ToxPath LLC, Pittsboro, United States, [4]Geneva University Hospital, Geneva, Switzerland, [5]SoCal PCH Ventures, San Bruno, United States, [6]Columbia University, Vagelos College of Physicians and Surgeons, New York, United States

Objectives: EB613 is being developed as the first once-daily oral PTH(1-34) tablet treatment for postmenopausal women with osteoporosis at increased risk for fracture. In Phase 2 (NCT04003467),

EB613 2.5 mg increased bone mineral density (BMD) associated with increased bone formation (PINP) & decreased bone resorption (CTX). We characterized early effects on trabecular & cortical bone of the proximal femur using 3D-DXA modeling.

Materials and Methods: In this post-hoc study, all Phase 2 study subjects from the EB613 2.5 mg (n=21) and placebo groups (n=38) who had DXA hip scans at baseline & 6 months were included. Scans were analyzed using 3D-Shaper® software to assess trabecular and cortical compartments, and 3D-DXA models were developed to show anatomical distribution of structural changes. For each parameter, % change from baseline for each subject and mean (SD) for both groups were calculated. Data were analyzed within groups vs baseline and between groups using t-tests.

Results: At 6 months, in subjects on EB613 vs placebo, areal BMD of the total hip (TH) and femoral neck (FN) increased 1.8% and 2.6%, respectively (both p<0.01). Integral volumetric BMD (vBMD) of the TH and FN increased with EB613 vs placebo by 1.7% (p<0.08) and 2.6% (p<0.03), respectively. TH trabecular vBMD increased 2.8% with EB613 (p=0.05 vs baseline; group difference NS) and FN trabecular vBMD increased 4.4% vs placebo (group difference p<0.03). While cortical vBMD changes with EB613 vs placebo were small and NS, cortical surface BMD increments with EB613 vs placebo were 1.5% and 2.1% in the TH and FN, respectively (both p<0.05; Figure). Cortical thickness increments with EB613 vs placebo were 1.3% in the TH (p=0.04) and 1.7% in the FN (p=0.056).

Conclusions: 6-months treatment with EB613 showed evidence of an early effect on both trabecular and cortical bone of the proximal femur, consistent with the dual mechanism of increased formation and decreased resorption. Safety and efficacy of EB613 will be evaluated in the planned Phase 3 trial.

SUSTAINED REDUCTION IN FRACTURE RATE IN PATIENTS WITH OI TREATED WITH SETRUSUMAB: FOURTEEN MONTH DATA FROM PHASE 2 OF THE PHASE 2/3 ORBIT STUDY

J. Nowicki[1], S. Gottesman[2], O. Carpenter[3], D. Velasco[4], M. Wallace[5], P. Smith[6], A. Imel[7], D. Luca[8], M. Byers[8], S. Krolczyk[8], E. M. Lewiecki[9]

[1]Medical University of Lodz, Lodz, Poland, [2]Washington University School of Medicine, St. Louis, United States, [3]Yale University School of Medicine, New Haven, United States, [4]Children's Nebraska, Omaha, United States, [5]Phoenix Children's Hospital, Phoenix, United States, [6]Shriner's Hospitals for Children, Chicago, United States, [7]Indiana University School of Medicine, Indianapolis, United States, [8]Ultragenyx Pharmaceutical Inc., Novato, United States, [9]University of New Mexico Health Sciences Center, Albuquerque, United States

Osteogenesis imperfecta (OI) is a rare genetic disorder of bone fragility and low bone mass with no universally-accepted treatment. Setrusumab is a fully human anti-sclerostin monoclonal antibody that improves bone mineral density (BMD), strength, and remodeling in adults with OI. Phase 2 of the Phase 2/3 Orbit study (NCT05125809) assessed its efficacy and safety in children and young-adults. Subjects with OI Types I, III, or IV, ages 5 to <26 years, were randomized 1:1 to receive 20 or 40 mg/kg setrusumab intravenously monthly. Once the last subject completed 6 months of treatment, all subjects switched to 20 mg/kg. Dose groups were pooled for analysis.

Twenty-four subjects (50% female, 75% <18 years old) with OI Type I (n=17/24, 71%) or III/IV (n=7/24, 29%) were assessed (mean, median treatment duration: 16, 15 months).

Subjects continued meaningful BMD improvement. A mean (SE) change from baseline (BL) in lumbar spine BMD of 14.19% (2.15%) was seen at Month (M) 6, and 22.25% (2.71%) at M12 (p<0.0001). Mean (SE) BL BMD Z-score improved by 0.85 (0.13) at M6, and 1.25 (0.17) at M12 (p<0.0001).

The median annualized pre-treatment fracture rate (excluding fingers, toes, face, skull, and morphometric vertebral fractures) fell from 0.72 to 0 (p=0.0014) after a mean 16 months of treatment, (67% calculated reduction). No safety concerns were identified at M14. Treatment-emergent adverse events (TEAE) supported the anticipated safety profile of setrusumab. Most related TEAEs (11/12, 92%) were mild (Grade 1), with no related serious TEAEs or cardiovascular TEAEs reported. No TEAEs led to study/treatment discontinuation or disruption.

We observed significant, clinically meaningful improvements from BL in lumbar spine BMD and BMD Z-score at M14. A clinically meaningful reduction in skeletal fracture rate was achieved with setrusumab (67%). Findings build upon those after 6 months, demonstrating the robustness and durability of setrusumab in OI.

OC6

PROGRESSIVE DECREASES IN FRACTURE INCIDENCE WITH ZOLEDRONATE USE >3 YEARS

I. R. Reid[1], A. M. Horne[1], B. Mihov[1], G. D. Gamble[1]

[1]University of Auckland, Auckland, New Zealand

Background

The anti-fracture efficacy of most osteoporosis drugs is assessed in trials of up to three years duration. However, treatment of osteoporosis is required long-term, so it is important to know whether effectiveness of treatment changes over time. To-date, this information has only been available from open extensions of the treatment groups from clinical trials. Such data are subject to selective loss of frailer patients from the cohort, and no placebo comparator group is available to permit reliable measurement of anti-fracture efficacy.

Methods

Our 6-year RCT of zoledronate or placebo every 18 months in 2000 osteopenic women aged >65 years is longer than most other trials of osteoporosis drugs, and only 3.6% of participants withdrew or were lost to follow-up (Reid IR et al, NEJM 379:2407, 2018). Therefore, anti-fracture efficacy can be validly compared between the first and second halves of this study.

Results

There were 178 non-vertebral fractures in the placebo group and 108 in the zoledronate group (excluding fractures of the hands, feet and face). Fracture rates per 1000 women-years in the placebo group were 28 (95%CI 23,35) and 32 (26, 40) in years 1-3 and years 4-6, respectively. In the zoledronate group, fracture rates were 23 (18, 30) and 13 (9, 18) per 1000 women-years in the first and second halves of the study. The rate ratios for non-vertebral fractures were 0.83 (0.60, 1.14) in years 1-3, and 0.40 (0.27, 0.58) in years 4-6 (between-period comparison, $P<0.05$). Rates ratios for total fragility fractures, which included vertebral fractures also, showed a similar pattern: years 1-3, 0.72 (0.54, 0.97); years 4-6, 0.37 (0.28, 0.50).

Conclusion

These findings suggest that the efficacy in non-vertebral fracture prevention of anti-resorptive drugs has been underestimated because of the short-term evaluation of their effects. Further, it indicates that longer term treatment with these drugs may yield greater benefit to patients.

OC7

COMPREHENSIVE COMPARATIVE ANALYSIS OF INFRAPATELLAR FAT PAD MORPHOLOGIES IN A LONGITUDINAL KNEE OSTEOARTHRITIS STUDY: NEW INSIGHTS INTO ITS ROLE AS A PROGNOSTIC MARKER

J.-P. Pelletier[1], P. Paiement[1], F. Abram[1], M. Dorais[2], J.-P. Raynauld[1], J. Martel-Pelletier[1]

[1]University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada, [2]StatSciences Inc., Notre-Dame de -l'Île-Perrot, Canada

Objective: No established markers effectively phenotype knee osteoarthritis (OA) patients into subgroups. Data on infrapatellar fat pad (IPFP) morphology predicting disease symptoms, structural changes, and knee replacement (KR) are sparse and conflicting. This 96-month longitudinal study aimed to identify the most effective prognostic markers by comparing various IPFP morphological features against these outcomes.

Methods: This study analyzed 1075 knees from the Osteoarthritis Initiative (OAI) progression cohort. Structural changes included cartilage, bone marrow lesions (BML), and joint effusion volumes assessed using quantitative and automated MRI systems. IPFP global and signal (hyper- and hypo-) intensity volumes and areas were measured using MRI combined with a newly fully automated neuron-driven technology[1]. Symptoms were evaluated using WOMAC. KR data were obtained from the OAI database. Data was collected at baseline, 12, 24, 48 and 96 months and analyzed using a mixed model for repeated measures and ANCOVA.

Results: Baseline characteristics were mild to moderate knee OA. Over time, WOMAC scores, cartilage volume, and IPFP global and hypointense signal volumes and maximal and hypointense signal areas decreased (all ≤ 0.001). Joint effusion and hyperintense signal volume and area increased (both ≤ 0.001). Associations were found between baseline IPFP morphologies and changes in cartilage volume (hypo- and hyperintense volumes, 48, 96 months, $p \leq 0.04$), BML volume (global volume 48 months, $p=0.05$; hyperintense area, 12 months, $p \leq 0.04$), and effusion volume (hypointense volume 48 months and hyperintense volume 96 months, $p \leq 0.05$). At baseline, smaller IPFP sizes (below median) were associated with cumulative KR at 96 months (global and hypointense volumes, $p \leq 0.04$ and maximal area, $p=0.05$).

Conclusions: This longitudinal study, leveraging an innovative IPFP assessment technology, highlights that IPFP volume (global and both signals) surpasses area metrics in predicting long-term OA structural changes, and smaller IPFP volumes and areas are linked with reduced KR need. These findings provide new insights into the usefulness of IPFP morphology as a predictive biomarker of knee OA outcomes, offering a new approach to stratifying knee OA patients.

RESULTS FROM A RANDOMISED CONTROLLED PHASE II TRIAL WITH LEVI-04, A NOVEL NEUROTROPHIN-3 INHIBITOR, DEMONSTRATE SUBSTANTIALLY IMPROVED PAIN AND FUNCTION WITHOUT DELETERIOUS EFFECTS ON JOINT STRUCTURE IN PEOPLE WITH KNEE OSTEOARTHRITIS

P. Conaghan[1], A. Guermazi[2], N. Katz[3], A. Bihlet[4], R. Dror[5], M. Perkins[6], B. Hughes[6], C. Herholdt[6], I. Bombelka[6], S. Westbrook[6]

[1]University of Leeds/Musculoskeletal Medicine/Chapel Allerton Hospital, Leeds, United Kingdom, [2]Boston University, Boston, United States, [3]Rin Sof Innovation Ltd, Boston, United States, [4]NBCD A/S, Soeborg , Denmark, [5]Prosoft Clinical, Chesterbrook, United States, [6]Levicept Ltd, Ramsgate, United Kingdom

Objective

To assess efficacy and safety of LEVI-04 in people with knee OA.

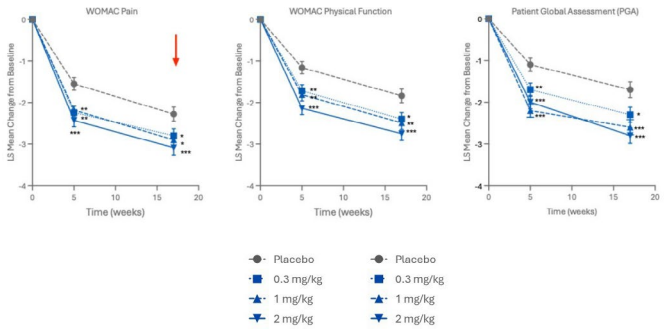
Materials and Methods

This was a 20-week PhII multicentre RCT in people with painful (≥4/10 WOMAC), radiographic (KL≥2) knee OA. Participants were randomised to baseline then 4-weekly IV placebo or 0.3, 1 or 2 mg/kg LEVI-04 through wk16, with safety follow-up to wk30. The primary endpoint was change in WOMAC pain to wk17, with secondary outcomes including function and PGA.

Results

518 people were enrolled, balanced across groups (mean age 63.1–65.4 years, mean BMI 29.3–30.3, proportion female 51.5–61.5%). Statistical significance was met for the primary and secondary efficacy endpoints (Figure 1) at wk5 and wk17 ($p<0.05$ vs placebo). LEVI-04 was well tolerated, with no increase in SAEs, TEAEs and joint pathologies, including rapidly progressive OA (RPOA), vs. placebo. SAEs reported were 0, 1 (0.8%), 3 (2.3%), and 3 (2.3%) in the 0.3mg/kg, 1mg/kg, 2mg/kg, and placebo groups, respectively. TEAEs occurred in 58.1%, 66.2%, 64.3% and 67.4% of participants in 0.3mg/kg, 1mg/kg, 2mg/kg, and placebo groups, respectively. There were 4 cases of RPOA Type 1: 2 in the 1mg/kg, 1 in the 2mg/kg and 1 in the placebo group. 2 subchondral insufficiency fractures were reported: 1 in a shoulder with pre-existing OA in the 1mg/kg group, and 1 in the knee in the placebo group. There were no reports of osteonecrosis or RPOA Type 2. 3 participants had a knee joint replacement; 1 in each of the active arms, all were KL grade 4 at study entry.

Figure 1. Efficacy Endpoints (arrow indicates primary endpoint)



Conclusion

LEVI-04 demonstrated significant and clinically meaningful improvement in pain, function, and other outcomes. LEVI-04 was well tolerated at all doses, supporting the concept of supplementing endogenous p75NTR as a treatment for OA and other pain conditions. Phase III trials are in planning.

OC9

A PHASE 1B RANDOMIZED CONTROLLED TRIAL EVALUATING SAFETY AND PHARMACODYNAMICS OF A NOVEL IL-1RA GENE THERAPY (GNSC-001) INJECTION IN KNEE OA: 6-MONTH INTERIM RESULTS

J. R. S. Tambiah[1], S. Jackson[1], M. Concepcion[1], S. Vijay[1], T. W. Chalberg[1], A. Annahita[1], P. G. Conaghan[2]

[1]Genascence Corporation, Palo Alto, United States, [2]University of Leeds, Leeds, United Kingdom

Objectives Evaluate safety of GNSC-001 dose regimens with / without corticosteroid (CS) immune-conditioning versus placebo (PBO) in knee OA participants (Pts) for 1 year and measure transgenic IL-1Ra levels in synovial fluid (SF). Six-month interim results are reported. **Materials and Methods** Knee OA Pts age 40-75 years, KL 2-3, WOMAC target knee pain ≥20/50 were randomized to 5 Groups (Gps): 1) GNSC-001 $1x10^{12}$ vector genomes (vg); 2) GNSC-001 $1×10^{12}$ vg + oral CS; 3) GNSC-001 $1×10^{13}$ vg; 4) GNSC-001 $1×10^{13}$ vg + oral CS; 5) PBO no CS. Gps 1 and 3 received 7 days oral CS (on Day -1 with 6-week taper). Open-label Grp 6 required knee SF aspiration prior to dosing and received 3 days oral CS (from Day -1) with IA CS (on Day 1). All Pts received IA GNSC-001 or PBO on Day 1 (Baseline [BL]), and had visits at Months 1, 3, and 6. **Results** BL characteristics [mean (±SD) or (%)] of 67 6-month completers were: female sex n= 52 (78%); age 60.9 (8.5) years; BMI 28.6 (4.3) kg/m^2; WOMAC Pain [0-100] = 61.9 (15.6) and Function = 62.4 (15.6); KL Grades 2, n= 35 (52.2%) and 3, n= 31 (46.3%). No deaths or safety-related withdrawals occurred. Two treatment-unrelated SAEs occurred. TEAEs across Gps [(n)(Pts>1 TEAE)] were: 1) 15(6); 2) 23(7); 3) 13(6); 4) 21(6); 5) 16(5); 6) 52(9). Target knee AEs (TKAEs) across Gps [(n)(Pts>1 TKAE)] were 1) 3(2); 2) 4(3); 3) 4(2); 4) 9(4); 5) 4(3); 6) 23(8). TKAEs >1 included arthralgia (n=12); swelling (n= 6); effusion (n=3) and stiffness (n=3). All TEAEs and TKAEs were Grade 1-2, apart from one Grade 3 AE (recurrent effusion) in Grp 6. Mean BL SF IL-1Ra level [pg/mL(±SD)] was 158.3 (327.3) pg/mL. Mean Month 6 lev-

els were (pg/mL±SD, n = Pts with >1 SF sample including Month 6): 1) 1006.7 (941.1) (n=4); 2) 2135.9 (2326.0) (n=7); 3) 245.5 (148.8) (n=5); 4) 3999.5 (4816.1) (n=7); 5) 128.7 (45.3) (n=6); 6) 2703.5 (2254.8) (n=11). **Conclusion** GNSC-001 was well tolerated with no treatment-related SAEs, and mostly mild / moderate TEAEs. Grp 6 trended higher in number of TKAEs; it was unclear if this was due to patient population differences, with SF aspiration required at entry, due to chance or CS regimen. All GNSC-001 groups showed persistently elevated IL-1Ra expression in SF, and immune-conditioning was associated with higher levels. Based on 6-month data, GNSC-001 shows promise for the treatment of knee OA.

OC10

EFFECTIVENESS OF CELECOXIB IN REDUCING OSTEOARTHRITIS (OA) PAIN IN PATIENTS WITH MODERATE AND SEVERE PAIN: ONCE-DAILY VS TWICE-DAILY DOSING

E. Choy[1], C. Walker[2], R. Chiaese[3], E. Biesheuvel[4], S. Suresh Kumbhar[5]

[1]Cardiff Regional Experimental Arthritis Treatment and Evaluation (CREATE) Centre, Section of Rheumatology, Division of Infection and Immunity, School of Medicine, Cardiff University, Cardiff, United Kingdom, [2]Global Medical Affairs, Viatris, United Kingdom, [3]Global Medical Affairs, Viatris, Italy, [4]Biometrics, Viatris, Amstelveen, Netherlands, [5]Biometrics, Viatris, Bangalore, India

Objective

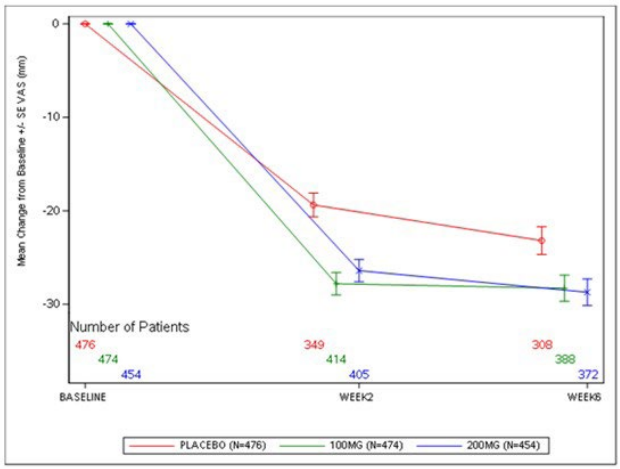
To assess the effectiveness of Celecoxib(100 mg BID or 200 mg OD) using Visual Analog Scale(VAS) score in reducing moderate(VAS≥40&≤69) to severe(VAS≥70) knee OA pain.

Material and Methods

A pooled analysis combined two previously published near identical 6 week studies of patients with OA of the knee. Participants received either placebo, 100 mg Celecoxib, or 200 mg Celecoxib. The primary endpoint was change in pain VAS scores upto week 6 from baseline. Pain scores were measured at baseline, week 2, and week 6.

Results

A total of 1404 participants either received placebo(n=476), Celecoxib as 100 mg(n=474), or Celecoxib as 200 mg(n=454). At baseline, 675 had moderate pain, 685 had severe pain, 44 patients had mild pain(VAS<40). The results confirming the efficacy of two doses of Celecoxib at week 6 are presented in figure1.



The 100-mm visual analog scale ranges from 0 (no pain) to 100 (very severe pain). Change from Baseline of VAS has been plotted over Time.

Figure 1. Change from baseline of patient's assessment of OA Pain-VAS at week 2&6

In patients with moderate pain, both 100 mg & 200 mg Celecoxib significantly reduced pain compared with placebo at week 2&6(LSM diff. -8.18 (p=0.0009) & -5.37(p=0.0318), respectively). In patients with severe pain, both 100 mg and 200 mg Celecoxib significantly reduced pain compared with placebo at week 2 (LSM diff. -8.96(p=0.0007) and -8.43(p=0.0015), resp. At week 6, Celecoxib 100 mg demonstrated no statistically significant difference with placebo, while Celecoxib 200 mg statistically significantly reduced pain (LSM diff. of -3.37(p=0.2592) and -7.45(p=0.0135), respectively).

Conclusions

Celecoxib (both dosing regimens) effectively reduced pain in patients with moderate and severe knee OA. Data from the 6 week interval may suggest that 200 mg OD per day might be the preferred regimen for severe pain management.

OC11

10-YEAR FOLLOW-UP AFTER INTRA-ARTICULAR INJECTIONS OF 2.5 % POLYACRYLAMIDE HYDROGEL FOR KNEE OSTEOARTHRITIS

H. Bliddal[1], A. Hartkopp[2], P. Conaghan[3], M. Henriksen[1]

[1]The Parker Institute, Copenhagen University Hospital Frederiksberg, Copenhagen, Denmark, [2]A2 Rheumatology and Sports Medicine, Holte, Denmark, [3]University of Leeds & NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

Objective:
To evaluate long term safety of intra-articular 2.5 % polyacrylamide hydrogel (iPAAG)

Material and Methods
Patients treated off-label with iPAAG for radiologically verified knee OA in the period 2010 until 2017 were recalled. Medical and surgical records were obtained on all recalled patients and scrutinized for possible adverse events or abnormal reactions related to the injection, and in the event of subsequent surgery, for peri- and post-operative complications for the treated knee(s). An interview was also conducted for retrospective self-reported adverse events after the injection of iPAAG. The time between IA injection and knee surgery was recorded.

Results:
A total of 61 patients (24 women and 37 men) participated. At the time of injection, mean age was 64 years (range 34-81) and mean BMI was 27 kg/m^2 (range 19-43 kg/m^2). Some patients had treatment of both knees and 89 knees were included. Observation time from the iPAAG treatment to follow-up was mean 9.92 years (range 7-14 years).
No significant AEs related to iPAAG were reported by patients or found in the records; thus, no allergic reactions, infections or systemic adverse events were noted.
In 39 cases (39/89, 43.8 %) a knee replacement was performed after a mean time lapse of 3.4 years (range 0.2-7.6 years). The mean time lapse was similar for all KL grades. Post surgical abnormal events were noted in 2 cases: 1 had prolonged knee bleeding and the other had an infection that required revision and prolonged antibiotics. These 2 patients had received multiple other injections including glucocorticosteroids, both before and after the iPAAG.

Conclusion:
Long-term results after iPAAG indicated a favourable safety profile of the product, with very few patients recalling pain or problems post-injection. Surgical records from subsequent knee replacements gave no indications of unusual adverse reactions.

Disclosure:
This work was supported by an institutional grant from Contura International A/S to the Parker Institute and the company had no influence on the design and execution of the study. None of the authors are employed by or have shares in this company.

EFFECTS OF INTRA-ARTICULAR HYALURONIC ACID INJECTIONS ON PAIN AND FUNCTION IN KNEE OSTEOARTHRITIS PATIENTS: AN UMBRELLA REVIEW OF SYSTEMATIC REVIEWS AND META-ANALYSES OF RANDOMIZED PLACEBO-CONTROLLED TRIALS

O. Bruyère[1], M. Alokail[2], N. Al-Daghri[2], J.-Y. Reginster[2], S. Sabico[2]

[1]University of Liège, Liège, Belgium, [2]King Saud University, Riyadh, Saudi Arabia

Introduction: Knee osteoarthritis (OA) is a prevalent and disabling condition characterized by pain and functional impairment. Intra-articular hyaluronic acid (IAHA) injections are widely used for symptom relief, but their efficacy remains debated due to conflicting conclusions across systematic reviews (SRs) and meta-analyses (MAs). This umbrella review aims to assess the symptomatic efficacy of IAHA in knee OA based on evidence reported by previously conducted SR and MA, identify factors contributing to discrepancies in SR/MA findings, and summarize consistent outcome trends.
Methods: This umbrella review followed Cochrane guidelines for overviews of reviews and adhered to the PRIOR reporting checklist. It was registered in PROSPERO (CRD42024625696). A systematic search was conducted in Medline (Ovid), Cochrane Database of Systematic Reviews (Ovid CDSR), and Embase, using a predefined Population/Intervention/Comparator/Outcome/Study design (PICOS) framework. SRs of randomized controlled trials (RCTs) evaluating IAHA efficacy on pain and/or function compared to placebo were included. Exclusion criteria were SRs including both RCTs and non-RCTs without separate synthesis of data from RCTs, scoping reviews, abstracts, commentaries, or narrative reviews. Two independent reviewers screened titles,/abstracts, and full texts, resolving disagreements by consensus. Risk of bias was assessed using the AMSTAR-2 checklist, classifying SRs as high, moderate, low, or critically low quality.
Results: Twenty-two SRs were included, with AMSTAR-2 quality ratings as follows: four high, one moderate, three low, and fourteen critically low. The majority (20/22) reported significant beneficial effects of IAHA on pain and function, with 15 SRs concluding positive outcomes, 3 reporting mixed conclusions, and 4 reporting negative conclusions. Among high/moderate-quality SRs, all five reported significant beneficial effects, with three concluding positively and two negatively. Negative or mixed conclusions were primarily attributed to restrictive inclusion criteria (e.g., large trial-only analyses, minimum patient numbers, long follow-up periods) and challenges in interpreting clinical relevance.
Conclusion: Most SRs and all high-quality SRs support the significant symptomatic efficacy of IAHA in knee OA. Negative interpretations arise when restrictive inclusion criteria challenge the clinical relevance of results. These findings highlight the need for standardized methodologies in SRs to provide clearer guidance for clinical practice.

OC13

ASSESSING BONE MINERAL DENSITY: A COMPARATIVE STUDY OF DXA AND RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY (REMS) IN ASIAN POPULATION

Y. Yoshino[1], Y. Asada[1], E. Tomatsu[1], S. Sekiguchi-Ueda[1], S. Shibata[1], T. Takayanagi[1], Y. Seino[1], Y. Sasaki[2], H. Takai[3], H. Ito[2], H. Sasaki[4], A. Suzuki[1]

[1]Department of Endocrinology, Diabetes, and Metabolism, Fujita Health University, Toyoake, Japan, [2]Department of Clinical Laboratory, Fujita Health University Hospital, Toyoake, Japan, [3]Department of Radiology, Fujita Health University Hospital, Toyoake, Japan, [4]International Medical Center, Fujita Health University Hospital, Toyoake, Japan

Objective: The Radiofrequency Echographic Multi-Spectrometry (REMS) method is a novel ultrasound diagnostic technique for measuring bone mineral density (BMD) in the lumbar spine (LS) and femoral neck (FN), with reports of a high correlation with dual-energy X-ray absorptiometry (DXA). However, clinical data in Asian population are still insufficient. This study aimed to compare BMD between the DXA and the REMS.

Methods: The study included 88 patients (M/F: 40/48) who underwent BMD assessment using both DXA and REMS at Fujita Health University Hospital in 2023. BMD measurements at the LS and FN were performed using DXA (Horizon W, Hologic, Inc., USA) and a REMS device (EchoS, Echolight S.p.A., Lecce, Italy). The mean age of the study subjects was 65.9 ± 14.8 years, and the BMI was 24.0 ± 4.2 kg/m². Comorbidities included type 2 diabetes mellitus in 76 patients, long-term glucocorticoid use (≥3 months) in 7 patients. Nineteen patients were receiving treatment for osteoporosis. Vertebral fractures and hip fractures were reported in 22 and 9 cases, respectively.

Results: At the LS, the mean T-score obtained by DXA was -1.00 ± 1.54, while REMS showed a significantly lower value of -2.48 ± 0.94 ($p<0.0001$). At the FN, DXA yielded -1.74 ± 1.16, whereas REMS showed -2.40 ± 1.05 ($p<0.0001$). Significant correlation was observed between DXA and REMS T-scores (LS: $R=0.294$, $p=0.0063$; FN: $R=0.541$, $p<0.0001$). Osteoporosis diagnosis rates differed: DXA classified 34 patients as having osteoporosis and 37 as osteopenia, whereas REMS identified 55 with osteoporosis and 28 with osteopenia. Among vertebral fractures patients, REMS classified all cases as osteopenia or osteoporosis, whereas DXA identified half as having normal BMD.

Conclusion: REMS provides a safe, radiation-free alternative for BMD assessment and has the potential to provide new insights into bone assessment independent of DXA.

The authors declare no conflicts of interest associated with this manuscript.

RAPID BONE MICROARCHITECTURE DECLINE, BUT NOT HIGHER FRACTURE RISK, IN MEN WITH ELEVATED FGF23 CONCENTRATION – THE STRAMBO STUDY

P. Szulc[1], D. Whittier[2], S. K. Boyd[2], L. C. Hofbauer[3], R. Chapurlat[1]

[1]INSERM UMR 1033, University of Lyon, Hospices Civils de Lyon, Lyon, France, [2]McCaig Institute for Bone and Joint Health, University of Calgary, Calgary, Canada, [3]University Center for Healthy Aging and the Division of Endocrinology, Diabetes, and Bone Diseases, Technische Universität Dresden, Dresden, Germany

Objective: Data on the association of fibroblast growth factor 23 (FGF23) with bone structure and fracture risk are limited. We studied the link of baseline FGF23 levels with the prospectively assessed bone microarchitecture decline and fracture risk over 12 years in older men.

Material and Methods: Serum FGF23 was measured at baseline in a cohort of 829 men aged 60-87 (Immunotopics, San Clemente, CA). Bone microarchitecture was assessed at the distal radius and distal tibia by HR-pQCT (XtremeCT I, SCANCO, Switzerland) at baseline and after 4, 8, and 12 yrs. Incident spine fractures were assessed on DXA scans. Self-reported incident non-spine fractures were confirmed by a health professional.

Results: At the distal radius, the rate of loss of total bone mineral density (Tt.BMD) increased with higher FGF23 levels (adjusted for confounders $p<0.001$). The rate of decrease in cortical thickness (Ct.Th) and density (Ct.BMD), and of trabecular area (Tb.Ar) expansion increased across the FGF23 quartiles ($p<0.01$ to <0.001). Failure load decreased faster ($p<0.01$) in the highest *vs.* the lowest FGF23 quartile (>32.3 *vs.* <17.4 RU/mL). Rates of change in trabecular density (Tb.BMD), number (Tb.N), thickness (Tb.Th), separation (Tb.Sp) or homogeneity of distribution (Tb.1/N.SD) did not correlate with the FGF23 level.

At the distal tibia, the rate of decrease in Tt.BMD, Ct.Th, Ct.BMD and failure load and the rate of Tb.Ar expansion increased across the FGF23 quartiles (all $p<0.001$ in multivariable models). Rates of change in the trabecular measures did not vary across the FGF23 quartiles.

After adjustment for age, BMI, BMD, falls and fractures, FGF23 level did not predict fractures (all fractures: n=157, HR= 0.95 per SD, 95%CI: 0.79–1.14; major osteoporotic fractures: n=60, HR= 1.02 per SD, 95%CI: 0.76–1.36).

Conclusion: In a cohort of older men followed prospectively for 12 years, higher FGF23 level was associated with faster cortical bone deterioration, but not with the risk of fracture.

NUMBER OF FRACTURES AND FRACTURE INCIDENCE IN RELATION TO BONE MINERAL DENSITY: AN INTERNATIONAL META-ANALYSIS

H. Johansson[1], N. C. Harvey[2], E. McCloskey[3], E. Liu[4], L. Vandenput[1], M. Lorentzon[1], W. D. Leslie[5], J. A. Kanis[3], _. Frax Meta-Analysis Cohort Group[6]

[1]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Mölndal, Sweden, [2]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [3]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom, [4]South Australian Health and Medical Research Institute (SAHMRI), Adelaide, Australia, [5]Department of Medicine, University of Manitoba, Winnipeg, Manitoba, Canada, [6]United Kingdom

Objectives Femoral neck bone mineral density (BMD) is an important determinant of fracture risk and an optional input into FRAX®. As one of a number of studies informing the next iteration of FRAX, the aim of this preliminary international analysis was to prospectively investigate, in men and women, the incidence and absolute number of fractures by baseline BMD T-score.

Materials and methods The analysis dataset comprised individual records of 160,035 men and women with information on BMD, from 51 cohorts in 25 countries. The total follow-up time was 1.3 million person-years. The risk of major osteoporotic fracture (MOF) or hip fracture (HF) was studied. The number of fractures and total person-years follow up time was summed by intervals of 0.5 SD in BMD T-score over all cohorts. The fracture incidence was calculated from number of fractures over total follow up of time in the interval.

Results Among the 48,811 men and 111,224 women, aged 68.3 (range 50-101), 17,968 individuals experienced one or more MOF and 5883 experienced one or more HF (1406 in men and 4477 in women). A minority of individuals had a BMD T-score <-2.5 (3.3% men and 16.1% women). For men 85.8% of the hip fractures occurred for those with BMD T-score equal or above -2.5; the corresponding figure for women was 60.7%. In the interval from -2.5 to -1, 59.4% of the hip fractures occurred for men and 52.7% of the women. Nevertheless, the highest fracture incidences are found for the lowest BMD T-scores (see figure for hip fractures in women). Similar findings were demonstrated for MOF and for men.

Conclusions These data confirm the importance of femoral neck BMD as a determinant of fracture risk but relatively low sensitivity (many fractures occur in individuals without osteoporosis). These data will inform the next iteration of FRAX.

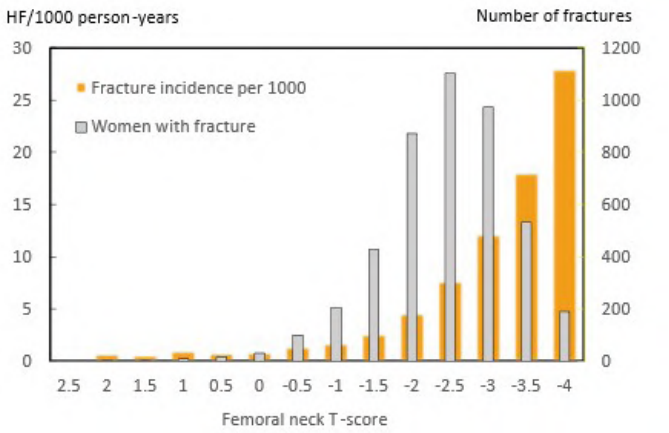

Figure. Number of women with at least one hip fracture (grey bars, right y axis)) and hip fracture incidence (orange bars, left y axis) in relation to BMD T-score in women (x axis) where "-2.5" represents -2.5≤x<-2.0, "-2" represents -2.0≤x<-1.5, etc.

TYPE I DIABETES MELLITUS IS ASSOCIATED WITH INCREASED FRACTURE RISK INDEPENDENT OF BONE MINERAL DENSITY: AN INTERNATIONAL META-ANALYSIS

N. C. Harvey[1], E. M. Curtis[1], H. Johansson[2], E. V. McCloskey[3], E. Liu[4], L. Vandenput[5], M. Lorentzon[5], W. D. Leslie[6], J. A. Kanis[2], Frax Meta-Analysis Cohort Group[2]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [2]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom, [3]MRC Versus Arthritis Centre for Integrated research in Musculoskeletal Ageing, Mellanby Centre for Musculoskeletal Research, University of Sheffield, Sheffield, United Kingdom, [4]South Australian Health and Medical Research Institute (SAHMRI), Adelaide, United Kingdom, [5]Sahlgrenska Osteoporosis Centre, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [6]Department of Medicine, University of Manitoba, Winnipeg, Canada

Objectives
In this international meta-analysis, we investigated the predictive value of type I diabetes mellitus for incident fracture in men and women, and whether this risk was independent of femoral neck bone mineral density (BMD).

Materials and methods
The interim analysis dataset comprised individual records of 78,130 participants (78.2% women) with information on diabetes status and BMD, from 14 cohorts across 19 countries. The total follow-up time was 0.7 million person-years. We investigated associations between the presence/absence of type I diabetes mellitus at baseline and risk of osteoporotic fracture or hip fracture using an extended Poisson model in each cohort. The covariates examined were age, sex, duration of follow-up and femoral neck BMD T-score. The results of the different studies were merged by using the inverse-variance weighted β-coefficients in random effects models.

Results
After adjustment for age and time since baseline, type 1 diabetes was associated with a greater risk of incident osteoporotic fracture in both men [hazard ratio (95% CI): 2.90 (1.30, 6.48)] and women [1.65 (1.23, 2.21)]. Similar associations were demonstrated for hip fracture in men, albeit with lower statistical certainty [4.22 (0.90, 19.71)], and in women [1.60 (1.02, 2.52)]. Although the effect was not statistically significant, adjustment for BMD T-score tended to slightly decrease the point estimate in men and increase it in women. For example, for incident osteoporotic fracture: men 2.28 (1.20, 4.35); women 1.74 (1.29, 2.34).
Conclusions
In one of the largest ever meta-analyses undertaken to date, type 1 diabetes was associated with increased fracture risk. The risk appeared largely independent of femoral neck BMD. These findings will inform the next iteration of the FRAX® calculator.

[1]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland, [2]Medimaps Group, Plan les Ouates, Geneva, Switzerland, [3]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom, [4]Comenius University Faculty of Medicine, 5th Department of Internal Medicine, University Hospital, Bratislava, Slovakia, [5]Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy, [6]Radiology Unit, Dimiccoli Hospital, Barletta, Italy, [7]Radiology Unit, Scientific Institute Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, [8]Medical University Graz, Department for Internal Medicine, Division for Endocrinology and Diabetology, Graz, Austria, [9]Department of Radiology and Division of Nuclear Medicine, Montefiore Einstein, New York, United States, [10]University of Wisconsin School of Medicine and Public Health, Madison, WI, United States

Objective: Over 37 million fragility fractures occur annually, yet early identification of high-risk individuals remains a major challenge. This study externally validates an AI-powered radiographic analysis tool designed for opportunistic detection of *very high bone fragility* risk in a European Caucasian cohort and an ethnically-diverse U.S.- cohort.
Methods: The multi-stage AI-driven bone fragility detection tool first applies an automatic detection and segmentation of lumbar vertebrae before fragility risk assessment. The very high bone fragility risk classifier was trained and validated using 16'622 paired lumbar-spine X-ray DICOM and DXA scans, with a further internal test set of 1`846 individuals. Two external cohorts were used for validation: a European cohort (N=220) and a U.S.-based cohort (N=647). Very high bone fragility risk was defined using DXA-derived criteria: Lumbar spine BMD T-score ≤ -2.5 and degraded trabecular bone score (TBS) < 1.23.
Results: In the internal test set, participants had a mean age of 62.2 ± 10.4 years, a BMI of 25.3 ± 4.2 kg/m², and a 15% prevalence of very high fragility risk. The AI model demonstrated an accuracy of 0.86 (95% CI: 0.82–0.90), a sensitivity of 0.76 (0.66–0.86), and a specificity of 0.87 (0.82–0.99). In the external validation, the European cohort, composed of White individuals, had a mean age of 68.3 ± 11.3 years, a BMI of 26.8 ± 12.9 kg/m², and a 22% prevalence of very high fragility risk. The AI tool achieved an accuracy of 0.83 (95% CI: 0.71–0.93), a sensitivity of 0.56 (0.32–0.70), a specificity of 0.92 (0.79–0.99), and an AUC of 0.86 (0.82–0.91) in this cohort. The U.S. cohort, which included 32% Black, 55% Hispanic, 6% Asian, and 7% White individuals, had a mean age of 67.3 ± 9.8 years, a BMI of 28.5 ± 5.7 kg/m², and a 11% prevalence of very high fragility risk. In this cohort, the AI tool achieved an accuracy of 0.87 (95% CI: 0.81–0.95), a sensitivity of 0.50 (0.23–0.55), a specificity of 0.92 (0.86–0.99), and an AUC of 0.84 (0.80–0.87).
Conclusion: This study externally validates an AI-driven X-ray analysis tool for opportunistic identification of individuals at very high bone fragility risk. The tool demonstrated robust performance and enhanced applicability for opportunistic screening considering its reduced false positive rates, in both a homogenous European cohort and an ethnically diverse U.S.-based cohort. Further validation will establish the tool's ability to predict fracture risk and treatment decision-making.

Cohort	Age (years)	BMI (kg/m²)	Very High Risk* (%)	Accuracy (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)	AUC (95% CI)
Internal Test n = 1,846	67.2 ± 10.4	25.3 ± 4.2	15%	0.86 (0.82-0.90)	0.76 (0.66-0.86)	0.87 (0.82-0.99)	0.88 (0.78, 0.98)
European Cohort n = 220	68.3 ± 11.3	26.8 ± 12.9	22%	0.83 (0.71-0.93)	0.56 (0.32-0.70)	0.92 (0.79-0.99)	0.86 (0.82-0.91)
U.S. Cohort n = 647	67.3 ± 9.8	28.5 ± 5.7	11%	0.87 (0.81-0.95)	0.50 (0.23-0.55)	0.92 (0.86-0.99)	0.84 (0.80-0.87)

COST-EFFECTIVENESS OF OPPORTUNISTIC OSTEOPOROSIS SCREENING USING CHEST RADIOGRAPHS WITH DEEP LEARNING IN GERMANY

M. Hiligsmann[1], R. Schmidmaier[2], J.-Y. Reginster[3]

[1]Department of Health Services Research, Maastricht University, Maastricht, Netherlands, [2]Department of Medicine IV, LMU University Hospital, LMU Munich, Munich, Germany, [3]King Saud University, Riyadh, Saudi Arabia

Objective: Deep learning models applied to chest radiographs can support opportunistic osteoporosis screening. This study evaluates the cost-effectiveness of this approach in German women aged 50 years and over.

Methods: A microsimulation Markov model estimated the cost per quality-adjusted life year (QALY) gained (€2024) for screening via chest radiographs with deep learning, followed by treatment, versus no screening and treatment. The patient pathways were based on the sensitivity and specificity of AI-enhanced radiographs and risk stratification per German osteoporosis guidelines. Women with a risk for vertebral or hip fracture below 5% received no treatment; those with 5–10% risk were prescribed alendronate, and those aged 65+ with risk >10% received sequential treatment starting with romosozumab. Assumptions and data were validated by a German clinical expert. Real-world medication persistence, realistic assumptions for probabilities of DXA examination post-screening detection and for treatment initiation rates were incorporated. Parameter uncertainty was analyzed through sensitivity analyses.

Results: Screening improved health outcomes, yielding more QALYs and fewer fractures while increasing treatment costs. The cost per QALY gained of opportunistic screening was estimated at €13,340 for all women aged 50+, well below the commonly accepted cost-effectiveness thresholds, which are generally in the range of €60,000. Optimizing follow-up, treatment initiation, and adherence enhanced cost-effectiveness, with dominance (higher QALYs at lower costs) achievable by halving medication non-persistence.

Conclusion: Opportunistic osteoporosis screening using chest radiographs with deep learning is a cost-effective strategy for German women aged 50+ under real-world conditions. Improving screening follow-up and medication adherence could further enhance cost-effectiveness and achieve dominance.

RELATIONSHIP BETWEEN COMORBIDITY, PHYSICAL ACTIVITY AND FRAILTY DIFFER ACCORDING TO EDUCATIONAL ATTAINMENT: FINDINGS FROM THE SOUTHAMPTON LONGITUDINAL STUDY OF AGEING (SALSA)

F. Laskou[1], L. D. Westbury[1], F. Kirkham-Wilson[1], G. Bevilacqua[1], N. R. Fuggle[1], E. M. Dennison[1], P. Aggarwal[2], H. P. Patel[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [2]Living Well Partnership, Southampton, United Kingdom

Objectives

Comorbidity is common among older adults and is known to be related to lower physical activity and increased risk of developing frailty. However, there is a paucity of research exploring the effect of education on these associations. We aimed to explore the potential interation effect of educational attainment on the relationship between comorbidity, physical activity and frailty among community-dwelling older people.

Methods

A cross-sectional analysis was conducted on 513 community-dwelling older participants aged 75-96 identified from primary care, who completed a questionnaire which ascertained educational attainment attainment (university degree/Higher National Diploma/higher professional qualifications vs not), number of comorbidities and physical activity. Participants with ≥ 3 of the following were regarded as living with frailty: lost more than 10 lb unintentionally in the past year; self-reported exhaustion in the past week (≥3 days); low physical activity (bottom sex-specific fifth of the distribution); low self-reported walking speed (very slow or unable to walk); or difficulty carrying 10 lb (a lot of trouble or unable). Body mass index (BMI) was calculated from self-reported height and weight. Number of comorbidities in relation to physical activity and frailty was examined using linear and logistic regression respectively, with stratification by educational attainment. Men and women were pooled, and all analyses were adjusted for age, sex, BMI and smoking status.

Results

Median (lower quartile, upper quartile) number of comorbidities was 2 (1, 3) among both men and women; 17 (7%) men and 42 (15%) women had frailty. Standard deviation differences in physical activity scores (95% CI) per unit increase in number of comorbidities were greater among less educated participants (-0.09 [-0.15, -0.03], p=0.006) compared to more educated participants (-0.02 [-0.17, 0.14], p=0.826). Similarly, odds ratios (95% CI) for frailty per unit increase in number of comorbidities were greater among less educated participants (1.39 [1.13, 1.72], p=0.002) compared to more educated participants (1.17 [0.69, 1.98], p=0.552).

Conclusions

The detrimental effects of multimorbidity on physical activity and risk of developing frailty may be greater among less educated participants. These findings suggest that multimodal health and wellbeing intervention strategies coordinated across the primary-secondary care interface could be targeted to this vulnerable group of older people.

RELATIONSHIPS BETWEEN CHANGE IN SEX HORMONES WITH CHANGE IN MEASURES OF SARCOPENIA: A LONGITUDINAL STUDY IN COMMUNITY DWELLING OLDER MEN

S. T. Hills[1], T. A. Mansfield[2], P. Cawthon[3], N. E. Lane[4], E. S. Orwoll[1]

[1]Oregon Health & Science University, Portland, United States, [2]San Francisco Coordinating Center, California Pacific Medical Center Research Institute, San Francisco, CA, United States, [3]California Pacific Medical Center Research Institute, San Francisco, CA, United States, [4]Division of Rheumatology, Department of Medicine, University of California Davis, Davis, CA, United States

Objective Assess longitudinal associations between changes in sex hormones and changes in measures of sarcopenia in older men.

Methods Men in the MrOS study had sex hormone (SH) measures and were followed for 14±0.6 years for changes in DXA lean mass and assessments of physical performance. At baseline, 1718 men (age 73±6) had SH measures, and 437 had measures at the end of follow-up (age 83.4±3.5). Steroids were assayed by GC/MS and SHBG by chemiluminescence. Physical performance and activity were assessed by validated methods. To assess associations of SH change with change in measures of sarcopenia, standardized SH values were used in mixed effects linear models adjusted for potential confounders (age, site, height, weight, alcohol use, high medication use, diabetes, hypertension, smoking history, eGFR, cardiovascular disease and self-reported health). Results are reported as the change in the outcome measure per 1 standard deviation (SD) change in the SH measure.

Results During year 14 of follow-up, there were declines in lean mass and all measures of physical performance, and simultaneous declines in mean total testosterone (TT), estradiol (E2), and estrone (E1), while SHBG increased. In the fully adjusted model, greater decline in TT was associated with greater loss in total lean body mass (tLBM) (0.27 kg/SD; 95% CI: 0.07, 0.5), appendicular skeletal lean mass (aSLM) (0.15 kg/SD; 0.04, 0.3) and grip strength (0.49 kg/SD; 0.2, 0.8); increase in SHBG with declines in chair stands (0.07 per 10 seconds/SD; 0.01, 0.14) and 6m walk speed (0.01 m/s/SD; 0.005, 0.02); decline in E1 with greater loss of tLBM (0.21 kg/SD; 0.02, 0.4), aSLM (0.18 kg/SD; 0.07, 0.3) and with increase in 6m walk speed (0.01 m/s/SD; 0.001, 0.02); decline in E2 with lesser loss in PASE (3.08/SD; 0.3, 5.9).

Conclusion There were small but significant associations between longitudinal change in SH levels and decreases in lean mass and physical performance, supporting that the development of sarcopenia in older men is related to changes in total testosterone, with some associations with SHBG, E1 and E2. These results add to the body of evidence regarding the complex interaction between sex hormones, aging and sarcopenia.

OSTEOSARCOPENIA AS A RISK FACTOR FOR DEPRESSION: LONGITUDINAL FINDINGS FROM THE SHARE STUDY

N. Veronese[1], F. S. Ragusa[2], S. Sabico[3], L. Dominguez[4], M. Barbagallo[2], G. Duque[5], L. Smith[6], N. Al-Daghri[3]

[1]Unicamillus University, Rome, Italy, [2]university of palermo, Palermo, Italy, [3]King Saud University, Ryhad, Saudi Arabia, [4]University of Kore, Enna, Italy, [5]McGill University, Montreal, Canada, [6]Anglia Ruskin University, Cambridge, United Kingdom

BACKGROUND: Osteosarcopenia (i.e., the co-existence of osteoporosis and sarcopenia) and depression are highly prevalent among older people. However, the association between osteosarcopenia and depression in older people is largely unknown. Therefore, the present study aims to investigate this possible association in a representative sample of the older adult population in Europe and Israel.
METHODS: The present analysis used data from multiple waves of the SHARE study. Osteosarcopenia was defined as the concomitant presence of osteoporosis and sarcopenia; depressive symptoms in the SHARE study were self-reported using the EURO-D scale. The association between the presence of osteosarcopenia at baseline in people free from depression and incident depression during 12 years of follow-up was analyzed using a Cox's regression analysis, adjusting for several baseline covariates.
RESULTS: 16,452 participants were included (mean age 63.7, SD 9.6; females 50.6%). During the follow-up period, 5,056 participants (31.1% of the initial population) became depressed. People affected by osteosarcopenia became depressed in more than half of the cases compared to a quarter of controls. After adjusting for several potential baseline confounding variables, only sarcopenia (HR, hazard ratio=1.17; 95% CI, confidence intervals 1.04-1.32; p=0.009) and osteosarcopenia (HR=1.27; CI 95% 1.12-1.58; p=0.003) were significantly associated with a higher risk of depression.
CONCLUSIONS: The present study identified a significant association between osteosarcopenia and depression over 12 years of follow-up. If future research confirms the present findings, it may then be prudent to target those with osteosarcopenia to aid in the prevention of onset depression.

Introduction: Sarcopenia, defined by the age-associated loss of skeletal muscle mass and function, significantly affects health-related quality of life (HRQoL). While the Sarcopenia and Quality of Life (SarQoL) questionnaire is recognized as the only disease-specific patient-reported outcome measure (PROM) for assessing sarcopenia-related HRQoL, a comprehensive quantitative evaluation of its psychometric properties is still lacking.
Objective: This systematic review and meta-analysis aimed to provide a quantitative summary of all evidence reported on the reliability, validity, responsiveness and floor/ceiling effects of SarQoL in older adults.
Methods: PRISMA-COSMIN guidelines for reporting systematic review of outcome measure instruments were followed. A systematic search for studies evaluating psychometric properties of SarQoL (i.e., reliability, validity, responsiveness and floor and ceiling effect) in older people was conducted on MEDLINE (via OVID), PsycINFO, Scopus and EMBASE. Studies published between 2013 and November 2024 in which individuals were diagnosed as being sarcopenic based on a consensual definition of sarcopenia. Study selection and data extraction were made by two independent reviewers. The COSMIN risk of bias tool was used to assess the methodological quality of the studies and summarize the psychometric properties of each tool. A random-effects model was applied for meta-analyses and subgroup and sensitivity analyses were performed to explore potential sources of heterogeneity and to assess the robustness of the findings.
Results: The systematic search identified 411 studies of which 25 fulfilled the inclusion criteria, including 4585 individuals of which 1311 were diagnosed sarcopenic. SarQoL demonstrated high reliability, with pooled Cronbach's alpha values consistently exceeding 0.80, and excellent test-retest reliability (ICC = 0.98). Validity assessments showed strong convergent correlations ($r > 0.54$) with related dimensions of generic SF-36 and EQ-5D, and weaker divergent correlations ($r < 0.47$), confirming construct validity. No floor or ceiling effects were observed, indicating an adequate range of response options. Responsiveness, evaluated in two studies using different methodologies, supported the ability of SarQoL to detect meaningful changes in HRQoL. The certainty of evidence was rated as high for reliability, validity and responsiveness.
Conclusion: SarQoL is a reliable and valid questionnaire for assessing HRQoL in sarcopenia. Its use, particularly among community-dwelling older individuals, for measuring HRQoL is highly reliable. This meta-analysis consolidates a decade of evidence and confirms the strong psychometric properties of SarQoL, with a high level of evidence.

OC23

BIOLOGICAL AGE-ACCELERATION ASSOCIATIONS WITH GRIP STRENGTH LEVEL AND LONGITUDINAL CHANGE: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

N. R. Fuggle[1], L. D. Westbury[1], N. Kitaba[2], J. W. Holloway[2], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [2]School of Human Development & Health, University of Southampton, Southampton, United Kingdom

Objectives
Low grip strength is a key component of sarcopenia and is related to increased morbidity and mortality. DNA methylation accumulates across the lifecourse and biological clocks have been devised to measure age-acceleration (whether an individual is biologically older or younger than their chronological age). Of interest is whether age-acceleration measures could predict individuals at high risk of muscle deterioration. We examined epigenetic

age-acceleration measures in relation to baseline level and longitudinal change in grip strength in a cohort of community-dwelling older adults.

Materials and methods

Analyses were based on a sample of 333 participants from the UK Hertfordshire Cohort Study. At baseline (1998-2004), participants underwent detailed health assessments and provided blood samples. At baseline and follow-up (2011), grip strength was measured using a Jamar dynamometer; conditional change in grip strength (independent of baseline level) from baseline to follow-up was also derived. DNA was extracted from peripheral blood leukocytes and DNA methylation at CpG sites was measured using the Infinium Human Methylation Beadchip arrays (Illumina Inc., San Diego, CA). Various age-acceleration measures were then ascertained (PCPhenoAge, PCGrimAge, and bAge). Age-acceleration measures in relation to baseline and conditional change in grip strength were examined using sex-stratified linear regression. Models adjusted for chronological age, and those additionally adjusted for anthropometric, lifestyle and socioeconomic characteristics were implemented. Regression coefficients (95% CI) corresponding to the difference in baseline grip strength (kg) per standard deviation increase in age-acceleration measures are presented.

Results

At baseline, mean (SD) age was 65.1 (2.8) years. Among men, greater age-acceleration according to bAge was related to lower baseline grip strength regardless of adjustments used (-1.29 (-2.46,-0.12), p=0.03 in fully-adjusted analyses). After adjustment for chronological age, greater age-acceleration according to PCPhenoAge (-1.35 (-2.46,-0.25), p=0.017) and PCGrimAge (-1.25 (-2.33,-0.16), p=0.024) were related to lower baseline grip strength among men but these associations were not robust to further adjustment. Associations were much weaker regarding baseline grip strength among women, and for both sexes regarding conditional change in grip strength.

Conclusions

A sex difference was observed in the relationship between a measure of biological age-acceleration and grip strength. This finding demands further investigation in larger cohorts.

OC24

TREATMENT-RELATED CHANGES IN TOTAL HIP BONE MINERAL DENSITY AND FRACTURE RISK REDUCTION FOR TRIALS WITH ACTIVE CONTROL AND SEQUENTIAL THERAPY: THE FNIH-ASBMR-SABRE PROJECT

T. Vilaca[1], L. Lui[2], M. Schini[1], S. Ewing[3], A. Thompson[3], E. Vittinghoff[3], D. C. Bauer[3], D. M. Black[3], M. L. Bouxsein[4]

[1]University of Sheffield, Sheffield, United Kingdom, [2]Research Institute, California Pacific Medical Center, San Francisco, United States, [3]Department of Epidemiology & Biostatistics, University of California, San Francisco, United States, [4]Department of Orthopedic Surgery, Harvard Medical School, Boston, United States

Objectives

In the SABRE Study, we showed that treatment-related differences in 24-month total hip bone mineral density (THBMD) changes are strongly associated with reduced fracture risk in placebo-controlled trials. We also determined the surrogate threshold effect (STE): the minimum THBMD change in a trial that would predict a significant reduction in fracture risk in trials. However, the availability of osteoporosis therapies limits use of placebo-controlled trials, and the need to sustain bone mineral density gains after anabolic therapies leads to the use of sequential therapy. This analysis aimed to determine if these associations and STEs apply to trials using active control or sequential therapies.

Material and methods

We used individual patient data from 19 trials: 16 randomized, placebo-controlled trials (14 anti-resorptive, 1 teriparatide, 1 odanacatib), and 3 trials with active control or sequential therapy (1 abaloparatide/alendronate and 2 romosozumab/alendronate or denosumab).

For each trial, we calculated the treatment-related difference in mean percentage change in THBMD at 24 months and the risk reductions for the entire follow-up period. We used logistic regression for radiologic vertebral fractures and Cox regression for all clinical fractures (combination of non-vertebral and clinical vertebral fractures). We performed linear meta-regression to estimate the study-level association (r^2 and 95% CI) between treatment-related differences in THBMD changes and fracture risk reduction, including the 16 placebo-controlled trials only and all the trials including 3 active control/sequential therapy trials and verified if the change in THBMD observed in the trials with active control or sequential therapy was greater than the STE calculated from placebo-controlled trials.

Results

We found consistent associations between treatment-related THBMD changes and fracture risk reduction for placebo-controlled trials only and all trials for vertebral fractures [r^2 (CI)= 0.73(0.33,0.84)vs.0.71(0.36,0.82)] and for all clinical fractures [0.71(0.32, 0.83)vs.0.72(0.39,0.83)] respectively. In trials with active control or sequential therapy, increase in THBMD was greater than STE and associated with a significant decrease in fracture risk (Table).

Conclusion

Our findings show that treatment-related changes in THBMD predict anti-fracture efficacy equally well, regardless of the trial design.

Table Validation of STE estimates in the 3 active controlled/sequential treatment trials. Each cell shows the OR or HR for fracture reduction and the 95% confidence interval. In the three trials, the mean THBMD % change was greater than the STE, in agreement with the significant fracture reduction observed.

Study	TH BMD % difference (95% CI)	Fracture risk reduction OR or HR (95% CI)	
		Vertebral	All clinical
		STE: 1.43	STE: 2.04
FRAME (Romo/Dmab)	4.57 (3.93, 5.21)	0.26 (0.16, 0.41)	0.66 (0.51, 0.84)

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [2]University of Bristol, Bristol, United Kingdom, [3]The Health Research Unit Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, [4]MRC Unit The Gambia @ London School of Hygiene and Tropical Medicine, Banjul, Gambia, [5]Department of Geriatrics, University of KwaZulu-Natal, Durban, South Africa, [6]MRC International Statistics and Epidemiology Group, London School of Hygiene and Tropical Medicine, London, United Kingdom, [7]Department of Rheumatology, University of KwaZulu-Natal, Durban, South Africa, [8]Birmingham Women's and Children's NHS Trust, Birmingham, United Kingdom

Objective: To determine the prevalence and associated factors for vertebral fractures(VF) in females and males in the Fractures-E3 study[1].

Methods: A population-based, cross-sectional study of community dwelling adults was conducted across three urban sites; Harare, Zimbabwe; Brufut/Sukuta, The Gambia; Kwamashu, South Africa (SA). Recruitment was stratified by sex and age (40-54, 55-69, ≥70 years). Prevalence of VF was determined using Genant semi-quantitative assessment on iDXA images in The Gambia and Zimbabwe, and algorithm-based-quantitative (ABQ)-method on lateral thoracic/lumbar spine radiographs in SA. Demographic and clinical factors were compared in those with and without prevalent VFs, by country and sex. Logistic regression determined associations between clinical factors and VF.

Results: The prevalence of VF was: 4.2% (M:4.3%, F4.1%) in SA (n=962), 8.0% (M:7.5%, W:8.4%) in Zimbabwe (N=1067), and 9.8% (M:8.5%, F:10.9%) in The Gambia (n=1130). In those aged ≥70y, prevalence was greatest in women; 20.8% (Gambia), 15.6% (Zimbabwe), 7.1% (SA). However, overall sex was not a risk factor for fracture. Increasing age was associated with presence of VF in all countries (odds ratios [95% confidence intervals] Gambia 1.07[1.05,1.09] per year; Zimbabwe 1.05[1.02,1.07]; SA 1.05[1.02,1.07]) as was prior adult fracture (Gambia 2.29[0.96,5.47]; SA 2.28[1.18,4.41]; Zimbabwe 2.18[1.15,4.13]). In The Gambia glucocorticoid use was associated with VF (3.25 [1.78,5.94]). Increasing BMI in SA (0.95[0.91,1.00]) and Zimbabwe (0.96[0.92,1.00]) was associated with lower odds of having a prevalent VF. In both countries, approximately 25% females had a T-score<-2.5 and 13% males.

Conclusion: VFs are common in African populations. Given the rising ageing population in countries with limited and stretched healthcare resources, it is important to understand further context-specific factors associated with fragility fractures such as bone trauma in the young, malnutrition, and HIV.

ENHANCING FRACTURE RISK PREDICTION: A COHORT-SPECIFIC MODEL INTEGRATING FRAXPLUS® VARIABLES FOR IMPROVED ACCURACY AND RECLASSIFICATION

M. Zoulakis[1], H. Johansson[1], N. C. Harvey[2], K. F. Axelsson[1], H. Litsne[1], L. Johansson[1], M. Schini[3], L. Vandeput[1], E. V. McCloskey[4], J. A. Kanis[5], M. Lorentzon[1]

[1]University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Sahlgrenska Osteoporosis Centre, Gothenburg, Sweden, [2]MRC Lifecourse Epidemiology Centre & NIHR Southampton Biomedical Research Centre, University of Southampton., Southampton , United Kingdom, [3]Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom, [4]MRC and Arthritis Research UK Centre for Integrated Research in Musculoskeletal Ageing, Mellanby Centre for Musculoskeletal Research, Sheffield, United Kingdom, [5]7 Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom

Objectives

The FRAXplus® tool provides adjustments for individual fracture risk factors not currently incorporated into FRAX, but only allows adjustment of FRAX probabilities for one FRAXplus® risk factor at a time. To overcome this limitation, we developed a cohort-specific model that integrates all FRAXplus® variables to more comprehensively predict major osteoporotic fractures (MOF) and hip fractures. This study aimed to evaluate the predictive accuracy

and reclassification performance of a cohort-specific multivariable model, both with and without adding FRAXplus® variables, for estimating 10-year fracture risk.

Methods

Using data from the SUPERB cohort of (n=3028), women aged 75-80 years, we developed two 10-year probabilities based on modified Poisson regression models: one based solely on FRAX risk factors and the other augmented with FRAXplus® variables. Clinical risk factors (CRFs) were collected via questionnaires and incident fractures captured using a regional x-ray archive over eight years of follow-up. Model performance was assessed using the area under the curve (AUC) and net reclassification improvement (NRI). Ten-year fracture probabilities were calculated for MOF and hip fractures, with participants reclassified according to MOF probability intervention threshold (IT) ≥26%.

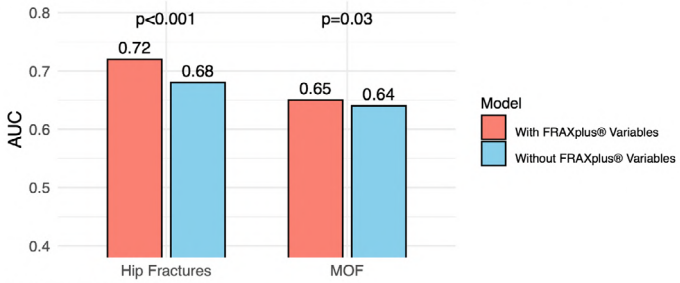
Results

Incorporating FRAXplus® variables significantly improved the model's predictive performance. For hip fractures, the AUC increased from 0.68 to 0.72 (p<0.001), and for MOF, the AUC improved from 0.64 to 0.65 (p=0.03). Reclassification analyses demonstrated significant NRI improvements of 2.6% (p=0.025) for MOF. Under the new model with FRAXplus® adjustments, 113 women had their 10-year probabilities reclassified above the IT: of these, 30 (26.55%) experienced fractures. Meanwhile, 159 women were reclassified below the IT, and among them, 27 (16.98%) experienced fractures.

Conclusions

The cohort-specific multivariable model incorporating FRAXplus® variables significantly enhances fracture risk prediction and reclassification compared to models with only the original FRAX model parameters. These findings highlight the benefit of FRAXplus® risk factors which may guide future iterations of the FRAXtool.

Cohort Specific Model With and Without FRAXplus® Variables



AUC: Area Under the Curve

ENGAGEMENT WITH AND TOLERABILITY OF AUGMENTED REALITY (AR) EXERGAMES AMONG OLDER WOMEN WITH OSTEOPOROSIS: RESULTS FROM A CLINICAL TRIAL

E. Thuilier[1], J. J. Carey[2], B. Whelan[2], M. Fitzgerald[3], J. Dingliana[4], M. Dempsey[5], S. Biggins[6], A. Brennan[1]

[1]University of Galway, School of Computer Science, Galway, Ireland, [2]University of Galway, School of Medicine, Galway, Ireland, [3]University of Galway, College Of Medicine Nursing & Health Sc, Galway, Ireland, [4]Trinity College Dublin, School of Computer Science and Statistics, Dublin, Ireland, [5]University of Galway, School of Mechanical Engineering, Galway, Ireland, [6]University Hospital of Limerick, Department of Physiotherapy, Limerick, Ireland

Background

Physical therapy is a proven intervention to reduce fall and fracture risk among people with Osteoporosis. To address engagement challenges with traditional therapy, virtual rehabilitation using exergames has emerged as a promising solution.

Purpose

To assess the tolerability of and engagement with augmented reality (AR) exergames among postmenopausal women with osteoporosis.

Methodology

We developed 4-bespoke AR exergames where virtual objects are overlaid on the real-word from active-videogames to create interactive physical activity experiences. These games (i.e. sit-to-stand, squat, arm-raises and step-up) were aligned with an approved physical therapy programme for osteoporosis patients and will be demonstrated during an oral presentation. A Phase I-II clinical trial was conducted over 8 weeks to assess safety, tolerability and change in function. Phase I included feedback about discomfort and motion sickness from all participants, while Phase II included feedback from the Intervention cohort concerning exergame engagement. The Intervention group used a Microsoft HoloLens-2 headset and a body-tracking camera to interact with virtual objects whose visual elements evolved weekly, based on participant feedback. Real-time visual and auditory feedback provided cues, motivation, and posture corrections. The Control group followed a traditional exercise programme comprising the 4 exercises.

Results

In Phase I, 65% of all participants reported no motion sickness and 81% no discomfort. Discomfort was generally described as mild pressure over the upper body (Figure 1). In Phase II, 41 women aged 60-86years attended bi-weekly, 20-minute sessions for 6-weeks: 21 control and 20 intervention. Fewer than 10% experienced AR previously. No patient died. 85% of the Intervention group reported enjoying the exergames.

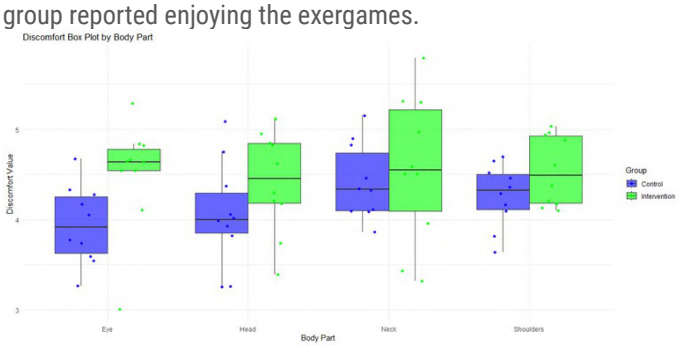

Figure 1: Discomfort

Conclusion

AR exergames were acceptable, enjoyable, and well tolerated among older women with osteoporosis. This innovative approach could improve engagement with and adherence to physical therapy. Larger clinical trials are needed to assess their effectiveness

in clinical practice.

OC28

EFFECTS OF ANTIDIABETETIC TREATMENTS ON FRACTURE RISK

G. Cavati[1], F. Pirrotta[1], E. Ceccarelli[1], G. Dipasquale[1], M. Garofalo[1], P. Cardamone[1], D. Merlotti[1], L. Gennari[1]

[1]Department of Medicine, Surgery and Neurosciences, University of Siena, Italy, Siena, Italy

Objectives: Treatments for type 2 diabetes (T2D) may exert both direct and indirect effects on bone, with potential implications on fracture risk. While insulin and thiazolidinediones have been associated with increased fracture risk, limited information exists about the effects of metformin and, to a greater extent, the most recent oral antidiabetic drugs (OADs), i.e. GLP-1 receptor agonists (GLP-1ra) or SGLT-2 inhibitors (SGLT2i). We assessed the effects of different antidiabetic treatments, alone or in combination, on fracture incidence in an outpatient cohort.
Methods: 403 T2D patients were followed from the baseline visit to the date of fracture event; subjects without fracture were censored at the end of follow-up. After a mean follow-up of 9 years, a total of 154 incident nontraumatic fractures (42 vertebral, 112 nonvertebral) were observed in 95 patients. Cox proportional regression models were used to examine the relationship of any treatment with incident fractures, with results presented as hazard ratios (HRs) and 95% CIs.
Results: Patients under insulin treatment showed the highest fracture incidence (reaching 54% at 9yrs) as compared with patients on OADs, equivalent to a HR of 1.88 (95% CIs, 1.15–3.05; p =0.01). Conversely, insulin treatment associated with OADs did not confer increased fracture risk versus OADs treatment alone (HR 1.24; 95% CIs 0.66–2.32). Among the different OADs, both metformin (HR 0.47; 95% CIs 0.30–0.75; p<0.005) and SGLT2i (HR 0.19; 95% CIs 0.05–0.81; p<0.05) were associated with decreased fracture incidence with respect to insulin treatment. All the HR levels remained statistically significant after controlling for covariates (diabetes duration and T2D complications). Moreover, the association between GLP-1Ra and SGLT2i (with or without metformin) was associated with the lowest fracture incidence (5.9%) among the different treatment regimens, albeit the HR did not reach the statistical significance, likely due to the limited number of cases (HR 0.17; 95% CIs 0.02–1.25; p=0.08).
Conclusions: These results further suggest the use of OADs such as metformin and SGLT2i (alone or in combination) over insulin treatment to reduce fracture risk in T2D patients.

OC29

GLP-1 RECEPTOR AGONISTS AND RISK OF BONE FRACTURES IN ELDERLY PEOPLE WITH TYPE 2 DIABETES

M. Kasher Meron[1,2], T. Hornik-Lurie[3], G. Twig[4,5,6], P. Rotman-Pikielny[1,2]

[1]Department of Endocrinology, Meir Medical Center, Kfar-Saba, Israel, [2]School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel, [3]Research Department, Meir Medical Center, Kfar Saba, Israel, [4]Division of Endocrinology, Diabetes and Metabolism, Sheba Medical Center, Ramat Gan, Israel, [5]Department of Preventive Medicine, School of Public Health, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv , Israel, [6]The Gertner Institute for Epidemiology and Health Policy Research, Sheba Medical Center, Ramat Gan, Israel

Objective: To assess the risk of fractures associated with glucagon-like peptide 1 receptor agonists (GLP-1 RA) therapy compared to sodium-glucose cotransporter-2 inhibitors (SGLT-2i) or dipeptidyl peptidase-4 inhibitors (DPP-4i) therapy in elderly people with type 2 diabetes.
Methods: This nationwide, population-based, cohort study included individuals with type 2 diabetes, ≥ 65 years, who initiated GLP-1 RA therapy or one of the comparators during January 2018–October 2022. The primary outcome was the first incident of vertebral, hip, pelvic, humerus, forearm or rib fracture. Anthropometric and clinical characteristics of patients, including osteoporosis and risk factors for fractures, were extracted from the electronic database. People were followed until fracture, death, or March 2024. After adjusting for propensity score, hazard ratios (HRs) with 95% confidence interval (CI) were estimated using stepwise Cox models, and the Fine-Gray model for competing risks. Subgroup analyses by age, sex, ethnicity, BMI, and osteoporosis were performed.
Results: Among 45,222 people, 73.0±6.4 years, 50% female, 66.5% were 65-75 years and 31.3% ≥75 years. During a median follow up of 35.3 (interquartile range 24.7-48.0) months, 3,618 (8.0%) had an incident fracture. Among 11,061 new users of GLP-1 RA and 34,161 of the comparator drugs, the overall incidence of fractures was comparable between groups ((2.82 (95%CI 2.63-3.02) vs. 2.75 (95%CI 2.65-2.85)), p=0.53, respectively, per 100 person years. In multivariate analysis for osteoporotic fractures (adjusted for multiple risk factors), initiating GLP-1 RA was associated with a 12% increased risk for bone fractures compared to the control group (HR 1.12, 95%CI 1.03-1.23, p=0.006). Repeating the analysis for competing risks, along with conducting various subgroup and sensitivity analyses, yielded results consistent with those of the main analysis.
Conclusions: Initiation of GLP-1 RA therapy was associated with an increased risk of incident fractures compared to SGLT-2i and DPP-4i, among elderly individuals with type 2 diabetes.

[1]Deakin University, Burwood, Australia, [2]Monash University, Clayton, Australia

Objective: To compare the effectiveness of a 6-month remotely-delivered, home-based functional resistance and impact training (FIT) versus structured walking (control) program for improving physical function in older adults with obesity undergoing caloric restriction (CR).

Material and Methods: Community-dwelling adults (n=116) aged ≥60 years with self-reported obesity (BMI ≥30 kg/m^2) and increased risk for sarcopenia (SARC-F score ≥2) commenced a 6-month CR intervention (750-1000 kcal restriction from habitual intake via dietary modification) delivered by an Accredited Practicing Dietitian using the Physitrack® smartphone app and telephone consults. Participants were randomised for 6 months to FIT (3-5 sessions/week of home-based muscle strengthening and weight-bearing impact exercises) or control (targeting 150 min/week of walking activity), delivered and monitored by an Accredited Exercise Physiologist using Physitrack®. The primary outcome was change in muscle power, determined by vertical jump power assessment using a ground reaction force platform. Secondary outcomes included changes in stair-climb power, 5x sit-to-stand time, gait speed, and Short Physical Performance Battery (SPPB) scores.

Results: At baseline, mean±SD age and BMI were 66.4±3.9 (range 60-84) years and 35.6±4.6 kg/m^2 respectively, and 74% of participants were female. During the 6-month intervention, 24 of 59 (41%) FIT and 18 of 57 (32%) controls were lost to follow-up, primarily due to loss of interest and illness. Intention-to-treat analyses demonstrated that mean body weight decreased significantly for both FIT (-2.3 kg; 95% CI -3.7, -1.0; P<0.001) and control (-1.7 kg; 95% CI -3.0, -0.5; P=0.006), with no difference between groups (P=0.508). Vertical jump power increased significantly for FIT (0.88 W/kg; 95% CI 0.19, 1.58; P=0.014) but not control (0.03 W/kg; 95% CI -0.63, 0.68; P=0.937) but these changes were not significantly different (P=0.079). Stair climb power also improved for FIT only (0.39 W/kg; 95% CI 0.17, 0.61; P<0.001), while sit-to-stand time, gait speed and SPPB scores improved in both groups (all P<0.05).

Conclusions: In older adults with obesity undergoing CR, FIT similarly improved physical function compared to walking. These findings should be interpreted cautiously given the high attrition observed which may raise concerns regarding the feasibility of these remotely-delivered exercise and weight loss interventions in this population.

OC31

MATERNAL BONE MINERAL DENSITY AT 4 YEARS POST-DELIVERY IS NOT AFFECTED BY PREGNANCY VITAMIN D SUPPLEMENTATION

R. J. Moon[1], S. D'Angelo[1], E. M. Curtis[1], K. A. Ward[1], K. M. Godfrey[1], C. Cooper[1], N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objectives

Mobilisation of the maternal skeleton during pregnancy and lactation ensures calcium is available for the fetus. There is evidence that pregnancy vitamin D supplementation increases offspring bone mineral density (BMD) in childhood, but there is limited data on the effect on maternal BMD. We assessed the effect of pregnancy vitamin D supplementation on the maternal skeleton in the medium term.

Materials and Methods

MAVIDOS was a randomised placebo-controlled trial of 1000 IU/day cholecalciferol (vitD) from 14-17 weeks gestation until delivery. Participants were invited to have a Dual-Energy Xray absorptiometry (DXA) scan of the whole-body (analysed less head: WBLH), lumbar spine (LS) and left hip at 4 years postpartum. A subset of the women also had a DXA scan within 2 weeks of delivery.

BMD at 4 years post-delivery was compared between groups using linear regression in unadjusted and adjusted (maternal age, further pregnancy, duration of lactation, height and weight) models. β (95%CI) represents the effect of vitD compared to placebo. In women with DXA at both time points, the effect of vitamin D was assessed using mixed effects modelling to account for repeated measures.

Results

443 (225 placebo, 218 vitD) participants had a DXA scan at 4 years post-delivery. BMD did not differ between the two randomization groups in unadjusted or adjusted analyses (adjusted WBLH β=0.000 (0.012, 0.012) g/cm^2; LS β=0.009 (-0.010, 0.027) g/cm^2; hip β=0.004 (-0.014, 0.022) g/cm^2).

223 women had DXA at birth and 4 years. In both randomisation groups, BMD increased from birth to 4 years post-delivery (placebo WBLH 6.3%, LS 1.2%, hip 2.2%; VitD WBLH 6.2%, LS 1.0%, hip 2.4%, p<0.05 for all). However, the randomisation group had no effect on BMD (p>0.05 for all).

Conclusions

Despite previously demonstrated benefits for the offspring skeleton, pregnancy supplementation with 1000 IU/day cholecalciferol did not have an effect, either positive or negative, on maternal BMD at 4 years post-delivery.

OC32

USING PROBIOTICS TO SUPPORT BONE HEALTH IN POSTMENOPAUSAL WOMEN: A RANDOMIZED, DOUBLE-BLIND, PARALLEL, PLACEBO-CONTROLLED, MULTI-CENTRE STUDY

J. L. Yumol[1], S. Binda[2], V. Nagulesapillai[2], W. E. Ward[1]

[1]Brock University, St. Catharines, Canada, [2]Rosell Institute for Microbiome and Probiotics, Montreal, Canada

Objective: To determine if a probiotic supplement could attenuate the loss of femur neck bone mineral density (FN BMD) and to assess its effect on fracture risk and markers of bone cell activity. *Material and Methods*: 72 postmenopausal women (40-59 years, not receiving pharmacotherapy for bone health) were randomized to receive a daily probiotic supplement or placebo for 48 weeks. FN BMD (DXA) and fracture risk (FRAX® assessment tool) were assessed at weeks 0 and 48. Serum bone markers (procollagen type 1 N-terminal propeptide, P1NP; bone-specific alkaline phosphatase, BAP; cross-linked C-telopeptide of type I collagen, CTx; osteocalcin, OC) were analyzed at weeks 0, 12, 24 and 48. *Results*: There was no significant time by treatment interaction for FN BMD or fracture risk. Independent of treatment group, FN BMD decreased (p = 0.034), while risk of hip (p = 0.003) and major osteoporotic fracture (p = 0.044) increased. Time by treatment interaction was significant for serum P1NP (p = 0.003) and CTx (p = 0.006) but not for serum BAP and OC. At week 12, serum P1NP was higher in the placebo group than the probiotic group (p = 0.008). Compared to baseline, serum P1NP increased in the probiotic group at week 24 (p = 0.006) and decreased in the placebo group at week 48 (p = 0.007). CTx increased over time with probiotics (p = 0.006). At endpoint, serum CTx was higher in the probiotic group than the placebo group (p = 0.008). Independent of treatment group, serum OC (p = 0.006) and BAP (p = 0.007) increased at weeks 24 and 48, respectively. *Conclusion*: Probiotics did not alter FN BMD or fracture risk, but the increase in bone cell activity suggests an opportunity to further examine the dose and duration of this novel combination of bacteria strains for supporting bone health in postmenopausal women.

Disclosures: SB and VN are employees of Lallemand Health Solutions that provided the investigational products and funding for the study. JLY received a Mitacs Accelerate Award.

RELATIONSHIPS BETWEEN MICRORNAS AND CORTICAL BONE IN CHRONIC KIDNEY DISEASE

C. Metzger[1], N. Chen[1], D. Mcmahon[2], M. Allen[1], R. Moyses[3], S. Moe[1], T. Nickolas[4]

[1]Indiana University, Indianapolis, United States, [2]Columbia University, New York, United States, [3]University of Sao Paulo, Sao Paulo, Brazil, [4]Washington University, St. Louis, United States

Objectives: Cortical (Ct) bone disease is a critical feature of renal osteodystrophy (ROD). However, most published histomorphometric data on the skeletal effects of kidney disease (KD) are based on trabecular (Tb) bone. ROD is defined by bone turnover (i.e., low, normal, high), and identification of ROD-type by bone turnover markers has been developed in the context of Tb turnover. Thus, knowledge gaps remain for our ability to assess Ct changes in KD – which drive the skeletal phenotype. In our prior work in a small cohort of patients with KD (JBMRplus 2020), we found that microRNAs identified Ct ROD-type and outperformed protein-based bone turnover markers. We validated our findings for Ct bone in a multi-ethnic cohort of 98 men and women across the spectrum of KD from the United States and Brazil.
Methods: Adults with KD underwent tetracycline double-label bone biopsy with quantitative histomorphometry. Blood at biopsy was stored at -80C for batch assay. Single reader histomorphometry was conducted. miRs-30b, 30c, 125, 155, 331 and 1299 were assayed based on our prior work. Comparisons between miRs, CKD Stage, and Ct bone formation (BFR %/yr) were determined. Diagnostic characteristics for low Ct turnover were determined with ROC and logistic regression analyses.
Results: The cohort was 52% female, with mean(SD) age 54(14) years. 51%, 30%, 18%, and 1% self-defined White, Mixed, Black and Asian race respectively. 28%, 23% and 49% had CKD stages 2-3, 4-5 and 5D respectively. Ct turnover in CKD5D was higher than in CKD2-3 and CKD4-5 ($p<0.05$ for both). All miR levels were lower in CKD5D then in CKD2-3 and CKD4-5 ($p<0.05$ for all). Correlations were significant between miRs-30c and -331 and Ct BFR (-0.21 and -0.21, $p<0.05$ for both). In ROC analyses, all miRs except 1299 discriminated low Ct turnover with positive predictive values (PPV) of 90% for miR-30b and -331 (table). Optimization of the AUC cutpoint for low Ct turnover and inclusion of miR-30b, 30c, 125 and 331 into a multivariable logistic regression model had an AUC 0.75 ($p< 0.05$) and a PPV 91%.
Conclusion: miR levels were related to Ct turnover from histomorphometry and discriminated low Ct turnover in a multi-ethnic cohort of patients with KD. Future work will optimize the models in conjunction with bone turnover markers.

Area Under Curve (AUC) for miRs and Low Ct Bone Turnover (BFR %/yr)

	AUC	p-value	Positive Predictive Value
miR-30b	0.71	<0.05	90%
miR-30c	0.74	<0.05	89%
miR-125	0.68	<0.05	81%
miR-155	0.62	<0.05	79%
miR-331	0.71	<0.05	90%
miR-1299	0.59	NS	78%
miR-30b, 30c, 125, 331	0.75	<0.05	91%

***Equal contributors listed in alphabetical order**

Objective(s): Pregnancy-associated osteoporosis (PAO) is characterized by reduced bone mineral density (BMD) and fragility fractures, typically manifesting in the third trimester of pregnancy. This condition arises from increased foetal calcium demands, leading to maternal bone resorption. Despite its clinical significance, PAO is often underdiagnosed due to the limitations of ionizing techniques like DXA (Dual-energy X-ray Absorptiometry), highlighting the need for early diagnosis and timely intervention. This study aims to evaluate calcium intake, dietary habits, and fracture risk (FR) factors during pregnancy, while monitoring bone health using ultrasound REMS (Radiofrequency Echographic Multi-Spectrometry) technology to identify skeletal fragility and prevent fractures.

Material and Methods: This prospective, longitudinal, multicenter study will allow the recruitment of women aged 18-45 y in their first trimester of pregnancy. Participants will complete two validated questionnaires, Predimed and AFEF, developed by the Observatory of Fractures from Fragility (OFF Italy), to assess dietary calcium intake, adherence to the Mediterranean diet, and FR factors. Bone health will be monitored using REMS technology, focusing on the femoral neck at three time points: the first and third trimesters of pregnancy and six months postpartum.

Results: The results of the study will stratify participants in two groups based on BMD: low and normal values. For each group, variations in bone quality and fragility will be assessed by defining a pregnancy-specific REMS -based Fragility Score cut-off to estimate fracture risk and prevent their occurrence.

Conclusion(s): This study will enhance understanding of the underlying primary factors of related to PAO and provide actionable insights into dietary and clinical predictors through the development of a dedicated FR chart. By utilizing targeted questionnaires and REMS technology, it aims to facilitate early diagnosis and effective management strategies, ultimately reducing FR in pregnant and breastfeeding women.

INTERACTIONS BETWEEN CALCIUM AND PROTEIN INTAKES, AND OSTEOPOROSIS MEDICATIONS ON HIP BONE STRENGTH: AN OBSERVATIONAL STUDY IN OLDER WOMEN

M. Papageorgiou[1], Y. Gugler[2], S. Ferrari[1], R. Rizzoli[1], P. Zysset[2], E. Biver[1]

[1]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland, Genève, Switzerland, [2]ARTORG Center for Biomedical Engineering Research, University of Bern, Switzerland, Bern, Switzerland

Objective: Osteoporosis medications (OM) are commonly prescribed with calcium supplements (CaS), without considering dietary factors, including calcium and protein adequacy. Their efficacy without concomitant CaS is largely undocumented. We explored whether changes in hip bone strength in response to OM are influenced by CaS use, dietary calcium and protein intakes.

Methods: We included data from older women (n=586, age mean±SD: 67±2 years) from the Geneva Retirees Cohort taking hormone replacement therapy (HRT, n=101) bisphosphonates/denosumab/raloxifene (BPs/D/R, n=67) or no OM (n=418). Changes (%/year) of finite element-based hip bone strength and 3D DXA hip parameters were evaluated using the 3D-SHAPER software 2.9.0 over 3.4±0.5 years. Dietary calcium and protein intakes (food frequency questionnaire) and CaS use were evaluated at baseline and follow-up.

Results: Mean total calcium intake (diet + supplements) was 1552±533 mg/day, with 71% of women achieving adequate intakes (≥1200mg/day). Calcium and vitamin D supplements were used by 52% and 62% of women, respectively (no OM: 47/59%, HRT: 50/58%, BPs/D/R: 81/90%). Women on HRT or BPs/D/R had improved hip strength and most bone parameters compared to women without OM. There were no differences in changes of bone strength or other bone parameters in either of the 3 treatment groups in an analysis by total calcium intake (low vs. sufficient). No differences were observed within each treatment group according to CaS use, except for a trend towards an attenuated loss of hip strength in women without OM taking CaS. Among women taking no OM with low dietary calcium intake, the degradation of cortical surface BMD (p=0.071) and thickness (p=0.048) were greater in those without vs. with CaS. The decrease of hip strength was not attenuated by HRT in women with low dietary calcium intake and no CaS vs. those with CaS (p=0.067). The effects of BPs/D/R on hip trabecular vBMD (p=0.009) and strength (p=0.044) were attenuated in women with low (<0.8g/kg/day) vs. adequate protein intake.

Conclusion: In this observational study, women with adequate calcium intake had similar changes in hip bone strength and BMD with OM regardless of CaS. Bone changes were more linked to OM and protein intake interactions.

A NATIONAL SURVEY OF AUSTRALIAN PRIMARY CARE CLINICIANS' KNOWLEDGE, BELIEFS, ATTITUDES, PRACTICES, PERCEPTIONS OF RESPONSIBILITY AND BARRIERS AND ENABLERS TO IDENTIFICATION AND MANAGEMENT OF SARCOPENIA

R. M. Daly[1], D. Scott[1], N. Kiss[1], M. Tieland[1], B. J. Braguley[1], J. J. Fyfe[1], R. Manocha[2]

[1]Deakin University, Institute for Physical Activity and Nutrition, Melbourne, Australia, [2]University of Sydney, Sydney Medical School, General Practice Clinical School, Sydney, Australia

Objective: Sarcopenia receives limited attention in primary care. This study aimed to explore general practitioners' (GPs) and practice nurses' (PNs) awareness, understanding, knowledge, beliefs, attitudes, practices, perceptions of responsibility, confidence, barriers and enablers to identification and management of sarcopenia.

Material and Methods: A national Australian, anonymous 33-item, online purpose-designed survey covering topics relevant to the study aims was undertaken from March to May 2024.

Results: Of 1364 respondents (97% GPs), 1141 (84%) completed all questions. Overall, 67% were somewhat/moderately familiar with the term sarcopenia and recognised it included low muscle mass (89%), muscle strength (66%) and poor function (53%), but 35% incorrectly identified 'low fitness' as a component. Knowledge on common signs/symptoms, risk factors, consequences, and treatments was high (82-99.7% correct response rate to 22/46 statements), but most did not recognise unrelated factors (only 10-18% recognised stiff/inflexible muscles, cramps and persistent muscle pain are not signs/symptoms) or ineffective treatment options (only 9-12% recognised any forms of exercise, aerobic exercise, and fruit/vegetable intake are ineffective treatments). Most clinicians (>80%) believed they should play an active role in sarcopenia identification/treatment, but only 23% currently screened/assessed for it, with 73% using a clinical assessment (mostly sit-to-stand), generally in patients with comorbidities, functional issues, malnutrition, and adults aged ≥60y. A high proportion (90%) indicated clinician education and screening/assessment (86%) should be prioritized in primary care, but 68% stated other factors were a higher priority, 47% had insufficient time, and only 23% had the confidence and knowledge to address sarcopenia in practice. Lack of referral options (56-62%) and access to appropriate tools (55-58%) were key barriers and protocol implementation and access to relevant training (81-84%) were the main enablers to identification/treatment.

Conclusion: Primary care clinicians in Australia are familiar with and have some intuitive understanding of, and positive attitudes and beliefs toward sarcopenia, but report it is not a priority and they lack knowledge, confidence, referral options, appropriate tools and time to address it in practice.

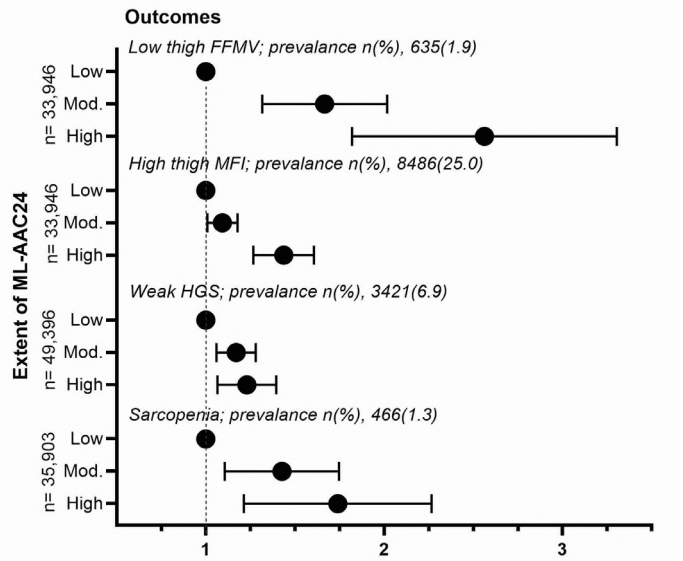
Objective(s): Abdominal aortic calcification (AAC) is associated with higher risk for cardiovascular events and can be identified

during routine osteoporosis testing on DXA-derived lateral spine images. Our automated machine learning algorithm assessing AAC (ML-AAC24) identifies individuals with higher fall and fracture risk [1]. However, the relationship between ML-AAC24 with muscle composition and strength, strong predictors of fracture risk, remain unclear. We examined if greater extent of ML-AAC24 is cross-sectionally associated with poorer measures of muscle composition, strength and sarcopenia in the UK Biobank Imaging Study.

Methods: ML-AAC24 extent was categorised as low (<2), moderate (2-5) and high (≥6). Magnetic resonance imaging-derived thigh fat-free muscle volume (FFMV) and muscle fat infiltration (MFI) was available in 33,946 people. Age and/or sex specific cut-points for low FFMV and high MFI were adopted (Fig). Muscle strength was assessed using hand grip strength (HGS, n=49,396). Muscle weakness (HGS <27 kg for male and <16 kg for female) and sarcopenia (low height-adjusted appendicular lean mass assessed from DXA and weak HGS, n=35,903) were categorised based on revised European guidelines. Logistic regression examined the associations between ML-AAC24 extent and the aforementioned muscle health measures.

Results: Participants mean age was 64.6 ± 7.8 years, 50.8% female. In multivariable-adjusted analysis, participants with moderate and high ML-AAC24 consistently had greater odds for having low FFVM, high MFI, weak HGS and sarcopenia, compared to those with low ML-AAC24 (Fig). Results were independent of established cardiovascular disease risk factors. When stratified by sex, results remained consistent across outcomes when comparing high to low ML-AAC24; with the exception of weak HGS in females.

Conclusion: ML-AAC24 severity was associated with poorer muscle composition and strength, as well as sarcopenia. These cross-sectional findings suggest that vascular disease has deleterious effects on muscle health. However, results need to be confirmed using longitudinal studies.



Odds ratio (95%CI)

Multivariable-adjusted logistic regression analysis for the cross-sectional association between ML-AAC24 extent and odds of having poorer muscle health measures. Proportion of individuals in low (reference), moderate and high ML-AAC24 was ~79%, 16% and 5%, respectively. Model adjusted for age, BMI, physical activity, smoking status, ethnicity, prevalent diabetes and atherosclerotic cardiovascular disease, geographic region in the UK, deprivation index and imaging year. Fat free muscle volume (FFMV) and muscle fat infiltration (MFI); hand grip strength (HGS); EWGSOP2-defined sarcopenia. Low FFMV adopted age- and sex-specific cut-points; i) 45-59 years: male <9.61 L, female <6.21 L; ii) 60+ years: male <9.01, female <5.93 L. High MFI was based on >75th percentile for male (>7.64%) and female (>8.75%).

ROMOSOZUMAB AND DENOSUMAB COMBINATION THERAPY IN POSTMENOPAUSAL OSTEOPOROSIS

G. Adami[1], F. Pollastri[1], C. Benini[1], A. Piccinelli[1], F. Montanari[1], D. Gatti[1], O. Viapiana[1], M. Rossini[1]
[1]University of Verona, Verona, Italy

Background

Transitioning from long-term denosumab to PTH-analogs or romosozumab may expose patients to a rebound phenomenon. Adding romosozumab to denosumab may offer a therapeutic alternative for postmenopausal women who sustain fractures while on denosumab.

Objectives

This study aimed to evaluate the effects of combining romosozumab with ongoing denosumab therapy in postmenopausal osteoporosis.

Methods

We conducted a combined 12-month prospective and 24-month retrospective observational study. Postmenopausal women were divided into three cohorts:

1. Treatment-naive patients initiating romosozumab (Naïve→Romo; M-24 to M+12),
2. Patients on denosumab who added romosozumab (Dmab→Dmab+Romo; M-24 to M+12),
3. Patients continuing denosumab (Dmab→Dmab; M-24 to M+12).

Bone mineral density (BMD) and bone turnover markers (BTMs; CTX and P1NP) were measured at key time points. A mixed model for repeated measures (MMRM) was used to assess percentage and absolute changes in BMD and BTMs, with treatment sequence, time, treatment-by-time interaction, and baseline BMD as fixed effects and patients as random effects.

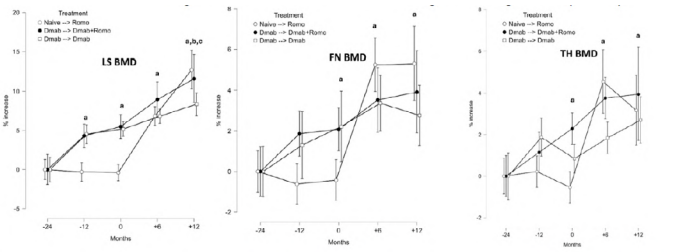
Results

A total of 139 patients participated: 90 were Naïve→Romo, 25 were Dmab→Dmab+Romo, and 24 were Dmab→Dmab. At lumbar spine M+12, the Dmab→Dmab+Romo group showed a trend toward greater BMD increases compared to the Dmab→Dmab group (+3.2%, SE 4.4; p = 0.074), as did the Naïve→Romo group compared to Dmab→Dmab (+4.4%, SE 3.7; p = 0.064). No significant differences were observed at the femoral neck or total hip. P1NP levels significantly differed at M+3 between the Dmab→Dmab and Dmab→Dmab+Romo groups (+24.4 ng/mL,

SE 12.6; p = 0.033), with a trend toward significance at M+6 (+13.4 ng/mL, SE 7.7; p = 0.057).

Conclusion

Romosozumab retains anabolic potential when combined with denosumab, supporting its use in patients with severe osteoporosis inadequately responding to long-term denosumab.



a, p value <0.05 vs baseline; b, p value 0.074 for Dmab →Dmab vs Dmab →Dmab+Romo; c, p value 0.064 for Dmab →Dmab vs Naive →Romo. Between-groups differences were tested with a mixed model for repeated measures (MMRM) using Satterthwaite and restricted maximum likelihood method with treatment sequence, time, treatment-by-time interaction, and baseline bone mineral density (BMD) as fixed effects and with patients as random effect. FIVE-YEARS OF CALCIUM SUPPLEMENTATION IS NOT ASSOCIATED WITH LONG-TERM RISK OF DEMENTIA IN OLDER WOMEN: POST-HOC ANALYSIS FROM A RANDOMISED CLINICAL TRIAL

N. Ghasemifard[1], J. R. Lewis[1], S. Radavelli-Bagatini[1], S. M. Laws[2], B. Stephan[3], K. Zhu[4], J. M. Hodgson[1], R. L. Prince[4], M. Sim[1]

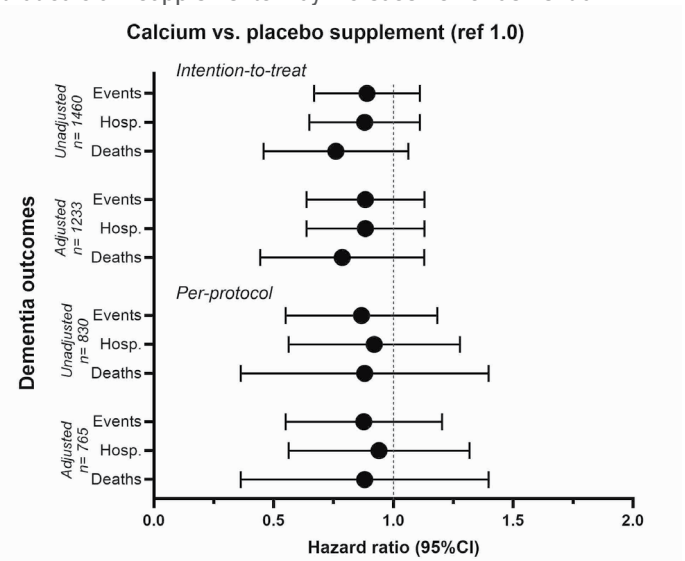
[1]Edith Cowan University, Nutrition and Health Innovation Research Institute, Western Australia, Australia, [2]Edith Cowan University, Centre for Precision Health, Western Australia, Australia, [3]Curtin University, Dementia Centre of Excellence, Curtin Enable Institute, Western Australia, Australia, [4]The University of Western Australia, Medical School, Western Australia, Australia

Objective: Calcium supplementation is a common strategy adopted to prevent bone loss, especially in older women. However, concerns have been raised around whether these supplements may increase dementia risk. To date, data investigating these concerns are limited. This post-hoc analysis of a 5-year double-blind, placebo-controlled randomised trial of calcium supplements evaluated the long-term risk for dementia in older women randomised to either calcium supplements or placebo.

Methods: 1460 community-dwelling Australian women aged 70 years and over, without cognitive impairment, took part in the Calcium Intake Fracture Outcome Study (CAIFOS) in 1998. Women received either 1200 mg of calcium carbonate per day (n=730) or an identical placebo (n=730) for 5 years. The effects of calcium supplementation on dementia outcomes were examined using unadjusted and multivariable-adjusted Cox regression analysis under both intention-to-treat (ITT) and per-protocol criteria (PP, ≥80% tablet compliance). Dementia outcomes were obtained from linked hospital and mortality records from baseline over the next 14.5 years.

Results: Mean age of women at baseline was 75.2 ± 2.7 years. Over 14.5 years, 269 women (18.4%) suffered a dementia event, comprising of dementia-related hospitalisations (n=243, 16.6%) and dementia-related deaths (n=114, 7.8%). Compared to placebo, calcium supplements were not associated with increased hazards for any of the dementia outcomes in unadjusted and multivariable-adjusted ITT and PP analysis (Fig). No significant differences in the cumulative dementia-free survival rates were observed between women randomised to calcium supplements or placebo for any dementia outcome (log-rank test, all p>0.05).

Conclusion: There was no association between randomisation of 1200 mg per day of calcium supplements over 5 years with long-term risk for dementia. These findings do not support concerns that calcium supplements may increase risk of dementia.



Hazard ratios (95%CI) for dementia events, hospitalisations and deaths for women provided calcium supplements (●), compared to placebo. Adjusted model included age, BMI, apolipoprotein E, prevalent diabetes and atherosclerotic cardiovascular disease, statin and aspirin use, physical activity, smoking status, dietary calcium and alcohol intake and socioeconomic status. Only women with complete data for all covariates were considered in adjusted analysis.

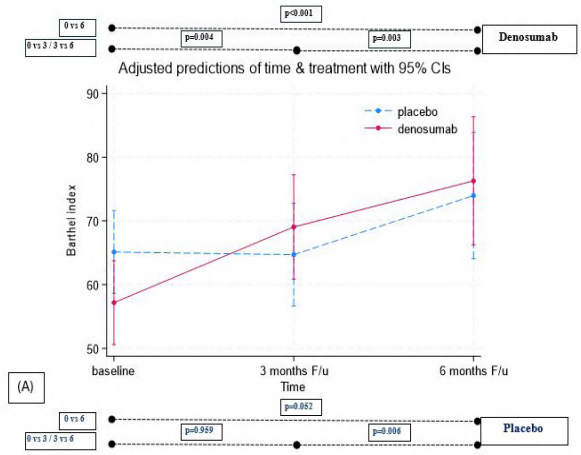
THE EFFECT OF DENOSUMAB ON FUNCTIONAL RECOVERY IN OLDER PATIENTS UNDERGOING SURGICAL FIXATION FOR INTERTROCHANTERIC FEMORAL FRACTURE: A RANDOMIZED, PLACEBO-CONTROLLED TRIAL

P. Athakitkarnka[1], E. Vanitchareonkul[1], A. Unnanuntana[1], P. Chotiyarnwong[1]

[1]Mahidol University, Bangkok, Thailand

Objective:
This study aimed to compare the effects of denosumab (Dmab) versus placebo on postoperative functional recovery at 6 months in older adults undergoing surgical fixation for intertrochanteric fractures.
Material and Methods:
In this double-blind, randomized, placebo-controlled trial, 85 older adults with isolated intertrochanteric fractures who underwent surgical fixation were enrolled. Participants were randomized to receive either Dmab or placebo within 2 weeks postoperatively. All patients received calcium and vitamin D supplementation. The primary outcome was functional recovery, assessed using changes in the Barthel Index (BI) from baseline to 3 and 6 months post-surgery. The secondary outcomes included the modified Harris Hip Score (mHHS), the Numerical Pain Rating Scale (NPRS), the Timed Up and Go test (TUG), and fracture healing evaluated by the Radiographic Union Score for Hip (RUSH).
Results:
The mean age of participants was 82.7 years, and 70 patients completed the 6-months follow-up. Patients receiving Dmab showed significantly greater BI improvement at 3 and 6 months compared with baseline, while those in the placebo group demonstrated significant BI improvement only between 3 and 6 months. Linear mixed-effects model confirmed a significantly higher mean change in BI in the Dmab group compared to placebo (11.2 vs 0.2, respectively; p = 0.043). No significant differences were observed between the two groups regarding mHHS, NPRS, or TUG at any time points. Similarly, fracture healing did not differ significantly between the Dmab and placebo groups, with comparable RUSH scores at both 3 and 6 months.
Conclusion:
Administering Dmab within 2 weeks after surgical fixation of an intertrochanteric fracture significantly enhanced short-term functional recovery, without negatively affecting fracture healing or union time. Therefore, Dmab is a safe and effective antiosteoporosis agent for improving postoperative functional outcomes and reducing future fracture risk in this patient population.



Barthel index	Denosumab		Placebo		Difference (95%CI)	Between group p-value[b]
	Mean change (95%CI)	Within group p-value[a]	Mean change (95%CI)	Within group p-value[a]		
3 months - baseline	11.2 (3.5, 18.9)	0.004	0.2 (-7.2, 7.6)	0.959	-11.0 (-21.7, -0.4)	0.043
6 months - baseline	20.6 (11.4, 29.8)	<0.001	9.0 (-0.1, 18.1)	0.052	-11.6 (-24.6, 1.3)	0.078
6 months - 3 months	9.3 (3.1, 15.4)	0.003	8.7 (2.5, 14.8)	0.006	-0.6 (-9.3, 8.2)	0.898

HORMONE THERAPY FOR FRACTURE PREVENTION – A SEX STRATIFIED APPROACH

M. McClung[1]

[1]Oregon Osteoporosis Center, Portland, OR, United States

Sex steroids play important roles in determining peak bone mass and in bone loss after menopause and with ageing. Adults with sex steroid deficiency experience bone loss and increased fracture risk. These observations justify the consideration of using of sex steroids to reduce fracture risk in patients with sex steroid deficiency.

Testosterone therapy increases bone mineral density (BMD) and bone strength in men with low serum testosterone level. In 4804 hypogonadal men randomly assigned to testosterone or placebo, followed for an average of 3.19 years, fracture rates were unexpectedly higher (3.50%) with testosterone vs placebo (2.46%); hazard ratio 1.43 (1.04–1.97). These results suggest that testosterone should not be prescribed to protect hypogonadal men from fracture.

Estrogen therapy in postmenopausal women prevents bone loss and significantly reduces fracture risk. In the Women's Health Initiative studies, menopausal hormone therapy significantly reduced rates of vertebral, hip and all clinical fractures in generally healthy postmenopausal women whose average age was 63 years. Because registration trials with estrogen have not been conducted in patients with postmenopausal osteoporosis, it is not approved as an osteoporosis treatment but is approved for preventing postmenopausal osteoporosis in some countries including the United States Specifics about the long-term safety of estrogen therapy are complex. The risk:benefit profile of estrogen is positive when treatment is begun near the time of menopause, especially in those with low BMD at high risk of developing osteoporosis. Guidance for the appropriate use of estrogen for the prevention of osteoporosis and fractures should be included in the next iterations of clinical guidelines.

In contrast to the skeletal effectives of estrogen in postmenopausal women, evidence for a salutary effect of testosterone therapy to reduce fracture risk in men is lacking.

PL2

ANTI-RESORPTIVES AND BONE FORMING THERAPIES: IN SERIES (SEQUENTIAL) OR IN PARALLEL (COMBINATION)?

E. V. McCloskey[1]

[1]Division of Clinical Medicine, School of Medicine & Population Health, University of Sheffield, Sheffield, United Kingdom

As with many other chronic, progressive non-communicable diseases, the effective treatment of osteoporosis and prevention of fractures remains an unmet need in many healthcare systems. The range of age-dependent fracture risk is wide and the need for long-term therapy essential. The latter is true whether strategies to reduce fracture burden are public health/population-based approaches or are adapted to address the individual patient. While a wide range of effective medications is available, the optimal strategy within any single complex clinical circumstance is often not addressed by randomised clinical trials due to cost and logistic restrictions; thus studies on treatment sequence or combinations tend to be limited in number, size and clinically relevant endpoints.

Within the clinical setting, the choice between the two main classes of osteoporosis medication (anti-resorptive and bone-forming/anabolic treatments) and whether these should be used in sequence (series) or in combination (parallel) will depend on patient-specific factors such as fracture risk, bone density, bone turnover and anticipated response to therapy. In those at moderate to high fracture risk, sequential therapy is a frequent choice as it is assumed to meet the needs of most patients; however, the increasing awareness that prior treatment with a particular class of medications can blunt the subsequent response to another class if needed has started to inform more debate about the actual order of the sequence. There is an increasing movement towards starting with anabolic agents (with the aim of building new bone) followed by anti-resorptive therapy (to maintain the bone mass attained and prevent further loss); this approach is certainly mandated in many guidelines in patients deemed to be at very high fracture risk. In the latter category, those at high imminent fracture risk in particular, for example following a recent vertebral or hip fracture, need the fastest possible gain in bone density something that can be delivered more readily by anabolic therapies. But is there also a role for combination or parallel treatment in this setting: Several studies have demonstrated that not all combinations have been shown to be more effective than sequential therapy, and increased costs and side effects need to be considered. This lecture will review the evidence base for sequential and combination approaches to management of osteoporosis.

PL3

OSTEOANABOLICS: TO LUMP OR TO SPLIT?

J.-Y. Reginster[1,2]

[1]WHO Collaborating Centre for Epidemiology of Musculoskeletal Health and Aging, Liège, Belgium, [2]Protein Research Chair, Bio-chemistry Dept, College of Science, King Saud University, Riyadh, Saudi Arabia

During the last years, the paradigm of the treatment of osteoporosis has significantly changed, following the publication by ESCEO and IOF of an algorithm for the management of patients at risk of fractures. Now, the classical "one-size fits all" treatment approach is obsolete. Patients should be treated on the basis of their fracture risk. Patients at imminent (very high) risk for fracture should receive, as first-line, background treatment, a bone forming agent (BFA) followed by the prescription of an anti-resorptive agent. Three BFA are currently marketed, two PTH Receptor 1 Agonists and an anti-sclerostin

antibody. PTH RA include Teriparatide and Abaloparatide while Romosozumab is the anti-sclerostin antibody. All of them have shown to significantly reduce fracture rates at all skeletal sites including spine, non-spine, major osteoporotic fractures and hip. They provide a greater anti-efficacy compared to anti-resorptive agents. All of them present a reasonable risk/benefit ratio with only minor concerns for the prescription of Romosozumab in patients with a previous history of cardiovascular disorders. After a BFA is stopped, an anti-resorptive agent should be prescribed to maintained the benefit obtained during treatment. When BFA are prescribed after the prolonged administration of a potent anti-resorptive agent, their beneficial effect on cortical bone is partially mitigated which suggests that an anti-resorptive agent could be prescribed during the first months of administration of the BFA. Sequential treatment associating a BFA and an anti-resorptive agent was shown to be cost-effective compared to an anti-resorptive agent alone and compared to no treatment. The benefit of BFA is particularly evident (clinically and economically) in patients at higher risk for fracture.

OBESITY STRATIFICATION IN PERSONALISED OSTEOPOROSIS MANAGEMENT

P. R. Ebeling[1]

[1]Department of Medicine, School of Clinical Sciences, Monash University, Clayton, Victoria, Australia

Obesity is accompanied by a higher bone mineral density (BMD), compared with non-obese age-matched peers. Low BMD affects only a minority of candidates for bariatric surgery with Class 3 obesity. While obesity defined by body mass index (BMI) is also generally associated with a lower fracture incidence despite higher BMD, fractures of the ankle, lower leg and humerus are more common in obesity. BMI is a better indicator of lean than fat mass, thus, higher lean mass, not fat mass, likely explains positive associations between higher BMI and BMD in older adults. Body fat distribution may be more predictive of osteoporotic fractures than BMI. Men with higher visceral adipose tissue levels have poorer bone mechanical properties, despite having similar BMD compared with those with low visceral adipose tissue. High waist circumference was also associated with an increased risk of hip fracture. Metabolic and endocrine factors associated with fractures in obesity include adipokines, type 2 diabetes, lower vitamin D levels, lower testosterone levels in men, and a higher falls risk. Fracture risk is highest in sarcopenic obesity where visceral fat and intra- and inter-muscular adipose tissue have adverse effects on bone health resulting in an increase in nonvertebral fractures.

Intestinal calcium absorption decreases, while bone loss (8% at the hip over 12 months), bone remodelling, and fractures all increase following both gastric bypass and restrictive bariatric surgery; fracture risk is greater following malabsorptive surgery. Guidelines recommend treating vitamin D deficiency with daily doses of >2,000 IU oral colecalciferol, adequate daily calcium and protein intakes, and promoting physical exercise before and following bariatric surgery. Parenteral antiresorptive therapy is reserved for those patients who have low BMD (T-score <-2), prior fragility fractures or high fracture risk. About 25% of bariatric surgery patients may develop mild hypocalcemia following antiresorptive therapy despite adequate calcium and vitamin D. Bariatric medicine causes similar reductions in body weight to bariatric surgery. Despite similar weight loss, liraglutide treatment reduced hip and spine BMD compared with exercise alone. Resistance exercise minimizes loss of lean mass and total hip BMD associated with glucagon-like peptide-1 (GLP-1) agonist treatment. A similar approach to maintaining bone health therefore seems sensible for patients initiating treatment with GLP-1 agonist treatment.

PL5

ADVANCES IN PERSONALIZED FRACTURE RISK ASSESSMENT: FRAX AND BEYOND

N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

We now have an enviable range of medications to improve bone mineral density across both antiresorptive and now anabolic mechanisms. Recent head-to-head studies have demonstrated superiority of teriparatide and romosozumab, compared with oral antiresorptives, both in terms of rapidity of onset and magnitude of effect. Until recently, guidelines for the management of osteoporosis have focused on the question of treatment versus no treatment. However, such findings have fuelled moves internationally, initially from ESCEO, supported by IOF, to promote a stratified approach to treatment, with choice of medication personalised according to baseline fracture risk. Different organisations espouse different definitions of very high fracture risk in this stratified approach, with the IOF-ESCEO favouring an absolute fracture probability threshold based on the European Guidelines using FRAX®. This stratified approach, predicated on baseline fracture risk, enables the most effective treatments, anabolic agents, to be targeted to those at very highest fracture risk. New understanding of genetic instruments for bone mineral density, and artificial intelligence approaches to risk assessment in big datasets, have suggested methods to, in years to come, stratify individuals at the level of healthcare systems. In future systems linking together such assessments, it may be possible to initially identify those likely to be at high fracture risk on the basis of information held in a medical records database. These patients could then be invited for subsequent clinical assessment and treatment, using FRAX and measurement of bone mineral density. In this presentation, I will review ways in which medication choices may be stratified according to individual characteristics and other considerations, and how these approaches might be integrated into novel clinical pathways.

PL6

MICRORNAS: NOVEL RISK PREDICTORS IN MUSCULOSKELETAL DISEASE?

L. Gennari[1]

[1]Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy

Over the past 3 decades a wide array of regulatory non-coding RNAs have emerged as crucial factors for gene regulation in most tissues. MicroRNAs (miRNAs) are a class of are highly conserved, small non-coding RNAs (generally consisting of 18-25 nucleotides) that play a crucial role in the regulation of messenger RNA expression, stability and translation, thereby modulating numerous cellular pathways, with likely implications for the pathogenesis of numerous common diseases, including musculoskeletal disorders. A rising number of experimental reports suggest that miRNAs contribute to every step of osteogenesis and bone homeostasis, from embryonic skeletal development to maintenance of adult bone tissue, by regulating the growth, differentiation, and activity of different cell systems inside and outside the skeleton. Likewise, emerging information from animal studies indicates that targeting miRNAs might become an attractive and new therapeutic approach for musculoskeletal diseases, even though there are still major concerns related to potential off target effects and the need for efficient delivery methods *in vivo*. Moreover, besides their recognized effects at the cellular level, evidence is also gathering that miRNAs are excreted and can circulate in blood or other body fluids with potential paracrine or endocrine functions. Thus, they could represent suitable candidates for becoming sensitive biomarkers in different pathologic conditions, including musculoskeletal disorders. Available evidence provided some indications about potential miRNA signatures associated with osteoporosis, fracture risk or other bone disorders (i.e. primary hyperparathyroidism) as well as with sarcopenia. However, results remain conflicting, in part due to differences in patient selection, type of samples, or analytical methods, so that no definitive conclusion can be reached at this stage. Further replication in prospective studies of larger population-based samples is therefore necessary to define more reliable miRNA signatures to be used in the clinical practice for diagnostic, preventive and therapeutic purposes.

PL7

NOVEL CONCEPTS: ASSESSMENT OF INTRINSIC CAPACITY

B. Dawson-Hughes[1]

[1]Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, United States

The world population is aging but there is a substantial gap between total longevity and healthy longevity. 'Intrinsic capacity' is the term used by the World Health Organization (WHO) to describe *"The composite of all of the physical and mental capacities that an individual can draw on for healthy longevity"*. To expand healthy longevity, the WHO has initiated a model program entitled "Integrated Care for Older People (ICOPE)". ICOPE involves monitoring and support for older adults in six domains: mobility, nutrition, vision, hearing, cognitive function, and mental health. Implementation of ICOPE includes screening, assessment, personalized interventions, and follow-up monitoring in the six domains. A large-scale study in France has demonstrated the feasibility of enrolling older adults in the ICOPE program (*Tavassoli N. Lancet Healthy Longevity 2022*). Between January, 2020 and November 2021, 10,903 older adults, mean age 76 years, were screened, and, of these, 7,367 were eligible for the program (that is, would potentially benefit in one or more of the six domains). Of those who were eligible, 70.4% had had their 6-month follow-up at the time of the first report, indicating that retention was higher than expected. The ICOPE implementation in the French study involves use of remote monitoring and digital data collection and tracking in combination with educating and involving primary care and other health care workers. The different steps in the ICOPE program will be reviewed during the presentation. Subsequent reports are expected to provide information on the impact of the program on the intrinsic capacity of ICOPE participants.

Other organizations are espousing the Healthy Longevity concept. For example, the National Academy of Medicine launched 'The Healthy Longevity Global Grand Challenge', a worldwide initiative to improve physical, mental, and social well-being for people as they age. The X-Prize competition has chosen 'Healthy Longevity' as its current theme. The healthy longevity movement not only aims to improve the lives of older adults, it addresses the reality that birth rates are declining and life expectancy is increasing, and increased productivity made possible by extending the healthy lifespan is needed to make all lives better.

PL8

OSTEOIMMUNOLOGY: A LEGACY DISCIPLINE?

W. F. Lems[1]

[1]Rheumatologist, Amsterdam UMC, Amsterdam, Netherlands

Bone mass and bone strength are strongly dependant on age, gender and hormones, but in recent years the negative effects of inflammatory cytokines (such as TNFα and IL-6) on bone, the so-called osteoimmunology, has been unraveled.

Clinically, this has been reflected by an increased fracture rate in individuals with low grade systematic inflammation, based on CRP-levels[1]. In patients with systematic inflammatory diseases, such as in rheumatic diseases and inflammatory bowel diseases, BMD is often lower and fracture rate higher than in healthy controls of the same age.

The negative effects of systemic inflammation is probably best studied in patients with rheumatoid arthritis (RA): both a low BMD in the osteoporotic range and vertebral- and nonvertebral fracture occurred roughly twice as much. Localized bone loss around the joints (bone erosions) are characteristic of RA.

Since both the generalized bone loss and the local bone loss are strongly related to inflammation, it could be expected that with effective anti-inflammatory drugs, the bone loss could be

prevented. We were among the first to demonstrate that with the TNFα blocker infliximab the usually occurring bone loss in RA could be prevented[2]. The same was later observed for another TNFblocker, adalimumab, and B-cell blockade, IL-6 blockade and JAK-inhibition.
We also showed in the BEST-trial with a treat to target design that local bone erosions could be prevented in more than 80% of patients during 10 years of treatment.[3]
Strikingly, very recent data with HRpQCT imaging have shown some repair of erosions in RA during treatment with baricitinib[4].
Thus, there are a lot of studies showing that with effective antirheumatic drugs, which are currently available in RA, both local and generalized bone loss can be minimized.[5] With the broad armamentarium of antirheumatic drugs it must be possible nowadays to have many RA-patients in clinical remission, with absence or only mild arthritic symptoms, and strong limitation of the negative effects on bone over time

WHEN SHOULD WE CONSIDER MOVING FROM MEDICAL TO SURGICAL MANAGEMENT IN OA OF THE KNEE & HIP?

P. Conaghan[1]

[1]University of Leeds/Musculoskeletal Medicine/Chapel Allerton Hospital, Leeds, United Kingdom

The surgical intervention with best outcomes for osteoarthritis (OA) is total joint replacement (TJR). Pain remains the main indication, though its persistence over time may be more important to patients than intensity at a single time point. Stiffness, sometimes indistinguishable from pain, and functional impairment are other drivers. The decision for surgery is also based on radiographic severity, general health, willingness to undergo operation, surgeon decision, financial considerations and patient expectations. The latter may be changing with patients considering joint replacement at an earlier age, driven by increasing obesity and sedentary lifestyles, being unwilling to accept sustained symptoms, and a desire to return to sport. A range of appropriateness tools have been developed though there has been varied uptake.
Before transitioning a patient to TJR, clinicians need to ensure adequate conventional therapy has been trialled for a given patient. The range of available therapies is sadly limited, but weight loss when relevant, muscle strengthening or physical therapy, and appropriate use of analgesics are standard therapies recommended in all OA guidelines. In hip OA, there are fewer therapeutic options, and given the better long-term outcomes (compared to knee TJR), hip replacement may be a more straightforward decision.
Can we optimise pre-operative care for knee TJR? A recent feasibility study provided a package of care for patients awaiting TKR and focussed on weight loss (using strict dietary replacements), analgesia and orthotics reviews and a package of quadriceps strengthening exercise. Of 60 people randomised, use of the various components varied and adherence was high. Significant improvement in quality of life was observed and 10% of patients cancelled their surgery. The advent of highly effective weight loss drugs, recently showing excellent benefits for OA pain and function, may change demand for surgery in this group.

PL10

SUCCESSFUL FRACTURE HEALING: DO OSTEOPOROSIS AND ITS TREATMENT MATTER?

M. Chandran[1]

[1]Osteoporosis and Bone Metabolism, Unit Department of Endocrinology, Singapore General Hospital, DUKE NUS Medical School, Singapore, Singapore

Fracture healing is a multistep process. Most fractures heal through a combination of intramembranous and endochondral ossification. Radiographic imaging is important for evaluating fracture healing and for detecting delayed union or non-union. The presence of callus formation, bridging trabeculae, and a decrease in the size of the fracture line over time are indicative of healing. Imaging must be combined with clinical parameters and patient reported outcomes. Animal data support a negative effect of osteoporosis on fracture healing, however clinical data shows conflicting results. Evidence does not support a delay in the initiation of antiresorptive therapy following acute fragility fractures. There is no reason for suspension of osteoporosis medication at the time of fracture if the person is already on treatment. Teriparatide treatment may shorten fracture healing time at certain sites such as distal radius, however, it does not prevent non-union or influence union rate. A beneficial effect of Romosozumab on fracture healing has not been demonstrated in clinical studies so far. Pre- or post-operative bisphosphonate use also does not negatively affect union in those undergoing spinal fusion surgery. Denosumab appears to improve pedicle screw fixation in spinal fusion surgery as does teriparatide. Overall, there appears to be no deleterious effect of osteoporosis medications on fracture healing or on union rates in spinal fusion surgeries. The benefit of treating osteoporosis and the urgent necessity to mitigate imminent refracture risk after a fracture should be given prime consideration. It is imperative that new radiological and biological markers of fracture healing be identified. It is also important to synthesize clinical and basic science methodologies to assess fracture healing, so that a convergence of the two frameworks can be achieved.

LESSONS FROM INTERVENTIONAL STUDIES CONDUCTED IN SARCOPENIA: ARE WE CLOSE TO A TREATMENT

F. Landi[1]

[1]Catholic University, Fondazione Policlinico Gemelli IRCCS, Rome, Italy, Rome, Italy

Sarcopenia, the age-related loss of muscle mass and function, is a major contributor to frailty, disability, and reduced quality of life in older adults. Over the past decade, numerous interventional studies have aimed to address the underlying mechanisms and explore potential treatments for sarcopenia. These studies have provided valuable insights into the roles of exercise, nutritional supplementation, and pharmacological agents in mitigating muscle loss and improving muscle strength and performance.
Exercise interventions, particularly resistance training, remain the cornerstone of sarcopenia management, with evidence demonstrating significant improvements in muscle mass and physical function. Nutritional strategies, such as protein supplementation and the use of specific nutrients like vitamin D and omega-3 fatty acids, have shown promise, particularly when combined with exercise. Recent pharmacological trials targeting anabolic pathways, myostatin inhibition, and inflammation modulation have yielded mixed results, highlighting both the potential and challenges of drug development for sarcopenia.
Despite these advances, the translation of findings into effective and widely applicable treatments remains a challenge due to heterogeneity in study populations, variability in intervention protocols, and limitations in clinical outcome measures. This presentation will summarize key lessons from interventional studies conducted in sarcopenia, discuss the progress made toward identifying effective treatments, and outline the gaps that need to be addressed to move closer to a standardized, evidence-based therapeutic approach for this condition.
Keywords: Sarcopenia, interventional studies, exercise, nutrition, pharmacological treatment, muscle health.

EL2

OSTEOPOROSIS IN INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASES (IRMDS)

G. A. Adami[1]

[1]University of Verona, Verona, Italy

Osteoporosis is a common yet often underdiagnosed complication in patients with inflammatory rheumatic musculoskeletal diseases (iRMDs). Chronic inflammation, prolonged glucocorticoid use, and reduced physical activity synergistically contribute to bone fragility, increasing fracture risk. This lecture will explore the complex interplay between inflammation and fracture risk, emphasizing recent advances in understanding and managing osteoporosis in the context of iRMDs.
Systemic inflammation in conditions such as rheumatoid arthritis (RA), spondyloarthritis (SpA), and systemic lupus erythematosus (SLE) disrupts bone homeostasis by favoring osteoclastogenesis and inhibiting osteoblast function. Key cytokines, including TNF-α, IL-6, and IL-17, directly promote bone resorption, while glucocorticoids, frequently prescribed to manage disease activity, exacerbate bone loss by suppressing bone formation. Consequently, patients with iRMDs exhibit higher rates of vertebral and non-vertebral fractures, even at a younger age compared to the general population.
Clinical management requires a multifaceted approach integrating inflammation control, bone-directed therapies, and lifestyle interventions. Emerging evidence highlights the role of biologics targeting TNF, IL-6, and IL-17 in mitigating bone loss, potentially offering dual benefits of disease control and fracture prevention. However, other targeted therapies (like JAKi) yielded controversial results, with some even apparently increasing the risk of fracture.
The lecture will discuss data from recent trials and observational studies demonstrating the impact of biologics on bone mineral density (BMD) and bone turnover markers. Additionally, the role of anti osteoporotic agents such as romosozumab and denosumab in patients with severe osteoporosis will be considered, with a focus on sequential and combination strategies to optimize bone health.
This lecture aims to provide clinicians with updated insights and practical tools to bridge the gap between inflammation control and bone protection.

EL3

BIOSIMILARS IN OSTEOPOROSIS MANAGEMENT

S. Silverman[1]

[1]Cedars-Sinai Medical Center Clinical Professor of Medicine, Cedars-Sinai Medical Center and UCLA School of Medicine, Beverly Hills, CA, United States

Objective: Understand the potential role of biosimilars in osteoporosis management
Discussion: A biosimilar is a biological medicine highly similar to another biologic medicine already approved (the so-called reference medicine). Because biosimilars are made in living organisms there may be some minor differences from the reference medicine which are not clinically meaningful. Biosimilarity means high similarity in terms of structure, biologic activity in efficacy, safety and immunogenicity profile.
Evidence acquired over 10 years of clinical experience has shown that biosimilars can be used safely and effectively in all their approved indications as other biologic medicines. By demonstrating biosimilarity, a biosimilar can rely on the safety and efficacy experience gained with reference medicine.
There are now multiple biosimilars in osteoporosis management for teriparatide and denosumab. The availability of biosimilars for osteoporosis management will significantly reduce the costs of medications for osteoporosis for both reference products and biosimilars and improve their availability to patients. Biosimilars to denosumab are cost effective in comparison to bisphosphonates which may influence their role in osteoporosis guidelines.

Interchangeability refers to the possibility of exchanging one medicine for another with the same clinical effect which can be done by either switching or substitution. Biosimilar interchangeability is regulated differently in the US and EU.
Healthcare professionals have a central role in educating patients and avoiding the nocebo effect. Providers are increasingly familiar and comfortable with prescribing biosimilars ; however there remains work to be done. Patient understanding of biosimilar products will be key to the utilization of these drugs. Patients want to hear first from their healthcare providers. Having the provider introduce the subject of biosimilars is a key part of the conversation with patients.
Conclusion: Biosimilars will play an important role in future osteoporosis management

PREGNANCY - AND LACTATION-RELATED OSTEOPOROSIS

M. L. Brandi[1]

[1]University Vita-Salute San Raffaele, Milan and FIRMO Foundation, Florence, Italy

Pregnancy and lactation-associated osteoporosis (PLO) is a rare condition characterized by fragility fractures occurring during late pregnancy or lactation, primarily affecting the spine and causing significant morbidity and back pain. PLO can lead to mobility impairment and work incapacity, with recovery taking up to several years.
Early diagnosis of pregnancy- and lactation-associated osteoporosis (PLO) is mandatory for a good outcome.
Standard care is not a matter of conventional guidelines and protocols, rather of a single case-by-case strategy. Immobilization due to multiple VFs, hip/femoral neck fractures, the use of orthopedic braces, and major surgical procedures (such as vertebroplasty or hip replacement) is part of the specific orthopedic approach. The decision to perform emergency cesarean in PAO is sometimes required based on complex and challenging multidisciplinary considerations. PLO requires stopping breastfeeding in order to resume the hypo-estrogenic and hyper-prolactinemic status and milk-associated calcium loss and potentially to reduce the levels of PTHrP. Calcium and VD supplements represent the accepted consensus regarding medication against PLO. Specific drugs against osteoporosis such as bisphosphonates, denosumab, teriparatide, and, romosozumab are selectively offered to patients after delivery up to a maximum of 5 years, depending on case.
The presentation will emphasize PLO severity, advocating for increased awareness and timely interventions. TPD emerges as a promising therapeutic option in certain cases.

WHICH PATIENTS SHOULD BENEFIT FROM A BONE-FORMING AGENT

E. M. Curtis[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Anabolic, or bone-forming therapies (namely teriparatide, abaloparatide and romosozumab), are crucial in the management of osteoporosis in patients at very high risk of fractures. In this patient group, the benefits of the most potent anabolic therapies have been demonstrated in a range of studies across the world. However in real-world clinical practice only a limited proportion of these high risk patients are appropriately identified and treated. The definition of very high fracture risk and recommendations for management of these patients differs between countries, as does the availability of bone-forming agents.

In this session, we will discuss the evidence for the use of bone forming-agents in patients at high or very high risk of fractures, and how these patients are best identified. We will consider the positioning of bone-forming agents within the long-term treatment strategy for osteoporosis. The barriers to the use of bone forming agents (and potential facilitators), from the patient and health economic perspective, will also be discussed.

ESCEO2

COMPARATIVE EFFICACY AND SAFETY OF CURRENTLY AVAILABLE BONE FORMING AGENTS

R. Rizzoli[1]

[1]Service of bone disease - Geneva university hospitals and faculty of medicine, Geneva, Switzerland

Anti-osteoporosis treatments display short-term high magnitude antifracture efficacy and long-term favorable safety profile. Head-to-head studies demonstrate greater rapidity of action and higher effect magnitude of anabolic compared with antiresorptive therapies in fracture risk reduction. In patients at very high or imminent fracture risk, the use of an anabolic agent as the initial treatment, followed by maintenance of the benefits with antiresorptive agent, offers a more effective strategy than first-line antiresorptive therapy for fracture risk reduction in these very vulnerable patients. Except some well recognized increase in heart rate and decrease in blood pressure, PTH-receptor 1 agonists like teriparatide or abaloparatide are not associated with higher risk of cardiac adverse event nor of bone cancer. The possible cardiovascular signal of romosozumab in patients with history of cardiac disorders or stroke should be verified in post-market surveillance. These sequential treatment regimens in very high risk patients are cost-effective. With the limitation of country specific drug registration and reimbursement policy, these regimens should become the standard of care for patients at very high or at imminent risk of fracture, considering their efficacy and safety.

RELATION BETWEEN COGNITIVE IMPAIRMENT AND BONE HEALTH

M. M. Rosa[1]

[1]Laboratory of Clinical Pharmacology and Therapeutics, Faculty of Medicine, University of Lisbon, Lisbon, Portugal

Objective

To discuss the multimodal relation between cognitive impairment and bone health.

Material and methods

A systematic search for publications of studies with terms “bone health”, “sarcopenia”, “cognitive impairment” and “dementia” was performed. Sixteen studies were identified where a screening tool for cognition was used, from 2007 onwards. Discussion on mechanisms of disease encompass both clinical and preclinical data.

Results

Cognition may relate to bone health and sarcopenia both through direct and indirect pathway. Direct: when the pathologic mechanism causing cognitive impairment also affects bone health. This includes mechanisms such as: a) inflammatory [Amyloid precursor protein (APP) and A β-amyloid are increased in both neurons, osteoblasts (impairing function and proliferation) and osteoclasts (promoting activity); Wnt/β-catenin promote synaptic health in the brain and osteoblast differentiation and increased bone mass; TREM2, protects microglia in the brain and controls the rate of osteoclastogenesis]; b) oxidative stress; and the well-known c) Oestrogen and Vitamin D deficiencies, all of which are shared between frail / sarcopenic and cognitively impaired patients. Indirect: where changes in cognition, behaviour or disease treatment ultimately induce worsening bone health. This includes a) diet restrictions; b) decreased mobility; c) decreased sun exposure; d) drug mediated increase of inattention and falls; e) Aggressive / risky behaviour / caregiver wellbeing; f) Loss of compliance (pharmacological and non-pharmacological interventions and diet).

Conclusion

There is cumulative evidence that cognitive impairment is closely linked to worsening of bone health via direct and indirect pathways. With the world population growing older and more cognitively impaired, there is need to understand better the relation with bone health and cognition. Knowledge of this relation will allow the development of measures to prevent and treat bone health and sarcopenia loss.

The Author has nothing to disclose.

DRUGS USED IN COGNITIVE IMPAIRMENT AND BONE HEALTH

E. Balkowiec-Iskra[1]

[1]Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Poland The Office for Registration of Medicinal Products, Medical Devices and Biocidal Products, Warsaw, Poland CHMP, SAWP, CNSWP, PCWP, ETF Member (European Medicines Age, WARSAW, Poland

Alzheimer's disease (AD) is the leading cause of cognitive impairment and dementia in subjects above 65 years of age. AD currently affects approximately 50 million people worldwide, and is the sixth-leading cause of death in the United States. Pathophysiological changes in the brains of affected individuals develop years before any clinical manifestations are observed.
Symptomatic treatments for AD dementia include cholinesterase inhibitors (donepezil, rivastigmine, galantamine) and N-methyl-D-aspartate antagonists (memantine).
Recently, disease modifying medicinal product lecanemab was approved in the EU for the treatment of adult patients with a clinical diagnosis of mild cognitive impairment and mild dementia due to Alzheimer's disease (Early Alzheimer's disease) who are apolipoprotein E ε4 (ApoE ε4) non-carriers or heterozygotes with confirmed amyloid pathology. Donanemab is currently under assessment at the EMA. In the US aducanemab, lecanemab and donanemab are approved.
Several pre-clinical studies showed that medications used for the treatment of cognitive impairment may impact bone function. Donepezil has been shown to affect energy metabolism and favour bone mass accrual in healthy young wild type mice[1]. Moreover improvement of bone quality by reducing the number of bone resorbing osteoclasts has been shown in donepezil-treated mice[2].
Osteoporosis and bone fractures are reported two-fold increased prevalence in subjects with AD, compared to healthy individuals at a similar age[3].
The epidemiological evidence suggest association between cognitive impairment and bone health (BMD and falls/fractures). The incidence of falls and fractures has been shown to be high in people with dementia in several studies. However, relationship between BMD and dementia is unclear and requires further studies. In a multicenter study of osteoporotic fractures, low BMD was found to be associated with lower cognitive scores in women[4]. It was also shown that higher rates of bone loss can be predictive of subsequent cognitive decline in older women[5] Moreover, an increased risk of dementia or AD was reported in subjects with history of distal radius, hip or spine fractures[6].
More studies are needed to further characterize the link between cognitive and bone disorders to facilitate development of novel therapeutic strategies.

ESCEO5

SPECIFIC CONSIDERATIONS FOR THE MANAGEMENT OF OSTEOPOROSIS IN THE OLDEST OLD

N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Osteoporosis and high fracture risk are lifelong considerations. Age is a major determinant of fracture risk and all other things being equal, fracture risk will rise with increasing years. Our ability to optimally manage bone health in the oldest old is impacted by several considerations. Firstly, despite advances in clinical care and policy, and the enormous efforts of bodies such as the IOF, fractures may still be viewed as an inevitable part of ageing; secondly, there is limited direct evidence for the efficacy of medications in this age group - sadly lack of evidence is sometimes interpreted as evidence of a lack of effect; thirdly, comorbidities such as renal impairment and gastrointestinal dysfunction become more common such that choosing an appropriate medication is less straightforward than at younger ages; fourthly, the body's ability to metabolise and handle medications may change with age, leading to the potential for greater risk of interactions, particularly given the frequency with which older individuals receive multiple medications.
In this session I will give an overview of the considerations relevant to the clinical assessment and management of osteoporosis and high fracture risk in the oldest old. I will address approaches across guidelines, issues of long-term efficacy and safety, focusing on a pragmatic approach to do the best for patients at high fracture risk in older age.

ESCEO6

SPECIFIC CONSIDERATIONS FOR THE MANAGEMENT OF OSTEOARTHRITIS IN THE OLDEST OLD

P. Conaghan[1]

[1]University of Leeds/Musculoskeletal Medicine/Chapel Allerton Hospital, Leeds, United Kingdom

With ageing populations, the 'oldest old' with osteoarthritis (OA) are rapidly increasing. Treatment options are few for this group and clinicians are increasingly challenged. With this in mind, ESCEO recently convened an expert working group to explore this issue.

While there is no agreed age cut point, generally 'oldest old' refers to those over 80 years old with high levels of dependence and co-morbidities. The high levels of multimorbidity in OA are highlighted in a Canadian insurance registry study included 500,000 participants, with 29% having hypertension, 20% depression, 19% chronic obstructive pulmonary disease, 10% diabetes and 6% congestive heart failure. This clearly presents a problem for many OA medications. Pain remains the main reason to treat OA, though in this age group, activity may limit weight-bearing pain.

The evidence base for any OA therapeutic interventions in the 'oldest old' is very poor. For various reasons, the mean age in OA trials is 60-65 yo, with few participants aged over 75. All OA guidelines recommend a mix of non-pharmacological and pharmacological therapies. The former involve muscle strengthening/ physical therapy (and compliance may be reduced in this group) and weight loss if needed; new anti-obesity therapies may offer some opportunities in obese and overweight though understanding safety in this group is needed.

SYSDOAs are recommended in ESCEO guidelines. Paracetamol is commonly used in this age group but analgesic benefits if any are small; dose and duration may be important for efficacy and safety. Polypharmacy will likely play a role in the pharmacokinetics of paracetamol (and other drugs) in the oldest old. Topical NSAIDs are likely safe and effective for some joint sites, but oral NSAIDs are problematic given the risks associated with co-morbidities and great care is required in monitoring patients using these agents. Intra-articular corticosteroids may offer some short-term relief for individual joints.

ESCEO7

THE DELINEATION OF ENDOTYPE AND PHENOTYPE TO IDENTIFY THE PATIENTS WITH KNEE OSTEOARTHRITIS WHO SHOULD BE TREATED

P. Conaghan[1]

[1]University of Leeds/Musculoskeletal Medicine/Chapel Allerton Hospital, Leeds, United Kingdom

The lack of successful OA clinical trials has made us reconsider who we should be treating – are there subgroups who may respond to a specific therapy? Most of us are familiar with the concept of a 'phenotype' – an observed disease characteristic; unfortunately this gives little clue as to a specific molecular pathways that drive the disease, which we term an endotype.

In OA trials we typically include patients with months of moderate-severe pain (chronic pain phenotype) and radiographic evidence of cartilage loss (cartilage phenotype). Some surgical studies have included patients with high degrees of malalignment, a mechanical overload phenotype. Others have included patients with synovitis, as an inflammatory phenotype. One problem with phenotypes is that the often overlap – for example, most patients with cartilage loss have some degree of synovitis. Recently machine learning has been employed to determine novel phenotypic clusters providing some insights.

Trials focusing on a cartilage phenotype have generally been disappointing, although sprifermin has shown some increase in MRI-detected cartilage after 18 months of therapy. Trials targeting subchondral bone marrow lesions with bisphosphonates were negative. In terms of analgesia, a trial of hand OA patients selected for chronic pain and the presence of synovitis and treated with methotrexate demonstrated benefits at 6 months. A novel neurotrophin modulator also demonstrated excellent analgesic benefits in a typical knee OA chronic pain phenotype.

In contrast, very few trials have targeted specific molecular pathways, because we are limited in the ability to identify specific biochemical or genomic biomarkers. And it is likely that multiple endotypes are involved in each phenotype. Work continues on identifying such biomarkers in blood and synovial fluid, with much focus on inflammatory phenotypes. These molecular changes likely occur years before any of the described OA clinical phenotypes.

ESCEO8

THE ROLE OF BIOMARKERS (IMAGING, BIOLOGICAL) IN THE IDENTIFICATION OF OSTEOARTHRITIC PATIENTS WHO SHOULD BE TREATED

F. Berenbaum[1]

[1]Sorbonne University, INSERM, Department of Rheumatology AP-HP Saint-Antoine hospital, Paris, France

The objective of this lecture is to evaluate the role of biomarker modalities in identifying knee osteoarthritis (OA) patients with significant unmet medical needs, guiding symptomatic and structural treatment approaches. This presentation synthesizes findings from key clinical trials and cohort studies, focusing on biomarkers such as X-rays, magnetic resonance imaging (MRI) and biochemical markers. Analyses included the identification of structural progressors, associations between synovitis markers and cartilage degradation, and predictors of total knee replacement (TKR). Biochemical markers were integrated to evaluate their relationship with imaging findings and clinical outcomes. Imaging revealed critical distinctions among OA subgroups. Structural progressors were identified using baseline Kellgren-Lawrence (KL) grades, with KL3 patients demonstrating

faster progression than KL2. MRI-based evaluations of synovitis and effusion-synovitis predict structural degeneration and risk of TKR. Sustained synovitis was associated with a higher likelihood of cartilage loss and OA progression. Elevated levels of biological biomarkers such as IL-6 and MMPs were associated with enhanced cartilage degradation and synovitis severity, providing complementary insights to imaging data. The interplay between imaging markers, biological biomarkers, and clinical outcomes underscores the potential of imaging-guided stratification for personalized OA management.

In conclusion, imaging techniques are pivotal in stratifying OA patients based on disease severity and unmet medical needs, enabling targeted interventions. Baseline imaging markers, such as synovitis and effusion severity, along with biochemical markers, could predict progression and guide treatment strategies, from pharmacological therapies (e.g., NSAIDs, intra-articular injections) to surgical interventions like TKR. Further research should refine imaging and biomarker-based endpoints for disease-modifying OA drugs (DMOADs).

ESCEO9

PHARMACOLOGICAL MODE OF ACTION (PTHR1 AGONISTS)

N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

The opposing effects of parathyroid hormone on bone according to its intermittent or chronic elevation were characterised in the 1990s and led to the subsequent development of PTHR1 agonists. These now include teriparatide and abaloparatide. Teriparatide is a synthetic peptide analogue of the first 34 amino acids of human parathyroid hormone. In contrast abaloparatide is a synthetic peptide analogue of the first 34 amino acids of human parathyroid hormone related peptide (PTHrP).

In this presentation I will discuss the similarities and differences related to the mechanism of action of these two medications. Important concepts include the differential binding to the R^0 and R^G confirmation of the PTHR1 receptor, with abaloparatide binding more strongly to the latter, resulting in a sharper spike of cyclic AMP release. This may favour anabolic over resorptive activity; indeed theoretical models of the "anabolic window" will be discussed. The outworking of these mechanisms on measurable factors such as bone turnover markers will be evaluated and the presentation will set the scene for an informed interpretation of subsequent efficacy findings.

ESCEO10

ANTI-FRACTURE EFFICACY OF PTH R1A

N. Veronese[1]

[1]Unicamillus University, Rome, Italy

Osteoporotic fractures represent a significant clinical and socioeconomic burden, particularly among aging populations. Recent advancements in osteoporosis management have centered on therapies targeting bone formation pathways. Parathyroid hormone receptor 1 agonists (PTH R1A) have emerged as a novel class of anabolic agents with promising anti-fracture efficacy. This presentation explores the role of PTH R1A in reducing fracture risk, particularly vertebral and non-vertebral fractures.

The presentation will summarize the pathophysiology of osteoporosis, emphasizing the balance between bone resorption and formation, and the limitations of traditional antiresorptive therapies. Key findings from pivotal clinical trials evaluating PTH R1A efficacy in fracture prevention will be reviewed, with particular attention to the reduction in vertebral and hip fractures observed in diverse patient populations and also taking in account recent meta-analyses about the topic.

Practical considerations for incorporating PTH R1A into clinical practice will also be discussed, including patient selection criteria, and dosing strategies. Comparative efficacy with other available anabolic agents and future directions for research and development will be highlighted.

This presentation will aim to provide physicians with an evidence-based understanding of PTH R1A as an important option in osteoporosis management, enabling more informed therapeutic decisions to improve patient outcomes and quality of life.

ESCEO11

SAFETY OF PARATHYROID HORMONE RECEPTOR (PTHR1A) AGONISTS IN THE MANAGEMENT OF OSTEOPOROSIS

E. M. Curtis[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Parathyroid hormone (PTH) and PTH-related protein (PTHrP) are hormones which play vital roles human bone metabolism/development, and have been targeted for therapeutic interventions in osteoporosis, namely through the development of the parathyroid hormone receptor agonists, abaloparatide and teriparatide. There is now considerable clinical trial and real world evidence to support the efficacy of these drugs in the treatment of osteoporosis.

It is, of course, important to balance efficacy of a medication against its safety profile. Whilst there were early rare observations of osteosarcoma in rats with high dose teriparatide treatment lifelong, this has not been borne out as a concern in human use. The vasodilating properties of these medications are well established, and may be associated with limited clinical side-effects; long-term cardiovascular safety has also been demonstrated. In this session we will discuss the safety of these medications, across a range of systems. We will consider the differences between teriparatide and abaloparatide and understand appropriate settings for their use in the context of efficacy and side effect profiles.

THE ROLE OF BONE ANABOLIC TREATMENT IN THE GERIATRIC POPULATION

R. Schmidmaier[1], M. Rippl[1], P. Grupp[1], S. Martini[1], K. Müller[1], O. Tausendfreund[1], M. Drey[1]

[1]Department of Medicine IV, LMU University Hospital, LMU Munich, Ziemssenstr. 1, 80336 München, Munich, Germany

Objective: Age is one of the most important determinants of fracture risk. Furthermore, comorbidities, reduced physical activity, and fall risk are strong risk factors for osteoporotic fractures. On the other hand, geriatric patients suffer from functional decline and reduced capacity of organ systems, which makes them highly vulnerable to stressors such as fractures. As teriparatide and romosozumab have been shown to be superior to oral bisphosphonates, many guidelines recommend first-line bone anabolic treatment for high-risk osteoporosis.
Methods: Expert opinion, review of the literature, and presentation of own scientific data.
Results: The proportion of patients with very high fracture risk according to the DVO (Dachverband Osteologie; umbrella organization of the German-speaking scientific societies dealing with bone health) risk calculator is quite high (about 50% in different studies) in the geriatric population. Characterization of the population reveals that patients have significantly reduced functional status, but only a small proportion has the most severe impairment of independence with special care needs. Furthermore, analysis of the presence of contraindications to bone anabolic drugs and antiresorptive drugs shows that almost all patients can be treated with at least any drug and that about 70% of the geriatric study population has no contraindication to any of the anti-osteoporotic medications.
Summary: The geriatric population includes many with very high fracture risk, whereas contraindications are rather rare, and most people still remain autonomous, which should be protected by considering anti-osteoporotic treatment consequently.

ESCEO-DVO2

MANAGEMENT OF PREGNANCY ASSOCIATED OSTEOPOROSIS

P. Hadji[1]

[1]Frankfurt Center of Bone Health and Endocrinology and Philipps-university of Marburg, Frankfurt/Main, Germany

Pregnancy and lactation-associated osteoporosis (PAO) is a rare, but severe form of premenopausal osteoporosis occurring predominantly during the last trimester of pregnancy or in the first months postpartum. The prevalence of PAO is estimated to be 4-8 for every million patients. However, because of the rarity of the disease a significant fraction of patients remains undiagnosed.
These patients are often undertreated, while the exact incidence of mild trauma leading to vertebral and non-vertebral fractures during pregnancy, puerperium and lactation remains unknown. The most common symptom of PAO is acute lower back pain due to bone marrow edema and vertebral fractures. Oftentimes, the diagnosis is difficult because patients do not present the common clinical risk factors for postmenopausal osteoporosis and these patients are generally healthy. As such, Bone Mineral Density (BMD) measurements are not available before the index pregnancy. If available, BMD results predominantly display a decreased Z-score, but it remains unclear whether the accelerated bone mass loss occurs before or during pregnancy. Therefore, the underlying pathophysiological mechanisms are not completely understood.
Beside increased weight-bearing and lordotic posture of pregnancy may predispose individuals with already low bone mass or skeletal fragility to low trauma spine fracture, genetic, environmental and endocrine factors, low calcium intake, vitamin D insufficiency as well as intake of glucocorticoids and heparin have also been proposed.
To date, about 200 case reports of PAO and one case-control study focusing on risk factor assessment have been reported, while evidence about long-term outcome with regard to subsequent fracture risk and the impact of treatment on BMD is currently missing. The aim of this talk is to summarize current knowledge on epidemiology, pathophysiology and treatment of PAO.

ESCEO-DVO3

OSTEONECROSIS OF THE JAW: NOVEL INSIGHTS AND CURRENT STATUS

S. Otto[1], K. Obermeier[1], R. Schmidmaier[2], E. Hesse[3], P. Poxleitner[4]

[1]Department of Oral and Maxillofacial Surgery, Ludwig-Maximilians University, Munich, Germany, [2]Medical Clinic and Polyclinic IV, Focus on Acute Geriatrics, University Hospital of Munich, Munich, Germany, [3]Heisenberg-Group for Molecular Skeletal Biology, Department of Trauma, Hand and Reconstructive Surgery, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany, [4]Center for Dental Medicine, Department of Oral and Maxillofacial Surgery and Regional Plastic Surgery, Medical Center-University of Freiburg, Freiburg, Germany

Osteoporosis is a chronic metabolic disease characterized by decreased bone mass and deterioration of microarchitecture leading to fragility and fracture. Antiresorptive therapy (AR) is one of the primary treatment options to prevent bone resorption and fractures. The most commonly used drugs are bisphosphonates or RANKL-inhibitors (denosumab), as well as a new sklerostin-inhibitor (romosozumab). Antiresorptive agents work by inhibiting osteoclast activity, thereby slowing the breakdown of bone tissue and maintaining bone density. Due to its mechanism, AR-drugs also play an important role in patients with osseous metastases to reduce further expansion.
Medication-related osteonecrosis of the jaw (MRONJ) is a rare side effect of AR-therapy. Data show that it occurs less frequently in osteoporosis patients than in patients with oncological indications due to lower dosing. The Pathogenesis of MRONJ was unclear for a long time and is still a subject of research. However, there are recent findings that indicate that local dental infections

play a key role.
Potentially pathogenic germs in the oral cavity, increase the risk of developing osteonecrosis of the jaw. This was shown in in vitro as well as in vivo large animal models. That understanding of the disease leads to new prophylactic strategies including optimization of oral hygiene and regular dental check-ups. Furthermore, new and innovative treatment options e.g. fluorescence guided surgical treatment have optimized the treatment outcomes and made surgical interventions less invasive.
Overall, MRONJ is a rare side effect in patients under AR therapy, which can successfully be treated surgically. Prevention and dental check-ups are vital for patients under AR-therapy and can prevent MRONJ.

ESCEO-DVO4

DEALING WITH ATYPICAL FEMUR FRACTURES

A. Kurth[1]

[1]Orthopaedic Institute Dr. Baron&Colleagues and Goethe University Frankfurt, Frankfurt/Main, Germany

Antiresorptive medications, including bisphosphonates (BPs) and denosumab (DMAB), are extensively utilized in the management of osteoporosis. While these drugs are effective in preventing osteoporotic fractures, the use of bisphosphonates is associated with rare but serious adverse events, such as osteonecrosis of the jaw and atypical femoral fractures (AFFs). An AFF is characterized by a spontaneous or low-trauma subtrochanteric or femoral shaft fracture, often complicated by delayed or nonunion and frequently occurring bilaterally. These fractures are classified as insufficiency fractures and commonly present with bone pain. Early detection of distinct radiographic signs, along with discontinuation of antiresorptive therapy, can potentially prevent the progression to completed atypical femoral fractures. Conservative management is recommended primarily for patients with incomplete fractures or severe comorbid conditions. For most cases of both complete and incomplete AFF, intramedullary nailing is considered the preferred treatment. Healing complications in atypical femoral fractures are an uncommon yet notable issue among users of antiresorptive drugs. Treatment with teriparatide (TPTD) following an AFF has shown promise in enhancing fracture healing, reducing the incidence of delayed union and nonunion, and shortening the time required for fracture recovery.

WHY AND HOW SHOULD WE TEST BIOCHEMICAL MARKERS OF BONE TURNOVER IN 2025?

H. P. Bhattoa[1], S. Vasikaran[2], K. Makris[3,4], E. Cavalier[5]

[1]Department of Laboratory Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary, [2]PathWest Laboratory Medicine WA, Murdoch, Australia, [3]Clinical Biochemistry Department-KAT General Hospital, Kifissia, Athens, Greece, [4]Laboratory for Research of the Musculoskeletal System "Th. Garofalidis", Medical School, University of Athens, Athens, Greece, [5]CHU de Liège and Centre de Recherche Intégré sur les Médicaments (CIRM), Department of Clinical Chemistry, University of Liège, Liege, Belgium

Biochemical markers of bone turnover (BTMs) provide valuable insights into the dynamic processes of bone remodeling, reflecting the balance between bone formation and resorption. The International Osteoporosis Foundation (IOF) and the International Federation of Clinical Chemistry and Laboratory Medicine (IFCC) recommend serum procollagen type I N propeptide (PINP) and β-C-terminal telopeptide of type I collagen (β-CTX-I) as reference markers for the diagnosis and management of osteoporosis. This abstract reviews advancements since the 2011 IOF-IFCC position paper, emphasizing why and how BTMs should be integrated into clinical practice in 2025.

Recent evidence confirms that elevated BTM concentrations, including PINP and β-CTX-I, correlate with increased fracture risk in postmenopausal women, independent of bone mineral density (BMD). However, the interaction of BTMs with other risk factors, such as those in the FRAX® algorithm, remains underexplored. Importantly, BTMs can guide treatment decisions, monitor therapeutic efficacy, and improve patient adherence to anti-osteoporotic therapy. For example, reductions in β-CTX-I and PINP during treatment with antiresorptive agents are associated with fracture risk reduction.

Advances in assay harmonization have improved the reliability of BTM measurements, yet challenges remain. Standardized patient preparation and sample handling protocols are critical to minimize pre-analytical variability. While PINP and β-CTX-I are suitable for patients with normal renal function, the utility of the total PINP (tPINP) and β-CTX-I is limited in chronic kidney disease (CKD) due to renal retention. Alternative markers, such as bone-specific alkaline phosphatase (BALP), intact PINP (iPINP) and tartrate-resistant acid phosphatase isoform 5b (TRACP5b), have shown promise in distinguishing high and low bone turnover states in CKD-associated osteoporosis and warrant further exploration.

To optimize the use of BTMs in 2025, we recommend continued efforts toward assay standardization and the development of reference intervals across diverse populations. Incorporating BALP and TRACP5b into clinical workflows can improve fracture risk assessment, treatment selection, and monitoring in CKD-associated osteoporosis. Ultimately, BTMs offer a non-invasive, cost-effective tool for advancing personalized approaches to osteoporosis management, aligning with the growing emphasis on precision medicine in musculoskeletal health.

ESCEO-IOF-IFCC2

WHAT DO BONE TURNOVER MARKERS BRING TO THE CLINICIAN, IN THE SCREENING, DIAGNOSIS AND MONITORING OF OSTEOPOROSIS IN 2025?

S. Silverman[1]

[1]Cedars-Sinai Medical Center Clinical Professor of Medicine, Cedars-Sinai Medical Center and UCLA School of Medicine, Beverly Hills, CA, United States

Objective: Understand the potential role of bone turnover markers in management of osteoporosis in 2025

Discussion: Not all physicians use bone turnover markers (BTMs). If they use bone turnover markers most will use CTX and P1NP. BTMs may be of value in the 1st year after starting medication as changes in DEXA are not yet apparent. A lack of change in bone markers may reflect adherence or lack of response. Bone turnover markers may measure the response to anabolic regimen such as PTH agonist. The anabolic response may wean by 18 months but may persist for 36 months or longer. BTMs may be of value in monitoring bisphosphonate holidays and suggest when to restart an oral bisphosphonate. They may be helpful in following Denosumab discontinuation and judging the need for repeat administration of iv zoledronic acid.

BTMs may also play a role in the initial evaluation when using FRAX with DEXA is close to but below treatment threshold by predicting rate of future bone loss. BTMs may also show the efficacy of an osteoporosis medication used in a patient who is on a medication which results in bone loss (e.g. aromatase inhibitors). BTMs may also be helpful in understanding a lack of BMD response on medication. BTMs may helpful in identifying patients with unexplained high bone turnover who may need a workup for secondary causes. BTMs may be of value in the management of CKD associated osteoporosis.

Barriers to use of BTMs include reimbursement by insurance payors, slow turnaround time, fasting requirement and varying reference values.

Conclusions: Bone turnover markers or bone status indices have the potential to help the clinician in osteoporosis management

ESCEO-IOF-IFCC3

WHAT IS THE ROLE OF BONE TURNOVER MARKERS IN CHRONIC KIDNEY DISEASE-ASSOCIATED OSTEOPOROSIS?

M. Haarhaus[1]

[1]Division of Renal Medicine; Department of Clinical Science, Intervention, and Technology; Karolinska Institutet; Karolinska University Hospital, Stockholm, Sweden

Chronic kidney disease (CKD) is highly prevalent among patients with osteoporosis and associated with an increased fracture risk. Progressive loss of renal function induces disturbances of mineral metabolism, severely affecting bone remodeling, mineralization, volume, and material quality. These disturbances

ultimately compromise bone strength and result in a condition that is increasingly referred to as CKD-associated osteoporosis. Skeletal remodeling in CKD shows great variability, from high turnover to abnormally low turnover.

Different therapeutic strategies for CKD-associated osteoporosis may be considered depending on the state of bone turnover. An assessment of skeletal remodeling is therefore key prior to formulating a treatment plan for bone fragility in CKD. Currently, circulating parathyroid hormone (PTH) is recommended for routine evaluation of bone turnover in CKD, but its use is flawed by a wide biologic variability, a large range of uncertainty, and J- or U-shaped associations with fracture risk and mortality. In contrast, both total alkaline phosphatase (ALP) and the bone isoform BALP demonstrate lower variabilities and positive linear associations with risk of fractures in these patients and may outperform PTH and bone mineral density by DXA in fracture risk prediction.

Importantly, the biomarkers of bone turnover currently recommended for the management of postmenopausal osteoporosis are not suitable in the setting of CKD, as they accumulate with kidney dysfunction. Instead, intact procollagen I N-terminal propeptide, tartrate-resistant acid phosphatase 5b, and BALP are not affected by renal function and can be measured in routine laboratories. Studies comparing these biomarkers to bone biopsy findings reveal decent diagnostic accuracies for both high and low bone turnover.

Bone turnover markers may be useful for treatment choice between antiresorptive and anabolic agents and for estimation of treatment responses in CKD. Higher levels of bone turnover markers associate with greater BMD gain following anti-resorptive therapy in late-stage CKD. Higher levels of bone turnover markers can also be used for risk-prediction of a hungry bone response with severe hypocalcemia following denosumab injections, parathyroidectomy, and initiation of calcimimetics for the control of severe hyperparathyroidism.

Bone turnover markers are thus essential for evaluation of bone turnover, risk-evaluation, treatment initiation, and assessment of treatment response in CKD-associated osteoporosis.

THE ROLE OF SEX STEROIDS IN THE HEALTH OF THE MUSCULOSKELETAL SYSTEM: A LIFETIME JOURNEY

A. R. Genazzani[1,2]

[1]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]University Unit of Gynecology and Obstetrics I, Pisan University Hospital, Pisa, Italy

Changes in body composition that occur in women at midlife also affect lean muscle mass, which, as opposed to fat mass, seems to decrease. Although sarcopenia cannot be currently attributed to the menopause, this degenerative process is more evident in ageing women than ageing men and seems to occur more rapidly after the menopause. However, MHT does not seem to confer a benefit in terms of gain in lean body mass. Although earlier studies had indicated preservation of muscle in women treated with MHT compared to placebo studies from large trials have not confirmed these results. Data from WHI bone mineral density (BMD) centers showed that lean body mass loss was smaller with either estrogen or estrogen-progestin treatment at 3 years compared to placebo, however, this result was lost by 6 years, with no differences between placebo and HT treatment groups. Similarly, the Danish Osteoporosis Prevention Study (DOPS), found no significant difference between treatment and control for change in lean body mass over 5 years. WHI data have revealed that estrogen and estrogen-progestin treatments result in less joint pain compared to placebo. Moreover, women treated with MHT develop less carpal tunnel syndrome. The WHI has also demonstrated a reduction in the percentage of women who undergo joint replacement surgery among women taking MHT compared to placebo, possible indicating a role for MHT in preservation of cartilage. Estrogen-progestogen treatment also seems to have a positive effect on intervertebral disc height, which correlates with T-score. Adequate disc height is important for the maintenance of shock-absorbing properties of the intervertebral disc and protecting the spine from vertebral compression fractures. Osteoporosis-related bone fractures decrease with years of MHT use. Stopping MHT, on the other hand, determines significant bone loss and increases risk of hip fracture as early as 2 years after stopping treatment.Research however is still lacking and should be promoted for a comprehensive understanding of the effects of MHT when initiated early after the onset of menopause.

ESCEO-ISGE2

WHEN THE OVARIES FAIL EARLY: PROTECTING THE BONE

S. Vujović[1]

[1]Faculty of medicine, University of Belgrade, National center for infertility and androcriinology of gender, Clinic of endocrinnology. diabetes and diseases of metabolism, University clinical ceenter of Serbia, Belgrade, Serbia

Almost all hormones influence bone density. Receptors for estradiol, thyreostimulating hormone (TSH), follicle stimulating hormone, (FSH) adrenocortical hormone (ACTH), prolactin, growth hormone (GH), Ghrelin, leptin, oxytocin, and vasopressin are expressed on the bones. The most crucial hormone for the bone health is estradiol. Hypoestrogenism thin trabecular part of the bone, leads to perforation and loose of connections between trabecules. Gene affecting bone mineral density (BMD) are LRP5 and ESR1.Premature ovarian insufficiency (POI) is hypergonadotropic hypogonadism, hypoestrogesnim, oligo- amenorrhoea in women younger than 40 years of age. OBJECTIVE: to make comparison in bone mass density depending of amenorrhoic period in POI. SUBJECTS: I group: 364 women less than 5 years of amenorrhoea , 34.1± 3.2 years of age, BMI 20.9 ± 1.8 kg/m^2. II group: 312 subjects, 43.1 ± 2.9 years of age, 6-10 amenorrhoic years, BMI 22.3 ± 2.1 kg/m^2. III group : 212 women, 53.3 ± 4.1 years of age,11-20 amenorrhoic years, BMI 23.7 ± 2.0 kg/m^2. Blood analysis for FSH, luteinizing hormone (LH), prolactin, estradiol, progesterone, testosteron, DHEAS, andristendion, , vitamin D, TSH were detected in all subjecst at 8 am. Hormone analysis were done by RIA. Bone mass density was measured on lumbar spine and hips (total and neck (by Lunar osteodensitometer). Statistics: Wilcoxon Mann Whitney test. RESULTS: significant difference was found between BMD between I vs. III group (T=-1.1 vs -2.1, p<0.01), and II vs III group (T= -1.2 vs -2.1 p<0.01). FSH and LH decreased during aging. Estradiol was low in all subjects, as well as progesterone. DHEAS significantly dereased by aging (4.1 ± 0.9 vs /2.7 ug/mL P<0.01). Testosteron and androstendion were low normal in all groups. Vitamin D was low in all groups. Low body weight, poor calcium intake, lack of regular exercise in hypoestrogenic women decreased trabecular bone score indicating accelerated loss of microarchitecture integrity. Estradiol therapy in adequate dosages has to be included at the time of diagnosis of POI. It is the first line therapy being the most potent stimulator of recovering homeostatic bone mechanism. All other insufficient hormones have to be added in order to protect bone density.

Key words: premature ovarian insufficiency, osteoporosis, estradiol

ESCEO-ISGE3

MENOPAUSE AND THE BONE: A MATTER FOR GYNECOLOGISTS

S. Lello[1], A. Capozzi[1], G. Scambia[1]

[1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Department of Woman and Child Health and Public Health, Rome, Italy

Since premenopausal period bone loss can occur, due to a decrease of progesterone and, after, of estrogen levels. During menopause and postmenopausal periods, bone loss increases progressively, leading to a skeletal conditions as osteopenia or osteoporosis, with an increased risk of fracture. Gynecologist, in clinical practice, is the specialist that can prevent this progressive bone loss and treat osteopenia/osteoporosis reducing related fracture risk.

It is well known estroprogestins prescription in pre-perimenopause can prevente bone loss and reduce significantly the risk of fracture in the subsequent menopausal period.

During menopausal and postmenopasal periods, menopausal hormone therapy (MHT) with estrogen (+ progestin in women with uterus), tibolone, or tissue selective estrogen complex (TSEC) can efficiently reduce the rate of bone loss. For standard dose of estrogen (e.g., 0.625 mg of conjugated estrogen or equivalent) a reduction of fracture risk has proven, while for lower doses (0.3 mg of conjugated estrogen or equivalent) the ability to prevent bone loss in comparison with placebo was demonstrated. Thus, MHT, even if prescribed for climacteric syndrome, can prevent in a significant manner bone loss and reduce the osteoporosis-related risk of fracture. MHT should be prescribed starting under 60 years of age or 10 years past menopause onset. If a woman do not present with vasomotor symptoms, gynecologist can choose Selective Estrogen Receptor Modulators (SERMs), which do not improve neurovegetative symptoms, but can reduce bone loss and risk of fracture. In particular, today we have two SERMs for which was reported a reduction of fracture risk: Raloxifene (significantly reducing vertebral fracture risk), and Bazedoxifene (significantly reducing vertebral fracture risk and, in a high-risk population, non-vertebral fracture risk). Thus, based on age or reproductive period of a woman, gynecologist can choose a therapy in a personalized manner. Evidently, for women with different conditions or age range, the choice may be on Bisphosphonates (antiresorptive agents), Denosumab (anti-RANKL antibody), or anabolic agents (Teriparatide, Abaloparatide) o dual-agent as Romosozumab (anti-sclerostin antibody).

In this way, the gynecologist has a position from which he can play a central role above all not only in the prevention, but also in the treatment of osteoporosis and related fracture.

ESCEO-EMAS Symposium Abstracts

ESCEO-EMAS1

ASSOCIATION BETWEEN EARLY MENOPAUSE AND FRACTURE RISK

P. Anagnostis[1]

[1]3rd Department of Internal Medicine, "Papageorgiou" General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Estrogen acts both at the osteoclast and osteoblast level, either directly through the estrogen receptor (ER)-alpha or indirectly, through the ER-beta in the cells of the immune system (T- and B-lymphocytes and macrophages). It also acts at the osteocyte level, by increasing the expression of the protein semaphorin 3A and decreasing the production of sclerostin. Therefore, menopause-associated estrogen decline leads to decreased osteoblastic and increased osteoclastic activity, predisposing to impaired bone quality.

Although the average age at menopause is 51±1 years, 10% of women enter menopause before the age of 45, a state termed "early menopause" (EM). A subcategory of EM is "premature ovarian insufficiency" (POI), defined as the menopause occurring earlier that 40 years, the prevalence of which is estimated at 1-3% of the menopausal population. Both women with EM and POI demonstrate a 2-fold increased risk of osteoporosis. Moreover, they may increase the risk of sarcopenia, since EM is associated with decreased muscle mass and POI with decreased muscle strength and performance. EM is also associated with increased risk of frailty, irrespectively of age and other risk factors.

All these data indicate increased propensity to falls and, subsequently, fractures. Indeed, according to a meta-analysis of 18 cohort studies (n=462,393 postmenopausal women), women with EM demonstrate a 1.4-fold fracture risk compared with those of normal age menopause (>45 or >50 years). This risk was not significant in women with POI, potentially indicating the beneficial role of hormone replacement therapy (HRT) in this population. Although, interventional randomized controlled studies (RCTs) conducted specifically in women with EM or POI are lacking, estrogen increases both spinal and femoral bone mineral density (BMD) in a dose-dependent manner and decreases the risk of all types of fractures in all ages, irrespectively of baseline fracture risk.

In conclusion, both EM and POI predispose to increased fracture risk, due to decreased BMD and increased risk of sarcopenia and frailty in later life, independently of age. However, future RCTs are needed to clarify the optimal dose and duration of therapy, as well as the post-HRT intervention strategy.

ESCEO-EMAS2

OVARIAN VOLUME AND BONE MINERAL DENSITY IN POSTMENOPAUSAL WOMEN

E. Armeni[1,2]

[1]Royal Free Hospital NHS Foundation Trust, London, United Kingdom, [2]Second Department of Obstetrics and Gynaecology, National and Kapodistrian University of Athens, Aretaieio Hospital, Athens, Greece

Objective: To investigate the possible link and explore the underlying pathophysiological mechanisms affecting changes in ovarian volume and bone density in postmenopause

Material and Methods: A review of the literature was conducted using publicly available databases such as PubMed. Studies of interest included those reporting data on ovarian volume, bone density, and relevant metabolic parameters (BMI, WHR, SHBG) in both pre- and postmenopausal women, where available. Data on age and menopausal status were also considered.

Results Ovarian volume is reduced after menopause, coinciding with a rise in cardiovascular risk factors, particularly central obesity, which is strongly associated with insulin resistance. While the precise relationship between insulin resistance and ovarian volume in postmenopausal women requires further investigation, studies in reproductively active women with PCOS demonstrate a link between higher insulin levels and increased ovarian blood flow, suggesting a potential trophic effect of insulin on ovarian function. However, the direct impact of insulin resistance and weight status on ovarian volume in postmenopausal women remains unclear. In contrast, the role of insulin resistance in bone health is more established. Available studies indicate that insulin resistance, synergistically with estrogen deficiency, is a major determinant of bone density, highlighting the complex interplay between metabolic status, hormonal changes, and skeletal health in postmenopausal women.

Conclusion. Ovarian volume in postmenopausal women is associated with metabolic parameters, potentially reflecting underlying insulin resistance. These findings suggest a complex interplay between ovarian function, metabolic status, hormonal milieu, and bone health in postmenopausal women, warranting further investigation.

ESCEO-EMAS3

WHAT DO CURRENT GUIDELINES RECOMMEND ABOUT MHT AND OSTEOPOROSIS PREVENTION IN MENOPAUSAL WOMEN?

A. L. Hirschberg[1]

[1]Department of Women's and Children's Health, Karolinska Institutet and Department of Gynecology and Reproductive Medicine, Karolinska University Hospital, Stockholm, Sweden

Postmenopausal osteoporosis is a result of accelerated bone loss after menopause as a consequence of prolonged estrogen deficiency. It is well-established from randomized clinical trials that menopausal hormone therapy (MHT) provides protection from bone loss in postmenopausal women. Different preparations of estrogen (oral, transdermal) with and without progestogens, as well as tibolone and selective receptor modulators are effective. Lower than standard doses of estrogen have also shown improvements in bone mineral density. MHT also provides protection from osteoporosis-related fractures in postmenopausal women not selected on the basis of osteoporosis, as was shown in the Women's Health Initiative (WHI) trial.

Positive effects on balance may contribute to the rapidly reduced risk of fracture after the initiation of MHT. However, after discontinuation of MHT treatment, accelerated bone loss and loss of protection from fracture occur, although no rebound fractures were seen in the WHI trial. Guidelines recommend women with premature ovarian insufficiency and early menopause to take MHT until the age of natural menopause to reduce the risk of osteoporosis and other health risks. Since MHT has not been investigated in women with established osteoporosis, it should not be the first line treat treatment for this group of women. It is still a controversy whether MHT should be used as first line treatment for prevention of osteoporosis in women younger than 60 years with natural menopause and without vasomotor symptoms. Recommendations about MHT and osteoporosis prevention by different guidelines will be discussed.

PREVENTING FRAGILITY FRACTURES IN THE OLDEST OLD: SPECIAL CONSIDERATIONS?

N. van der Velde[1,2]

[1]Consultant Geriatrician Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Director, European Geriatric Medicine Society, Genoa, Italy

Fragility fractures in the oldest old (individuals aged 85 and above) represent a major and growing healthcare burden with significant impacts on functional outcomes and quality of life. Firstly absolute risk is high since age is a key determinant of fracture risk and besides, especially in this age group fractures are associated with high morbidity, mortality, and diminished quality of life. For the oldest old, both those who have experienced fractures and those at high risk, osteoporosis management and fracture prevention pose unique challenges due to factors such as physiological aging, frailty, polypharmacy, and comorbidities. Special considerations are needed to tailor osteoporosis management to the oldest old, as standard clinical approaches may not be directly applicable.

Furthermore, the oldest old are often underrepresented in clinical trials, particularly in randomized controlled trials (RCTs) where older participants are typically healthier than those seen in real-world settings. This makes the translation of trial outcomes to clinical care for this population challenging.

This presentation will address the complexities of fracture risk assessment in the oldest old, with a focus on tools that integrate clinical judgment with evidence-based guidelines. Key considerations will include the role of bone mineral density (BMD) testing and vertebral fracture assessment, alternative diagnostic markers, and the role of clinical risk factors in fracture prediction. Additionally, the evidence of pharmacological interventions in the oldest old will be discussed, considering multimorbidity, polypharmacy, frailty, and limited life expectancy. Non-pharmacological strategies will also be addressed. Ethical and practical aspects of treatment decisions in the oldest old will be highlighted, emphasizing the importance of individualized care that balances fracture prevention with the risks of polypharmacy and potential adverse effects. The goal of this session is to promote a nuanced understanding of osteoporosis and fracture prevention in this vulnerable group and encourage innovative and personalized approaches to optimize care and outcomes for the oldest old.

EUGMS-ESCEO2

PREVENTING FRAGILITY FRACTURES: SIMILARITIES AND DIFFERENCES IN APPROACHES BETWEEN LMICS AND EUROPE

C. Gregson[1,2]

[1]Global Health & Ageing Research Unit | Musculoskeletal Research Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom, [2]The Health Research Unit of Zimbabwe (THRU ZIM), The Biomedical Research and Training Institute, Harare, Zimbabwe

Preventing fragility fractures within a population or country, requires a sequence of steps: systematic fracture risk assessment of individuals with clinical risk factors (CRFs) for fracture, understanding of the level of fracture risk above which evidence supports intervention, initiation of both non-pharmacological and pharmacological treatments, monitoring of treatment adherence, timely identification of fractures should they occur, and intermittent re-evaluation of fracture risk and treatment. This pathway of care requires health workforce education and training, established models of care (e.g., fracture liaison services [FLS]), with regular audit and review. Such care pathways are well established in high-income countries, but only 16% of the world's population lives in a high-income setting.

Countries with a gross national income per capita of <$14,005/year are described as LMICs (n=136); <$1,145 if a low-income country. Currently most FLS are found in high-income countries, e.g., in sub-Saharan Africa only 2 FLS are listed within the Capture the Fracture programme, whereas FLS in South America and Southeast Asia are expanding rapidly. Compared to Europe, approaches will need to vary for multiple reasons, e.g., scale (e.g., China and India now have 280 and 149 million people age 60 years and older), variation in CRFs for fracture (e.g., HIV is more prevalent; malnutrition likely contributes more to fracture risk).

Multiple challenges to fracture prevention currently exist in LMICs. There are currently important evidence gaps; validated fracture risk assessment approaches are needed that consider contextually relevant CRFs and avoid reliance on inaccessible DXA scanning, country-specific intervention thresholds are needed, non-pharmacological management needs to be co-developed and context-specific (e.g., baobab juice and soya chunks are calcium-rich). The lack of osteoporosis medicines on the WHO essential medicines list, is a major barrier to treatment access. In many LMICs health systems have evolved to provide episodic, acute care, for infectious and maternal health – now preventative and long-term care, often of multimorbidity, is needed.

Fortunately, opportunities exist for fracture prevention approaches in LMICs through, e.g., access to generic pharmaceutical agents, integration with well-established HIV programmes, and a culture of monitoring & evaluation within health systems. However, given rapidly increasing longevity, development is needed now, to curtail future fracture burdens.

EUGMS-ESCEO3

INTEGRATING FALL RISK PREVENTION WITHIN FRACTURE MANAGEMENT- PRACTICAL STEPS TO INTEGRATE MANAGEMENT

T. Masud[1,2]

[1]Consultant Physician, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, [2]President-Elect, European Geriatric Medicine Society, Genoa, Italy

Osteoporosis fractures cause much morbidity, mortality and economic cost to health and social care services. In the pathogenesis of low trauma fragility fractures such as at the hip, wrist, humerus and pelvis, there are two important determinants: bone fragility (osteoporosis) and propensity to falls. Both in the prevention of first fragility fractures and in the management of patients who have suffered a fracture, we can intervene, firstly by prescribing osteoporosis medication to strengthen bone, and secondly to assess for and implement measures to reduce the risk of falls (and therefore further fractures).

The World Falls Guidelines (WFG), a collaboration of 96 world experts from 39 countries, provide a framework on how to implement falls prevention in the post-fracture rehabilitation process (Montero-Odasso et al, Age Ageing 2022). The WFG algorithm classifies all injurious falls (including those with fragility fractures) as being at high risk of further falls and advises a multifactorial fall risk assessment followed by a individualised tailored intervention. Important aspects include assessments of gait, balance, medications, environment, nutrition, as well of cardiovascular, musculoskeletal, neurological and cognitive systems. Appropriate interventions may consist of strength and balance exercises, deprescribing, environmental modification, diagnosing and treating relevant medical conditions, and optimising vision and nutrition.

Involvement of ortho-geriatricians working with multidisciplinary teams have made a huge difference in the treatment hip fracture patients to implement the required guidelines. For other fragility fracturs the development of Fracture Liaison Services (FLS) have proven to be the key to identify patients that need appropriate secondary fracture prevention. However, it is important that FLS includes falls assessment and onward referral to appropriate fall prevention pathways to optimise effectiveness.

[1]Department of Movement Sciences and Health, University of West Florida, Florida, United States, [2]Department of Clinical Sciences Lund, Orthopedics, Clinical Epidemiology Unit, Lund University, Lund, Sweden, [3]Department of Medicine, University of Toronto, Toronto, ON, Canada, [4]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, United States, [5]Department of Orthopaedics, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China, [6]Department of Physiology and Pharmacology Schulich School of Medicine and Dentistry, The University of Western Ontario, London, ON, Canada, [7]Department of Medicine, The University of Western Ontario, London, ON, Canada, [8]Western Bone and Joint Institute, London, ON, Canada, [9]Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Oslo, Norway, [10]Department of Clinical Sciences Lund, Orthopedics, Lund University, Lund, Sweden

Objective(s): As an initiative by Osteoarthritis Research Society International (OARSI), our aim is to develop, refine, and validate EsSKOA classification criteria.
Material and Methods: We utilize the American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) framework for criteria development, which incorporates: 1) generation of a list of candidate items that should be considered in development of the criteria; 2) data collection and analysis to examine the ability of the candidate items, individually and in combination, to discriminate people with EsSKOA from other causes of knee symptoms (mimickers) and from individuals with established knee OA; 3) informed by the evidence, a consensus-based decision analysis process to identify factors (and relative weights) that influence the probability that the individual has EsSKOA; and finally, 4) refinement and validation.
Results: We have completed Phase 1 – item generation. We have solicited clinician-, researcher-, and patient perspectives, and used multiple methods to generate a list of candidate items potentially useful in identifying EsSKOA. This included an online survey of OARSI members, a scoping review of the literature, and post-hoc analysis of a qualitative study of people with knee OA, which informed a three-round modified Delphi exercise via online surveys. This work along with a cross-sectional survey of individuals with knee OA, identified candidate items in 7 domains. Additionally, we surveyed a diverse international group of clinicians across various disciplines, including sports medicine, family medicine, physical therapy, orthopedic surgery, and rheumatology, to identify common mimicker conditions in the differential diagnosis of undiagnosed knee symptoms. In Phase 2, redundant items will be consolidated to develop a parsimonious set of items for consideration. Phase 2 will generate the evidence base for Phase 3 criteria development.
Conclusion(s): Despite past three decades of intensive research efforts, we have yet to see regulatory approval of a novel therapy that prevents, slows or halts knee osteoarthritis (OA) progression. Establishing classification criteria to identify individuals with Early-stage Symptomatic Knee OA (EsSKOA) will usher in a new era of clinical trials for promising OA therapies in individuals at a disease stage when disease-modifying interventions may be more likely to succeed.

ESCEO-OARSI2

DIAGNOSTIC CRITERIA FOR EARLY-STAGE KNEE OSTEOARTHRITIS: OPPORTUNITIES AND CHALLENGES

J. Runhaar[1], M. Kloppenburg[2], M. Boers[3], J. W. J. Bijlsma[4], S. M. A. Bierma-Zeinstra[1,5]

[1]Erasmus MC University Medical Center Rotterdam, Department of General Practice, Rotterdam, Netherlands, [2]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands, [3]Amsterdam UMC, 3Department of Epidemiology & Biostatistics, Amsterdam, Netherlands, [4]University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands, [5]Erasmus MC University Medical Center Rotterdam, Department of Orthopedics & Sports Medicine, Rotterdam, Netherlands

Despite the high prevalence of knee OA and its burden to patients and healthcare systems, the diagnosis of knee OA is not straightforward. Criteria used in clinical practice to diagnose knee OA include the ACR-criteria, EULAR criteria, and NICE criteria. Unfortunately, ACR and EULAR criteria seem to identify patients at late stage disease only and NICE criteria showed low specificity for knee OA, which could hamper the acceptance of the diagnosis among clinicians.
With a lack of treatment options that can cure OA, there is general consensus that a shift in focus towards early diagnosis and treatment is warranted. By identifying OA patients early in the disease, treatment can potentially start prior to the occurrence of irreversible joint damage, before pain becomes chronic and triggers sensitization of the central nervous system, and before severe decline in physical functioning has occurred. In theory, in the early phase of OA, treatment options are applied when the disease is more amenable to modification.
To facilitate the diagnosis of early-stage knee OA in clinical practice, CREDO (CRiteria for Early Diagnosis of Osteoarthritis) was developed and validated, using a national cohort of 761 patients aged 45-65 years who presented with knee pain in primary care and were followed for 10 years. The lack of a gold standard for early-stage knee OA posed a major challenge to CREDO. Methods to overcome this challenge and for development and validation of CREDO will be discussed during the symposium. Final set of criteria included patient characteristics (age and BMI), three individual WOMAC questions, and items from physical examination (joint line tenderness and effusion). CREDO showed

acceptable discriminatory ability (AUC 0.75 ± 0.002) and good internal and external validation results. Ongoing activities include transforming the criteria into clinically useful tools, such as a risk calculator and a decision tree, and evaluations of potential treatment options for patients diagnosed with early-stage knee OA, such as exercise therapy. These challenges and opportunities for early-stage knee OA diagnosis will be addressed during the symposium.

FRAGILITY FRACTURES OF THE PELVIC RING – MINIMAL INVASIVE TREATMENT OPTIONS

M. Hanschen[1]

[1]Department of Trauma Surgery University, Hospital Klinikum rechts der Isar, Technische Universität München, Munich, Germany

Fragility fractures of the pelvic ring, primarily affecting elderly individuals with osteoporosis or low bone density, represent a significant clinical challenge due to their associated morbidity, prolonged recovery, and increased risk of mortality. These fractures often result from low-energy trauma, such as falls from standing height. The management of pelvic ring fractures has traditionally involved complex, open surgical interventions, but advances in minimally invasive techniques have revolutionized treatment strategies, offering promising alternatives.

Minimally invasive treatment options for fragility fractures of the pelvic ring aim to reduce surgical trauma, shorten recovery times, and minimize complications. Key approaches include percutaneous fixation using screws, plates, and specialized devices that stabilize the pelvic ring while avoiding large incisions.

While the benefits of minimally invasive approaches are clear, careful patient selection is critical. Factors such as fracture type, bone quality, and overall health status must be considered to optimize outcomes.

SICOT-ESCEO-IOF2

DECISION MAKING IN THE MANAGEMENT OF FRAGILITY FRACTURES OF THE ACETABULUM

U. Mezzadri[1], F. Addevico[1], E. Lunini[1], N. Cosmelli[1], F. Bove[1]

[1]Grande Ospedale Metropolitano Niguarda, Milan, Italy

Objective

The incidence of fragility fractures of the acetabulum is increasing in the elderly population. The optimal treatment is still controversial. The main challenges are the management of frail patients with comorbidities and bad bone quality, which makes it challenging to obtain a good reduction and fixation of the fracture.

Material and methods

We retrospectively analyzed 54 patients over 65 years old treated surgically between 2017 and 2023 in our institution with, at least 1 year of follow up, we excluded polytrauma patients.

We used the Letournel classification to classify the fracture and used the Matta criteria to judge the reduction quality of the fracture.

We evaluated the clinical and radiological outcome in outpatient clinic and used the Harris hip score and Womac scale.

Results

We surgically treated 54 patients (40 male, 14 female), mean age 72yo (65-88).

Most common fracture patterns were Both column (30%), Anterior column (22%) and Anterior column posterior emi transverse (15%).

We mostly used as anterior approach modified Stoppa with and without iliac window (22 cases), we treated percutaneously 4 patients. Only 3 patients were treated with fixation and hip replacement.

Mean follow-up was 2.2 years, quality of reduction was good in 56% o patients, imperfect in 40% and poor in 6%.

Mean Harris Hip Score was 82(good), mean Womac score 22.

Mortality at 1 year 9%, hip prosthesis conversion at 1 year 13%.

We had an overall 20% complication rate (2 superficial infections, 2 deep infections, e femoral head AVN, 2 peritoneal lesions, 2 bleeding from obturator vessels, 1 algodistrofic syndrome).

Conclusion

Our results suggest that fixation of fragility acetabular fractures is a feasible treatment with satisfactory results and reasonable conversion rate to prosthesis. Even if often the quality of the reduction isn't perfect, the elderly, as shown in literature, seems to tolerate better mild arthritis changes of the hip.

SICOT-ESCEO-IOF3

INTERDISCIPLINARY COMPREHENSIVE CARE OF FRAGILITY FRACTURES IN GERMANY

V. A. Koeppen[1]

[1]Department of Orthopaedics and Trauma, Klinikum Freising-Academic teaching hospital in cooperation with MRI and TUM, Freising, Germany

Objective: Germany has unique traits regarding interdisciplinary comprehensive care of fragility fractures.

Material and Methods: Differences between the „German approach" to fragility fractures compared to other European practices were analyzed by literature review and comparison of current national guidelines.

Results: There are remarkable differences when comparing current German standards to our European neighbors, with regard of diagnostics and treatment of osteoporosis, and orthogeriatric comanagement.

Concerning osteoporosis treatment, FRAX and its' derivatives are commonly used in Europe to estimate fracture risk. Thus, national osteoporosis guidelines base their treatment recommendations on the predicted 10-year fracture risk, calculated from 12 risk items. When using the risk calculator from the 2023 German Dachverband Osteologie guideline on osteoporosis (DVO-Leitlinie) 36 risk factors are used to predict fracture risk over a three-year period. Therby the German DVO Leitlinie especially factors imminent fracture risk in. Specific therapeutic recommendations vary across Europe, as the definition of high vs. very high fracture risk differ.

In Germany only a minority of patients with a fragility fracture are enrolled in a fracture liaison service (FLS). The national osteoporosis guideline recommends structured post fracture care, but the number of hospitals that offer FLS is low, and the thoroughness of secondary fracture prevention variegates.

The implementation of structured interdisciplinary care of

proximal femoral fractures has been boosted greatly by the mandatory guidelines of the federal joint committee (G-BA) in place since January 2021. Due to this legislation hospitals treating proximal femoral fractures have been required to ensure that next to specific exigencies regarding surgical treatment, also geriatric and physiotherapeutic comanagement are implemented. Penalties when disregarding this regulation, have led to most trauma departments nowadays having orthogeriatric comanagement.
Already prior to the GBA- regulations, hospitals implementing surgical and geriatric cotreatment for all fragility-fractures, could be certified as geriatric trauma centers (Alters-Trauma-Zentrum). Within the last ten years nearly 200 hospitals have been certified and thereby spurred geriatric traumatology in Germany.
Conclusion: Treatment of fragility fractures in Germany has made great progress by implementing orthogeriatric comanagement and new osteoporosis guidelines emphasizing imminent fracture risk. Nevertheless, treatment reality in Germany and Europe leaves room for improvement. Learning from each other's successes and failures will help to further improve fragility fracture care.

FIFTEEN YEARS OF EXPERIENCE WITH ATYPICAL FEMUR FRACTURES

J. Schilcher[1]

[1]Department of Orthopedic Surgery and Department of Biomedical and Clinical Sciences, Linköping University, Linköping , Sweden

Background: Atypical femur fractures (AFF) were first identified in 2005, demonstrating a strong correlation with bisphosphonate therapy and reduced bone turnover. Despite advancements, AFF continues to present challenges for researchers and clinicians concerning the underlying pathophysiology, diagnostic criteria, optimal surgical interventions, and the influence of bisphosphonate treatment duration on AFF risk relative to the reduction of fragility fractures.
Methods: The epidemiology and radiographic characteristics of AFF were analyzed using radiographic adjudication and Swedish Registers. Histological analyses and sequential radiographs were employed to examine the healing process of AFF following intramedullary (IM) nailing. Register data were utilized to compare the reoperation risk in AFF patients with those having other femoral shaft fractures. Ongoing international collaborations aim to further elucidate the impact of bisphosphonate treatment duration on AFF risk.
Results: Our studies revealed a strong association between bisphosphonate treatment and AFF, which was dependent on the treatment duration. In a small prospective study, no delays in the healing response were observed in patients treated with IM nailing. Register studies indicated an increased rate of reoperations in patients with complete AFF, although these reoperations were due to reasons unrelated to AFF. The use of IM nails with fixation in the femoral head and neck for treating complete AFF significantly reduced reoperations compared to IM nails with standard proximal interlocking screws.
Conclusion: This presentation will cover the currently accepted pathophysiological mechanisms underlying AFF. It will discuss the recommended surgical treatments and identify which interventions may be unnecessary for achieving successful surgical outcomes. The importance of accurate diagnosis and methods to achieve it will also be addressed.
Keywords: Atypical femur fractures, bisphosphonates, epidemiology, radiology, histology, bone matrix, microcracks, orthopaedics
Acknowledgements: To patients, collaborators, authorities and funding agencies making the work possible.
Disclosure: nothing to disclose.

PAGET'S DISEASE OF BONE: MANAGEMENT LESSONS FROM PIVOTAL STUDIES

E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre University of Southampton, Southampton, United Kingdom

Paget's disease of bone is a focal bone disorder characterised by increased bone remodelling and disorganised bone structure. There appears to be a genetic cause in some cases. Recent epidemiological studies highlight a decreasing incidence of the condition, mirrored by an apparent decreasing clinical severity. Pain is the most common presentation, but recent studies have suggested that such pain is commonly due to osteoarthritis at an unaffected site. Bisphosphonates have been shown to be effective in management of the disease, with zoledronate an effective and commonly used therapy. Patients with Paget's disease undergoing joint arthroplasty of an affected joint appear to have a more difficult time medically and surgically in the perioperative period, but implant longevity appears similar. Treatment guidelines have been produced for the condition by international societies and will be briefly reviewed.

EMD has no conflicts of interest to declare

MTE2

INFLUENCES OF PARENTAL HEALTH ON THE NEXT GENERATION BONE

R. J. Moon[1,2], E. M. Curtis[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [2]Paediatric Endocrinology, Southampton Children's Hospital, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

There is increasing evidence that in utero and early life exposures are important to lifelong bone health and fracture risk. Increasing bone mineral accrual during fetal life and childhood might delay the onset of osteoporosis.
In this session, we will outline the accrual of bone mineral throughout the life course and how observational and intervention studies have shown that parental health, lifestyle factors and diet, in particular maternal calcium and 25-hydroxyvitamin D [25(OH)D] status are associated with offspring bone mineral density. We will present findings from the MAVIDOS randomised controlled trial of vitamin D supplementation in pregnancy, which has demonstrated a positive effect of pregnancy vitamin D supplementation on offspring bone health into mid childhood.
Potential mechanisms for the effects of environmental exposures on early life programming of bone health, including epigenetic mechanisms, will also be discussed.

MTE3

FRACTURE RISK IN CANCER SURVIVORS : BONE FRAGILITY BEYOND METASTASES

C. Confavreux[1]

[1]Hospices Civils de Lyon - Université Claude Bernard Lyon 1, Lyon, France

Major advances have been obtained in cancer treatment for the last ten years and a significant number of patients are now cured or benefit from prolonged remissions, even in the metastatic setting. The post-cancer phase is a new stage during which patients have to recover from medical treatments - which can be very demanding - and return to their personal, social, emotional and professional lives. Nevertheless, many of them suffer after-effects, remain tired and have limited physical capacity. These patients need to be offered a multi-dimensional medical assessment to identify areas of fragility and offer personalised care. With regard to bone health, in addition to the usual assessment, rheumatologists will reconstruct the patient's oncological history, the various therapies affecting bone that the patient has received and the outlook for the patient's oncological development (age, prognosis, maintenance treatment, hormonal status, weight change, etc.). A summary of all these elements will enable us to propose optimal bone management. Using practical examples, we will look at different oncological situations and treatments that affect bone and propose therapeutic approaches despite the absence of recommendations.

MTE4

ADVANCES IN THE MANAGEMENT OF OSTEOGENESIS IMPERFECTA

M. L. Brandi[1]

[1]Firmo Foundation, Florence, Italy

Osteogenesis Imperfecta (OI) is a clinically and genetically heterogeneous group of diseases characterized by brittle bones. Though genetic mutations in COL1A1 and COL1A2 account for approximately 85-90% of OI cases, there are now more than twenty genes described, responsible for rare forms of OI
Drugs currently used to improve skeletal health in OI were initially developed to treat osteoporosis and clinical trials are ongoing to study their effectiveness in OI adults. Additionally, novel bone-protective agents are in preclinical studies and various phases of OI clinical trials.
Although clinical trial data are limited, bisphosphonates and teriparatide may be useful in improving bone mineral density. As of yet, no clinical trials are available that adequately evaluate the usefulness of current therapies in reducing fracture risk.
Several therapeutics, including teriparatide, setrusumab, anti-TGF-β antibodies, and allogeneic stem cells, are being studied in clinical trials. Preclinical studies involving Dickkopf-1 antagonists present promising data in non-OI bone disease, and could be useful in OI. Research is ongoing to improve therapeutic options for adults with OI and clinical trials involving gene-editing may be

possible in the coming decade.
Recently, the chemical chaperone 4-phenylbutyrate (4-PBA) has been proposed as an innovative drug for OI based on its ability to restore intracellular homeostasis, stimulate secretion, and ameliorate collagen-producing cell functions, positively affecting bone properties. N-benzylglycine showed a higher stability than 4-PBA and it represents a novel potential available compound to target altered homeostasis in OI with the aim to ameliorate the disease phenotype.
The presentation will focus on these different aspects of diagnosis and treatment.

MTE5

IS THERE A ROLE FOR SYSADOAS IN THE MANAGEMENT OF OSTEOARTHRITIS?

O. Bruyère[1]

[1]Research Unit in Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium

Osteoarthritis (OA) is a highly prevalent chronic condition, particularly in aging populations, and represents a significant burden on healthcare systems and patient quality of life. The management of OA has traditionally focused on symptom relief through pharmacological and non-pharmacological approaches, while disease-modifying strategies remain elusive. Symptomatic Slow-Acting Drugs for Osteoarthritis (SYSADOAs), including compounds such as glucosamine, chondroitin sulfate, and diacerein, have been proposed as a therapeutic option to address the structural and symptomatic components of OA. This presentation evaluates the current evidence on the efficacy and safety of SYSADOAs in OA management. While some studies suggest that SYSADOAs may provide modest symptomatic relief and possibly slow the progression of structural damage, results across clinical trials remain inconsistent, often influenced by study design, product quality, and patient heterogeneity. Recent meta-analyses have highlighted the need for distinguishing between pharmaceutical-grade and over-the-counter products, as well as the importance of adhering to standardized treatment regimens. This session will also address ongoing controversies surrounding the cost-effectiveness of SYSADOAs and their integration into clinical practice guidelines. Emerging data from long-term studies and real-world evidence will be discussed to clarify their potential role in personalized OA management. Ultimately, the presentation aims to provide clinicians with practical insights into the use of SYSADOAs, fostering informed decision-making tailored to individual patient needs.

MTE6

VACCINATION AND MUSCULOSKELETAL DISORDERS

S. Maggi[1]

[1]CNR Institute of Neuroscience, Aging Branch, Padova, Italy

Despite their undeniable benefits, the role of vaccines in patients with musculoskeletal disorders are seldom discussed. Emerging evidence suggests a bidirectional relationship between infectious diseases and musculoskeletal disorders, such as sarcopenia and osteoporosis, wherein infections can exacerbate muscle wasting and bone loss, and sarcopenia can impair immune function, increasing susceptibility to infections. This session explores the complex interplay between these conditions, emphasizing underlying mechanisms, clinical outcomes, and preventative strategies.
Acute infectious diseases, such as COVID-19, influenza, RSV, and pneumococcal pneumonia can accelerate sarcopenia, osteoporosis and fracture risk through systemic inflammation, oxidative stress, and catabolic pathways. Pro-inflammatory cytokines, including TNF-α and IL-6, play a central role in mediating muscle breakdown and bone loss during infections. Moreover, infections can lead to malnutrition, physical inactivity, and hormonal imbalances, further exacerbating musculoskeletal disorders. Conversely, sarcopenia impairs the immune response, reducing the body's ability to combat infections and recover from illness. This creates a vicious cycle that can worsen overall health outcomes. Patients with sarcopenia or osteoporosis are at greater risk of prolonged hospitalizations, frailty, and mortality when infected. Early recognition and targeted interventions, including nutritional support, resistance exercise, and anti-inflammatory treatments, are critical for managing sarcopenia in the context of infectious diseases.
Vaccination against these infectious diseases can indirectly protect musculoskeletal health by reducing the incidence and severity of infections, thereby minimizing inflammation-related muscle and bone loss and mobility restrictions. Despite the benefits, vaccination coverage in vulnerable populations, such as older adults, remains suboptimal. Public health initiatives emphasizing the importance of immunization for overall health, including muscle and bone health, are crucial.

MTE7

OSTEOPOROSIS MANAGEMENT IN TRANSGENDER PATIENTS

J.-M. Kaufman[1]

[1]Department of Endocrinology, Ghent University Hospital, Ghent, Belgium

Individuals with gender dysphoria experience a gender identity that differs from the sex assigned at birth: trans men are assigned female at birth (AFAB) but self-identify as male; trans women are assigned male at birth (AMAB) but identify as female; non-binary trans persons identify as neither exclusively male or female. In addition to social transition, trans persons may seek gender-affirming medical care, i.e. hormonal treatment and/or surgery inducing and maintaining body changes more congruent to the self-identified gender. Gender-affirming hormonal treatment (GAHT) in trans men consists of testosterone treatment; GAHT in trans women consists of a testosterone-lowering drug, nowadays often a GnRH analogue (GnRHa), and estradiol. In non-binary trans people, hormonal treatment is tailored to the individual needs (e.g. partial masculinisation, partial feminisation) using various non-standardized treatment regimens. Hormonal treatment of transgender adolescents consists of suppression of pubertal development with a GnRHa followed, if gender dysphoria persists, by GAHT usually from around age 16y.

Findings on bone health in people with gender dysphoria under GAHT have mostly been reassuring, so that for the majority of trans persons the same guidelines for maintenance of bone health and management of osteoporosis apply as for the general population. General screening of trans persons by DXA is therefore not recommended. Nevertheless, some trans persons are at increased risk of osteoporosis and may need a closer follow-up.

Both in trans men and trans women, bone mass is generally well maintained under GAHT at the commonly used dosages. However, before initiation of any treatment trans women (AMAB) have a lower bone mineral density (BMD), a smaller cortical bone size; a higher prevalence of low BMD and osteoporosis compared to healthy cismen; possibly resulting from a lower level of physical activity. Fracture risk in trans women ≥50y is greater than in cis men and similar as in cis women. Therefore, for trans women the threshold for referral for DXA assessment should be low if additional osteoporosis risk factors or poor compliance for GAHT. BMD assessment is also advisable in case midlife dosage lowering or cessation of estrogen treatment is considered.

There is a lack of data on bone health implications of the diverse individualized hormonal treatment modalities in non-binary trans persons. Monitoring of BMD is advisable for non-binary trans persons on individualized schemes involving low and/or irregular steroid hormone dosing, which may be suboptimal for maintenance of skeletal health.

Adolescent trans girls (AMAB), but not trans boys (AFAB), have a lower pretreatment BMD Z-score compared to the cis-gender reference. GnRHa monotherapy impairs physiologic pubertal BMD increase, resulting in decrease of BMD Z-scores both in trans girls and boys. Upon initiation of GAHT BMD and Z-scores increase with at least partial recovery. In short term assessments recovery of pretreatment values is often incomplete. This is mainly so in trans girls and there is a substantial prevalence of low BMD in young adult trans women. Long-term follow-up of adult trans persons treated since adolescence showed reassuring full BMD recovery in trans men and at the hip measurement sites in trans women, whereas persistent lower BMD values are observed at the lumbar spine measurement site in trans women. The latter may be related to issues of estrogen dosage. Close long-term follow-up of trans women on GAHT since adolescence is thus advisable and additional research in this area is needed.

In addition to the general bone health-promoting measures such as adequate intake of calcium and vitamin D, adequate physical activity, avoidance of alcohol and smoking, strategies to optimize bone health in trans persons include monitoring of adequacy of sex steroid exposure and patient compliance for GAHT. As to the use of DXA for risk assessment, current guidelines for the general population advise to use the NHANES reference for women to calculate T-scores both in women and men, so that there is no specific issue for T-score calculations in trans persons. There are no studies on the treatment of osteoporosis performed specifically in trans persons. Treatment decisions and treatment modalities for trans persons with high fracture risk can be based on the guidelines for osteoporosis in the general population.

MTE8

BIOCHEMICAL MARKERS OF BONE TURNOVER: WHEN AND WHICH?

E. Cavalier[1]

[1]Department of Clinical Chemistry, University of Liege, Liege, Belgium

The dynamic process of bone remodeling is critical in maintaining skeletal health and integrity. Biochemical markers of bone turnover (BTMs) provide a non-invasive window into this process, offering insights that are imperative for the diagnosis and management of osteoporosis and other metabolic bone diseases. This session will explore the two primary categories of BTMs: bone formation markers, such as procollagen type I N-terminal propeptide (PINP), and bone resorption markers, like C-terminal telopeptide of type I collagen (CTX-I). We will discuss their clinical relevance in assessing fracture risk, monitoring therapy effectiveness, and their role in personalized medicine. Special attention will be given to the challenges of assay variability and the need for standardization to enhance the utility of these markers in clinical practice. The session aims to provide a deep dive into when each marker should be ideally utilized and which markers offer the most reliable clinical information for specific scenarios, including the impact of chronic kidney disease (CKD) on BTM interpretation. By the end of this session, participants will gain a thorough understanding of how to effectively integrate BTMs into their clinical toolkit to improve patient outcomes.

MTE9

GIOP: PRESENT AND FUTURE

G. Adami[1]

[1]University of Verona, Verona, Italy

Glucocorticoid-induced osteoporosis (GIOP) remains the most common secondary form of osteoporosis, affecting up to 50% of patients receiving long-term glucocorticoid therapy. Despite its prevalence and well-defined pathophysiology, GIOP is frequently underdiagnosed and undertreated, leaving many patients at risk for fragility fractures. This session will provide a comprehensive overview of current strategies and emerging therapies for the prevention and management of GIOP, with an emphasis on practical considerations for daily clinical practice.

Glucocorticoids exert rapid and profound effects on bone, leading to increased bone resorption, decreased bone formation, and compromised bone quality. Fracture risk rises early, often within the first 3-6 months of glucocorticoid initiation, underscoring the importance of proactive bone health management. International guidelines recommend risk assessment and initiation of bone-protective agents for patients receiving ≥2.5 mg of prednisone (or equivalent) for ≥3 months.

This session will cover practical approaches to fracture risk assessment, including the use of fracture risk assessment tools with glucocorticoid adjustments and trabecular bone score (TBS) to refine risk prediction. Special attention will be given to the selection of pharmacologic interventions, with bisphosphonates (e.g., alendronate, zoledronic acid), denosumab and the role of anabolic agents (teriparatide, abaloparatide and romosozumab) will be explored, particularly for patients at high fracture risk.

Looking to the future, emerging data on combination and sequential therapies, as well as potential new targets such as sclerostin inhibitors and anti-inflammatory bone agents, offer promise for addressing unmet needs in GIOP management. Additionally, the session will address practical aspects of monitoring, including follow-up DXA scans, bone turnover markers, and strategies for de-escalation or transition of therapy after glucocorticoid tapering. Interactive case discussions will provide real-world applications and foster collaborative learning.

MTE10

MAGNESIUM, NUTRITION, AND MUSCULOSKELETAL DISORDERS

N. Veronese[1]

[1]Unicamillus University, Rome, Italy

Magnesium, a vital mineral involved in over 300 enzymatic reactions, plays a pivotal role in maintaining musculoskeletal health. Despite its importance, magnesium deficiency remains an under-recognized issue in clinical practice, often masked by nonspecific symptoms. This presentation will underscore the critical interplay between magnesium, nutrition, and the pathogenesis and management of musculoskeletal disorders, aiming to enhance physicians' awareness and clinical strategies.

Emerging evidence links magnesium deficiency to a spectrum of musculoskeletal disorders, including osteoporosis, sarcopenia, chronic low back pain, and fibromyalgia. Magnesium's contributions to bone health—through regulation of bone mineral density and parathyroid hormone secretion—are well-documented. Additionally, its influence on muscle function, including energy production, protein synthesis, and electrolyte balance, positions it as a key factor in preventing muscle weakness and cramps.

Dietary insufficiency, altered absorption, and increased renal excretion are common causes of magnesium deficiency, compounded by aging, chronic illnesses, and medication use, such as proton pump inhibitors and diuretics. While dietary magnesium intake from sources like nuts, seeds, and green leafy vegetables is paramount, supplementation may be warranted in clinically significant deficiency.

For physicians, integrating magnesium status assessment into the diagnostic workup for musculoskeletal complaints can offer valuable insights. This abstract advocates for a proactive approach to recognizing and addressing magnesium deficiency in clinical settings, emphasizing its potential to mitigate disease progression and improve patient outcomes. Enhanced understanding and application of magnesium's role in musculoskeletal health can significantly influence therapeutic success.

MTE11

AI FOR PATIENT MANAGEMENT: TRANSFORMING HEALTHCARE DELIVERY?

N. Fuggle[1,2]

[1]Associate Professor in Rheumatology, University of Southampton, Southampton, United Kingdom, [2]Honorary Consultant Rheumatologist, University Hospitals Southampton, Southampton, United Kingdom

Artificial Intelligence (AI) is ushering in a paradigm shift across the clinical spectrum, redefining approaches to drug discovery, administrative efficiency, computer vision, and risk stratification. In healthcare, the integration of machine learning algorithms and deep learning models has been particularly impactful, underpinning Clinical Decision Support Systems (CDSSs) and advancing diagnostic precision, such as the enhanced detection of pulmonary nodules on chest Computed Tomography (CT) scans.

In day-to-day clinical practice, AI-driven tools capable of ambiently recording consultations and automating labour-intensive administrative tasks—such as clinical note-taking and correspondence generation—are rapidly gaining adoption. These innovations have the potential to alleviate the administrative burden on clinicians, thereby enabling a greater focus on direct patient care. However, it remains imperative to rigorously evaluate whether these theoretical efficiencies translate into tangible improvements in patient outcomes in real-world settings.

In the field of osteoporosis, among the most developed tools are those leveraging computer vision for opportunistic screening

and diagnosis. In particular, automated measurement of bone mineral density (BMD) and incidental vertebral fractures on routine imaging represents a potential advance in screening and secondary fracture prevention.

This "Meet the Expert" session will provide a comprehensive overview of the latest developments in clinical AI, with a distinct focus on its application to bone health. Emphasis will be placed on tools that directly influence patient management, examining their integration into the clinical workflow and their impact along the patient journey. Attendees will gain a nuanced understanding of the potential benefits and risks of these novel technologies.

MTE12

OSTEOARTHRITIS: A BONE OR A JOINT DISORDER?

R. Chapurlat[1]

[1]INSERM UMR 1033-LYOS, Université Claude Bernard-Lyon 1, Hôpital E Herriot, Lyon, France

Osteoporosis (OP) and osteoarthritis (OA) are two common conditions associated with aging, also more frequent in women. They share some risk factors, including sex, age, inflammation and genetics. Other risk factors seem to have opposite effects in the two conditions, such as BMI, BMD and mechanical loading. Reasoning based on the role of these risk factors, however, may be a superficial approach in some cases because the different phenotypes of OA involve various biological pathways.

Specifically, the changes in subchondral bone during the evolution of OA suggest common pathophysiologic mechanisms. Both OP and OA have a strong genetic polygenic background, but without evidence of common genetic heritability. Local and systemic inflammation are risk factors for both OP and OA. High BMI is a risk factor for OA, but the relationship between BMI and OA differs across joints. Similarly, higher BMI is somewhat protective for hip fracture but increases the risk of humerus and ankle fracture. Lower BMI is a risk factor for hip fracture but may be protective for OA.

The link between bone mineral density (BMD) and OA is controversial, because of the confounding effect of osteophytes and of the interaction between BMI and BMD. Strong relationships have been observed for osteophytes, enthesophytes and high bone mass phenotypes, suggesting subsets of OA patients with increased bone formation. Despite generally higher BMD in OA, the risk of fracture is increased in OA patients, perhaps mediated by a greater propensity to fall and impaired mobility of vertebral bodies.

Women are more commonly affected by OP and OA. Estrogen deficiency has been involved in both increased bone resorption and cartilage degradation. Estrogen replacement tends to protect from both phenomena.

In summary, OP and OA may share common biological mechanisms. The link between BMD, BMI and fracture risk in OA is dependent on the stage, definition and location of OA and the way BMD is measured. Parallel biologic phenomena, however, do not necesseraly imply a unified mechanistic framework.

CSA-OC1

BARRIERS AND SOLUTIONS FOR GLOBAL ACCESS TO OSTEOPOROSIS MANAGEMENT

J. A. Kanis[1]

[1]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom

A key advance in the field of osteoporosis was the development of the conceptual and densitometric definitions of osteoporosis by the World Health Organization, cementing the role of dual-energy x-ray absorptiometry in bone health management. It has provided a platform for drug development, a means of characterising fracture sites as osteoporotic and a standardised methodology to describe its epidemiology worldwide. However, whilst low bone mineral density is a strong risk factor for fracture, many individuals who do fracture have normal or only modestly reduced bone mineral density. Furthermore, the same T-score has a different clinical significance depending on age and geography. The field is therefore moving towards calculation of absolute fracture risk, most frequently using the FRAX® tool, which incorporates bone mineral density as a risk factor rather than an indication for treatment. Uptake of this new direction has been variable internationally, with many parts of the world, particularly low and middle-income countries, still predicating treatment on bone mineral density, despite poor availability of densitometry in many such settings. Whereas the densitometric definition should be maintained, this should not be confused with an intervention threshold. The presence of a fragility fracture apart, reimbursement criterion based on clinical risk factors and not solely dependent upon DXA BMD offers a solution, perhaps best termed "high fracture risk syndrome".

CSA-OC2

APPROACHES TO RISK BASED POPULATION SCREENING: INSIGHTS FROM THE ROSE STUDY AND FREM DEVELOPMENT IN DENMARK

K. H. Rubin[1]

[1]Research Unit OPEN, Department of Clinical Research, University of Southern Denmark, Odense, Denmark

Objective: This presentation aims to provide an update on the latest developments in population screening, focusing on case-finding and automated fracture risk prediction. Drawing from Danish experiences, it highlights the strengths and limitations of the ROSE screening program and the FREM model.

Material and Methods: The presentation outlines different population screening approaches for osteoporosis, including the potential use of machine learning (ML) for automated fracture risk prediction. Two Danish approaches will be discussed *Self-reporting of risk profile*: The ROSE study included approximately 35,000 women aged 65–80 years in a ten-year follow-up of the ROSE randomized screening trial. The trial evaluated the effectiveness of a screening program utilizing FRAX to identify women for DXA, guiding standard osteoporosis treatment. *Automated assessment of risk profile*: The FREM model applies ML to predict one-year risk of major osteoporotic fractures in the Danish population aged ≥45 years. The FREM_ML employs the multiple Additive Regression Tree (DART) boosting algorithm, trained and validated on registry data from 2,472,912 individuals without prior osteoporosis diagnoses or related treatment.

Results: The ROSE program demonstrated positive outcomes for those who completed the full screening process but also revealed that many high-risk individuals did not participate. Consequently, self-administered questionnaires may not be efficient for systematic screening due to low and differential uptake which can negatively impact health equity. The FREM_ML, designed for potential automated implementation in general practice, offers a data-driven method for identifying individuals at high fracture risk. The open-source FREM_ML boosting model, combined with explainable AI, has the potential to serve as an effective decision-support tool for physicians, aiding in referrals for DXA scanning. Data-driven approaches could enhance the screening process, making it more efficient and cost-effective.

Conclusion: Population-based risk screening has advantages and limitations. Automated, data- driven approaches, as shown by FREM_ML could be a way forward. The Danish experience highlights their potential in early screening and prevention. The FREM_ML decision-support system, integrating age- and sex-based DXA thresholds, may aid in early osteoporosis detection and fracture prevention. This underscores the feasibility of incorporating automated models into opportunistic screening programs in general practice, improving accessibility and equity in osteoporosis screening.

THE FACT AND FICTION OF AI IN OSTEOPOROSIS

N. Fuggle[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Artificial Intelligence (AI) has gone from the stuff of science fiction to the forefront of technological, enterprise and media interest, but how does it play out in healthcare? In this talk we will fractionate the robust reality from the substantial hype.

Computer vision has long led the way in clinical AI and osteoporosis is no exception with significant developments in the ability of machine learning to opportunistically identify fractures and bone mineral density from routinely performed medical imaging. Large Language models are swiftly coming up behind and making inroads into the growing administrative burden stifling clinical staff.

All this, and more, will be explored in this CSA session.

TARGETING THE MUSCLE–BRAIN AXIS: THE RECIPROCAL RELATIONSHIP BETWEEN COGNITIVE IMPAIRMENT AND SARCOPENIA- DOES IT REPRESENT A NEW PARADIGM IN SARCOPENIA?

Y. El Miedany[1], N. Gadallah[2], M. Sarhan[3], M. Elgaafary[4], W. Hassan[5], N. El Gharbawy[2], S. Moussa[2], S. Fathi[2], N. Fouda[2], D. El Mikkawy[2], O. Saboony[2], A. Safar[2], W. Elwakil[6], S. Mahran[7], M. Elkaramany[8], N. M. Ahmed[3], M. Y. Mahgoub[5], A. Samir[3]

[1]Canterbury Christ Church University, Meopham, Gravesend, United Kingdom, [2]Ain Shams University, Rheumatology, Physical Medicine and Rehabilitation, Cairo, Egypt, [3]Egyptian Food Bank, Cairo, Egypt, [4]Ain Shams University Community and Public Health, Cairo, Egypt, [5]Benha University, Rheumatology, Physical Medicine and Rehabilitation, Benha, Egypt, [6]Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt, [7]Assiut University, Rheumatology, Physical Medicine and Rehabilitation, Assiut, Egypt, [8]American university Cairo, Cairo, Egypt

Background: Cognitive impairment and sarcopenia are increasingly linked, with research showing that individuals experiencing muscle loss and weakness associated with sarcopenia are also more likely to exhibit cognitive decline, particularly in areas like processing speed and executive function; this connection suggests a potential shared underlying mechanism between muscle health and brain function, although the exact pathways are still being investigated. This work was carried out by the Egyptian Academy of Bone and Muscle health in collaboration with the Food Bank Egypt.

Objective: To evaluate the bidirectional association between sarcopenia and cognitive impairment in a community based assessment.

Methods: This was a cross-sectional study carried out to assess sarcopenia and cognitive function amongst adults (over 50-years old) and older adults (176-subjects, 115 females and 61 males) living at care homes in Egypt. Assessment for risk of sarcopenia in cognitive impaired patients was carried out using SARC-F questionnaire. To quantitatively assess for sarcopenia, every subject was evaluated for: 1. Muscle strength: this included: measurement of the Handgrip strength; 2. Dynamic strength tests: including chair stands or timed up-and-go tests as well as, 3. Muscle function: Gait speed: Measures walking speed over a 4-meter distance. Cognitive impairment assessment was carried out using the Mini-Mental State Examination (MMSE) tool. Falls risk assessment was assessed by using the Falls Risk Assessment Scale (FRAS). Statistical analysis was carried out to analyse the relationship between sarcopenia and cognitive impairment.

Results: There was significant association ($p< 0.01$) between sarcopenia measures and cognitive decline. 66% of the patients with cognitive impairment had high SARC-F score. Assessment of muscle strength in subjects with cognitive impairment revealed that the prevalence of weak hand grip was 86%, whereas assessment of dynamic strength tests revealed chair stand test was impaired in 81.4% and time-up-and-go was impaired in 53.5%. Similar significant association ($p< 0.01$) was reported on assessment of outcome of muscle function which revealed impaired gait speed in 95.3% in subjects with cognitive impairment. Patients with cognitive impairment were at high risk of falls with mean Falls risk score of 4.84 ± 0.6 ($P<0.5$) in comparison to subjects without cognitive impairment.

Conclusion: Sarcopenia is significantly associated with an increased risk of cognitive impairment. This raises the possible role for muscle-derived mediators (myokines) in mediating muscle–brain crosstalk and highlights the importance of promoting muscle health through exercise and nutrition as a potential strategy for preventing cognitive decline in older adults.

[1]FEMECOT (Mexican Federation of Orthopedics and Trauma Colleges), GUADALAJARA, Mexico, [2]AMMOM (Mexican Association of Bone and Mineral Metabolism), GUADALAJARA, Mexico, [3]SEFRAOS (Spanish Society of Osteoporotic Fractures), Vitoria-Gasteiz, Spain, [4]Spanish Society of Orthopedic Surgery and Traumatology (SECOT), Madrid, Spain, [5]Colombian Society of Osteoporosis and Mineral Metabolism (ACOMM), Bogota, Colombia, [6]Colombian Society of Orthopedic Surgery and Trauma (SCCOT), Bogota, Colombia, [7]Spanish Society of Bone Research and Mineral Metabolism. (SEIOMM), Madrid, Spain

Background

The prevalence of arthroplasty is increasing. Nearly two thirds of patients undergoing elective arthroplasty procedures have low bone mineral density (LBMD), among those, only 32.8% were receiving treatment at the time of surgery. (1)

In recent years, evidence that defines osteoporosis as a risk factor for arthroplasty complications has emerged. However, it has not affected the perioperative osteoporosis treatment rate. (2) Bone quality is underestimated and undertreated prior to elective arthroplasty.(3)

Materials and methods

A group of 7 national societies (FEMECOT, AMMOM, ACOMM, SCCOT, SECOT, SEFRAOS, SEIOMM.) developed a joint statement position on the diagnosis of osteoporosis and perioperative bone optimization in candidates for arthroplasty. "Arthroplasty Bone Optimization"

A scoping review of the available literature was performed, followed by a systematic review and meta-analysis. Subsequently, a Delphi Modified method was used to gather the different positions.

Results and recommendations

Recommendation 1: Patients scheduled for elective arthroplasty

should undergo a bone health assessment (BHA).
Experts' concordance: 100%
This assessment should evaluate risk factors and clinical signs of osteoporosis and low bone quality. Additionally, a bone mineral density (BMD) DXA scan should be performed for those with one or more risk factors for osteoporosis, meeting ISCD or regional indications for DXA testing.
Recommendation 2: If poor bone quality is observed during surgery and a bone health assessment has not been conducted promptly, a complete BHA, including a DXA scan, is imperative.
Experts' concordance:71.4%
Recommendation 3: In the arthroplasty candidate, If LBMD or osteoporosis are noticed, bone loss related factors should be corrected, and appropriate treatment for osteoporosis should be started before or right after arthroplasty.
Experts' concordance: 90.5%
The use of Anti-resorptive and bone anabolic agents have been shown to reduce periprosthetic bone loss, complications and non-septic revision rates after joint arthroplasty
Recommendation 4: In arthroplasty candidates, the diagnosis of osteoporosis or low bone mineral density (LBMD) should not delay the surgery.
Position 5: Monitoring axial and periprosthetic bone mineral density through DXA protocols can help identify bone loss in central and periprosthetic areas in patients with risk factors or osteoporosis.
Experts' concordance: 83.3%
Conclusions
Perioperative bone optimization is an approach that should be considered in all patients who are candidates for arthroplasty. We encourage the orthopedic surgeon and multidisciplinary team to diagnose and treat the arthroplasty candidate's bone by screening for bone-loss-related factors, diagnosing osteoporosis, and starting treatment. Following these recommendations could lower PPBL, complications, and aseptic revision rates after arthroplasty.

ACCURACY OF ARTIFICIAL INTELLIGENCE FOR VERTEBRAL FRACTURE ASSESSMENT BY DXA SCAN

P. Sinlapavilawan[1], K. Homsapaya[2], O.-A. Phruetthiphat[3]

[1]Bangkok Hospital Muangraj, Ratchaburi, Thailand, [2]Kasetsart University, Sriracha, Thailand, [3]Phramongkutklao Hospital, Bangkok, Thailand

Background: Established osteoporosis patients with hip fractures often remain underdiagnosed for osteoporotic vertebral compression fractures (OVCFs). Our hospital's standard of care for assessing hip fracture patients and coexisting OVCFs involves bone mineral density evaluation using dual-energy X-ray absorptiometry (DXA) scans and Vertebral Fracture Assessment (VFA) tools. YOLOv8 (You Only Look Once version 8), a powerful and efficient object detection model, has the potential to detect occult vertebral collapses, graded by the Genant classification, aiding in the early identification of OVCFs.
Purpose: To design and validate a multi-stage deep learning system for the automated detection, localization, and classification of OVCFs from DXA scans and VFA tools in established osteoporotic patients.
Materials and Methods: Data from 548 hip fracture patients who presented to our hospital from January 2018 to September 2024 were collected. DXA scan and VFA images of 344 patients were retrospectively evaluated. Spine specialists marked and classified fractures according to the Genant classification (0, 1, 2, 3), considering the upper and lower endplates and the posterior wall. Radiological diagnosis confirmed these classifications. YOLOv8 was employed for vertebral fracture detection. VFA results were categorized into two precision groups: bounding box-based (B) and mask-based (M). Model performance was evaluated using recall, F1-score, mean average precision (mAP50), and mean average precision across IoU (Intersection over Union) values from 50% to 90% (mAP50-95).
Results: The mean age of the 548 patients (262 female, 286 male) was 79.82 years (SD 8.62 years). Among them, 138 had intertrochanteric fractures, 203 had femoral neck fractures, and 5 had multiple fractures. The DXA scan and VFA images of 344 patients were recruited (138 with intertrochanteric fractures and 203 with femoral neck fractures). Bounding Box-Based Metrics (B) composed of Precision: 0.6635 (66.35% of predictions were correct), Recall: 0.8803 (88.03% of fractures were detected), F1-Score: 0.7567 (average of Precision and Recall), mAP50: 0.9609 (excellent performance in detecting positions at an IoU of 50%), and mAP50-95: 0.6881 (lower accuracy at higher IoU thresholds). Additionally, Mask-Based Metrics (M) composed of Precision: 0.5827 (lower precision compared to bounding box-based metrics), Recall: 0.8399 (83.99% of collapsed areas were detected), F1-Score: 0.6880, mAP50: 0.8937 (good performance), and mAP50-95: 0.5245 (lower accuracy at higher IoU thresholds). The final image shows an overlap of 90% between G1 and 81% between G2.
Conclusion: The artificial intelligence model can accurately and

automatically detect and classify OVCFs in established osteoporotic patients using DXA scans and VFA tools, according to the Genant classification. While the bounding box-based metrics outperformed the mask-based metrics, both demonstrated strong potential for clinical applications.

GLP-1 RECEPTOR AGONISTS AND RISK OF BONE FRACTURES IN ELDERLY PEOPLE WITH TYPE 2 DIABETES

M. Kasher Meron[1,2], T. Hornik-Lurie[3], G. Twig[4,5,6], P. Rotman-Pikielny[1,2]

[1]Department of Endocrinology, Meir Medical Center, Kfar-Saba, Israel, [2]School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel, [3]Research Department, Meir Medical Center, Kfar Saba, Israel, [4]Division of Endocrinology, Diabetes and Metabolism, Sheba Medical Center, Ramat Gan, Israel, [5]Department of Preventive Medicine, School of Public Health, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv , Israel, [6]The Gertner Institute for Epidemiology and Health Policy Research, Sheba Medical Center, Ramat Gan, Israel

Objective: To assess the risk of fractures associated with glucagon-like peptide 1 receptor agonists (GLP-1 RA) therapy compared to sodium-glucose cotransporter-2 inhibitors (SGLT-2i) or dipeptidyl peptidase-4 inhibitors (DPP-4i) therapy in elderly people with type 2 diabetes.
Methods: This nationwide, population-based, cohort study included individuals with type 2 diabetes, ≥ 65 years, who initiated GLP-1 RA therapy or one of the comparators during January 2018–October 2022. The primary outcome was the first incident of vertebral, hip, pelvic, humerus, forearm or rib fracture. Anthropometric and clinical characteristics of patients, including osteoporosis and risk factors for fractures, were extracted from the electronic database. People were followed until fracture, death, or March 2024. After adjusting for propensity score, hazard ratios (HRs) with 95% confidence interval (CI) were estimated using stepwise Cox models, and the Fine-Gray model for competing risks. Subgroup analyses by age, sex, ethnicity, BMI, and osteoporosis were performed.
Results: Among 45,222 people, 73.0±6.4 years, 50% female, 66.5% were 65-75 years and 31.3% ≥75 years. During a median follow up of 35.3 (interquartile range 24.7-48.0) months, 3,618 (8.0%) had an incident fracture. Among 11,061 new users of GLP-1 RA and 34,161 of the comparator drugs, the overall incidence of fractures was comparable between groups ((2.82 (95%CI 2.63-3.02) vs. 2.75 (95%CI 2.65-2.85)), p=0.53, respectively, per 100 person years. In multivariate analysis for osteoporotic fractures (adjusted for multiple risk factors), initiating GLP-1 RA was associated with a 12% increased risk for bone fractures compared to the control group (HR 1.12, 95%CI 1.03-1.23, p=0.006). Repeating the analysis for competing risks, along with conducting various subgroup and sensitivity analyses, yielded results consistent with those of the main analysis.
Conclusions: Initiation of GLP-1 RA therapy was associated with an increased risk of incident fractures compared to SGLT-2i and DPP-4i, among elderly individuals with type 2 diabetes.

SARCOPENIA AND ELECTROCARDIOGRAPHIC MARKERS OF ARRHYTHMIA RISK IN OLDER ADULTS

O. Erdogan[1], T. Erdogan[2], Z. Fetullahoglu[2], D. Erbas Sacar[3], D. Seyithanoglu[2], O. Kumet[4], S. Ozkok[2], M. A. Karan[2], G. Bahat[2]

[1]Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery, Training, and Research Hospital, Istanbul, Turkiye, [2]Istanbul University Faculty of Medicine, Department of Geriatric Medicine/Istanbul Musculoskeletal Health Consortium, Istanbul, Turkiye, [3]Kartal Dr. Lutfi Kirdar City Hospital, Istanbul, Turkiye, [4]University of Health Sciences Turkey, Van Training and Research Hospital, Van, Turkiye

Background: Cardiac arrhythmias are prevalent among older adults and significantly increase morbidity and mortality. Sarcopenia, a progressive skeletal muscle disorder, is associated with systemic inflammation, oxidative stress, and structural remodeling, potentially affecting cardiac function. This study investigates the relationship between sarcopenia and electrocardiographic (ECG) parameters indicative of arrhythmia risk.
Methods: A cross-sectional retrospective study was conducted with 283 community-dwelling older adults (≥60 years) who underwent comprehensive geriatric assessments. Sarcopenia was diagnosed based on the EWGSOP2 criteria, incorporating handgrip strength (35 kg for male and 20 kg for female) and skeletal muscle mass index (SMMI) (SMM/BMI). ECG parameters, including QTc interval, P-wave dispersion, Tp-Tend interval, and fragmented QRS, were measured. Multivariate logistic regression was performed to analyze the association between sarcopenia and ECG abnormalities.
Results: Sarcopenia was identified in 35.7% of participants, who were older (mean age 75.9 ± 6.3 years, $p < 0.001$) compared to non-sarcopenic individuals. Fragmented QRS (17.0% vs. 8.2%, $p = 0.032$) and atrial fibrillation (6.9% vs. 1.6%, $p = 0.038$) were significantly more prevalent in sarcopenic patients. P-wave dispersion, which reflects atrial electrical heterogeneity and remodeling, a known predictor of atrial fibrillation, was higher in the sarcopenia group (51.95 ± 16.94 ms vs. 46.79 ± 16.66 ms, $p = 0.042$). Fragmented QRS, an indicator of heterogeneous ventricular depolarization often associated with myocardial fibrosis or scarring, was independently associated with sarcopenia (OR: 2.415, 95% CI: 1.051–5.547, $p = 0.038$) in multivariate analysis.
Conclusion: Sarcopenia is associated with significant alterations in ECG parameters indicative of arrhythmia risk, including fragmented QRS and P-wave dispersion. These findings suggest that sarcopenia may contribute to electrical remodeling and arrhythmogenesis. Further prospective studies are warranted to explore the causal pathways linking sarcopenia and arrhythmias.

AN ARTIFICIAL INTELLIGENCE ALGORITHM TO IMPROVE DIAGNOSIS OF VERTEBRAL FRACTURES EMBEDDED IN FRACTURE LIAISON SERVICES CAN REDUCE FRACTURES AND REDUCE COSTS

R. Pinedo-Villanueva[1], G. Fabiano[1], F. Clemeno[1], M. K. Javaid[1]

[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Objective

To estimate the patient benefit and economic impact of integrating an artificial intelligence (AI)-enabled vertebral fracture (VF) identification algorithm into optimally-run FLSs.

Material and Methods

The Nanox-AI HealthVCF algorithm was implemented into the radiology workstream of three UK NHS hospitals. The AI analysed existing CT scans and flagged those with potential moderate/severe fractures for local clinical confirmation. Patients with confirmed scans were referred to the local FLS for further assessment and management. Using a microsimulation model[1], the impact of the AI on patient outcomes and health and social care costs was estimated for 1,000 male and 1,000 female patients with confirmed VF over five years. We used observed FLS performance metrics before and after AI implementation from the FLS-Database of England and Wales and expert opinion from FLS leads to populate the model comparing results under pre-AI observed FLS to AI optimised-FLS settings.

Results

Subsequent hip, spine or other major osteoporotic fractures were 6.8% and 4.4% lower under the AI + optimised FLS setting for female and male simulated patients, leading to 44 and 59 quality-adjusted life years gained, respectively. Less subsequent fractures led to lower health and social care resource use: AI + optimised FLS would save 378 bed days per 1,000 female patients and 206 per 1,000 male patients, with reduced need for long-term institutional care after a fracture by 17 and 12 fewer years of long-term institutional care, respectively. FLS costs including medication would be higher under the AI + optimised FLS but these would be offset, partially for males and entirely for females, by savings in health and social care leading to extra costs of £62 per male patient and savings of £117 per female patient over the five years. The difference was driven by higher risk of hip after VF for women compared to men.

Conclusion

While VF are common and put patients at high imminent fracture risk, FLSs have struggled to identify this subgroup. Despite differences in age and higher mortality, adding AI to flag potential vertebral fractures can lead to substantial reductions in subsequent fractures and in health and social care costs. These findings support the widespread integration of AI into FLSs as both clinically and cost-effective.

HIGH-DOSE VITAMIN D THERAPY (300,000 IU MONTHLY): IMPLICATIONS FOR OSTEOARTHRITIS, OSTEOPOROSIS AND ARTERIAL STIFFNESS IN VITAMIN-D DEFICIENT PATIENTS

S. Sokolovic[1], I. Sokolovic-Tahtovic[2]

[1]ASA Hospital Sarajevo, Sarajevo, Bosnia & Herzegovina, [2]KCUS, Sarajevo, Bosnia & Herzegovina

Introduction:

Vitamin D deficiency is associated with skeletal disorders such as osteoarthritis (OA) and osteoporosis (OP), as well as non-skeletal conditions like arterial stiffness, a marker of cardiovascular health. The use of high-dose vitamin D therapy (300,000 IU monthly) has gained interest as an efficient means to correct deficiency and improve related health outcomes. In Osteoarthritis, high-dose regiemens may enhance anti-inflammatory effects. in Osteoporosis, clinical studies have shown improvements in lumbar spine and femoral neck BMD following high-dose vitamin D supplementation in deficient individuals. Vitamnin D may reduce arterial stiffness by modulating endothelial function, reducing vascular calcifications, improvement in pulse wave valve velocity and vascular compliance.

Material and Method:

The open prospective clinical study of 124 female patients suffering from Osteoarthrits and Osteoporosis, divided in a two groups by 62 each. The inclusion criteria was Vitamin D deficiency. Arterial stiffness was measured using Agedio device providing parameters from pulse wave velocity, central blood pressure, augmentation index, stroke volume etc. All. cardiovasular risk factors were included in a study and analysed accordingly. High-Dose Vitamin D Therapy (300,000 IU monthly) was applied intramuscularly and Vitamin D levels were measured one month later. Arterial stiffness was measured in all after one month accordinigly.

Results: The average age for Osteoarthritis group was 68,5 years and for Osteoporosis patients 66 years. The vascular age expressed as the value of arterial stiffness in Osteoarthritis group was app 5 years older than biological age. In Osteoporosis group this values wass 3 years difference. Vitamin D level in average was 16,7 ng/ml. After one month, following high dose Vitamin D application, the vitamin D level significantly increased to 24,5 ng/ml. Arterial stiffness was improved to 4 years in group I and to 3 years in group II respectively.

Conclusion: The high dose of vitamin D (300,000 monthly) is highly effective in a rapidly restoring adequate levels of 25-hydroxyvi-

tamin D, particularly in individuals with severe deficiency. This regime has shown efficiency in achieving appropriate serum levels within one month. This improvement had a postive effectiveness on arterial stiffness in osteoarthritis and osteoporosis patients.

DESTRESSING MINDS. STRENGTHENING MUSCLES. YOGA AND ITS EFFECT ON MUSCLE STRENGTH IN HEALTHY INDIVIDUALS. A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

P. Bajaj[1], L. Nagendra[2], M. Samuel[3], M. Chandran[4]

[1]1.National University Health System and Ministry of Health Holdings, Singapore, Singapore, Singapore, [2]2.JSS Medical College, JSS Academy of Higher education and Research, Mysore, India, Mysore, India, [3]3.Systematic Review Unit, NUS Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, [4]Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore General Hospital. DUKE NUS Medical School, Singapore, Singapore

Background: Muscle strength is crucially associated with BMD and falls risk. Yoga, an ancient practice that in general combines poses (asanas) and breathing exercises (pranayama), involves seated, standing, as well as supine postures that target most major muscle groups. Though its effects on balance, BMD and falls risk have been evaluated recently(1), studies exploring yoga's effects on muscle strength have not been systematically reviewed before. We evaluated randomized controlled trials (RCTs) comparing yoga's effects on hand grip strength (HGS) and lower limb strength (LLS) against no intervention controls (NIC) and active interventions (AC) such as Pilates, core stabilization exercises, and Taichi in healthy individuals.

Methods: We systematically searched scientific databases following a predefined protocol. Heterogenous data were qualitatively summarized. We conducted a meta-analysis of studies comparing yoga to NIC and AC, using standardized mean differences (SMDs) to pool outcomes.

Results: Twenty-five RCTs involving 1817 participants aged 6–90 years were analyzed. Yoga styles included Hatha, Ashtanga, Iyengar, Bikram etc. Yoga significantly improved HGS compared to NIC [SMD 0.50 (95% CI: 0.04–0.97); P=0.03; I²=77%]. A single study that compared yoga to AC reported positive HGS effects, with no between-group differences. Yoga also significantly enhanced LLS compared to NIC [SMD 1.51 (95% CI: 0.86–2.15); P<0.00001; I²=84%] and AC [SMD 0.44 (95% CI: 0.14–0.74); P=0.004; I²=8%]. Intervention lengths, and assessment methods showed significant heterogeneity.

Conclusion: Yoga significantly enhances HGS and LLS in healthy individuals compared to controls, with modest improvement in LLS and comparable benefits in HGS to AC. Future research should standardize protocols to better explore optimal yoga practices for muscle strengthening and their mechanisms.

HIGH-THROUGHPUT SEQUENCING OF BONE METABOLISM GENES AND THEIR ASSOCIATION WITH OSTEOPOROSIS RISK

M. Marozik[1], A. Rudenka[2], V. Samokhovec[3], K. Kobets[1], E. Rudenka[2]

[1]Institute of Genetics and Cytology of the National Academy of Sciences of Belarus, Minsk, Belarus, [2]Belarusian State Medical University, Minsk, Belarus, [3]1st Minsk City Clinical Hospital, Minsk, Belarus

Objective: The study aims to investigate the association of genetic variants in bone metabolism-related genes with the risk of osteoporosis using high-throughput sequencing technology. By identifying key genetic contributors, the research seeks to enhance early diagnostic strategies and personalize preventive measures for individuals at high risk.

Material and Methods: The study cohort consisted of 456 individuals (recruited at 1st Minsk City Hospital, Belarus), including 251 with osteoporosis and 205 age- and sex-matched controls. DNA was extracted from peripheral blood, followed by targeted sequencing of 68 genes implicated in bone metabolism using the Illumina platform, generating an average coverage depth of 100×. Functional annotations of significant variants were obtained using ANNOVAR and *in silico* tools such as SIFT and PolyPhen-2.

Results: A total of 1,238 single nucleotide variants (SNVs) and small insertions/deletions were identified across the targeted genes. Statistical analysis revealed significant associations between osteoporosis risk and several genetic variants. In the *COL1A1* gene, the rs1800012 T allele was associated with a 1.8-fold increased risk (p = 0.002). The *VDR* rs731236 variant correlated with reduced BMD (p = 0.005). The rs9533156 G allele in

the *RANKL* gene was linked to elevated susceptibility (p = 0.01), while the *OPG* rs2073617 T allele exhibited a protective effect (p = 0.004). Additionally, the rs4754 A allele in the *SPP1* gene was associated with decreased BMD (p = 0.003), the rs2234693 C allele in the *ESR1* gene was linked to increased osteoporosis risk (p = 0.007), and the rs59983488 T allele in the *RUNX2* gene was associated with impaired bone formation (p = 0.002). Pathway enrichment analysis highlighted disruptions in Wnt/β-catenin signaling and osteoclast differentiation as key contributors to osteoporosis pathogenesis. Variants with predicted deleterious effects exhibited strong functional relevance in regulatory regions of the affected genes.

Conclusion: This study underscores the critical role of genetic variants in bone metabolism-related genes in modulating osteoporosis risk. These findings provide a foundation for the development of genetic screening tools and targeted interventions aimed at reducing osteoporosis-related morbidity and mortality.

OCs10 - P1056

SARCOPENIA AND BONE HEALTH PARAMETERS IN POSTMENOPAUSAL WOMEN WITH DIFFERENT TYPES OF OSTEOPOROTIC FRACTURES

N. Grygorieva[1], A. Musiienko[1], D. Kurylo[1], A. Iniushina[1]

[1]D. F. Chebotarev Institute of Gerontology National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

The research **aim** was to study sarcopenia and bone health parameters depending on the presence of various osteoporotic fractures in postmenopausal women.

Materials and Methods.

In the single-centre study, we examined 139 females aged 51-87 years (mean age 69.2±7.8 years), divided into three groups: 1 - healthy subjects without any previous fractures (n=50), 2 - patients with previous forearm fractures (FFs, n=39) and women with previous vertebral fractures (VFs, n=50).

Anthropometric measurements, including height, weight, and body mass index, were obtained using standard clinical methods. Muscle strength was evaluated using hand dynamometry and the "sit-to-stand" test. Muscle mass (appendicular muscle mass (ALM) and appendicular muscle mass index) was determined using dual-energy X-ray absorptiometry (DXA, Hologic). The diagnosis of sarcopenia was confirmed using EWGSOP2 criteria. Also, by DXA, we measured bone mineral density (BMD) in the lumbar spine (LS), femoral neck (FN), total hip (TH) and radius as well as trabecular bone score (TBS).

Results.

The examined did not differ in age, main anthropometric parameters (height, weight and body mass index) and menopausal status (menopause age and duration of postmenopausal period). However, the increased risk of confirmed sarcopenia was revealed in the patients with VFs (OR=2.71, 95% CI: 1.02-7.20; p = 0.045) but not in subjects with FFs (OR=0.60, 95% CI: 0.18-1.95; p=0.40). FN and TH BMD were significantly lower in patients with various osteoporotic fractures (FN BMD - group 1: 0.70±0.14; group 2: 0.63±0.10; group 3: 0.61±0.09 g/cm^2, respectively, F=9.96; p=0,00009) whereas LS BMD and TBS were reliable lower only in subjects with VFs (LS BMD - group 1: 0.89±0.19; group 2: 0.83±0.16; group 3: 0.80±0.14 g/cm^2, respectively. TBS - group 1: 1.23±0.10; group 2: 1.21±0.08; group 3: 1.17±0.10 un., respectively). We did find significant differences in radius BMD and ALM parameters depending on the presence and types of osteoporotic fractures. Also, we did not reveal reliable differences in muscle strength parameters between patients from the study groups.

Conclusion.

Patients with VFs have lower bone strength and quality, as well as an increased risk of sarcopenia compared to subjects without previous fractures, which should be counted in their management.

APPROACH OF PHYSIATRISTS TO LOW BACK PAIN IN EUROPE, RESULTS OF A RESEARCH AND WHO GUIDELINE

F. Dincer[1,2,3,4]

[1]Professor of Physical and Rehabilitation Medicine, Ankara, Turkiye, [2]President Turkish Society of Rehabilitation Medicine, Ankara, Turkiye, [3]ESCEO Scientific Advisory Board Member, Ankara, Turkiye, [4]ESPRM Chair Musculoskeletal Disorders Com., Ankara, Turkiye

Background: Low back pain (LBP) is the most common type of musculoskeletal pain, thus it is one of the most commonly encountered conditions in Physical and Rehabilitation Medicine. According to WHO guideline; Chronic primary low back pain (CPLBP) is defined as; a persistent or recurrent pain experience of more than three months that is not reliably attributed to an underlying disease process or structural lesion. (2)
The physicians who are primarily responsible for the nonsurgical management of LBP are physiatrists.
Objective: Our present study aimed to investigate the approaches of physiatrists to low back pain across Europe. Preferences, tendencies, and priorities in the diagnosis, management, and treatment of LBP, as well as the epidemiological data pertaining to LBP in PRM practice were evaluated in this Europe-wide study. (1)
Methods: A cross-sectional descriptive survey study was undertaken to define the clinical approach of physiatrists for low back pain. An internet based-survey was prepared and distributed to physiatrists of the European countries by email. The responses were collected in an online survey site (SurveyMonkey®). A total of 576 physiatrists from most European countries participated in the survey.(1)
Results: The results show that physiatrists frequently deal with patients with LBP in their daily practice. Most patients are not referred to other departments and are treated with various conservative methods. Less than one-fifth of patients are primarily referred for surgery. The physiatrists believe that a clear diagnosis to account for cases of low back pain is rarely established. The most common diagnosis is discopathy. History and physical examination remain the most valuable clinical evaluation tools for low back pain according to physiatrists. Less than half the patients require a magnetic resonance imaging. Non-steroidal anti-inflammatory drugs are the most commonly prescribed drugs for low back pain. Exercise, back care information, and physical therapy are the preferred conservative treatments. More than half of the physiatrists offer interventional treatments to patients with low back pain.
Conclusion: Our present study is a preliminary report that presents the attitudes of European physiatrists in the management of low back pain. Further researches are warranted to standardize the conservative management of LBP.(1)
The WHO guideline addresses the following overarching question: "What are the health and well-being benefits and harms of non-surgical interventions in the management of chronic primary low back pain, with or without spine-related leg pain, in community-dwelling adults in primary or community care settings, including older people (60 years and older), compared with placebo, no intervention or usual care?"(2) In this presentation,the details of our research and the recommendations of WHO guideline for non-surgical management of chronic primary low back pain in adults in primary and community care settings will be presented and discussed in details.

UPDATE IN DIAGNOSIS AND MANAGEMENT OF LOW BACK PAIN

A. Winkelmann[1]

[1]Physical and Rehabilitation Medicine, Department of Orthopaedics and Trauma Surgery, Musculoskeletal University Center Munich (MUM),University Hospital, LMU (Ludwig-Maximilians-University), Munich, Germany

Background LOW BACK PAIN (LBP) is the leading musculoskeletal contributor of disability worldwide, with increasing prevalence and inflicts a significant burden on the individuals affected, and limits mobility and activities, leading to early retirement from work and to reduced quality of life (1-3).

Aim

This update provides an evidence based overview of the important strategies in diagnosis and management of individuals with low back pain (LBP). With a good management of LBP the aim is to reduce borders for activities and participation in daily life caused by LBP and to improve the quality of life.

Methods

Reviews, meta-analysis, guidelines with the keywords low back pain, diagnosis, therapy, non-pharmacological and non-surgical approaches or management, rehabilitation were reviewed by PubMed-listed publications until January 10th 2025.

Results

In every stage of diagnosis and management of LBP it is important to plan and deliver a holistic and person-centered care (information and shared decision, support to understand the nature of LBP, managing expectations regarding pain and recovery, showing individual ways how to perform regular valued activities, with respect to the person´s needs, contexts, preferences, capacities and comorbidities), based on a biopsychosocial approach. (4)
For Diagnosis of LBP recommendations focus on standardized comprehensive clinical evaluations combining patient medical history including psychosocial factors, and physical examination,

but selective imaging only when red flags are present (e.g., suspected malignancy, fractures). In a first diagnosis stage it is important to look at red flags and rule out serious pathologies or identify specific causes of LBP. In 85–95% of cases, its specific etiology is not clear, and therefore, it is known as non-specific (NSLBP). Most of the episodes of NSLBP improve significantly in the first 6 weeks, although 6% and up to 40% seem to experience symptoms beyond 3 months, which is classified as chronic (CNSLBP). (5,6) Therefore risk factors for chronicity (yellow flags), psychosocial factors should be assessed already in the early acute state of LBP and if present to start early a multidisciplinary care.(7) The assessed restrictions in activities of daily life and the attention to psychosocial factors and comorbidities should guide us when selecting therapy and rehabilitation strategies.(7,8,9)

Following non-surgical Management strategies should be offered especially for chronic LBP as part of care in most contexts as Recommendations in favor (4):

Structured and standardized education/ advice, some physical therapies (exercise programmes, needeling therapies, manual therapy/ spinal manipulative therapy, massage), some psychological therapies (cognitive behavioural therapy, operant therapy), some medicines/ pharmacological therapies (first line non-steroidal anti-inflammatory drugs (NSAIDs, not to older people), topical Cayenne pepper [in other guidelines/reviews also muscle relaxants, but not topical Cayenne pepper]), Multi-component biopsychosocial care (that addresses at 2 or more factors that may influence a pain experience – physical, psychological, [and/] or social).

Recommendations against (4) as part of routine care in most contexts were some physical therapies (traction ultrasound, TENS, lumbar braces/belts), some medicines (opioid analgesics, antidepressants, anticonvulsants, skeletal muscle relaxants, glucocorticoids, injectable local anaesthetics, Devil´s claw, White willow), pharmacological weight loss.

Differences of guideline recommendations (4,7,8,9,10,11,12,13,14,15,16) for non-pharmacological and pharmacological therapies/ management strategies for LBP (focus to NSLBP) will be discussed within the presentation. As management approaches the following Non-Pharmacologic treatments (increasingly recommended over Pharmacological approaches) are partly recommended (without a single best evidence / recommendation for one of the non-pharmacological treatments): education for self-management, general-/ muscle strengthening-/ endurance-/ aerobic-/ aquatic exercise, mind body exercise (MBE) like Pilates/ Tai Chi/ Yoga, cognitive behavioral therapy, Mindfulness-based stress reduction, Multidisciplinary comprehensive biopsychosocial/ Multimodal care, occupational therapy, Massage, Heat wrap, Spinal manipulation, Acupuncture). For chronic LBP one may consider as pharmacological treatment antidepressants or anticonvulsants for neuropathic pain management.

Discussions and Conclusions

In every stage of diagnosis and management of LBP a person-centered approach should be sought. Within the diagnosis red flags (signs for serious pathologies or dangerous courses), yellow flags (risk factors for chronicity), the individual capacity for activities and participation, and comorbidities should be assessed. Selective imaging should be made only when red flags are present.

The aim in management of LBP is to support those affected by LBP for best possible performance in their daily life for valued activities based on the assessed individual factors with non-pharmacologic (e.g. education including self-management, exercise, MBE, cognitive behavioral therapy, Multidisciplinary biopsychosocial care) and pharmacologic (NSAIDs as first line) strategies, also in combination if necessary for return to their valued activities.

WHAT DO WE KNOW ABOUT PREFERENCES OF PATIENTS AT RISK FOR FRACTURES?

L. Nagendra[1,2]

[1]JSS Medical College, Mysore, India, [2]Maastricht University, Maastricht, Netherlands

Poor adherence to anti-osteoporosis treatments is a significant barrier to optimal disease management, partly due to a misalignment between treatment characteristics and patient preferences. This presentation will share findings from a recently published systematic review of 14 quantitative preference studies involving 4714 participants (Hintzpeter et al. The Patient 2024 Nov;17(6):619-634). These studies focused on the relative importance of various treatment attributes, with process-related attributes (50%) and outcome-related attributes (40%) being the most frequently studied. The review revealed that treatment efficacy was the most important factor for patients, outweighing considerations such as administration methods, cost, and side effects. Preference heterogeneity was observed in 86% of the studies, highlighting diverse patient priorities. These findings emphasize the need to incorporate patient preferences into osteoporosis treatment planning to improve adherence and clinical outcomes. By aligning treatment options with individual preferences, healthcare providers can foster more patient-centered care, leading to better outcomes for patients at risk of osteoporosis-related fractures.

NSS4

INTEGRATING PATIENTS PREFERENCES AND PERSPECTIVES INTO OSTEOPOROSIS CARE AND POLICY DEVELOPMENT: AN ACADEMIC PERSPECTIVE

M. Hiligsmann[1]

[1]Maastricht University, Maastricht, Netherlands

This presentation will explore four critical themes in integrating patient preferences and perspectives into osteoporosis care and policy development from a research-focused viewpoint. These themes include: 1) roles of patient preferences in decision-making, 2) empowering patients through shared decision-making, 3) leveraging patient-reported outcomes to elevate the patient voice, and 4) enhancing patient involvement in research and policy development. Through the presentation of scientific examples, we will discuss key lessons learned from research, offering practical insights on how patient preferences and perspectives can be meaningfully incorporated into clinical practice, research, and policy decisions. The goal is to provide the audience with actionable strategies and tools to enhance patient engagement in osteoporosis care and research, ensuring that patient experiences, preferences, and needs are authentically reflected in the decision-making process across all levels of healthcare and policy development.

NSS5

INTEGRATING PATIENT PREFERENCES AND PERSPECTIVES INTO OSTEOPOROSIS CARE AND POLICY DEVELOPMENT: THE PATIENT PERSPECTIVE

A. Botto-Van Bemden[1]

[1]Musculoskeletal Research International, Miami, United States

This presentation will explore four key themes in integrating patient preferences and perspectives into osteoporosis care and policy development from the patient's point of view. These themes include: 1) roles of patient preferences in decision-making, 2) empowering patients through shared decision-making, 3) leveraging patient-reported outcomes to elevate the patient voice, and 4) enhancing patient involvement in research and policy development. Practical examples and lessons learned from patient engagement will be shared, equipping attendees with strategies to promote genuine patient involvement in shaping care and policy. The goal is to provide the audience with actionable strategies and tools to enhance patient engagement in osteoporosis care and research, ensuring that patient experiences, preferences, and needs are authentically reflected in the decision-making process across all levels of healthcare and policy development.

NSS6

A MESSAGE FROM THE BONE: HOW BONE-SECRETED FACTORS AFFECT MUSCLE GROWTH AND FUNCTION

G. Duque[1]

[1]Dr. Joseph Kaufmann Chair in Geriatric Medicine; Faculty of Medicine and Health Sciences, McGill University; Principal Investigator - Bone, Muscle, and Geroscience Group - Research Institute of the McGill University Health Centre, Montreal, Canada

Bone-secreted factors play a significant role in regulating muscle growth and function, a relationship often referred to as "bone-muscle crosstalk." Bones secrete various signaling molecules, known as osteokines, as well as extracellular vesicles containing microRNAs, which influence muscle tissue in ways that are increasingly recognized as essential for musculoskeletal health. These bone-secreted factors include anabolic factors such as osteocalcin or Insulin-Like Growth Factor-1 (IGF-1) and catabolic or inhibitory factors such as Fibroblast Growth Factor 23 (FGF23), RANKL, or sclerostin. Bone diseases, such as osteoporosis, affect the profile and message of these factors by favouring the secretion of catabolic/inhibitory osteokines and microRNAs. This is considered one of the pathophysiological mechanisms of osteosarcopenia. This side of the bone-muscle interaction is critical for maintaining muscle mass and function throughout life. Therapies targeting specific bone-secreted factors, like osteocalcin supplementation, or RANKL and sclerostin inhibition, are under investigation for treating age-related muscle weakness and promoting overall musculoskeletal health.

NSS7

THE ROLE OF FAT IN MUSCLE/BONE CROSSTALK: AN ADDITIONAL COMPLEX PLAYER

T. Kim[1]

[1]Assistant Professor of Medicine at UCSF and Staff Physician at the San Francisco VA Health Care System, San Francisco, United States

Fat tissue, particularly the fat found within and around muscles and bones, plays a significant role in the crosstalk between those two tissues, influencing both muscle and bone health. Fat cells secrete various signaling molecules called adipokines, which impact muscle and bone function, metabolism, and inflammation. Fat stored within muscles is increased in aging, obesity, and metabolic diseases. Excessive intermuscular adipose tissue (IMAT) is associated with reduced muscle strength and function, potentially due to infiltration of inflammatory cells, reduced muscle quality, and affects on muscle regeneration. High levels of marrow fat can negatively impact bone density and strength by competing with osteoblasts for stem cell precursors, reducing bone formation. Marrow fat cells also secrete pro-inflammatory cytokines, contributing to a local environment that favors bone loss and may impair bone-muscle communication. Systemically, excess adipose tissue, especially in obesity, leads to chronic low-grade inflammation through the release of inflammatory

cytokines like TNF-α and IL-6. In bone, this chronic inflammation can accelerate bone resorption (breakdown) and suppress bone formation, contributing to osteoporosis and increasing fracture risk and in muscle, inflammatory cytokines promote muscle catabolism, leading to muscle wasting and reduced function, a phenomenon seen in both aging and obesity. Fat quantification in muscle and bone could be used as a diagnostic tool for osteosarcopenia and a predictor of adverse outcomes associated with this condition. In addition, targeting adipokines, reducing intramuscular and marrow fat, and controlling inflammation are potential therapeutic strategies to improve bone and muscle health in conditions involving fat dysregulation.

NSS8

A MESSAGE FROM THE MUSCLE: HOW MUSCLE-SECRETED FACTORS AFFECT BONE METABOLISM AND FUNCTION

O. D. Messina[1]

[1]Rheumatologist, Investigaciones Reumatologicas y Osteologicas (IRO) Medical Center, Buenos Aires, Argentina

Muscle tissue communicates with bone through various signaling molecules called myokines. These muscle-secreted factors influence bone metabolism, growth, and overall function. Irisin, which is released by muscles during exercise, promotes osteoblast activity, leading to increased bone formation. In contrast, myostatin is a negative regulator of muscle growth and, when overexpressed, can reduce muscle mass and lead to weaker bones. Inhibition of myostatin has been associated with increased bone formation, highlighting its role in the muscle-bone relationship. IGF-1 from muscle promotes bone formation and repair by stimulating osteoblast proliferation and differentiation. Higher levels of IGF-1 are linked to improved bone density and strength. IL-6 is released by muscles during exercise and has a complex role; in controlled amounts, it can stimulate bone formation. However, chronic high levels of IL-6 (often found in inflammation) can lead to bone resorption and osteoporosis. Overall, these muscle-derived factors, together with muscle-secreted microRNAs, are critical in maintaining bone health and preventing bone-related diseases. Exercise, which enhances the release of many beneficial myokines, is often recommended to strengthen both muscle and bone through this interconnected pathway.

NSS9

RISK FACTORS FOR VERTEBRAL FRACTURE

P. Hadji[1]

[1]Frankfurt Center of Bone Health and Endocrinology and Philipps-university of Marburg, Frankfurt/Main, Germany

Osteoporosis, a condition characterized by low bone mineral density (BMD), is a primary contributor to vertebral fragility. Studies indicate that individuals with osteoporosis have a significantly higher risk of sustaining vertebral fractures, even from minor falls or everyday activities. Vertebral fractures hereby represent a major health issue, particularly among the aging population, leading to significant morbidity, disability, and increased healthcare costs. Age is one of the most critical risk factors, with the incidence of vertebral fractures rising in individuals over 50 years. Postmenopausal women are particularly vulnerable due to the rapid decline in estrogen levels, which plays a crucial role in maintaining bone density. Gender differences also play a significant role, as women are more likely to experience vertebral fractures than men, primarily due to hormonal changes and differences in peak bone mass. However, men are not exempt, especially those with risk factors such as low testosterone levels or chronic diseases that affect bone health. Lifestyle factors are equally important in assessing fracture risk. Sedentary behavior, smoking, and excessive alcohol consumption, poor vision, balance issues, and unsafe living conditions can increase the likelihood of falls have been linked to decreased bone density and increased fracture susceptibility. Regular physical activity, particularly weight-bearing exercises, is essential for maintaining bone strength and reducing the risk of fractures. Comorbid conditions significantly influence the likelihood of vertebral fractures. Chronic diseases such as rheumatoid arthritis, diabetes, and chronic kidney disease can lead to bone loss and increase fracture risk. Additionally, certain medications, particularly long-term use of corticosteroids, have been shown to adversely affect bone health, further elevating the risk of vertebral fractures. The lecture aims to provide a comprehensive overview of the multifactorial risk factors associated with vertebral fractures, emphasizing the need for early identification and intervention.

NSS10

GERMAN GUIDELINE FOR THE DIAGNOSIS AND TREATMENT OF OSTEOPOROTIC THORACOLUMBAR VERTEBRAL FRACTURES

A. Kurth[1]

[1]Orthopaedic Institute Dr. Baron&Colleagues and Goethe University Frankfurt, Frankfurt/Main, Germany

Osteoporosis is currently one of the most common diseases among the aging population. One of its most significant clinical consequences is the occurrence of various bone fractures, with vertebral compression fractures being particularly noteworthy. Every year, up to 400,000 such vertebral fractures are diagnosed in Europe, particularly affecting elderly patients. Classifications for osteoporotic fractures have existed for over 50 years, but only a few have been widely adopted into clinical practice. The primary goal of any treatment for osteoporotic vertebral fractures is pain reduction and the rapid mobilization of patients. Conservative treatment can achieve reliable pain relief, early mobilization, prevention of additional fractures, and the preservation of quality of life. Surgical treatment is indicated only if these goals cannot be accomplished through conservative therapy alone.
In German-speaking regions, the OF classification is increasingly used for the classification of osteoporotic fractures. This

classification, developed through a validated consensus process by the Osteoporotic Fractures Working Group of the DGOU, consists of 5 subgroups (OF 1 to OF 5) and is based on conventional X-ray, MRI, and CT imaging. The new guidelines include 50 recommendations on diagnostics, conservative treatment (such as orthotics, pain management, and physical therapy), surgical interventions (vertebroplasty, kyphoplasty, ventral and dorsal instrumentation, implants, prophylactic cement augmentation, etc.), rehabilitation, complications, and follow-up.

NSS11

30 YEARS OF KYPHOPLASTY: A MILESTONE IN SPINE CARE IN OSTEOPOROSIS

R. Pflugmacher[1]

[1]Chief Physician Clinic for Orthopaedics and Spinal Surgery at Mechernich Hospital, Mechernich , Germany

Kyphoplasty, a minimally invasive procedure designed to treat vertebral compression fractures, has transformed spine care over the past 30 years. First introduced in the early 1990s, it represented a significant breakthrough in addressing the debilitating effects of osteoporosis and spinal trauma, offering patients a chance to regain mobility and alleviate chronic pain.

The innovation began with the use of balloon-assisted bone augmentation, allowing the restoration of vertebral height and the stabilization of fractures using polymethylmethacrylate (PMMA) cement. Early adopters quickly recognized its potential to reduce pain, improve spinal alignment, and enhance the quality of life in patients who previously had limited options beyond conservative management or invasive surgery.

Over the decades, kyphoplasty has undergone significant advancements. Early techniques have been refined, making the procedure safer, more effective, and accessible to a broader range of patients. Innovations in imaging technology, such as real-time fluoroscopy, have improved procedural accuracy, while the development of biocompatible materials has reduced complications associated with cement leakage.

Clinical studies over the years have solidified kyphoplasty's role as a preferred treatment for osteoporotic fractures, particularly in elderly populations. Research has consistently demonstrated its ability to provide immediate pain relief and improved functional outcomes compared to non-surgical options. Additionally, the procedure has expanded to treat fractures caused by cancer metastases and traumatic injuries.

Today, kyphoplasty is a cornerstone of minimally invasive spine surgery, performed worldwide with excellent success rates. Its evolution over three decades is a testament to the intersection of innovation and clinical expertise, transforming the landscape of spine care. As we look to the future, ongoing research into materials and techniques promises to further enhance outcomes and expand the applications of this remarkable procedure. Kyphoplasty's journey is a true reflection of progress in modern medicine.

NSS12

UNDERLYING BONE HEALTH: IS IT IMPORTANT TO SURGICAL OUTCOMES?

P. D. Cummings[1]

[1]TOCA at Banner Health, Scottsdale, Arizona, United States

Compromised bone health, sarcopenia, and associated risk factors are prevalent in patients undergoing orthopaedic surgical procedures. Failure to recognize these factors pre-operatively can lead intra- and post-operative complications affecting overall outcomes. Related complications or failures secondary to compromised bone health are associated with increased health care costs, prolonged or repeated surgeries and/or hospitalizations, decrease in patient function, and an overall increase in patient morbidity and mortality.

NSS13

ORTHOPAEDIC SURGERIES AFFECTED BY COMPROMISED BONE HEALTH

N. Koumontzis[1]

[1]Student at University of West Virginia, West Virginia, United States

Bone health, sarcopenia, and associated risk factors significantly impact the outcomes of various orthopedic surgeries. Unfortunately, many patients' lack of bone integrity is often unrecognized in the pre-operative period, leading to compromised surgical results. Joint replacement surgeries are highly affected as poor bone quality increases the risk of implant loosening or failure. Spinal surgeries, including spinal fusion and vertebroplasty, rely on strong bone to achieve proper fusion and stability. Fracture repair procedures often face challenges in osteoporotic or brittle bones, where screws and plates may not hold effectively. Procedures like rotator cuff repairs and ligament reconstructions involving bone anchors and other methods of fixation are less secure in compromised bone. Ultimately, bone integrity is a determining factor in the durability and success of many orthopedic procedures and must be accurately assessed prior to surgical intervention.

NSS14

DEVELOPMENT OF PRE- AND POST-OPERATIVE BONE HEALTH PROGRAMS FOR ORTHOPEDIC SURGICAL PATIENTS

I. Esposito[1]

[1]TOCA at Banner Health, Scottsdale, Arizona, United States

Early recognition and treatment of pre-operative compromised bone health is paramount for the optimization of orthopaedic surgical outcomes. Unfortunately, recognition of compromised bone health in some patients is not realized until the intra- or post-operative period. Utilizing our individualized 4-Pillar Assessment,

we will provide practitioners with the necessary tools to perform a comprehensive bone health assessment and examination. From this information Health Care Professionals can develop a Multidisciplinary Assessment Profile (MAP) and an Integrated Care Plan (ICP) for treatment.

NSS15

WHAT DID BASIC RESEARCH TELL US ?

A. Peri[1]

[1]Pituitary Diseases and Sodium Alterations Unit, Endocrinology, Careggi University Hospital, University of Florence, Florence, Italy

Hyponatremia is the most common electrolyte disorder among hospitalized patients, with a prevalence of about 30%, and the most frequent etiology is the syndrome of inappropriate antidiuresis (SIAD). Interestingly, an association between mild, chronic hyponatremia and bone loss and fractures has been reported. The mechanisms underlying bone alterations in hyponatremia have been investigated in vivo and in vitro. Experimental data obtained from a rat model of SIAD and from murine pre-osteoclast cell cultures demonstrated that low extracellular [Na^+] is associated with a reduced trabecular and cortical bone content and with increased osteoclastogenesis and bone resorptive activity. These findings are not surprising, if we consider that about 30 % of total body sodium resides in the bone and slightly less than half of it is exchangeable with the serum pool. Thus, it can be hypothesized that chronic sodium depletion might promote the mobilization of bone stores with consequent demineralization. The maintenance of bone homeostasis is based on the dynamic balance between matrix deposition and resorption. Matrix deposition is warranted by osteoblasts, which derive from mesenchymal stromal cells (MSCs). MSCs establish functional relationships with other bone marrow resident cells and contribute to the generation of a complex microenvironment that affects bone homeostasis. Noteworthy, it has been shown that in low extracellular [Na^+] human MSCs are preferentially committed to differentiate toward an adipogenic phenotype at the expense of osteogenesis. A similar shift has been demonstrated in osteoporosis due to different causes. Furthermore, the binding of vasopressin, which is involved in the etiopathogenesis of hyponatremia due to SIAD, to the vasopressin type 1a receptor increases the formation of bone-resorbing osteoclasts and at the same time inhibits osteoblastogenesis. Overall, the available data strongly support a role of low [Na^+] in promoting bone loss.

NSS16

HYPONATREMIA AND BONE DENSITY

L. Potasso[1]

[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland

In the past decades, both preclinical and clinical studies as well as case reports have suggested a possible causal relationship between chronic hyponatremia (serum sodium<135 mmol/l) and bone loss. In humans, many studies investigated the possible relationship between hyponatremia and bone, using both bone mineral density (BMD) measured by dual-energy x-ray absorptiometry (DXA) and markers for osteoblasts' (serum P1NP, osteocalcin) and osteoclasts' (serum CTX, NTx-creatinine ratio) activation.

In 2009, analysis of data from NHANES III study showed increased odds for hip osteoporosis in hyponatremic adults[1]. These results were in line with those of a metanalysis from 2016, showing lower hip BMD in hyponatremic patients[2]. In 2016, a secondary analysis of the INSIGHT trial showed a significant decrease of bone resorption index (urine NTx-creatinine ratio divided by serum osteocalcin) in the tolvaptan group[3]. In 2019, a case report showed a normalized DXA in a patient with 11 years valproic acid induced hyponatremia after discontinuation of valproic acid and resolution of hyponatremia[4]. More recently, our group performed two secondary analyses in patients with the syndrome of inappropriate antidiuresis (SIAD) showing that hyponatremia normalization increases bone formation index (the ratio between P1NP and CTX), primarily positively affecting P1NP[5,6]. Moreover, another analysis of data from NHANES in 2024 showed that mild hyponatremia is associated with loss of bone mass at the hip measured by DXA, but not with relevant changes in trabecular bone score[7]. These findings show a relevant interaction between hyponatremia and bone density, suggesting hyponatremia correction to mitigate bone-related complications.

HYPONATREMIA, FALLS AND FRACTURES

P. Tzoulis[1]

[1]Department of Medicine, Univesity College London, London, United Kingdom

Objectives: The key objectives of this review are to summarise the evidence to date about the association of hyponatremia with falls and fractures, exploring the related pathophysiological mechanisms, and to suggest a practical approach in day-to-day care in order to improve patient outcomes.

Materials and Methods: We conducted an extensive PubMed search until October January 2025 with the combination of the following keywords: 'hyponatremia' or 'sodium' or 'SIADH' and 'falls' or 'fractures' or 'bone', as MeSH Terms.

Results: Review of numerous observational studies confirms a significant independent association of, even mild, hyponatremia with two- to three-fold increase in the occurrence of bone fractures. Hyponatremia is a risk factor for osteoporosis with a predilection to affect the hip, while the magnitude of association

depends on the severity and chronicity of hyponatremia. Chronic hyponatremia increases the risk for falls by inducing gait instability and neurocognitive deficits. Besides the detrimental impact of hyponatremia on bone mineral density and risk of falls, it also induces changes in bone quality. Emerging evidence suggests that acute hyponatremia shifts bone turnover dynamics towards less bone formation, while hyponatremia correction increases bone formation.

Conclusions: The key unanswered question whether treatment of hyponatremia could lower fracture risk highlights the need for prospective studies, evaluating the impact of sodium normalization on bone metabolism, incidence of falls and occurrence of fractures. Recommendations for clinical approach should include measurement of serum sodium in all individuals with fracture or osteoporosis. Also, hyponatremia, as an independent risk factor for fracture, should be taken into consideration when estimating the likelihood for future fragility fracture and in clinical decision-making about pharmacological therapy of osteoporosis. Until it is proven that normalization of sodium can lower fracture occurrence, correcting hyponatremia cannot be universally recommended on this basis, but should be decided on a case-by-case basis.

ADVANCING OSTEOARTHRITIS TRIALS AND THERAPEUTIC DEVELOPMENT THROUGH CLINICAL PHENOTYPING AND MOLECULAR ENDOTYPING

A. Mobasheri[1,2,3,4]

[1]University of Oulu, Oulu, Finland, [2]State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, [3]Sun Yat-sen University, Guangzhou, Guangdong, China, [4]Université de Liège, Liège, Belgium

Background: Osteoarthritis (OA) is the most prevalent form of arthritis and a leading cause of pain and mobility impairment worldwide. OA is a mechano-inflammatory joint disease characterized by progressive cartilage degradation, synovial inflammation, and structural changes in subchondral bone and other joint tissues. Emerging evidence reveals that OA is a heterogeneous and complex disease, encompassing diverse clinical phenotypes and distinct molecular endotypes (Mobasheri and Loeser, 2024). Clinical phenotypes refer to observable traits and patient characteristics, while molecular endotypes capture the underlying biological mechanisms and molecular signatures driving the disease. Despite this knowledge, conventional therapeutic approaches and most OA clinical trials have not sufficiently accounted for this variability, often resulting in suboptimal outcomes.

Objective: This presentation will synthesize evidence from recent biomarker-focused research to underscore the critical role of molecular endotyping in developing targeted disease-modifying osteoarthritis drugs (DMOADs).

Methods: A comprehensive review of the literature was undertaken, focusing on the identification of OA phenotypes and endotypes and their implications for therapeutic development.

Results: Variability in terminology notwithstanding, research from the recently completed Innovative Medicines Initiative IMI-APPROACH project (Angelini et al., 2022; Hannani et al., 2025) and ongoing programs such as ERA-NET Neuron GO-PAIN and the COST Action CA21110 (NetwOArk) has underscored the importance of molecular endotypes. These subtypes, defined by distinct molecular mechanisms, provide a framework for more precise molecular classification of OA. This enables the development of more effective, personalized therapeutic strategies (Hannani et al., 2024).

Conclusion: As evidenced by IMI-APPROACH and validated in OAI-FNIH, integrating biochemical markers, imaging data, and clinical features can uncover molecular endotypes with distinct therapeutic responses. Panels of biochemical markers show potential for identifying disease subgroups and enriching clinical trials with treatable endotypes. This molecular stratification enhances trial efficiency and therapeutic outcomes by selecting patient subsets most likely to benefit from specific treatments. Future research should prioritize multi-omics data integration to refine molecular endotyping approaches and evaluate their utility in clinical trial settings, advancing the development of targeted OA therapies.

ENDOTYPING OSTEOARTHRITIS BY INTEROGATING THE PATHOBIOLOGAL BIOACTIVITY PRESENT IN OSTEOARTHRITIC SYNOVIAL FLUID

T. J. M. Welting[1]

[1]Professor of Molecular Cartilage Biology - Department of Orthopedic Surgery - Maastricht University and Maastricht University Medical Center, Maastricht, Netherlands

Objective:
Tools for identifying osteoarthritis patient endotypes are needed to develop targeted therapies and select the right patient for the right treatment. The biomolecular influence of OA-SF on cell signaling responses may provide cell-integrated information on the broader pathobiological status of joints and could provide a novel means to endotypes OA. The aim of this study was to develop a set of cell-based transcription factor activity reporter assays as explorative tools to endotype OA-SF.

Methods:
SW1353 Nano-luciferase transcription factor activity reporter cell lines were developed for NFκB, SRE, SRF, AP1, cAMP and SIE. These reporter assays were used to scree SFs of 160 end-stage knee OA patients. K-means clustering was used to identify OA-SF subgroups from the cell reporter data. The Pearson's r coefficient was determined for each reporter combination. RNAseq was performed on SW1353 cells stimulated with OA-SFs from subgroups. Multivariable regression analysis was performed to develop a reporter assay-based OA-SF scoring method.

Results:
K-means clustering of the OA-SF-induced reporter responses identified three OA-SF subgroups. To study the biological effects of the OA-SF subgroups, SW1353 cells were stimulated with OA-SF from the subgroups. RNAseq analyses on these samples demonstrated that two of the three OA-SF subgroups induced transcription of ribosome-related genes ("high-translation groups"). The other subgroup did not provoke this response ("low-translation group"). Correlation analysis showed that five reporters (NFκB, SRE, SRF, AP1 and CRE) correlated highly with each other (Pearson's r>0.75). SIE responses correlated poorly with the other reporter assays (-0.25<Pearson's r<0.25), indicating that the OA-SF-induced SIE cell signaling response is unique from the other tested reporters. Using multivariable regression, it was identified that the combination of AP1 and SIE responses separated the low-translation group from the high-translation groups almost as efficiently as the six reporters combined. Ongoing work is focusing on validating this scoring system using an independent cohort of OA-SFs.

Conclusion:
We identified two groups of OA-SF endotypes that differ in their capacity the induce transcription of ribosome-related genes, and which can be stratified using a combination of the SIE and AP1 cell reporter assays. This may provide a novel basis to separate OA endotypes.

NSS20

INSIGHTS INTO OA ENDOPHENOTYPES FROM RECENT CLINICAL TRIALS

P. Conaghan[1]

[1]University of Leeds/Musculoskeletal Medicine/Chapel Allerton Hospital, Leeds, United Kingdom

The OA field has struggled to find biomarkers reflective of underlying mechanistic pathways, that would define an endotype. New data from recent trials may provide insights into one pathway. Although interleukin-1 (IL-1) is known to play a role in OA pathogenesis, results from animal model studies have been mixed and clinical trials using anti-IL-1 therapies have failed to deliver convincing analgesic or structural benefits, despite some design limitations.

However a post hoc analysis of a large trial of the IL-1β inhibitor canakinumab, from the Canakinumab Anti-Inflammatory Thrombosis Outcomes Study (CANTOS) trial, has raised questions about who we should enrol in trials. In CANTOS, which was not an OA trial, over 10,000 patients who had previous myocardial infarction and elevated highly-sensitive CRP (hsCRP), were randomised to one of 3 doses of canakinumab or placebo subcutaneously every 3 months and treated for a mean of 3.7 years. The post hoc study demonstrated a marked reduction in total joint replacements (which can be assumed to be a surrogate measure of joint pain) in all active canakinumab arms compared to placebo. Similar results were seen in people who reported having OA at baseline. There was also a reduction in OA joint problems reported as adverse events. Another large cardiovascular-focussed trial explored the potential benefits of low-dose colchicine, which is an inflammasome (producer of IL-1) inhibitor; this also demonstrated a reduction in joint replacements. Various hypotheses can be drawn about what these studies are telling us, including selecting patients for inflammation biomarkers. A recent RCT treated knee OA patients with methotrexate and achieved its primary outcome of pain reduction at 6months. Sub analysis of that trial showed increased benefit in patients with elevated hsCRP. Perhaps we are getting closer to a biomarker for an inflammatory or metabolic phenotype.

NSS21

OBESITY SHAPES THE INFLAMMATORY MOLECULAR ENDOTYPES OF SYNOVIAL FIBROBLASTS IN OSTEOARTHRITIS

S. W. Jones[1,2]

[1]Department of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom, [2]National Institute for Health and Care Research (NIHR) Birmingham Biomedical Research Centre, Birmingham, United Kingdom

Objective
Emerging perspectives suggest the heterogeneity of osteoarthritis (OA) is underpinned by distinct molecular endotypes[(1)], including

'low repair,' 'bone-cartilage,' 'metabolic,' and 'inflammatory' subtypes[2]. Among these, the inflammatory subtype has garnered significant interest due to its potential to exacerbate cartilage degeneration and promote joint pain[3] .

Research, including our own, has demonstrated that fibroblast-like synoviocytes (synovial fibroblasts; SFs) are central mediators of OA synovial inflammation, and how in hip OA patients with obesity, SFs adopt a more inflammatory phenotype[4].

Given obesity is a significant risk factor for OA development in both load-bearing and non-load bearing joints, we comprehensively profiled the phenotype of SFs across different joint sites in patients with normal-weight or obesity. Through this analysis, we sought to elucidate how obesity shapes the inflammatory molecular endotype of OA SFs, and to disentangle the metabolic effects and mechanical effects of obesity[5].

Materials and Methods

SFs from the synovium of n=32 OA patients with normal-weight or obesity (NRES:16/SS/0172) were characterised by proteomics (Olink, Luminex), metabolism (Seahorse) and RNA-sequencing. Immunohistochemistry was performed by Vectra.

Results

Our findings reveal that the phenotypic inflammatory landscape of OA SFs is influenced independently by obesity and anatomical site. Specifically, pathway analysis of single-cell RNA-seq data identified four distinct SF endotypes: (i) "activated" and (ii) "immune cell recruiters", which were both predominant in OA patients with obesity and characterised by elevated expression of inflammatory genes e.g., CXCL12 and Chemerin, (iii) "stressed/arresting", which were predominant in normal-weight, and (iv) "proliferative" fibroblasts. Spatial mapping showed that obesity-associated inflammatory SFs localised to both the synovial lining and sublining layers, distinguished by c-Fos expression. In contrast, normal-weight associated "stressed/arresting" SFs were confined to the lining layer and marked by c-Myc expression.

Conclusion

Our findings underscore the role of obesity in shaping the molecular landscape of OA by driving specific inflammatory endotypes, and provide further rationale for the therapeutic targeting of specific SF subtypes. Ultimately, building upon these insights and the foundational work from others in identifying distinct molecular endotypes may provide a critical line of sight between molecular target and patient, thus paving the way to stratifying patients for personalised therapeutic interventions and facilitating optimal clinical trial designs.

CLINICAL APPLICATION OF LONGITUDINALLY STABLE MOLECULAR ENDOTYPES IN OSTEOARTHRITIS: PATHWAYS TO PRECISION MEDICINE

C. Thudium[1], M. Hannani[1], A. C. Bay-Jensen[1]

[1]Immunoscience, Nordic Bioscience, Herlev, Denmark

Heterogeneity of osteoarthritis (OA) is an obstacle to developing disease-modifying OA drugs (DMOADs) which historically have treated clinical trial populations with a one-size-fits-all approach. Recent efforts in biomarker research and molecular endotyping have taken us closer to personalized interventions by providing tools for improved patient stratification into druggable subgroups. Based on soluble biomarkers and machine learning, the IMI-APPROACH consortium established three endotypes of 1) structural damage, 2) low tissue turnover, and 3) inflammation.

One of the key aspects of endotypic stratification is whether individuals remain in their designated endotype over time, as a fluctuating endotype would impede its applicability in clinical trials. Longitudinal assessment of the biomarkers revealed an average endotype stability of 55% over 18 months. This stability was validated in the placebo group of the oral salmon calcitonin (SMC) phase III trials. The stability of the endotypes over time and recapitulation in a separate OA population highlights the utility of enriching for targeted subpopulations in clinical trials.

Clustering models are key to identify population-level endotypes, but their utility for clinical trial enrollment is limited. In this case predictive patient-level models are more suitable by providing real-time actionable endotype designations. Recently, we showed it is possible to predict endotypes with logistic regression models based on a panel of 6 biomarkers in the SMC trials where a reduction in WOMAC pain was demonstrated for the structural damage endotype.

Biomarker-informed endotyping allows more precise identification of tissue-relevant molecular drivers, enabling the transformation of OA from a phenotypically treated condition to a disease guided by mechanistic insights. Future studies will focus on linking longitudinally stable endotypes with patient-reported outcomes and treatment efficacy to improve the success of DMOAD trials.

NSS23

OSTEOPOROSIS AND ANCIENT HISTORY

G. Altamar[1]

[1]Specialist in Internal medicine and Geriatrics ; Specialist in Health management ; Professor of Geriatrics – Universidad del Valle ; Colombian Osteoporosis Association (ACOMM) President, Cali, Colombia

The World Health Organization (WHO) definition of osteoporosis describes it as a systemic skeletal disease characterized by low bone mass and micro-architectural deterioration of bone tissue, with a consequent increase in bone fragility and susceptibility

to fracture risk. In these days, women and men lives longer and experience progressive bone loss and fractures, in addition changes in nutrition habits, modernity amenities have largely replaced the bone-loading activities that promote osteogenesis. Despite this, osteoporosis is not a disease only of the modern era. Paleopathology, the study of diseases in the past, using different sources focused on the pivotal papers from different geographic samples, suggests the disease was present at least five millennia ago. In this symposium, we will review how the evidence of bone loss and osteoporosis, in civilizations in the ancient age (the part of history that begins with the invention of writing and ends with the fall of the Roman Empire in 5th century). Also, we will discuss the difference between methods and studies, how it could apply the evidence and hypothesis about reproductive lifespan and nutrition were possible factors associated with reduced bone mass, to our modern osteoporosis practice.

OSTEOPOROSIS IN ART

A. F. Coy[1]

[1]Fundacion SantaFe Bogota, Bogota, Colombia

Osteoporosis like many other diseases has a representation in art. Although the clinical manifestation of osteoporosis is a fracture, its representation could be related to the disability related to the fracture or the loss of height which is displayed in many paintings that will be mentioned. The “arrival of the English ambassadors”, painted by Vittore Carpaccio, has been considered one of the best representations of osteoporosis. It shows an old lady that is portrayed in the lower hand corner of the art piece, which has been considered to be the governess of Ursula, the daughter of King Maurus of Venice. She is sitting on the steps of a staircase away from the rest. The consideration of osteoporosis comes from a trunk that is apparently shorter considering the length of her legs and a hump on her back. This painting is located at the Gallerie dellÁccademia, Venice. 1,4

The second piece was created by Spanish painter Francisco de Goya in 1799 and is known as “El Chitón” and represents two women close to each other and the women of the left is old and has a cane. According to the article by Curate, the characteristics that are related with the disease are a shorter truck compared to the length of the lower extremities, a humped back, the use of a cane and flexion of the knee. This art piece is located at the Museo Nacional del Prado in Madrid, Spain. 2,4

Although there are multiple paintings that represent those characteristics mentioned before the last painting that will be mentioned is the “Three ages of women” created by G. Klimt an austrian painter. The painting depicts three different stages of life one being a child, the second one a mother given that is holding the child figure and the one considered here and old women, that is the women on the left and you can see a hump on the back which represents the osteoporosis. This painting is currently at

the National Gallery of Modern Art in Rome, Italy. 3

HISTORY OF OSTEOPOROSIS PHARMACOLOGICAL TREATMENT

M. McClung[1]

[1]Oregon Osteoporosis Center, Portland, OR, United States

Although osteoporosis has been known about for centuries, the potential for treating osteoporosis began ~80 years ago when Albright observed a relationship between estrogen deficiency and vertebral fractures. Modern studies using changes in bone mass and fracture incidence began in the 1970's demonstrating preservation of bone mineral density (BMD) and reduced vertebral fracture risk with estrogen, leading to its FDA approval in 1986 for preventing and later treating osteoporosis. Calcitonin was approved in 1984 based on prevention of total body calcium loss. After the BMD increase with fluoride was shown to be associated with increased fracture risk, FDA guidelines from 1994 required 3 year fracture endpoint studies in patients with osteoporosis for regulatory approval for osteoporosis treatment. Estrogen had not met that criterion, and approval for osteoporosis treatment was withdrawn. Based upon placebo-controlled trials with an average of ~2500 subjects in postmenopausal women at high risk of fracture, nasal calcitonin plus six new anti-remodeling or osteoanabolic drugs received approval between 1995 and 2003. The availability of these drugs, some of which were quite effective in reducing fracture risk, made it unethical to enroll very high risk patients in placebo-controlled studies. Subsequent studies enrolling lower risk patents with osteoporosis required much larger study populations (average 6700 subjects with concomitant expense) to achieve statistical power to demonstrate fracture risk reduction. An alternative is to use an active control arm, allowing enrollment of high risk subjects but also requiring large patient numbers. The expense of these large trials is a deterrent for drug development. Regulatory agencies are considering the strong evidence supporting the use of treatment-related changes in hip BMD as a surrogate for fracture risk reduction. If that strategy is approved, registration trials could be smaller, shorter and less costly.

NSS26

ASSESSING SEDENTARY BEHAVIOURS USING THE PATIENT REPORTED OUTCOME MEASURES (PROMS)

C. Beaudart[1]

[1]University of Namur, Namur, Belgium

Over the past two decades, there has been a notable shift in health systems towards a more patient-centered model of care. The Institute of Medicine has defined patient-centered care as "care that is respectful of and responsive to individual patient preferences, needs, and values". This paradigm shift has been fueled by a broad coalition of stakeholders, including clinicians, pharmaceutical companies, and regulatory agencies, who recognize the necessity of integrating patient-reported outcomes measures (PROMs) alongside traditional clinical biomarkers. This recognition has underscored the significance of considering not only clinical indicators but also the subjective experiences and perspectives of patients.
One potential application of PROMs is in assessing the self-perception of sedentary behaviors and physical activity levels. PROMS questionnaires focused on these behaviors can capture unique patient insights into their lifestyle patterns and activity levels, providing a valuable complement to traditional metrics. In this symposium lecture, we will explore the rationale for using such questionnaires, we will discuss why it is essential to capture patient-centered outcomes in this area, identify the range of available PROMs and patient-reported experience measures (PREMs), and provide guidance on their appropriate use in clinical and research settings.
Additionally, the lecture will cover the development and validation process for PROMs and PREMs, outlining key methodological steps, statistical considerations, and validation processes necessary to ensure that these tools accurately reflect the patient's voice. We will also examine best practices in the translation of PROMs for broader applicability across diverse patient populations, ensuring that these instruments remain culturally relevant and understandable. Through this scientific and educative presentation, attendees will gain a deeper understanding of how PROMs and PREMs can enhance patient-centered care and the broader implications of these tools for research and clinical practice in promoting better health outcomes and patient engagement.

NSS27

THE IMPACT OF SEDENTARY BEHAVIOUR ON PHYSICAL CAPACITY ACROSS LIFETIME

M. Aubertin-Leheudre[1]

[1]Université du Québec à Montréal, Quebec, Canada

With age, inter-individual variability in health or physiological status increases, suggesting that chronological aging cannot be considered as a good health biomarker. It has been proposed to measure biological aging since it may inform of the need for lifestyle interventions before aging acceleration leads to adverse clinical or public health events. Lifestyle behaviours (i.e., being physically activite or sedentary) have been identified as factors able to modulate biological aging. Indeed, investigations showed a strong relationship between being active and having good fitness throughout age. However, mixed results have been reported regarding the link between muscle power or muscle strength and the level of physical activity. It has been suggested that this inconsistency may be explained by the fact that some of these studies did not control for sedentary behaviour. The prevalence of sedentariness is increasing, constitutes a major public health issue, and may contribute to premature aging. However, the role of sedentary behaviour on muscle function remains misunderstood. For example, studies performed in middle-aged and older adults reported no associations between sedentary behaviour and handgrip strength but also mixed results regarding gait speed, lower-limb muscle strength or estimated lower-limb muscle power. Therefore, with the aging of the population and the decrease of healthy life expectancy, it appears important to better understand the impact of being inactive or sedentary behaviours alone on successful ageing but also their interrelationship with physical activity. To fill these gaps, the presentation will present new data showing the independent and interactive associations of sedentary and physically active behaviour on physical function and performance throughout age (20 to 92 years old). Overall, this presentation will show how adopting an active lifestyle but also reducing sedentary time should be considered as preventive measures against physical aging process.

NSS28

THE IMPACT OF SEDENTARY BEHAVIOUR VERSUS PHYSICAL ACTIVITY ON BONE HEALTH

O. Bruyère[1]

[1]University of Liège, Liège, Belgium

Bone health is strongly influenced by lifestyle choices, particularly the contrast between sedentary behaviour and physical activity. Sedentary behaviour, characterized by prolonged periods of inactivity such as sitting, is associated with an increased risk of bone-related health problems. Prolonged inactivity is associated with lower bone mineral density (BMD), compromised bone architecture and increased susceptibility to fractures. This relationship is of particular concern given the increasing prevalence of sedentary lifestyles in modern societies. Conversely, regular physical activity is widely recognized for its beneficial effects on skeletal health. Weight-bearing exercises, such as walking, running and resistance training, stimulate bone formation by placing mechanical stress on the skeleton, which in turn increases bone mass and strength. Physical activity not only prevents the decline of BMD, but also improves bone quality and supports structural integrity. For example, several studies have shown that resistance training has significant benefits for bone density in both younger and older adults. In addition, high-impact activities have been shown to be beneficial in slowing bone loss and maintaining bone mass, particularly in postmenopausal women who are at higher risk of osteoporosis. Research also points to the role of specific types of activity in reducing the risks of sedentary behaviour. Even low- to moderate-intensity activities, such as walking, contribute to bone health if performed regularly, suggesting that incorporating more exercise into daily routines can counteract the harmful effects of inactivity. In conclusion, promoting regular physical activity and reducing sedentary time are essential strategies for optimizing bone health. This dual approach could significantly reduce the incidence of osteoporosis and fractures, particularly in the ageing population.

INTRODUCTION: ART, MUSIC, DANCING AND HEALTH

O. D. Messina[1]

[1]Rheumatologist, Investigaciones Reumatologicas y Osteologicas (IRO) Medical Center, Buenos Aires, Argentina

Art has been a powerful form of expression. It speaks to our emotions and thoughts and has been a force that drives social change and creates awareness on relevant issues. Art making has been adopted as a health intervention in several disciplines. Our understanding of this concept is still limited but the 21st century has seen a growing interest in these concepts[1]. There is abundant literature on this topic and the World Health Organization has published a scoping review on it[2]. It is desirable that Health Professionals find ways to investigate and get involved on this topic and to engage patients in active and receptive participation in arts. This includes patients with osteoporosis[3].

DO PATIENTS BENEFIT FROM ARTISTIC ACTIVITIES? WHAT'S THE EVIDENCE?

J. L. A. Morales Torres[1]

[1]Rheumatologist. Hospital Aranda de la Parra and Director, Morales Vargas Centro de Investigacion, León GTO, Mexico

What is the relationship between engagement in creative arts and specific health outcomes? Growing evidence points to positive health effects of music engagement; forms of therapy based on visual arts; movement-based creative expression; expressive writing and other forms of art in reducing adverse physiological and psychological outcomes in several diseases. However, it remains largely unknown the actual extent to which these interventions enhance health status[1]. If we define health as the attainment of the highest level of physical, mental and social well-being, we understand the value of arts, as they may be instruments to help patients cope, to achieve their potentials, to be productive and active members of a community. Some methodological issues still limit our understanding of these issues, but it is easy to see how the traditional gap between art and science may be a fertile soil to set interdisciplinary partnerships and innovative forms of creative research. The notion that arts are "nice" but not necessary for health and wellbeing is being challenged and this change allows some glimpses of new attitudes towards a new role for art-based interventions[2,3]. Current views arise from evidences drawn from research on the effect of diverse art forms on some non-communicable diseases (Parkinson's disease, dementia, cancer, chronic pain, etc.), where diverse outcomes include neurobiological processes that may be conductive to scientific inquiry. Information on osteoporosis and art is still scant, but experiences from other conditions allow an optimistic view. Art making as a health intervention, understood as "a creative diversional and expressive process that allows an individual to create their own artwork to improve the individual's physical, cognitive, emotional and psychological health and/or wellbeing"[3], is subject to research, but existing evidence may lead us, Clinicians to include Arts in our daily practice.

ARTISTS AND ACTIVISM

J. L. A. Morales Torres[1]

[1]Rheumatologist. Hospital Aranda de la Parra and Director, Morales Vargas Centro de Investigacion, León GTO, Mexico

Art has been a powerful form of expression. Art speaks to our emotions, challenges and thoughts. Art has been a powerful force driving social change and creating awareness around pertinent issues. Art should not be submissive. Artistic and creative expression are part of the freedom of expression. The role of artists as creators of aesthetically beautiful products, has been also a vehicle for messages and interactions with audiences, and with this, frequently challenges societal norms and calls for change. Is asking an artist to produce a specific work to convey a health-specific message a limit to his or her freedom? Or is it a form of commitment with a desirable leading role? Commission of art may be a form to develop health specific messages. An open communication between the commissioner and the artist will maintain the integrity of the message within a free expression from the artist[1,2]. A few examples will be presented.

POTENTIAL MECHANISMS FOR TANGO AND BONE

K. M. Javaid[1]

[1]Rheumatologist, Professor of osteoporosis and adult rare bone diseases, NDORMS, University of Oxford, Medical Sciences Division, Oxford, United Kingdom

Tango, a beautiful and passionate dance, became a popular dance form around the world since its birth in 19th century in Argentina and Uruguay. Several possible health benefits have been adjudicated to Tango, including cardiovascular health, improved balance and coordination, mental health, weight loss and increased flexibility[1]. Several publications have focused on some of those benefits[2] and there is even a meta-analysis on its effect on Parkinson's disease[3]. Patients with osteoporosis, particularly those with fractures, show significant impacts on physical function[4]. Patients with osteoporosis commonly present some barriers to overcome those limitations, including fear of fracturing and lack of knowledge on key exercise components[5]. Although research is still limited, there are several possible positive impacts of tango dancing in those patients.

MULTIPLE SCLEROSIS. AN AUTOIMMUNE DISEASE

I. Kostoglou-Athanassiou[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Multiple sclerosis is a systemic autoimmune disease which results in demyelination of central nervous system neurons. The disease has a variable course and may run either a rather benign course or a progressive course leading to disability. Multiple sclerosis may be associated with osteoporosis which may lead to fractures. Multiple sclerosis is treated with immunomodulatory agents, including corticosteroids which may affect bone metabolism. In addition, the disease itself is an autoimmune disease. Autoimmune diseases are accompanied by the release of inflammatory cytokines which induce osteoclastogenesis, affect bone metabolism and may induce osteoporosis. Multiple sclerosis may be associated with vitamin D deficiency. Vitamin D deficiency may induce osteomalacia and secondary osteoporosis. Multiple sclerosis causes mobility limitation which may also affect bone metabolism and may induce muscular dysfunction which affects bone metabolism. Multiple sclerosis is also accompanied by dysautonomia or the dysregulation of the autonomic nervous system. Dysautonomia may cause osteoporosis via multiple mechanisms.

NSS34

OSTEOPOROSIS IN THE CONTEXT OF MULTIPLE SCLEROSIS

L. Athanassiou[1]

[1]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece

Multiple sclerosis is accompanied by an increased risk of osteoporosis which may lead to fractures. Multiple sclerosis causes demyelination, inflammation and neuronal axonal damage which leads to disruption of neuronal function. Disrupted neuronal function causes muscle weakness, sensory function impairment and impairment of balance and vision. Multiple sclerosis leads to reduced bone mass and osteoporosis. It has been suggested that multiple sclerosis is a cause of secondary osteoporosis. Various factors lead to osteoporosis. Reduced physical activity and limited exposure to mechanical load of the bones contributes to osteoporosis. Vitamin D deficiency may also be implicated in the pathogenesis of osteoporosis in the context of multiple sclerosis. Vitamin D deficiency has been observed in multiple sclerosis and may be implicated in the disease pathogenesis. The use of immunomodulatory agents, corticosteroids in particular, may also be implicated in the pathogenesis of osteoporosis. Thus, osteoporosis is a characteristic of multiple sclerosis and may lead to fractures.

NSS35

TREATMENT OF OSTEOPOROSIS IN MULTIPLE SCLEROSIS

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Multiple sclerosis may be associated with osteoporosis and fractures. A scoring system has been developed for the assessment of the risk for the development of osteoporosis and fractures in multiple sclerosis patients, which takes into account traditional risk factors as well as the use of various drugs such as antidepressants and anticonvulsants as well as the history of falls. Osteoporosis is a multifactorial disease and should be treated by a multidimensional way including modification of the way of life, involving cessation of smoking and alcohol and augmentation of physical activity. All the medications applied in the treatment of osteoporosis may be used in patients with multiple sclerosis. Bisphosphonates, in particular alendronate in the effervescent form may be applied in the treatment of osteoporosis in multiple sclerosis. Denosumab may also be applied. However, when denosumab is withdrawn, alendronate should be used in order to stabilize bone mineral density. The use of calcium and vitamin D is also essential in the management of osteoporosis in the context of multiple sclerosis.

NSS36

FALLS AND PREVENTION IN MULTIPLE SCLEROSIS

Y. Dionyssiotis[1]

[1]Physical Medicine and Rehabilitation Department, National Rehabilitation Center EKA, Athens, Greece

Multiple sclerosis may be accompanied by osteoporosis. A propensity to falls is also observed in patients with multiple sclerosis. Osteoporosis and falls may lead to fractures. Fractures may need surgical management and may further compromise patient mobility in multiple sclerosis. Dysautonomia, mobility limitations and impaired bone metabolism as well as the use of drugs for the treatment of multiple sclerosis may contribute

to falls. Falls may lead to fractures and further limitations in mobility completing a vicious cycle. Falls should be prevented in patients with multiple sclerosis. The use of physical therapy in the management of multiple sclerosis may improve balance and may contribute to the prevention of falls. The use of walking aids may also contribute to the prevention of falls in the context of multiple sclerosis. It should be kept in mind that multiple sclerosis is a chronic disease, which may lead to further deterioration of mobility and a professional team should be helping the patient to improve mobility, balance and prevent falls.

NSS37

THE IMPACT OF VERTEBRAL COMPRESSION FRACTURES (VCF'S)

U. Akarırmak[1]

[1]İstanbul University-Cerrahpaşa, Faculty of Medicine, PM&R Department, Istanbul, Turkiye

Osteoporosis (OP) is defined as a systemic disorder characterized by low bone mass and weakening of bone with increased risk of fracture, with approximately 27% of fragility fractures occurring at the spine. VCF's in acute or chronic stages, are a major cause of pain, morbidity and disability. Back pain, height loss, spinal deformity, hyperkyphosis, decreased physical and reduced pulmonary function, loss of mobility and quality of life may be the outcomes. Another very important aspect is that VCF's are highly predictive of future vertebral and other osteoporotic fractures. About 55% of hip fracture patients have experienced a previous VCF. Nearly half of VCF's are not detected clinically or by radiology. Thoracic hyperkyphosis and other changes of spinal alignment in cervical and lumbar spine, cause a definite propensity to falls. Posture changes are associated with decreased spinal extensor muscle strength, increased spinal loads, unstable gait, loss of balance and increased risk of falls. All of these changes, also with the contribution of osteosarcopenia and weakening of quadriceps muscle strength are possibly responsible for the following vertebral fracture cascade.

Early detection of a VCF is of great value and should be assessed in all patients to ensure that patients receive OP treatment on time. Treatment of pain and OP in the patient with acute VCF, combined with pain medication, bracing, education and planning for osteoporosis treatment is the essential approach. The work up of the VCF patient and start of osteoporosis medication if possible within a few weeks have to be organized. In subacute and chronic stages of VCF tailored stabilization, posture and strengthening exercises, braces and rehabilitation are important issues. Also augmentation in selected patients has to be considered. Evaluation of balance status and falls risk is another crucial aim in the prevention of fractures and following functional impairments. A close follow up of the patient with VCF is the main goal for secondary prevention of further fragility fractures.

NSS38

KEY REHABILITATION PRINCIPLES IN VERTEBRAL FRACTURES

S. Tüzün[1]

[1]Istanbul University- Cerrahpaşa Faculty of Medicine, PM&R Department, Istanbul, Turkiye

Vertebral fractures due to osteoporosis are becoming increasingly common as the global population ages. Most patients with osteoporotic vertebral fractures remain asymptomatic, highlighting the silent nature of the disease. However, once a vertebral compression fracture occurs, it creates a biomechanical environment that predisposes individuals to additional fractures, initiating the so-called "vertebral fracture cascade." This cascade contributes to progressive kyphotic angulation, impaired biomechanics, and an increased risk of falls, leading to a vicious cycle in osteoporotic patients. As such, managing the osteoporotic spine is a crucial component of osteoporosis care.

Rehabilitation plays a pivotal role in breaking this cycle by preserving spinal stability and improving muscle strength through tailored exercise programs. Effective rehabilitation goals include muscle re-education, resistance training for strength enhancement, proprioception improvement, bone mineral density optimization, pain relief, and reduction of kyphosis.

A comprehensive assessment of the spinal status is essential prior to initiating any rehabilitation program. This includes evaluating posture, kyphotic angle, acute or chronic vertebral fractures, and the presence of painful paravertebral muscle spasms. Strengthening the back extensor muscles is particularly critical, as these muscles are vital for spinal stability and alignment.

In cases of recent vertebral fractures, rehabilitation should begin cautiously, often with exercises in the sitting position, and progress gradually. Weight-bearing and loading exercises are generally more effective than endurance exercises for increasing bone density. Strengthening the axial musculature improves spinal mobility, reduces kyphosis, and decreases the risk of further vertebral fractures.

Non-weight-bearing activities such as swimming and cycling, while not directly improving bone density, are valuable components of the rehabilitation plan. These activities enhance neuromuscular coordination, balance, and overall physical function, thereby reducing the risk of falls and associated complications.

Rehabilitation for vertebral fractures must be personalized, taking into account the unique needs and physical condition of each patient. A well-structured and individualized approach is essential for optimal outcomes in managing vertebral fractures and improving quality of life in patients with osteoporosis.

NSS39

BRACING IN VERTEBRAL FRACTURES: MYTHS AND FACTS

R. Terlemez[1]

[1]İstanbul University-Cerrahpaşa, Faculty of Medicine, PM&R Department, Istanbul, Turkiye

Vertebral compression fractures are the most common type of osteoporotic fragility fracture, which represents a major cause of morbidity and significant cost to the healthcare system. The management of acute vertebral compression fractures remains controversial. Differences in management strategies may arise from the fact that these injuries are managed by physicians from different specialities. In fact, variations in the use of braces are one of the most debateable issues in clinical practice. But there is no confusion that the pain control, early mobilization, and neurologic stability are the primary goals of the treatment.

Braces have been shown to reduce pain, but their effects on long-term functionality and fracture progression could not been demonstrated. Additionally, recent studies showed that there is no superiority between rigid and soft braces in terms of long-term pain or functionality. For females over 50 with thoracic and lumbar compression fractures, there is moderate quality evidence to support the use of rigid bracing for up to six months following injury. Considering both patient compliance and cost-effectiveness, soft braces appear to be a suitable option especially for pain control. Additionally, rigid bracing can precipitate skin breakdown, negatively impact pulmonary mechanisms, and increase caretaker burden. As such, an initial use of soft bracing for compression fractures may be a reasonable alternative to rigid orthosis. Regardless of the type of brace used, the likelihood of a severe failure resulting in neurological deficit is very low for patients with compression fractures. In fact, the evidence indicates that the primary advantage of bracing is a slight improvement in short-term pain management.

Following an acute vertebral compression fracture, more focus should be placed on osteoporosis assessment/ optimization and less on rigid bracing. This is particularly valid in cases where the patient is not previously diagnosed with osteoporosis. The presence of a single vertebral compression fracture increases the risk of subsequent fractures by fivefold and the risk of hip and other fractures by up to three folds.

NSS40

VERTEBRAL AUGMENTATION: WHO AND WHEN?

C. Öztürk[1]

[1]Istinye University Medical School, Orthopaedic Spine Surgery, Istanbul, Turkiye

The management of spinal injuries in osteoporotic patients focuses on achieving optimal clinical outcomes by ensuring spinal stability and, when necessary, optimizing neurological function. Effective treatment should mitigate the detrimental effects of injury, alleviate pain, enhance functional recovery and quality of life, and minimize associated morbidity.

In osteoporotic patients without neurological deficits, vertebral augmentation techniques such as indirect reduction with kyphoplasty, titanium vertebral body stents, or percutaneous cement-augmented pedicle screw fixation (with or without kyphoplasty or stenting) are commonly employed. In contrast, patients with neurological deficits require anterior decompression through mini-open or endoscopic approaches to address the compromised neural elements.

Comparative studies of kyphoplasty and titanium implants reveal similar biomechanical properties; however, kyphoplasty involves the use of significantly more cement. Titanium implants, on the other hand, better maintain anterior vertebral height, offering an advantage in preserving spinal alignment.

For thoracolumbar fractures without neurological deficits, particularly in flexion-distraction injuries or burst fractures with a flexion-distraction component, bone cement-augmented posterior percutaneous pedicle screw fixation combined with titanium vertebral body stents is recommended. Indications for vertebral augmentation include:

- Deficiency of anterior bone stock on CT
- Vertebral body height loss exceeding 30%
- Sagittal index between 15 and 25 degrees.

In the absence of these indications, percutaneous pedicle screw fixation alone can suffice, providing tension band stability.

In cases involving neurological deficits or when fractures progress to necrotic bone, mini-open anterior support and/ or decompression, as well as endoscopic decompression with instrumentation, are critical for effective management.

By carefully evaluating individual patient profiles and fracture characteristics, clinicians can determine the most appropriate timing and method of vertebral augmentation to ensure optimal outcomes in osteoporotic vertebral fractures.

NSS41

WHAT DO WE KNOW ABOUT OSTEOARTHRITIS: DOES IT TRANSLATE BETWEEN AFFECTED SPECIES?

E. Troncy[1,2], A. Delsart[1], M. Frezier[1], M. Lefort-Holguin[1], C. Otis[1], A. Castel[1,3], B. Lussier[1,2,3], M. Moreau[1,2], J. Martel-Pelletier[1,2], J.-P. Pelletier[1,2]

[1]Groupe de recherche en pharmacologie animale du Québec (GREPAQ), Université de Montréal, Montréal, Canada, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montréal, Canada, [3]Department of Clinical Sciences, Faculty of Veterinary Medicine, Université de Montréal, Montréal, Canada

Objective: To edit a narrative review comparing the osteoarthritis (OA) phenotype observed in natural models of OA in cats and dogs, as well as in experimental models in rats when justified.

Material and Methods: Data extraction from the literature and a 30-year experience in studying OA in pets focused on comparing different aspects of the OA phenotype: 1) prevalence; 2) localization; 3) risk factors; 4) detection and diagnosis; 5) OA mechanisms from the joint to nervous system alterations.

Concurrent validation of experimental OA models was conducted when justified.
Results: Osteoarthritis is a degenerative joint disease that has long been recognized as a major cause of chronic pain in cats and dogs. In Western countries, its prevalence is approximately 25% in the adult population and can reach as high as 65-85% in older animals. It could be of primary (mostly in cats) or secondary (in dogs) origin, and risk factors include congenital joint malformations (such as dysplasia), post-traumatic issues, sterilization, size and weight, as well as environmental factors (obesity, excessive activity). It affects all appendicular joints (hip, stifle, hock and elbow) as well as the (lumbar) vertebral axis (cats). A trilogy of OA-associated pain is observed in pets, including biological (functional dysfunctions), psychological (behavioural changes, cognitive dysfunction) and social (changes in human-animal and animal-animal interactions) dimensions. Originally, the emphasis was placed on the biomechanical pain associated with cartilage degeneration and joint (articular) sclerosis. This perspective has evolved to incorporate structural remodelling, including neuroplasticity and peripheral and central sensitization. Chemical OA models in rats lack face validity, whereas the MI-RAT© model, which involves surgically-induced stifle instability and calibrated treadmill exercise, has been validated for spinal neuropeptidomics, neuroepigenetics, structural changes, and pain phenotype.
Conclusion: The translation of experimental animal pain to natural OA models is becoming increasingly appropriate for better characterization and proposal of effective clinical treatments of chronic pain.

NSS42

SOMATOSENSORIAL AND NEUROLOGICAL ALTERATIONS IN FELINE AND CANINE OSTEOARTHRITIS

A. Delsart[1], A. Castel[1,2], C. Otis[1], B. Lussier[1,2,3], F. Péron[4], N. Quaegebeur[5], P. Grandjean[5], M. Moreau[1,3], J. Martel-Pelletier[1,3], J.-P. Pelletier[1,3], E. Troncy[1,3]

[1]Groupe de recherche en pharmacologie animale du Québec (GREPAQ), Université de Montréal, Montréal, Canada, [2]Department of Clinical Sciences, Faculty of Veterinary Medicine, Université de Montréal, Montréal, Canada, [3]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montréal, Canada, [4]Parc de la Chapelle, Plescop, France, [5]Groupe d'acoustique de l'Université de Sherbrooke (GAUS), Department of Mechanical Engineering, Université de Sherbrooke, Sherbrooke, Canada

Objective: To evaluate whether sensitization is linked to deficits in stimulus transmission and integration or co-morbidities. The hypothesis proposed that hypersensitized individuals face a higher risk of nerve conduction damage, sensory changes, and cognitive decline.
Material and methods: Healthy (H) and osteoarthritic (OA) adult neutered cats (n=6 H, n=12 OA) and dogs (n=4 H, n=8 OA for nerve conduction) were assessed for peripheral (paw withdrawal threshold, PWT) and spinal (response to mechanical temporal summation, RMTS) sensitization, with lower values indicating higher levels of sensitization. Nerve conduction (motor and sensory) of the tibial and ulnar nerves was tested under standardized general anesthesia. Stimulus integration was recorded with somatosensorial (SEP), auditory (AEP) and visual (VEP) evoked potentials under dexmedetomidine sedation. Sensorial perception was evaluated for olfaction (binary behavioural response – repulsion to unpleasant odour) and audition (number of high-frequency sound repeated stimuli). Statistical analyses were based on data distribution (α=0.05).
Results: The OA cats or dogs experienced a decrease of more than 20% in their tibial and ulnar nerve amplitudes and velocities compared to H (P<0.05). The OA cats showed increased SEP and AEP latencies and amplitudes (P<0.036) but displayed lower VEP (P<0.046) results compared to H. The PWT was positively correlated with nerve conduction velocity (r>0.48, P<0.045) and VEP (ρ=0.747, P=0.004) results but negatively correlated with SEP (ρ=-0.428, P=0.037) and AEP (ρ=-0.800, P=0.003) latencies. The RMTS score was positively correlated with VEP latencies (ρ=0.589, P=0.042) and negatively with SEP latencies (ρ=-0.484, P=0.017), smell aversion (ρ=-0.653, P=0.026) and responses to auditory stimulation (ρ=-0.811, P=0.002).
Conclusion: Nerve conduction alterations were reported in individuals with OA. Hypersensitized cats were characterized by decreased nerve conduction amplitude and velocity, along with increased SEP and AEP latencies. These cats were more repulsed by unpleasant smells and less sensitive to repeated repulsive sounds. Chronic pain associated with OA is linked to alterations in nerve transmission, leading to changes in the perception of sensory stimuli. This raises concerns regarding the classification and therapeutic management of OA pain.

NSS43

EVIDENCE-BASED EFFICACY IN MANAGING OSTEOARTHRITIS IN COMPANION ANIMALS

E. Troncy[1,2], A. Delsart[1], M. Lefort-Holguin[1], C. Otis[1], A. Castel[1,3], B. Lussier[1,2,3], M. Moreau[1,2], J. Martel-Pelletier[1,2], J.-P. Pelletier[1,2]

[1]Groupe de recherche en pharmacologie animale du Québec (GREPAQ), Université de Montréal, Montréal, Canada, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montréal, Canada, [3]Department of Clinical Sciences, Faculty of Veterinary Medicine, Université de Montréal, Montréal, Canada

Objective: Conduct a scoping review on the pharmaceutical and non-pharmacological management of osteoarthritis (OA) in dogs and cats.
Material and Methods: Data were extracted from the literature, and a classification of therapeutic approaches was proposed based on their efficacy and the quality of the referenced studies. The quality of each study was evaluated through its experimental design, such as randomized, blinded, prospective, placebo-controlled, and the use of objective, validated pain assessments

(favoured over subjective non-validated scales) and their statistical analysis.

Results: Over the past 30 years, the efficacy of non-steroidal anti-inflammatory drugs (NSAID) for treating OA in dogs and cats has been documented in 40 and 15 publications, respectively. However, many of these studies have significant shortcomings that raise concerns about the reliability of their findings. For example, only 13 studies in dogs and 8 in cats used objective assessment measures such as podobarometric gait analysis or actimetry. The remaining studies relied on subjective evaluation scales that were only partially validated, if at all. Side effects were well-documented and continue to be a major concern with NSAID use, particularly in cats. Other analgesic treatments that have been explored include anti-NGF monoclonal antibody (mAb), tramadol, gabapentin, and the anti-viral drug amantadine. The two latter treatments provided limited evidence of efficacy, supported by only a few studies. While mAb gained immediate popularity, their indications for use remain unclear and comprehensive guidelines for their safe and efficient application (safety of drug combinations, emergence of subpopulations more sensitive to side effects) are lacking. Despite the publication of 25 articles regarding disease-modifying OA drugs (DMOAD) in dogs, none demonstrated compelling structural or analgesic efficacy. Caloric restriction and omega-3 polyunsaturated fatty acids (marine oil or green-lipped mussels) were identified as the most effective non-pharmacological therapies, with an impressive effect size of $d = 0.99$. Both joint injections of biologics and physiotherapeutic modalities showed limited evidence of effectiveness. No studies have specifically addressed sensitization as a treatment option, while other therapies offered only anecdotal evidence; however, sensorial enrichment appears promising.

Conclusion: Pets have a more extensive therapeutic arsenal than humans with OA, but it is still not perfect.

NSS44

GUIDELINES ADDRESSING IMMINENT RISK STRATEGIES

A. F. Coy[1,2]

[1]Fundacion SantaFe Bogota, Bogota, Colombia, [2]Professor of Internal Medicine Universidad del Bosque y Universidad de los Andes, Bogota, Colombia

Osteoporotic fractures increases fracture risk, disability and mortality. According to ASBMR/BHOF 2024, definition of imminent risk is a patient with a recent fracture or condition which translates into higher risk of subsequent fractures. On this scenario clinician shall consider different options available to in order decrease the risk of fractures.

Pharmacological interventions for imminent risk shall act quickly and reduce fracture risk as much as possible. Anabolic agents are the first choice. Starting treatment with anabolic is also ideal given that, when followed by antiresorptives, BMD increases continuously in opposite to what happens when anti-resorptives are used before osteoanabolics.

Osteoanabolic therapy have more probalitity of achieving higher targets. The Dutch guideline of osteoporosis and fracture prevention, published in 2024, does not consider imminent but high risk. It states that teriparatide should be given to postmenopausal women with a T score ≤ -1.5 in the femoral neck, total hip or lumbar spine and at least 2 grade 2 vertebral fractures or 1 grade 3 vertebral fracture and romosozumab should be considered with T score ≤ -2.5 in the femoral neck or total hip and at least 1 grade 2 or 3 vertebral fracture or a T Score ≤ -2 in the femoral neck or total hip and at least 2 grade 2 or 3 vertebral fractures.

The Endocrine Society guideline, published in 2020, does not use the term imminent risk but rather high and very high risk. The algorithm doesn't imposes anabolic-first approach but also recommends zoledronic acid and denosumab.

European guidelines for osteoporosis in postmenopausal women, published in 2019, also brings the definition of very high risk but does not go into details about antiresorptive or anabolic-first treatments.

This part of the session will address the guidelines that introducet the concept os very high and risk as well the recommended pharmachological options for each one of the guidelines.

TREATMENT DISCONTINUATION AND INTERMITTENT USE OF BISPHOSPHONATES

G. Altamar[1]

[1]Specialist in Internal medicine and Geriatrics ; Specialist in Health management ; Professor of Geriatrics – Universidad del Valle ; Colombian Osteoporosis Association (ACOMM) President, Cali, Colombia

Osteoporosis is a silent chronic disease characterized by reduced bone strength and increased risk of fracture. Since osteoporosis is a lifelong disease, attention to a prompt and long-term reducing fracture risk is necessary, so the beginning and the sequences of pharmacological treatment need to be accounted. As the guides encourage, start with osteoanabolic therapy is mandatory for patients with very high risk of fracture. After completing a course of therapy and once they have reached a treatment target, they should be switched to a high potent antiresorptive drug like denosumab (DMAB) for 5 to 10 years. In a future evaluation, when fracture risk is acceptable or no longer imminent or high risk for fractures, DMAB could be discontinued, but this is not an easy task. In this scenario, considering the pharmacodynamics of antiosteoporosis medications, two different regimens have been proposed, oral alendronate (ALN), starting 6 months after the last denosumab injection or zoledronic acid (ZOL) 9 months after the last DMAB injection.Once a patient reaches an acceptable fracture risk or treatment target, they can move from trying to achieve a higher BMD or reaching a lower fracture risk. This can be achieved with short, intermittent courses of an oral bisphosphonate such as ALN every two years or with infrequent doses of ZOL every 3 to 5 years. This last practice, known as intermittent therapy, promotes enhancement and consolidates the benefits achieved, especially in reduction of their fracture risk and maintenance of bone mineral density (BMD).

NSS46

SEQUENTIAL AND COMBINATION THERAPIES MOSTLY SUPPORTED OR AVOIDED

B. Muzzi Camargos[1]

[1]Densitometry Unit Coordinator - Rede Materdei de Saúde, Belo Horizonte, Minas Gerais, Brazil

The sequencing of pharmacological interventions on osteoporosis is recommended irrespectively large clinical studies for fracture outcomes are scarce.

When considering therapeutic sequencing or combinations, it is important to evaluate wheter an ongoing intervention has been successful or not.

The occurrence of a fragility fracture or a significant BMD loss, during treatment, imposes major changes on the risk stratification. One example is the widely recommended introduction of an osteoanabolic medication after a fragility fracture for patients previously on resorptives like hormone replacememt therapy, bisphosphonates and denosumab.

The discontinuation of denosumab elicits to a rebound effect with higher bone resorption rates wich demands an immediate usage of potent anti-resorptive medications such as alendronate or zoledronic acid. Although the exact pathophysiology of this phenomenon is not clear, the detrimental effects of denosumab discontinuation should be avoided at all costs.

There is also evidence regarding the risk of transitioning from denosumab to teriparatide. On this switch, a rapid decline in spine BMD may occur at the hip and distal radius. Incremental changes on bone remodeling can be deleterious for skeletal health within the first six months.

Another potentially ominous situation is the simultaneous - or combined - use anti-resorptives like two different bisphosphonates and the combination of bisphosphonates with denosumab. There are serious concerns about a potential oversuppression of bone turnover leading to higher risk of atypical femur fractures and osteonecrosis of the jaw.

A similar strategy is recommended after osteoanabolic treatment cessation when an oral or intravenous bisphosphonates are recommended to the maintenance of teriparatide's benefits. On this case, denosumab showed higher BMD improvements than alendronate.

Other medication regimens widely recommended or avoided for osteoporosis treatmemt will be addressed in this part of the session.

BONE HEALTH IN PATIENTS WITH NON-METASTATIC PROSTATE CANCER ON ANDROGEN DEPRIVATION THERAPY (ADT) – AN OVERVIEW

N. Napoli[1]

[1]Unit of Endocrinology and Diabetes, Department of Medicine, Università Campus Bio-Medico di Roma, Rome, Italy

Androgen deprivation therapy (ADT) is the main treatment of patients with non-metastatic prostate cancer. Except for estrogen and androgen receptor inhibitors, ADT results in a drastic drop in testosterone level, to less than 5% of normal levels. Testosterone deficiency and therefore estrogen deficiency, sarcopenia, increased adiposity and insulin resistance, and concomitant glucocorticoid treatment, are all contributing factors that negatively affect bone health in patients with prostate cancer on ADT. The rate of bone loss on ADT is as high as 4-10% in years 1 and 2, and continues at a lower rate thereafter. ADT is associated with an increased relative risk of any fracture and of hip fracture by 20-70%, compared to controls.

Recent data derived from trials on androgen receptor inhibitors (apalutamide, enzalutamide, darolutamide) in patients with non-metastatic prostate cancer show an associated increased risk of falls and fractures. Further studies are needed to elucidate the mechanism of the musculo-skeletal impact of these agents.

NSS48

SUMMARY OF THE EVIDENCE ON BONE AGENTS IN PATIENTS WITH PROSTATE CANCER ON ADT

M. Chakhtoura[1]

[1]American Univ. of Beirut, Beirut, Lebanon

We conducted a systematic review and meta-analysis of randomised controlled trials in men with non-metastatic prostate cancer on androgen deprivation therapy (ADT), receiving bisphosphonates (BP), denosumab (Dmab) or placebo/control. We identified 23 trials on BP (17 trials on zoledronic acid and 5 trials on oral BP), and 2 trials on Dmab. There was no reduction in fracture risk with oral or intravenous BP. One trial on Dmab showed a significant reduction in the risk of new morphometric fracture, diagnosed based on findings of T4-L4 radiographs, by 85% at 12 months and by 69% at 24 months.

Treatment with BP or Denosumab for 12 months increased bone mineral density at the hip by 1.5-3.8%, and at the lumbar spine by 4.0-6.8%, compared to placebo/control. The most reported adverse events were gastrointestinal side effects across all types of antiresorptives, followed by acute phase reactions, jaw osteonecrosis and hypocalcemia.

NSS49

RECOMMENDATIONS FOR THE MANAGEMENT OF PATIENTS WITH PROSTATE CANCER ON ADT

D. Kendler[1]

[1]UBC Division of Endocrinology, Vancouver, Canada

Denosumab is FDA approved for fracture prevention in patients with prostate cancer on ADT. Oral and intravenous bisphosphonates were shown to prevent bone loss, while data on fracture is scarce. All patients with prostate cancer on ADT should have a baseline bone mineral density and fracture risk assessment using FRAX

The indications to start a bone active agent in this population include the presence of a previous fragility fracture at > 50 years, a T-score at the lumbar spine or at the hip ≤ −1.5, or a T-score between -1.5 and -1 in the presence of one or more risk factors (age >65 years, smoking, BMI <24 kg/m^2, family history of hip fracture and the use of oral glucocorticoids for > 6months), or a high FRAX above the intervention threshold for major osteoporotic fractures, according to each country's osteoporosis guidelines.

NSS50

LESSONS LEARNED FROM IMPLEMENTING AND MAINTAINING FLS IN SINGAPORE

M. Chandran[1]

[1]Osteoporosis and Bone Metabolism, Unit Department of Endocrinology, Singapore General Hospital, DUKE NUS Medical School, Singapore, Singapore

The implementation of Fracture Liaison Services (FLS) in Singapore underscores the critical importance of secondary fracture prevention in an aging population. Setting up the OPTIMAL secondary fracture prevention program at Singapore General Hospital in 2008 and running it albeit with many ups and downs over the last 17 years has been a fulfilling yet challenging journey. We initiated this program with the conviction that a Fracture Liaison Service (FLS) is essential for improving patient outcomes and reducing the burden of fragility fractures While the program has had immense success in identifying and assessing many patients with fragility fractures, sustaining its success has required constant innovation and collaboration.

A significant challenge is overworked manpower, with the team stretched thin between patient care and program operations. Frequent leadership transitions exacerbate this, as each new head of our collaborating departments requires reorientation to the program's goals. Misconceptions among healthcare providers—such as the belief that FLS can only succeed if osteoporosis medications are provided for free are a stumbling block, overshadowing the program's broader value which extends beyond pharmacotherapy to encompass patient identification, diagnostic workup, follow-up, and education.

Patient follow-up is another persistent issue. It is not feasible to keep stable patients on anti- osteoporosis medications in the hospital system. On the other hand, the issue of who will provide continuity of care if they are discharged to primary care remains a

challenge. To address this, we are collaborating with departments like Geriatrics and our polyclinics to develop clear discharge criteria and shared care protocols.
The lack of funding for osteoporosis medications and continued care in polyclinics due to block funding models adds another layer of complexity. This system covers fracture care but excludes key components of osteoporosis management, leaving gaps in care. We are advocating for policy changes, including expanding funding to cover medications, DXA scans, and follow-ups, and demonstrating the cost-effectiveness of integrated care through pilot studies and economic modeling.
We are also looking at innovative ways to enable early identification and assessment of patients with osteoporosis and fragility fractures. This includes LLM models to identify second fractures that occur in patients in between clinic visits and AI solutions that identify osteoporosis from radiological images performed for other reasons.
Despite the challenges, the program underscores the critical value of interdisciplinary collaboration, technology-driven solutions, and stakeholder engagement. The lessons learned reaffirm that secondary fracture prevention is not only a clinical necessity but a sustainable model of care. Our focus now is on scaling the program, embedding it into routine care, and ensuring that no patient at risk of secondary fractures is left behind. Simply put, FLS makes both clinical and health economic sense.

NSS51

LESSONS LEARNED FROM MENTORSHIP IN SWITZERLAND

T. Chevalley[1]

[1]Service of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, 1211, Geneva 14, Switzerland

Fragility fractures are a major concern for public health in Switzerland representing 82,000 fragility fractures per year in 2019, with an expected increase of 37.5% of this number by 2024 with significant associated costs. Thanks to a mentoring program under the direction of the Swiss Association Against Osteoporosis (ASCO/SVGO), the implementation of FLS in Switzerland has increased significantly over the last 4 years, from 10 in 2020 to 22 FLS mapped on the Capture the Fracture Map of the Best Practice Framework. This mentorship program is essentially based on two major events per year which are organized for team members already involved in FLS or for those who wish to create a new FLS: an online coaching clinic in the spring delivered both in French and German to allow a better interaction of participants in their mother tongue and a face to face Swiss/ALPS FLS Network Meeting in autumn. Before this FLS Network Meeting, the champions of the FLS fill out a questionnaire on their activity during the previous year (and sometimes a poster), and thus the progression of the main key performances indicators can be shared between the FLS. In addition, the FLS are also asked to describe what were their major accomplishment and greatest challenge during the previous year. To encourage exchanges of experiences between the FLS team members during these events, workshops on different topics are addressed such as: Collaboration with GP's, FLS education material for GPs & patients; How to follow up patients (mail, phone, person…..); Identification of Previously Unrecognized Vertebral Fracture. The major objective of this mentorship program is to increase and consolidate the interactions of members of the Swiss FLS network to ensure the development of new FLS and improve the quality of existing ones.

NSS52

NAVIGATING CHALLENGES IN THE FIGHT FOR FRACTURE LIAISON SERVICES IN SOUTH AFRICA

T. Hough[1]

[1]NOFSA CEO, Cape Town, South Africa

This abstract presents an overview of the Fracture Liaison Services (FLS) in South Africa and the role of the National Osteoporosis Foundation of South Africa (NOFSA) in the establishment and development of these services. It delves into the initiatives undertaken by NOFSA, the main challenges faced, moments of significant setbacks, and how we are trying to overcome these hurdles, culminating in valuable lessons still being learned!
Fracture Liaison Services are critical in managing patients with fractures, aiming to reduce subsequent fracture risk through comprehensive assessment and treatment plans. In South Africa, these services have proven essential but face numerous ongoing challenges due to resource constraints and awareness issues. NOFSA has been at the forefront, actively promoting FLS as a standard of care for fracture management. Though advocating for policy change, providing education, and fostering collaboration between healthcare providers is an ongoing struggle, NOFSA has spearheaded several initiatives to try and integrate FLS into the healthcare system.
One of the significant initiatives includes NOFSA's partnership with mostly private hospitals to establish pilot FLS programs, aiming to demonstrate the feasibility and benefits of structured fracture management. Despite these efforts, the journey has not been without challenges. Financial constraints, insufficient government and private Medical Aids support, as well as lack of public awareness have hindered widespread adoption. Specific obstacles have led to moments of defeat, such as the closure of some FLS programs and lack of funding, threatening the momentum of any progress made.
However, overcoming these challenges is possible through persistent advocacy, and international collaboration, especially from the IOF's Capture the Fracture (CTF) team. Learning from these experiences, NOFSA is trying to engage more stakeholders and leveraging data to highlight the cost-effectiveness of FLS. This data is however very sparse.
In conclusion, the case of FLS in South Africa underlines crucial lessons: the need for sustained advocacy, the effectiveness of collaborative networks, and the importance of data in driving funding and policy decisions. As the fight against osteoporosis and related fractures continues, these experiences provide crucial insights into developing sustainable healthcare interventions in resource-limited settings.

NSS53

THE GLOBAL BURDEN OF SARCOPENIA

F. Gimigliano[1]

[1]Department of Mental and Physical Health and Preventive Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy

Sarcopenia, a progressive loss of skeletal muscle mass, strength, and function, primarily affects older adults and represents a significant public health concern globally. Although it has been recognized as a disease (ICD-10: M62.84), there is no universally accepted diagnostic criterion, leading to considerable variability in prevalence estimates and complicating efforts to quantify its global burden. Prevalence rates vary widely depending on the diagnostic criteria applied, ranging from 10% to 27% in individuals over 60 years and peaking at 86% in some population subsets using certain muscle mass-only measures. Severe sarcopenia prevalence is reported between 2% and 9%. Men are generally more affected than women, particularly under diagnostic frameworks like the European Working Group on Sarcopenia in Older People (EWGSOP2), though opposite trends are observed with criteria like the International Working Group on Sarcopenia (IWGS).

The etiology of sarcopenia is multifaceted, involving biological, hormonal, and lifestyle factors. Its onset often begins as early as the fourth decade of life, with an accelerated decline in muscle strength relative to mass, highlighting the critical role of strength-based diagnostics. Sarcopenia is strongly linked to adverse outcomes, including increased risk of falls, prolonged hospitalizations, functional dependence, and higher mortality rates. Economic implications are substantial; in the United States alone, sarcopenia-related healthcare costs reached $18.5 billion in 2000.

This global health challenge disproportionately affects regions with aging populations, with the highest prevalence observed in Oceania and South America, particularly under EWGSOP definitions. Risk factors such as undernutrition, comorbidities, and inactivity exacerbate its impact. Despite advancements in understanding sarcopenia, the lack of standardized diagnostic and assessment tools hinders effective global surveillance and intervention development.

To mitigate sarcopenia's burden, future efforts should prioritize harmonizing diagnostic criteria, adopting population-specific cutoffs, and implementing comprehensive public health strategies. These include early detection, promotion of resistance training, adequate protein intake, and addressing underlying health disparities. Recognizing sarcopenia as a critical determinant of healthy aging is essential to reduce its societal and economic impacts.

NSS54

MULTIMODAL EXERCISE AND NUTRITION: THE PILLARS OF SARCOPENIA TREATMENT

G. Iolascon[1]

[1]Multidisciplinary Department of Medical and Surgical Specialties and Dentistry, University of Campania "Luigi Vanvitelli", Naples, Italy

Sarcopenia, characterized by progressive loss of skeletal muscle mass, strength, and function, is a significant challenge in aging populations. It contributes to increased fall risk, disability, and poor quality of life. Effective management requires a comprehensive approach emphasizing lifestyle modifications, particularly exercise and nutrition. This abstract synthesizes findings on multimodal strategies for treating sarcopenia, highlighting the synergistic role of physical activity and dietary interventions.

Resistance training (RT) is the cornerstone of sarcopenia management. It promotes muscle hypertrophy, enhances strength, and improves energy metabolism. Regular RT has been shown to counteract muscle atrophy even in chronic diseases and conditions associated with sarcopenia. While aerobic exercises primarily enhance energy metabolism, they also support physical function and cardiovascular and muscle endurance. A combination of RT and aerobic activities, often supplemented with balance and flexibility exercises, yields superior outcomes in muscle mass preservation and functional improvements.

Nutritional interventions complement exercise in sarcopenia management. Adequate protein intake, particularly leucine-rich sources, stimulates muscle protein synthesis. Supplements such as omega-3 fatty acids, vitamin D, and beta-hydroxy-beta-methylbutyrate (HMB) have shown promise in enhancing muscle mass and function. Emerging evidence also suggests that the gut-muscle axis, influenced by prebiotics and probiotics, may play a role in mitigating sarcopenia by modulating systemic inflammation and metabolic pathways.

For patients with frailty or other chronic conditions, personalized, multimodal approaches integrating tailored exercise regimens with nutritional optimization are crucial. This strategy not only addresses sarcopenia's multifactorial pathogenic mechanisms but also enhances overall health outcomes, functional independence, and quality of life. Ongoing research into the precise mechanisms of sarcopenia and its relationship with aging and chronic diseases underscores the importance of these pillars. While current findings advocate for combining exercise and dietary interventions, more high-quality trials are needed to refine guidelines for dose, intensity, and long-term adherence.

In conclusion, multimodal exercise and nutrition serve as the foundation for sarcopenia treatment, offering significant potential to mitigate its impact and improve the well-being of older adults. This integrated approach aligns with the principles of preventive and regenerative medicine, fostering resilience against aging-related muscular decline.

NSS55

DIGITAL TECHNOLOGIES IN SARCOPENIA TREATMENT: THE RIGHT THERAPY FOR THE RIGHT PATIENT

A. Moretti[1]

[1]Multidisciplinary Department of Medical and Surgical Specialties and Dentistry, University of Campania "Luigi Vanvitelli", Naples, Italy

Sarcopenia, a progressive loss of skeletal muscle mass, strength, and function, represents a growing concern in aging populations due to its association with decreased mobility, increased fall risk, and reduced quality of life. Despite advances in conventional treatments, delivering personalized and effective therapies remains a challenge. Emerging digital technologies—including artificial intelligence (AI), wearable devices, and mobile health platforms—are now revolutionizing sarcopenia management, offering innovative solutions for tailoring therapies to individual patient needs.

AI-powered tools such as smart insoles and pose estimation systems are paving the way for more precise diagnostics and interventions. By analyzing gait patterns and joint mechanics, these technologies facilitate the development of digital biomarkers, which can accurately classify and monitor sarcopenia progression. Smart insoles equipped with pressure sensors and inertial measurement units (IMUs) provide real-time feedback on movement and balance, while AI models process data to offer actionable insights. Pose estimation technology, using computer vision and deep learning algorithms, further enhances assessments by capturing detailed biomechanical data.

Wearable devices and mobile applications have also emerged as key enablers of remote rehabilitation and patient engagement. These tools support personalized exercise regimens designed to strengthen muscles, improve balance, and enhance overall physical function. For instance, telehealth platforms integrate wearable data to monitor adherence and provide real-time feedback, ensuring that patients perform exercises safely and effectively. Mobile apps featuring exercise demonstrations, reminders, and progress tracking enhance compliance and allow for adaptive adjustments based on individual performance.

Additionally, integrating nutritional and psychological interventions into digital platforms promotes a holistic approach to sarcopenia management. AI-driven dietary analysis tools and virtual coaching provide tailored nutritional guidance, while telepsychology services address the emotional and cognitive aspects of adherence to treatment.

This convergence of technology and healthcare underscores a shift toward patient-centered, data-driven care. By overcoming traditional barriers—such as accessibility, cost, and lack of personalization—digital health solutions enable scalable and efficient sarcopenia treatment. As research continues to refine these technologies, their integration into routine care has the potential to deliver the right therapy to the right patient at the right time, transforming outcomes for individuals affected by sarcopenia.

NSS56

BONE FRAGILITY AND OSTEOPOROSIS IN CHILDREN AND ADOLESCENTS: WHEN AND HOW TO DIAGNOSE IT?

Y. Makhlouf[1], L. Zakraoui[1]

[1]University Tunis El Manar, Faculty of Medicine of Tunis, Mongi Slim hospital, Rheumatology department, Tunis, Tunisia

Although rare, osteoporosis in children and adolescents requires prompt diagnosis to enable timely treatment and prevent long-term complications.

The diagnosis of osteoporosis among pediatric patients is defined by the presence of a low bone mineral density, indicated by a Z-score≤ -2.0 standard deviations, in conjunction with a clinically significant fracture history, or the occurrence of low-energy vertebral fractures.

Secondary osteoporosis is the most frequent form in pediatric populations and arises from various underlying conditions. Common causes include chronic inflammatory diseases such as juvenile idiopathic arthritis, prolonged use of glucocorticoids, endocrine disorders like malabsorption syndromes, and nutritional deficiencies (e.g., calcium or vitamin D). Affected children and adolescents should undergo a thorough diagnostic workup, including assessment of clinical history, radiography, biochemical investigation.

NSS57

BONE FRAGILITY AND OSTEOPOROSIS IN CHILDREN AND ADOLESCENTS: WHEN AND HOW TO TREAT IT?

S. Miladi[1], L. Zakraoui[1]

[1]University Tunis El Manar, Faculty of Medicine of Tunis, Mongi Slim hospital, Rheumatology department, Tunis, Tunisia

Children and adolescents with chronic diseases are at increased risk for bone fragility and subsequent osteoporotic fractures. Efficacy and safety of available treatment of osteoporosis prescribed for adults remain unclear in pediatric population.

Preventive strategies such as balanced diet, physical activity, optimized calcium and vitamin D intake are the keystone of management of osteoporosis in young patients.

Indication of anti-osteoporotic treatment do not relay on the results of the Bone mineral density but on the presence of non-traumatic fracture. Bisphosphonates seem to be safe and well tolerated in children. Recent studies are published on the safety and efficacy of targeted-drugs such as denosumab.

Algorithm of management of corticosteroid-induced osteoporosis on children and adolescents are different from other secondary osteoporosis. Preventive strategies remain an important pillar of the treatment. Bisphosphonates are indicated in case of high dose corticosteroids used for long period.

NSS58

A SIGNIFICANT PROBLEM FOLLOWING OSTEOPOROTIC FRACTURES: COMPLEX REGIONAL PAIN SYNDROME (CRPS)

Y. Gökçe-Kutsal[1]

[1]Hacettepe University, Faculty of Medicine, Department of Physical Medicne and Rehabilitation (retired), Ankara, Turkiye

Complex Regional Pain Syndrome (CRPS) is a chronic pain condition that primarily affects the distal extremities, characterized by abnormal sensory, motor, vasomotor, sudomotor, and trophic findings. It typically develops following fractures, surgeries, trauma, or strokes, with pain that is disproportionate in intensity or duration to the inciting event. The most common trigger is a fracture, particularly of the distal radius.

Notable risk factors for CRPS include advanced age, female sex, and osteoporosis. Pain and functional limitations in the affected limb frequently hinder daily activities and significantly impair quality of life. Women are four times more likely to develop CRPS than men, with incidence increasing with age and peaking between 50 and 80 years. In the United States, the 5-year incidence is approximately 0.079%, while in South Korea, the prevalence is 26 per 100,000 individuals.

The potential pathophysiological mechanisms underlying CRPS include central sensitization, vasomotor dysfunction, autoimmunity, inflammation, psychological distress, brain changes, and genetic predisposition. However, it remains uncertain whether these mechanisms are causative or secondary to the condition's symptoms.

Early diagnosis and treatment are crucial for achieving optimal outcomes. Diagnosis is guided by the Budapest criteria, which require: ongoing pain disproportionate to the inciting trauma, reported symptoms in three categories and observed signs in two categories (i.e., sensory, vasomotor, sudomotor/edema, and motor/trophic), exclusion of other plausible diagnoses through a thorough history and examination. The Valencia consensus has further refined the assessment of fluctuating symptoms, symptom spread beyond a single limb, and the definitions of asymmetry and related changes.

NSS59

CAN WE TREAT COMPLEX REGIONAL PAIN SYNDROME (CRPS) BY PHARMACOLOGICAL AGENTS?

Y. Kirazlı[1]

[1]Ege University, Medical Faculty, Department of Physical Medicine and Rehabilitation, Izmir, Turkiye

At present, there is no FDA-approved pharmacological treatment for patients with CRPS. A variety of pharmacological agents have been studied for CRPS, but most have been small and/or of low quality trials.

Bisphosphonates have emerged as an effective treatment for CRPS pain through interacting with the immune system and regulating expression of nerve growth factor. Meta-analysis shows that biphosphonates provided late (beyond one month) but not early (within one month) pain relief. Ketamine, a strong NMDA receptor antagonist, has been shown to be effective in the treatment of CRPS. IV ketamine infusion can provide clinically effective pain relief in the short term (three to four-weeks follow-up). Biphosphonates and ketamine showed more adverse events but no serious side effects compared with placebo.

Free radical scavengers such as DMSO and N-acetylcysteine (NAC) are widely used in the treatment of CRPS due to the excess free radical production generated by an overt inflammatory response to tissue injury. However, current studies have demonstrated no evidence to support the use of these.

There is evidence to support glucocorticoids in CRPS, but the ideal administration route and dose remain unclear. High doses of glucocorticoids have been found beneficial in CRPS, especially in its early stages. NSAIDs are being used in clinical practice to target the pain and inflammation underlying CRPS, but the study did not find a significant difference when compared with placebo. Significant reductions of pain and sensory disturbances in acute-stage CRPS patients were found on intravenously administered magnesium in a pilot study.

Careful selection and prompt initiation of appropriate pharmacotherapy may optimize pain relief in CPRS. Ketamine and bisphosphonates seem to be the best treatments for CRPS when compared with placebo without severe adverse events. However high-quality and long-term RCTs are still required.

NSS60

THE ROLE OF NON-PHARMACOLOGICAL APPROACHES IN THE MANAGEMENT OF COMPLEX REGIONAL PAIN SYNDROME (CRPS)

A. A. Küçükdeveci[1]

[1]Ankara University, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Ankara, Turkiye

Guidelines for the management of CRPS recommend an interdisciplinary/multidisciplinary, holistic, individually-tailored approach that incorporates pharmacological and non-pharmacological interventions. Non-pharmacological strategies include patient education, rehabilitation interventions, and psychological therapy. Rehabilitation, including physical and occupational therapy combined with relevant exercise program is the first-line treatment for CRPS and should be started as soon as possible together with pharmacological pain relief.

Rehabilitation interventions, usually administered as multi-modal therapies, aim to achieve functional restoration. Functional restoration emphasizes graded physical activity, desensitization and normalization of sympathetic tone, edema control, exercises for flexibility, isometric and isotonic strengthening as well as stress loading, and normalization of the use of the limb in daily life in the context of activities and participation. Various physical modalities (e.g TENS, fluidotherapy, therapeutic ultrasound, pulsed electromagnetic field therapy, low-laser therapy) can be used for their analgesic, anti-inflammatory and tissue-healing accelerating effects. Sensory-motor retraining approaches, mirror therapy and graded motor imagery, may improve disturbed body perception and cortical reorganisation thereby decreasing pain and disability. Pain exposure therapies may be appropriate for patients who have fear of movement. Recent systematic reviews on rehabilitation interventions in CRPS reported some evidence regarding the effectiveness of mirror therapy, graded motor imagery, pain exposure therapy, aerobic exercises, and multi-modal therapy. Evidence regarding other interventions was uncertain due the lack or low methodological quality of trials.

Psychological therapies aim to manage pain, distress and disability by addressing the psychological aspects of the condition. These therapies include cognitive behavioural therapy, acceptance and commitment therapy, counselling and relaxation techniques.

Interventional therapies, including sympathetic and other nerve blocks, neuromodulation techniques (transcranial magnetic stimulation, spinal cord stimulation, dorsal root ganglionstimulation) and neurolytic sympathetic procedures, can be offered for people who have severe pain and disabilty despite conservative treatments.

QUALITATIVE AND QUANTITATIVE CHANGE IN FLS/PFC IN LATAM. AN OVERVIEW

J. F. Torres-Naranjo[1,2]

[1]Centro de Investigación Ósea y de la Composición Corporal, CIO, Guadalajara, Mexico, [2]FLS Mentor and member of CTF Governance for LATAM, Mexico, Mexico

The Capture the Fracture (CTF) mentorship program has driven substantial growth in fracture liaison services (FLS) across Latin America, increasing the number of active FLS to 83 (Bronze, Silver, or Gold) and Best Practice Framework (BPF) applications. Patient enrollment has risen significantly, with treatment adherence projected to improve by 60%. Key achievements include the implementation of integrated electronic records and interdisciplinary care models. However, challenges persist, such as fragmented data systems and disparities in access. Future efforts aim to expand mentorship, standardize registries, and enhance evaluation capabilities to achieve a 30% reduction in refractures.

NSS62

KEY PERFORMANCE INDICATORS OF PFC/FLS IN LATAM. EXPECTED OUTCOMES BASED ON BC IN MEXICO AND COLOMBIA

A. Medina[1,2,3]

[1]Department of Endocrinology. Hospital de San José. Bogotá, Bogota, Colombia, [2]Asistant Professor Universidad Nacional de Colombia, Bogota, Colombia, [3]Associate Professor Fundación Universitaria de Ciencias de la Salud (FUCS), Bogota, Colombia

Objective: To describe KPIs performance before and after the occurrence of the IOF Capture the Fracture® Mentorship Programme in Latin America.

Methodology: Data was collected by the International Osteoporosis Foundation (IOF) Capture the Fracture® programme (CTF), Best Practice Framework (BPF) from 2019 to 2024. A multicenter longitudinal analysis was performed on the different KPIs in order to establish patterns for each country, as well as general trends in terms of absolute and relative frequencies. The information was analyzed in R version 4.3.2.

Results: CTF Mentorship Program has established a network of FLSs experts in different countries to foster secondary fracture prevention strategies by increasing the number and performance

of FLSs. In LATAM, the programme initiated in Mexico in 2019, followed by Brazil and Colombia in 2020 and Argentina in 2021.
Given the gap in treatment and follow-up of patients with fragility fracture, CTF developed a set of complementary KPIs.
The KPIs before mentoring (BM) were analyzed in 2019 and after mentoring (AM) in 2020-2023 for Mexico, Brazil, Colombia and Argentina. 2024 was not included since available data was incomplete.
According to the CTF BPF, a PFC/FLS is expected to identify more than 80% of patients with fragility fractures. Starting treatment at 16 weeks, follow-up of treatment, falls and refractures must be assessed. These indicators are classified as low, intermediate, or high (< 50%, 50–80%, and > 80%, respectively).
Identification of hip and vertebral fractures increased by 52% and 87% in 2021 respectively and decreased towards 2023. All patients with hip fracture were evaluated by the FLSs. The biggest difficulty was the access to densitometry in healthcare centers. As for treatment initiation before week 16, the number of FLS doubled AM as did the number of those whith a follow-up plan. AM 100% of FLSs re-evaluated treatment adherence, 90-100% of FLS carried refracture assessment AM vs 83% BM. Risk of falls was re-evaluated by 82% BM vs 100% AM.

Conclusion

KPIs improved after mentoring in the four LATAM countries where the CTF Mentorship programme was conducted. Specifically, indicators related to fracture identification, evaluation and treatment initiation. Additonally, the mentorship programme contributed to improving performance assessment of PFC/FLS.

NSS63

SUCCESSFUL COUNTRY SPECIFIC STRATEGIES TO IMPROVE AND INCREASE THE NUMBER OF FLS

E. Castro Osorio[1]

[1]University of Caldas, Caldas, Colombia

After FLS mentors were trained, a country specific plan was developped in order to assess current status of FLS already mapped on the CTF map of best practice to specifically assess their state of development, key challenges and topics of interest of FLS coordinators. The initial diagnosis was made through country surveys lead by the IOF regional office and the country mentors. Based on the findings, country specific mentors and the IOF regional teammembers designed tools aimed to create a knowledge community of FLS, support health medical teams to initiate post fracture care programmes as well as contribute with FLS teams to set quality improvement plans and influence national policy members to foster secondary fracture prevention programmes. Several editions of IOF copyright activities took place from 2021 to 2024 in Argentina, Brazil, Colombia and Mexico. As a result, the number of FLS in Latin America increased from 45 in December 2019 to 141 in December 2024, with 45 FLS submitting new data and improved own category with the CTF programme. From a policy perspective, the mentroship programme was also key in the road to reach an strategic collaboration with Mexico IMSS orthogeriatric strategy (which added 10 new country specific mentors), develop the budget benefit calculator for Mexico and Colombia, set a national secondary fracture prevention coalition in Mexico (who penned the Call to Action Mexico[1] published in june 2024).

NSS64

CHALLENGES AHEAD. GATHERING KEY DATA FOR MONITORING PERFORMANCE AND IMPROVING QUALITY OF PFC/FLS

M. Diehl[1]

[1]Hospital Italiano de Buenos Aires · Department of Internal Medicine, Buenos Aires, Argentina

FLSs and fracture audits aim to improve post-fracture care and outcomes based on local reality. Pasos® Program is a structured management model based on the Argentine Hip Fracture Registry, international standards and quality indicators for FLSs. It allows the gathering of key data including the initiation of osteoporosis treatment and adherence, aiming to improve care quality and optimize resources. Pasos represents a pioneering regional initiative to address these challenges effectively.

NSS65

PREGNANCY, AND LACTATION A CHALLENGE FOR THE SKELETON

A. Naglaa[1]

[1]Rheumatology, and Rehabilitation, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Both pregnancy and lactation are physiologic conditions mostly occurring in young women, in which calcium homeostasis is high. During this time, female physiology adapts to fulfill the fetal and neonatal calcium and phosphorus requirements. However, there is a small percentage of women that do experience fragility fractures during these times of life.
Pregnancy and lactation-associated osteoporosis (PLO) is an infrequent condition defined by the occurrence of non-traumatic fractures – most frequently vertebral – during the third trimester of gestation and/or the first months of postpartum.
Fractures may be also precipitated in lactating women by increased mechanical strain from the carrying and bending maneuvers with the baby and associated paraphernalia.
Almost a quarter of these patients will sustain a subsequent fracture, and this fracture risk correlates with the number of fractures at time of diagnosis.
Calcium homeostasis is significantly altered during lactation. Accordingly, many regulatory mechanisms such as renal calcium reservation, intestinal absorption, and bone resorption are stimulated. However; little is still known about the regulatory mechanism of calcium metabolism during lactation, and

according to recent studies, genetic factors might also play a relevant role in this condition.
Although there is consensus about discontinuation of lactation and calcium and vitamin D-supplementation as the first steps in the treatment of these patients, there is still controversy regarding the long-term and/or pharmacological management of this condition.
Use of anti-resorptive medications could conceivably blunt postweaning recovery, given that combination therapy blunts the effect of anabolic treatment in women with osteoporosis. The anecdotal data suggest that bone gains from anabolic treatment may persist in reproductive age women without anti-resorptive treatment.
However; women with PLO need to be informed about their potential subsequent fracture risk before deciding for further pregnancies.

NSS66
MOVEMENT RECOMMENDATIONS FOR PREGNANT AND LACTATING WOMEN

M. H. Abu-Zaid[1]

[1]Rheumatology, Faculty of Medicine, Tanta University, Tanta, Egypt

Health benefits of physical activity during pregnancy include reduced risk of excessive gestational weight gain and conditions such as gestational diabetes, preeclampsia, preterm birth, varicose veins, and deep vein thrombosis. There is some evidence that physical activity during pregnancy is associated with a reduced length of labor and delivery complications. However, vigorous leisure activity is associated with decreased birth weight.
Physical activity can decrease symptoms of postpartum depression. Combined with caloric restrictions, it can also help to lose weight after delivery.
Guidelines on physical activity during pregnancy provide recommendations for health professionals as to whether to prescribe physical activity and if so, in what manner. Guidelines from a variety of organizations help address questions about physical activity, such as how long, how far, how often, and at what intensity,
In 2020, the World Health Organization (WHO) released its guidelines on physical activity and sedentary behavior, In line with the global call for action, the development of national guidelines on physical activity has been encouraged and considered as a fundamental constituent of a coherent and comprehensive framework that outlines physical activity policies for public health action.
Recently published 24-hour movement guidelines for adults aged 18– 50 years old provided examples of integration of sleep, sedentary behavior, and physical activity with special consideration for pregnant and postpartum adult women. This should help in the decision-making process and are intended for endorsement by the policymakers.

NSS67
ABDOMINAL AORTIC CALCIFICATION, WHAT IT IS AND WHY IT IS IMPORTANT

J. R. Lewis[1]

[1]Nutrition and Health Innovation Research Institute, School of Medical and Health Sciences, Edith Cowan University, Perth, Australia

Background: In older individuals at high risk of musculoskeletal disorders, after the skeleton, the most calcified structure in the body is often the vasculature. One of the first sites where vascular calcification occurs is in the abdominal aorta. This abdominal aortic calcification (AAC) is commonly seen on lumbar spine and abdominal investigations, particularly vertebral fracture assessment in older people. Typically, it has not been reported due to uncertainty over its prognostic importance and difficulties assessing the extent of calcification. It is essential to improve our understanding of abdominal aortic calcification for both bone and vascular health during ageing.
Objectives: This presentation will provide an overview of how common AAC is, its links with subclinical cardiovascular disease in other vascular beds, how it differs from subclinical disease in other vascular beds and its prognostic importance for cardiovascular events and all-cause mortality from a systematic review and Meta-Analysis. We will also discuss the latest advanced in the automated assessment of AAC and the association with cardiovascular events in routine bone density testing and middle-aged community dwelling adult settings.
Results: AAC is one of the first sites where vascular calcification is observed and is related to risk of atherosclerotic vascular disease in other vascular beds. The prognostic importance of AAC for a multitude of cardiovascular outcomes has been established through a large systematic review and meta-analyses and provides complimentary prognostic information to coronary and carotid imaging. We have recently also published the methods for automated assessment of AAC on vertebral fracture assessment images using the Kauppila 24-point scoring system.
Conclusions: This presentation will provide an overview of what AAC is, what is not, and outline recent advances in the field as well as highlighting areas for future research.

NSS68
ABDOMINAL AORTIC CALCIFICATION AND MUSCULOSKELETAL OUTCOMES

P. Szulc[1]

[1]INSERM UMR 1033, University of Lyon, Hospices Civils de Lyon, Lyon, France

Background: Severe abdominal aortic calcification (AAC) is associated with poor musculoskeletal health status regardless of the method used for the AAC assessment (X-ray, DXA, CT, human reader, AI algorithm).
Objectives: Present the association between AAC and musculoskeletal outcomes.

Results: Severe AAC is associated with lower bone mineral density (BMD) measured by DXA. However, data are discordant and depend on the cohort (e.g., age range), statistical model (threshold for AAC, adjustments) and skeletal site. More limited data suggest poor bone microarchitecture (thinner cortices, lower trabecular number) in older adults with severe AAC. Some studies show more rapid bone loss in individuals with severe AAC, but the results are discordant. Severe AAC is associated with higher prevalence and incidence of fractures (Gebre, J Gerontol A Biol Sci Med Sci, 2023). The link between severe AAC and fracture is found consistently for the spine and hip fractures in men and women and after adjustment for confounders (age, BMD, prior fractures); however, the predictive power of AAC decreased with the follow-up duration. By contrast, the associations between AAC and non-spine-non-hip fractures were inconsistent. Data on the link between AAC and muscle mass and strength are more limited and discordant. Finally, severe AAC was also associated with higher risk of injurious fall necessitating hospitalization.
Conclusions: Several mechanisms may underlie these associations. AAC, poor bone status and low muscle mass and strength may share risk factors (smoking, inflammation, oxidative stress etc.). Severe AAC may impair blood supply of bone and muscles. Low muscle strength and cardiovascular diseases (of which AAC is a valuable marker) may jointly contribute to the higher risk of fall. Finally, poor bone status and falls may jointly contribute to the higher risk of fracture.

NSS69

ABDOMINAL AORTIC CALCIFICATION AS A NOVEL RISK FACTOR FOR FALLS AND FRACTURES IN ROUTINE CLINICAL PRACTICE

W. D. Leslie[1]

[1]University of Manitoba, Winnipeg, Canada

Background: Abdominal aortic calcification (AAC) is strongly associated with cardiovascular events. Emerging evidence suggest that AAC may also be a clinically useful marker for adverse musculoskeletal outcomes such as falls and fracture.
Objectives: Since 2010 the Manitoba BMD Program has been routinely using DXA-based vertebral fracture assessment (VFA) images to identify vertebral fractures in qualifying individuals. These same VFA scans can be used opportunistically to accurately score AAC using machine learning algorithms (ML-AAC). We review our experience with ML-AAC assessment in the routine clinical practice setting.
Results: Elevated ML-AAC scores robustly predict a range of major adverse cardiovascular events. More recently, we have shown that these scores predict risk for hospitalization-associated falls and incident fractures independently from other clinical risk factors. For example, increasing ML-AAC and vertebral fracture status contribute additively to risk for subsequent major osteoporotic fracture, hip fracture and any clinical fracture.
Conclusions: DXA-based vertebral fracture assessment (VFA) can be used in routine clinical practice for ML-AAC scoring in addition to vertebral fracture recognition. These complementary measures can contribute to risk assessment across multiple domains: cardiovascular, falls, and fracture.

NSS70

PROVISION OF ABDOMINAL AORTIC CALCIFICATION RESULTS TO PATIENTS

J. T. Schousboe[1]

[1]Park Nicollet Clinic and HealthPartners Institute, Minneapolis, United States

Background: Identification of abdominal aortic calcification (AAC) is potentially highly clinically significant if this indicates risks of future cardiovascular and other adverse health events that to the patient and clinician were previously unknown.
Objective: The aim of this presentation is to briefly describe our recent randomised controlled trial providing AAC results and use individual patient cases to illustrate clinical circumstances where identification of AAC may justifiably alter recommended management of patient cardiovascular disease and fracture risks.
Results: Provision of AAC may improve cardiovascular risk factor control over 12 weeks. AAC may also change assessment of cardiovascular disease risk from intermediate to high warranting more aggressive treatment of hyperlipidemia and/or blood pressure. AAC may change estimated risk of fracture from intermediate to high, warranting recommendation for fracture prevention therapy. AAC may change estimated risk of fracture from high to very high, warranting consideration of anabolic therapy. In instances where AAC identification does not alter CVD or fracture risk classification, the presence of AAC conceivably may increase perceived importance of therapy to the patient.
Conclusions: AAC has the potential to alter management of both cardiovascular disease and fracture risk factors significantly and appropriately. However, additional investigations are needed to determine the degree to which identification of AAC and appropriate communication of its significance to health care providers and patients does alter patient risk management choices.

NSS71

INTRODUCTION IN BONE, MUSCLE AND FAT INTERACTIONS

I. Kostoglou – Athanassiou[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Athens, Greece

The concurrent occurrence of osteoporosis, sarcopenia, and obesity is apparent in neurodisabled (NDS) individuals. The interplay among bone, muscle, and adipose tissue in NDS is intricate and affected by many physiological alterations stemming from immobilization, modified muscle tone, and nervous system dysfunction. The interaction of bone, muscle, and adipose tissues is essential for sustaining general health, and this link is especially important in NDS. Sarcopenia diminishes physical activity, leading

to reduced energy expenditure and heightened risk of obesity and immobilization-related bone loss. An elevation in visceral fat provokes inflammation, which facilitates the onset of sarcopenia. Osteoporosis, sarcopenia, and sarcopenic obesity are linked to metabolic diseases, morbidity, and death. Comprehending these connections is crucial for formulating successful intervention and rehabilitation strategies.

NSS72

(OSTEO)SARCOPENIA AND SARCOPENIC OBESITY IN NEURODISABLED INDIVIDUALS

Y. Dionyssiotis[1]

[1]Head of 2nd PMR Department, National Rehabilitation Center EKA, Athens, Greece

Osteosarcopenia is a syndrome characterized by concurrent loss of bone mineral density and reduction in muscle mass, strength, and function, which may be avoided. Despite the heightened prevalence of osteoporosis risk factors in individuals with neurodisabilities (NDS), no guidelines exist. Variations in injury type, disease progression, life expectancy, residual mobility and functionality, ambulation and standing ability, pharmacological treatment, spasticity levels, and depression further complicate the pathophysiology of bone-muscle loss and fat gain. Sarcopenia and osteoporosis are highly prevalent in NDS; nevertheless, the extent of disability attributable to osteosarcopenia syndrome remains undetermined. Muscle degeneration and dysfunction occur with aging; however, in neurological illnesses characterized by muscular atrophy, muscle loss can manifest at younger ages. The etiology of sarcopenia in NDS is intricate. One factor is the unloading of impaired skeletal muscle, leading to deconditioning in any muscle that remains inactive. Reduced muscle mass can be attributed to neurogenic injury, resulting from muscular atrophy and impaired regulation by the central nervous system. Neurological impairment results in the inactivation and subsequent unloading of the impacted skeletal muscle. The risk of diminished physical activity ability commences soon following the injury. Disuse, spasticity, and microvascular injury contribute to significant morphological, and enzyme histochemical alterations observed in paralyzed skeletal muscle, resulting in modified functional characteristics and atrophy. The mortality of motoneurons and muscle denervation must contribute to the pronounced atrophy observed in muscles. Malabsorption results in protein deficiencies and muscle catabolism. Thyroid hormonal imbalances, hypercortisolism, and insulin resistance contribute to sarcopenia due to protein insufficiency. Sarcopenic obesity has lately been characterized as a unique entity. It is marked by a detrimental cycle involving muscle and adipose tissue, which includes proinflammatory cytokines, oxidative stress, and insulin resistance, potentially leading to frailty and increased mortality risk. Significant alterations in body composition encompass an augmentation of body fat and a reduction in skeletal muscle and bone mass. The intricate interaction of shared pathophysiological pathways, including heightened bone resorption, proinflammatory cytokines, oxidative stress, insulin resistance, hormonal alterations, and reduced physical activity, underpins the strong association between osteoporosis, sarcopenia, and sarcopenic obesity. A detrimental loop may occur between the buildup of adipose tissue and the reduction of skeletal muscle mass and bone density, as they exert reciprocal effects on one another.

NSS73

SARCOPENIA IN HEMIPLEGIA AND STROKE

M. Papadatou[1]

[1]PMR Physician, Postgraduate Program in Metabolic Bone Diseases, National and Kapodistrian University of Athens, Athens, Greece

A significant reduction linked to neurogenic lesions results in stroke related sarcopenia. This type of secondary sarcopenia is challenging to define using the existing sarcopenia criteria for this cohort. Stroke is a condition that significantly affects the human body. The brain damage incurred adversely affects numerous bodily systems. The outcome of sarcopenia following a stroke involves many processes and their associated illnesses that transpired post-event. The resultant sarcopenia is attributable to multiple factors post-stroke, including denervation and reinnervation of muscle units, restricted muscle utilization and mobility, spasticity that emerges during the recovery phase, structural alterations as a response to adaptation to the subsequent conditions, as well as the systemic impact of brain injury on the body. Sarcopenia following a stroke is consequently a result of multiple influences. While one might assume that the pathophysiology of post-stroke sarcopenia resembles that of age-related sarcopenia, significant differences have been identified. The body adopts distinct mechanisms leading to muscle tissue disorder in post-stroke sarcopenia, although some similarities with age-related sarcopenia persist. Characteristics of sarcopenia following a stroke have been recorded: Following a stroke, there is a swift reduction in motor units, a structural alteration in skeletal muscle, subsequent disability which predominantly dictates the residual function based on the degree of brain lesion, and continuously affects it etc. It is important to note that the changes in the structure, function, and quantity of skeletal muscles are independent of the patient's age.

NSS74

DISCUSSION IN BONE, MUSCLE AND FAT INTERACTIONS

I. Kostoglou – Athanassiou[1], Y. Dionyssiotis[2], M. Papadatou[3]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Athens, Greece, [2]Head of 2nd PMR Department, National Rehabilitation Center EKA, Athens, Greece, [3]PMR Physician, Postgraduate Program in Metabolic Bone Diseases, National and Kapodistrian University of Athens, Athens, Greece

Recommendations have been proposed regarding the overall treatment and management of osteosarcopenia, primarily in elderly able-bodied individuals, focusing on exercise, nutrition, and pharmacological interventions under investigation. However, there is a deficiency of disease-specific guidelines for the management, treatment, and potential prevention of NDS individuals requiring comprehensive care. Currently, exercise combined with appropriate nutritional adjustments to facilitate weight loss while minimizing muscle loss may be employed for the prevention and management of sarcopenic obesity. Lack of physical exercise and poor dietary practices lead to the rising prevalence of this condition among the NDS population. This NSS evaluates health concerns and emphasizes the necessity for tailored solutions.

NSS75

DECODING SKELETAL COMPLICATIONS IN BONE METASTASES

P. Juárez Camacho[1]

[1]Group Leader at Bone and Cancer Research Group- Biomedical Innovation Department Center for Scientific Research and Higher Education at Ensenada (CICESE), Ensenada, Baja California, Mexico

Bone and bone marrow serve as significant locations for cancer spread. The onset of bone metastases is often associated with a worse prognosis. The consequences of bone metastases are often devastating, and once tumors metastasize to bone, they are incurable and cause skeletal complications, including severe pain, fractures, spinal nerve compression, and paralysis.
The prevention and management of bone metastases are essential to cancer treatment protocols. Nonetheless, the current therapeutic alternatives for patients with bone metastatic disease are limited in their effectiveness and can lead to increased morbidity. As a result, most modern treatments are primarily palliative.
Tumor cells can disseminate early but remain dormant in the bone, often for years. Interactions with bone cells, such as osteoblasts and hematopoietic stem cells, promote dormancy.
The bone microenvironment can inhibit tumor growth by inducing dormancy and suppressing processes like angiogenesis and immune responses. A deeper understanding of the interplay between the tumor cells and the bone microenvironment is crucial for creating novel, more successful therapies that increase patients' quality of life and clinical results.
In this talk, we will review what molecular and cellular mechanisms drive bone metastasis, how the tumor cells metastasize to the bone, interactions between tumor cells and the bone marrow niche to influence the tumor cell behavior and their ability to colonize bone, and frequent preclinical models to study cancer spreading to bones.

NSS76

TREATMENT OF BONE METASTASIS – STATE OF THE ART 2025

C. Confavreux[1]

[1]Hospices Civils de Lyon - Université Claude Bernard Lyon 1, Lyon, France

Bone metastasis corresponds to the localization of tumor cells in bone, at a distance from the primary tumor. Many bone metastases are asymptomatic. However, it has been estimated that 50% of patients with bone metastases will develop major complications such as : severe bone pain, hypercalcemia and pathologic long bone or vertebrae fractures.Major advances have been obtained in cancer treatment for the last ten years and a significant number of patients now benefit from prolonged remissions, even in the metastatic setting. Thus, to preserve mobility and prevent bone metastasis complications is essential. This should be done in harmony with the oncology care programme and patient's wishes and condition. Regarding bone metastases, the challenge is to identify metastatic locations that are at risk of complications (pain, fracture and neurological risk) to propose a personalised strategy after a systematic decision-making algorithm. The treatment strategy is based on local and systemic bone treatments. In complex cases we advice to follow a multidisciplinary approach with onco-rheumatologists, orthopedic surgeons, interventional radiologists, radiotherapists and oncologists at the bone metastastasis multidisciplinary consultation meeting (BCM3).

NSS77

CTIBL – SIZE OF THE PROBLEM AND TREATMENT OPTIONS?

P. Hadji[1]

[1]Frankfurt Center of Bone Health and Endocrinology and Philipps-university of Marburg, Frankfurt/Main, Germany

Osteoporosis is one of the most frequent diseases in postmenopausal women leading to an increased fracture risk due to the physiologic loss of the bone protective effects of estrogen. Hereby, several risk factors for fracture such as prevalent fracture, low BMD, age, family history, use of glucocorticoid use etc. have been identified. Additionally, the further reduction of endogenous estrogens with chemotherapy (CHT), GnRH-analoga or aromatase inhibitors (AI) continuously increases fracture

risk. Breast cancer (BC) on the other hand is the most frequent cancer type in women. Recent reports indicated a continuous increased incidence while mortality, due to early diagnosis and treatment improvements is decreasing. Dependent on specific tumor characteristics, radiation, chemotherapy (CHT), antibody treatment as well as endocrine treatment has been introduced into the adjuvant clinical treatment setting.
Some but not all of this cancer specific treatments interfere with bone turnover leading to an accelerate bone loss referred to as cancer treatment induced bone loss (CTIBL). Whereas CHT leads to an unspecific increased of bone resorption, Aromatase inhibitor (AI) reduces residual serum endogenous estrogen level and is associated with a decrease of bone mineral density (BMD) and increased fracture risk. Independent of the type of AI administered, bone loss is 2-3 fold increased compared to healthy, age matched postmenopausal controls. Therefore several guidelines have emerged to help managing CTIBL in women with BC including strategies to identify and treat those at highest risk for fractures.
The lecture will summarizes the current knowledge on CTIBL and fracturing risk and indicates current treatment guidelines and intervention options.

NSS78

WHAT ARE 'A LARGE LANGUAGE MODEIS' AND HOW CAN THEY BE DEPLOYED IN OSTEOPOROSIS?

N. Fuggle[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Artificial intelligence is rapidly moving from the realms of science fiction, into the real-life deployment in clinical workflows. Computer vision leads the way in the use of AI in clinical practice but Large Language Models (LLMs) are catching up and may soon overtake computer vision as the major use-case of AI in healthcare.
In order to prepare for this wave of development, this presentation will take the audience from LLM-naïve to expert via comprehensive explanations of tokenisation (the process of breaking text into smaller units, like words or subwords, for easier processing), prompt-engineering (designing and refining input prompts to guide AI models, optimizing their responses for specific tasks or outcomes) and an examination of the transformer model architecture (transformer models being at the heart of the Generative Pre-trained Transformer (GPT, as in ChatGPT) which sits at the forefront of AI development).
We will finish by exploring case studies of LLMs in use in clinical practice, including ambient recording of clinical consultations, from which the electronic patient record notes are automatically created as well as the patient letter and any other correspondence. We will consider how this can be used in the field of osteoporosis and the risks and limitations (including LLM 'hallucinations').

NSS79

HEALTH EQUITY CONSIDERATIONS WHEN USING AI IN CLINICAL PRACTICE

J. Alderman[1,2,3]

[1]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom, [2]National Institute for Health and Care Research (NIHR) Birmingham Biomedical Research Centre, Birmingham, United Kingdom, [3]University of Birmingham, Birmingham, United Kingdom

There is much fanfare regarding the deployment of artificial intelligence (AI) in clinical practice. However, the deployment of AI raises profound challenges for health equity, particularly in its potential to exacerbate existing disparities in healthcare access and outcomes. This presentation will critically examine health equity considerations in the use of AI within clinical practice, with a focus on data diversity, inclusivity and generalisability.
The STANDING Together initiative is a set of recommendations designed to mitigate these risks. Developed through an international consensus process involving representatives from 58 countries, STANDING Together provides guidance for those creating and using health datasets on minimising biases in AI health technologies. The recommendations address the complexities of health data and the importance of context, aiming to ensure the development of safe and effective AI tools that benefit everyone, regardless of background. www.datadiversity.org Ultimately, this presentation will emphasize that the ethical and equitable application of AI is not merely a technical challenge but a moral imperative in clinical practice.

NSS80

AI FOR VERTEBRAL FRACTURE SCREENING: A UK PERSPECTIVE – AN UPDATE FROM THE ADOPT STUDY

K. M. Javaid[1,2]

[1]NIHR Biomedical Research Centre, University of Oxford, Oxford, United Kingdom, [2]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Opportunistic vertebral fracture detection has the ability to identify patients for secondary fracture prevention who would otherwise fly under the radar. It uses computer vision (a form of AI) to automatically identify vertebral fractures can be missed as part of the radiology review. This is not simply because the CT scan (for example) is performed to investigate anther pathology, (e.g. lung cancer) but because the sagittal sections, on which vertebral fractures can be identified, are not processed or available. This provides an opportunity to identify patients who have had vertebral fractures and are therefore at risk of further fractures, arrange bone assessment and intervene to reduce their fracture risk. Fracture Liaison Services provide a potential vehicle via which to manage these patients once they are identified by

radiology departments.
In the final presentation in this symposium we will share the latest insights from the recent AI-enabled Detection of Osteoporosis for Treatment (ADOPT) study of a computer vision approach to opportunistically identify vertebral fractures from routinely performed CT scans. The trial is led by Professor Kassim Javaid and includes 7 centres across the United Kingdom.

NSS81

DXA QUALITY, COMMON ERRORS AND CLINICAL IMPACT

N. Binkley[1]

[1]University of Wisconsin School of Medicine and Public Health, Madison, WI, United States

When performed well, DXA is an outstanding clinical tool to assess skeletal status. Notably, DXA scans are often an integral component of osteoporosis diagnosis, fracture risk assessment and treatment monitoring. Unfortunately, issues exist with DXA acquisition, analysis and interpretation such that low quality reports are generated. Indeed, globally, DXA errors have been reported to occur in up to 90% of scans. Such errors can be due to incorrect scan acquisition/analysis or subsequent interpretation. These errors may lead to incorrect clinical care decisions such as undertreatment, excessive use of laboratory testing or prescription of unneeded pharmacologic therapy. This presentation will provide example cases where DXA errors led to incorrect BMD or T-score calculation negatively impacting clinical decision-making. Specific common errors including inappropriate information for osteoporosis diagnosis, BMD monitoring and vertebral fracture identification will be noted and how to avoid them considered.

NSS82

THE ABCS OF DXA AND HOW TO IMPROVE

D. Krueger[1]

[1]University of Wisconsin School of Medicine and Public Health, Madison, WI, United States

It is well documented that bone density assessment by dual-energy x-ray absorptiometry (DXA) is often suboptimal worldwide. Published data suggests technical errors are common and related to incorrect patient positioning, acquisition and/or analysis. Inappropriate positioning and acquisition can contribute to inadequate imaging of necessary anatomy, suboptimal region of interest placement or inappropriate soft-tissue sampling. Similarly, analysis errors can result in incorrect bone mineral density (BMD) calculation and associated T- and Z-scores. These mistakes contribute to interpretation errors which may result in incorrect diagnosis and monitoring inaccuracies.The purpose of this presentation is to provide a basic review of hip and spine DXA acquisition and analysis using GE and Hologic densitometers. This will include examples of common errors and how to identify them. Finally, guidance on how to improve testing and promote acquiring a high-quality exam will be reviewed.

NSS83

EXPANDING DXA FUNCTIONALITY TO ENHANCE CLINICAL CARE

K. Ward[1]

[1]MRC Lifecourse Epidemiology Centre University of Southampton, Southampton, United Kingdom

With the progression of DXA technology has come opportunity for extended utility. The greater spatial resolution of the most commonly used DXA machines means that radiograph-quality images are now obtained. These technical developments enable imaging of lateral views of the lumbar and thoracic spine for vertebral fracture assessment (VFA) and full-length femur imaging (FFI) for assessment of atypical femur fractures (complete and incomplete). Both offer advantageous by enabling a comprehensive set of scans to be performed on DXA without the requirement for extra radiographs. Furthermore, image processing methods applied to DXA images have led to a texture-based analysis of PA lumbar spine scans, giving the Trabecular Bone Score, which has been shown to predict fracture independently of BMD. Clinical guidelines for the application of these non-BMD tools exist.
The aim of this part of the symposium will be to briefly discuss each of these methodologies, the principles behind them and advantages and disadvantages of each.

NSS84

INTRODUCTION: ORAL HEALTH AND BONE HEALTH. A QUOTIDIAN DILEMMA?

J. L. A. Morales Torres[1], O. D. Messina[2]

[1]Rheumatologist. Hospital Aranda de la Parra and Director, Morales Vargas Centro de Investigacion, León GTO, Mexico, [2]Rheumatologist, Investigaciones Reumatologicas y Osteologicas (IRO) Medical Center, Buenos Aires, Argentina

Oral health problems are very common all over the world. Up to half of the population has disorders as untreated caries, severe periodontal disease, anodontia and even forms of oral cancer[1]. The frequency of poor oral health in older people is considered very high worldwide, with a notable impact on general health and quality of life[2].
Osteonecrosis of the jaw is a rare but devastating complication. It tends to occur in patients undergoing invasive dental procedures who are receiving certain medications, particularly anti-resorptives (for the treatment of osteoporosis and bone complications of some tumors) and anti-angiogenic agents (for the treatment of some forms of cancer). It is currently known as medication-related osteonecrosis of the jaw (MRONJ)[3]. Current treatment guidelines agree on the need to limit, as far as possible, elective invasive bone procedures during treatment with these groups

of medications and emphasize the convenience of identifying dental and oral problems that may require invasive interventions with a higher risk of complications with MRONJ[3]. Clinicians who diagnose osteoporosis and a high risk of fractures in a patient should frequently consider the initiation of anti-resorptive drugs (bisphosphonates or denosumab), which are recommended as first-choice agents in a high percentage of these patients[4]. How can we improve identification of major oral health problems? Who should be referred for a dental treatment before the use of certain drugs?

NSS85

THE OVERALL IMPACT OF ORAL HEALTH IN THE ELDERLY

H. Gutiérrez Hermosillo[1]

[1]Hospital Aranda de la Parra and Escuela Nacional de Estudios Superiores Unidad León, UNAM, León GTO, Mexico

Worldwide life expectancy has increased significantly. Osteoporosis increases as age advances and in the forthcoming years we will face enormous numbers of osteoporosis-related fractures[1].Osteoporosis is a global major health problem. Despite this, big gaps remain on the treatment of this disease[2], one of the reasons for this, may be the fear of developing jaw osteonecrosis, conceptually related with drugs widely used to treat osteoporosis[3]. As a person grows older, there are high possibilities to need an increasing number of medications, many of them adversely affecting the bone. Also, advancing age is associated with lower levels of serum vitamin D, closely related to musculoskeletal health[4,5].

The prognosis of an elder is closely related to oral health. Aging brings an increase in diverse oral pathologies carrying a risk of chronic low-grade inflammation (inflammaging), which is related to frailty and osteoporosis per se, and in a bidirectional mode, to periodontitis and oral health[6]. Several factors directly affect oral health, including age, poor oral hygiene, nutritional status, and smoking. Despite these facts, in clinical practice not every patient has a proper oral examination from their physicians treating osteoporosis. In this symposium we address a practical approach to these problems, intimately linked and frequently forgotten.

OSTEOPOROTIC FRACTURES AND MEDICATION RELATED OSTEONECROSIS OF THE JAW (MRONJ): SOBERING STATISTICS

F. Fidencio Cons Molina[1]

[1]Clínica de Artritis y Osteoporosis and Facultad de Medicina UABC, Mexicali BC, Mexico

Treatment with **anti-resorptive agents** such as bisphosphonates and denosumab is one of the most effective strategies for reducing the risk of osteoporotic fractures, significantly decreasing the associated morbidity and mortality. These therapies prevent millions of fractures annually, improving quality of life and preserving functional independence in older adults.

However, a rare but important concern is **medication-related osteonecrosis of the jaw (MRONJ)**, which occurs infrequently in patients receiving these therapies at standard doses for osteoporosis. The estimated risk is extremely low, with an incidence of less than 0.1% when used according to established clinical guidelines. The risk may increase in the presence of invasive dental procedures or predisposing factors such as periodontal disease.

In contrast, patients treated with **much higher doses of anti-resorptive agents** for the management of **metastatic bone malignancies** or advanced cancers face a significantly increased risk of MRONJ, ranging from 1% to 12%. This is due to the substantially higher potency and frequency of doses required to control cancer progression.

Conclusion: The benefit of reducing the risk of fractures through anti-resorptive therapy far outweighs the extremely low risk of developing MRONJ when these agents are used at standard doses for osteoporosis treatment. **Dental prevention** and proper oral health management are essential to further minimize this risk, particularly before initiating long-term therapy, ensuring a

favorable risk-benefit balance in the comprehensive management of the patient.

NSS87

IMPROVING ORAL SCREENING: THE ORAL HEALTH ASSESSMENT TOOL

J. L. A. Morales Torres[1]

[1]Rheumatologist. Hospital Aranda de la Parra and Director, Morales Vargas Centro de Investigacion, León GTO, Mexico

Although uncommon, MRONJ has devastating impacts on those who suffer from it. Dental health professionals fear the possibility of facing such conditions. Current treatment guidelines agree on the need to limit, when possible, performing invasive dentoalveolar operations (tooth extraction or implant placement), planning to perform them before starting therapy with certain drugs[1]. It is important to evaluate (and address) the coexisting risk factors to develop MRONJ, particularly exposure to glucocorticoids and tobacco[1].

Is the average Clinician qualified to identify meaningful features of oral health? A study in United Kingdom revealed several gaps in the ability of general practice trainees to identify common problems in oral health[2]. A prospective study in prostate cancer patients showed that instituting strict dental health surveillance reduced significantly the risk of MRONJ compared to those patients subject to dental treatments driven by symptoms[3]. Interactions between clinicians and dental health professionals may lead to improvements in general health, quality of life and even life expectancy of their patients[4].

Oral Health Assessment Tool (OHAT) may be instrumental in improving clinicians' dexterity in the identification of oral health problems and to refer patients to appropriate dental treatments[5]. Better screening for oral health problems, may be accessible to the busy clinician and have a positive impact on general and skeletal health of patients at risk.

VITAMIN D: FROM NATIVE TO ACTIVE FORM IN CKD-ASSOCIATED OSTEOPOROSIS

R. M. A. Moysés[1]

[1]LIM 16, Nephrology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Chronic kidney disease (CKD) is a recognized cause of osteoporosis, with a complex pathophysiology involving the interplay of uremic toxins, disturbances in mineral metabolism, and alterations in immune, endocrine, neurohormonal, and gut systems. Vitamin D deficiency is common in patients with CKD, and may be associated with secondary hyperparathyroidism and abnormal mineralization. Current guidelines recommend supplementation with native vitamin D to avoid these complications. However, data on skeletal outcomes in patients receiving vitamin D supplementation are lacking. Active vitamin D derivatives have been used to manage hyperparathyroidism in these patients. However, excessive suppression of parathyroid hormone and a reduced bone formation rate may lead to decreased bone quality, thereby increasing the risk of fractures. Also, they could be associated with hypercalcemia and hyperphosphatemia. Therefore, these compounds should be prescribed with caution.

NSS89

VITAMIN K: INSTRUCTIONS FOR USE IN SKELETAL FRAGILITY

M. Fusaro[1,2]

[1]National Research Council (CNR), Institute of Clinical Physiology (IFC), Pisa, Italy, [2]Department of Medicine, University of Padova, Padova, Italy

Vitamin K acts as a carboxylase coenzyme, catalyzing the carboxylation of several vitamin K-dependent proteins.

Beyond its well-known effects on blood coagulation, it also exerts relevant effects on bone and the vascular system.

An adequate vitamin K intake is important to obtain sufficient levels of carboxylated (active form) vitamin K-dependent proteins, such as osteocalcin and matrix Gla protein, to prevent bone and vascular health. Another bone-related action Vitamin K is a ligand of the nuclear steroid and xenobiotic receptor (SXR) (in murine species Pregnane X Receptor: PXR), expressed in osteoblasts. There are two main types of vitamin K vitamers: Phylloquinone (or PK) and Menaquinones (MKn).

Epidemiological studies showed that its deficit was associated with increased fragility fractures, vascular calcification, and mortality. It has been highlighted that the uremic state is a condition of greater vitamin K deficiency than the general population.

However, few available studies, especially in CKD patients, have pre-specified outcome bone fractures, indicating that we need more clinical studies to confirm that vitamin K is a potential therapeutic agent for bone fractures.

NSS90

THE STATISTICIAN IN DETECTING FRAUD AND NEGLIGENCE IN CLINICAL TRIALS

G. Tripepi[1]

[1]Institute of Clinical Physiology of the National Research Council (IFC-CNR) of Reggio Calabria, Reggio Calabria, Italy

Clinical trials are the cornerstone of evidence-based medicine, but the integrity of the data on which they rest can be undermined by fraud and negligence. The role of statisticians in identifying and mitigating these issues is crucial, especially when considering the far-reaching consequences of compromised research. This talk will focus on how fraud and negligence can manifest in clinical trials, with particular attention to studies in the fields of osteoporosis and vitamin K. Osteoporosis, a debilitating condition affecting millions globally, has been the subject of numerous clinical trials investigating treatments and interventions. Likewise, vitamin K's role in bone health has been increasingly examined. However, the contamination of trial data—whether through falsified results, selective reporting, or data manipulation—can skew scientific understanding, leading to misguided clinical recommendations and patient care. We will explore how fraudulent activities such as data fabrication, protocol deviations, and selective outcome reporting can go undetected, especially when trials are published without rigorous statistical scrutiny. This is further compounded by negligence, where methodological oversights or statistical errors go uncorrected, creating false confidence in results. The secondary concern is the impact of such compromised data on systematic reviews and meta-analyses, which are essential for synthesizing evidence across multiple studies. Contaminated or biased trial data can introduce significant distortions into the conclusions drawn in these reviews, ultimately influencing clinical guidelines and treatment decisions. The integrity of the systematic review process is therefore dependent on statisticians being vigilant in detecting these issues, applying appropriate statistical techniques, and promoting transparency in data reporting.

This presentation will describe an example of fraud and negligence in literature and will highlight the tools and methods statisticians use to uncover fraud and negligence in clinical trials, including data verification, integrity checks, and advanced statistical techniques for detecting anomalies. Through case studies from osteoporosis and vitamin K research, we will examine the broader implications of compromised trial integrity on public health and policy. The session will conclude with recommendations for improving the transparency and rigor of clinical trial reporting, emphasizing the essential role of statisticians in safeguarding the reliability of clinical evidence.

NSS91

VITAMIN D IN SKELETAL FRAGILITY: A CLINICAL CASE

H. S. Jørgensen[1]

[1]Dept. of Clinical Medicine, Aarhus University, Aarhus, Denmark

A 56-year-old man with diabetic nephropathy and rapid loss of kidney function presented with severe hyperparathyroidism shortly after initiating dialysis therapy. Parathyroid hormone (PTH) levels were 80-100 pmol/L, with hyperphosphatemia (phosphorus 3.0-3.0 mmol/L), normocalcemia (total calcium 2.54 mmol/L) and low levels of 25-hydroxyvitamin D (21 nmol/L). Should vitamin D insufficiency be corrected?

Chronic kidney disease-mineral and bone disorder (CKD-MBD) is a complex condition of disturbed calcium and phosphate metabolism leading to secondary hyperparathyroidism with negative effects on bone and vascular health, contributing to the morbidity and excess mortality of patients with CKD. Drivers of hyperparathyroidism in CKD include phosphate retention, low levels of calcium, and insufficient levels of active vitamin D. With the reduction in nephron mass, the kidneys' ability to produce active vitamin D is reduced; however, extra-renal activation of vitamin D occurs even in patients who are anephric[1], providing a rationale for vitamin D supplementation in kidney failure. Supplementation with cholecalciferol reduces PTH levels in randomised trials, though results are inconsistent[2]. Implementing vitamin D supplementation as routine care in dialysis units leads to decreased severity of hyperparathyroidism[3]. A recent European consensus paper concluded that all patients with CKD, including those in kidney failure receiving dialysis therapy, should receive vitamin D supplementation targeting 25-hydroxy-vitamin D levels >75 nmol/L, to delay the onset, and improve the control of, secondary hyperparathyroidism.[2] Thus, in this case, vitamin D supplementation should be initiated with appropriate monitoring to ensure target levels are reached.

NSS92

THE SILENT EPIDEMIC OF OSTEOPOROSIS AMONG ADULTS WITH INTELLECTUAL DISABILITIES

E. Burke[1,2], J. Ryan[3], L. Lynch[1,2], A. Power[4]

[1]School of Nursing and Midwifery, Trinity College Dublin, Dublin, Ireland, [2]Trinity Centre for Ageing and Intellectual Disability Trinity College Dublin, Dublin, Ireland, [3]Nursing and Midwifery Planning and Development, HSE Dublin & South-East Ireland, Dublin, Ireland, [4]Wexford Intellectual Disability Services, Wexford, Ireland

Objective: To establish the state of the science of bone health in a population of older adults with intellectual disability.

Material and Methods:

This study is part of the Intellectual Disability Supplement to the Irish Longitudinal Study on Ageing (IDS-TILDA), a longitudinal ageing study [2007 – ongoing] collating data across all life domains via pre-interview questionnaires, face-to-face interviews and objective health measures (OM). Data is collected every 3 years which describes a datawave. A 10% representative sample, randomly selected from the National Intellectual Disability Database at Wave 1, included 753 participants, with the sample refreshing to 762 at Wave 5, resulting in an 84% retention rate for continuing participants, refreshment was due to loss to follow up as a result of deaths and participants ageing out of younger groups. The GE lunar Achilles (QUS) was used to establish bone quality in the OM. Participants are aged 40 years and above, living independently or with family, in community group homes or in residential services and of all levels of intellectual disability [mild/moderate, severe/profound]. Participants were asked to provide their doctor's diagnosis of chronic health conditions including osteoporosis.

Results

In total, 19% had a doctor's diagnosis of osteoporosis however on OM 32% were within the osteoporotic range and a further 29.4% within the osteopenic. Increased age, level of intellectual disability and reduced mobility are associated with decreases in bone density. Interestingly, being a younger participant (< 65yrs) and having no mobility issues are associated with an increased likelihood of having osteoporosis but not a doctor's diagnosis. Sex has no association in this population with osteoporosis however severe/profound level of intellectual disability ($p<0.0001$) and having difficulty walking ($p<0.001$) pose increased risk, with medications [antiepileptic ($p=0.004$), and proton pump inhibitors ($p=0.018$)] contributing to an increased likelihood. Concerningly just 25.4% reported having attended DXA.

Conclusion

These findings underscore the need for a critical reassessment of diagnostic criteria and risk assessment tools for those with intellectual disability. The conventional model of osteoporosis risk may be insufficient considering changing epidemiological patterns in this cohort. Recognising this is crucial for effective prevention, diagnosis, and treatment of osteoporosis for all.

NSS93

EXPLORING DIETARY DEFICIENCIES IN ADULTS WITH INTELLECTUAL DISABILITIES CONTRIBUTING TO POOR BONE HEALTH

J. Ryan[1], L. Lynch[2,3], A. Power[4], E. Burke[3]

[1]Nursing and Midwifery Planning and Development, HSE Dublin & South-East Ireland, Dublin, Ireland, [2]School of Nursing and Midwifery, Trinity College Dublin, Dublin, Ireland, [3]Trinity Centre for Ageing and Intellectual Disability Trinity College Dublin, Dublin, Ireland, [4]Wexford Intellectual Disability Services, Wexford, Ireland

Objective

To examine dietary intake in adults with intellectual disability in Ireland and establish patterns that impact on skeletal health.

Material and Methods:

Data from this study was drawn from the IDS-TILDA study. In total N=609 participants took part in the study. Participants completed a food frequency questionnaire (FFQ) comprised of questions on dietary intake across 6 food shelves. These included: Shelves 1) Fruit and vegetables, 2)wholemeal cereals, 3)Milk, yogurt, cheese, 4)Meats, poultry, fish, eggs, 5)Fats and oils, and 6)High sugar, salt. Consumption levels ranged from never/less than once per month, to 6+ portions per day (PPD). The responses were converted into measurable components based on the food pyramid recommended daily amounts (RDA) and mapped to the food shelves. Chi-squared analysis examined the relationship between the FFQ and individuals of all levels of intellectual disability, aged 40 years and above, living independently, in community group homes or in supported residential services.

Results:

This study revealed alarmingly low compliance with nutritional guidelines for key nutrients such as calcium rich products and vitamin D in foods like milk, yoghurt and cheese (shelf 3) with 53%, (n=309/583) of participants not meeting RDA levels. Of those who had a doctor's diagnosis of osteoporosis, 3 in 10 participants were not taking either Vitamin D or calcium supplementation. Similarly, just 18.9%, (n=110/583) of participants met the RDA for foods containing protein (shelf 4) necessary for bone health and repair. Conversely, consumption of foods high in fat, salt and sugar 68%, (n=394/597) (shelf 6) far exceeding recommendations, exacerbating the risk of poor skeletal health.

Conclusion: Dietary intake plays a critical role in bone health, yet adults with intellectual disabilities often fail to meet the recommended dietary allowances essential for maintaining musculoskeletal health. This study examines the dietary intake patterns of a sample of older adults with intellectual disabilities in Ireland and established the imbalanced intake of specific nutrients that play a crucial role in bone health. Overall, considering the high levels of debilitating bone health among this population the collective impression of dietary intake patterns increases their risk further of poorer bone health.

NSS94

SEDENTARY BEHAVIOUR AND ITS IMPLICATIONS FOR THE BONE HEALTH OF THOSE WITH INTELLECTUAL DISABILITY

L. Lynch[1,2], A. Power[3], J. Ryan[4], E. Burke[1,2]

[1]School of Nursing and Midwifery, Trinity College Dublin, Dublin, Ireland, [2]Trinity Centre for Ageing and Intellectual Disability Trinity College Dublin, Dublin, Ireland, [3]Wexford Intellectual Disability Services, Wexford, Ireland, [4]Nursing and Midwifery Planning and Development, HSE Dublin & South-East Ireland, Dublin, Ireland

Objective
To examine the interplay between sedentary behaviour and inactivity, with skeletal health as measured by the GE lunar achilles (QUS).
Materials and methods
Using Wave 5 IDS-TILDA interview data and objective measurements, sedentary behaviour, activity levels and the barriers faced by individuals with intellectual disability, including mobility issues, environmental constraints, and lack of accessible exercise opportunities are explored. Individuals with all levels of intellectual disability, aged 40 years+, living in a variety of circumstances were included (N= 762), with N=502 completing the objective measures. A GE lunar achilles (QUS) was used to measure bone quality, which was classified into normal, osteopenia or osteoporosis. The Rapid Assessment of Physical Activity (RAPA) questionnaire and an activPAL accelerometer were used to determine activity and sedentary levels.
Results
Sedentary levels of almost 70% were observed. The RAPA identified just 23% of participants met recommended activity guidelines with over 77% inactive. Approximately 65% of participants needed an aid to walk across a room with 60% of participants reporting no difficulty walking 100yards while 18% could not do it at all. The magnitude of the relationship between the QUS osteoporosis category and physical activity [those who were underactive] was (r) 0.59 (p=0.008). Similarly, with consideration to mobility, QUS scores decrease progressively with increasing mobility difficulty, with medium to large effects observed for those with some difficulty (effect size = -0.55, p = 0.0061), a lot of difficulty (effect size = -0.82, p = 0.0060), and very large effects for those unable to mobilize (effect size = -1.77, p < 0.0001), indicating a strong association between reduced mobility and poorer bone health.
Conclusions
Sedentary behaviour and inactivity are significant contributors to poor bone health and are observed at very high rates among this cohort. However, there is an indication that increased activity levels are emerging as protection for bone health. Approaches to improve activity levels among those with intellectual disability need to be creative and engaging to overcome barriers and aversion to exercise. Addressing sedentary behaviour is essential to improving bone health and overall quality of life for adults with intellectual disability.

NSS95

INNOVATIVE SOLUTIONS: THE ECHOLIGHT REMS DEVICE FOR ACCESSIBLE BONE HEALTH SCREENING FOR ADULTS WITH INTELLECTUAL DISABILITY

A. Power[1], L. Lynch[2,3], J. Ryan[4], E. Burke[2,3]

[1]Wexford Intellectual Disability Services, Wexford, Ireland, [2]School of Nursing and Midwifery, Trinity College Dublin, Dublin, Ireland, [3]Trinity Centre for Ageing and Intellectual Disability Trinity College Dublin, Dublin, Ireland, [4]Nursing and Midwifery Planning and Development, HSE Dublin & South-East Ireland, Dublin, Ireland

Objective: This research study evaluated the feasibility of using an alternative bone health assessment system, namely the Echolight, for people with intellectual disabilities. The Echolight stands as an innovative technology utilising radiofrequency echographic multi-spectrometry (REMS) and it is less demanding in terms of patient positioning compared to the conventional DXA scan.
Methods and Materials: Eighty-four participants with intellectual disability inclusive of mild, moderate or severe/profound levels from service providers in Ireland over the age of 40 years participated in the study. A process-effectiveness design was employed, to establish the feasibility of the Echolight device assessment process with people with intellectual disability. Data was collected from participants via pre, and post scan questionnaires and data generated from the Echolight assessment. Feasibility was defined by >70% success rate of completion and evaluated from the participant experience.
Results: In total, 96% (n=81/84) of the participants completed the assessment successfully with 92.9% of the participants noting they found the scan easy to engage in and 96.2% confirming they would recommend Echolight bone scan to a friend. Overall, 72.5% of participants previously never accessed DXA or alternative bone health screening. A total of 26.2% (n=22/81) were identified to have osteoporosis and a further 36.9% (n=31/81) were within the osteopenic range. Of those who had compromised bone health (n=53/81), 59% (n=33/53, P<.001) had not received a doctor's diagnosis and were unaware of their bone health status.
Conclusion: The Echolight's non-invasive nature, rapid assessment process, and ability to operate in community settings significantly enhance its feasibility for people with intellectual disabilities. The comprehensive demographic analysis in this study provided insight into the correlation between intellectual disability and bone health issues and illustrates the experiences with the Echolight device across various cognitive functioning levels in a group of adults with intellectual disability. The Echolight REMS device offers a transformative approach to osteoporosis diagnosis and monitoring and expands access to reliable bone health screening, paving the way for timely interventions and improved bone health outcomes for this population.
This study was funded by the Nursing and Midwifery Planning and Development unit, Health Service Executive, Dublin & South-East, Ireland.

NSS96

RECOGNIZING AND MANAGING SARCOPENIA IN CHILDREN: REFERENCE MUSCLE MASS VALUES FROM A EUROPEAN COHORT

T. Kizilkurt[1,2]

[1]Istanbul Multidisciplinary Consortium on Bone and Musculoskeletal Health, Istanbul, Turkiye, [2]Istanbul University, Istanbul Medical School, Department of Orthopedics and Traumatology, Istanbul, Turkiye

Sarcopenia, traditionally considered an aging-related condition, is increasingly recognized in pediatrics, where low muscle mass (LMM) affects growth and health outcomes. Normative muscle mass values are critical for assessing LMM in children, yet current references are limited to a few studies conducted in specific populations, underscoring the need for further research. We aimed to establish age- and sex-specific reference values for muscle mass in healthy children, representing a new population cohort. A cross-sectional analysis of healthy children aged 5–14 years was conducted. Muscle mass was measured using Bioelectrical Impedance Analysis (BIA) after a minimum 8-hour fasting period. Percentile values for Fat-Free Mass (FFM) and Lean Body Mass (LBM) were calculated by age and indexed to weight, height squared, and BMI. In total, 844 healthy children (388 girls, 456 boys) were included. Age- and sex-specific percentiles for FFM and LBM were established and reference values for FFM and LBM adjusted by BMI were reported for the first time. In this session, we will present the methology of our work in detail and provide normative reference values for muscle mass in children, offering a valuable tool for monitoring growth and diagnosing conditions such as sarcopenia and malnutrition.

NSS97

MOLECULAR INSIGHTS, PATHWAYS AND CANDIDATES FOR NOVEL INTERVENTIONS IN SARCOPENIA

S. Ozkok[1,2]

[1]Istanbul University, Istanbul Medical School, Department of Internal Medicine, Division of Geriatrics, Istanbul, Turkiye, [2]Istanbul Multidisciplinary Consortium on Bone and Musculoskeletal Health, Istanbul, Turkiye

Sarcopenia is a skeletal muscle disorder characterized by a progressive and generalized decline in muscle mass and function. Over the years, numerous breakthroughs have highlighted potential pharmacotherapies with promising findings; however, the multifactorial nature of sarcopenia complicates the development of a single effective treatment. Unlike traditional disease models that focus on singular pathways, sarcopenia arises from a complex interplay of factors, including imbalance in protein turnover, mitochondrial dysfunction, hormonal changes, and chronic low-grade inflammation. Therefore, an ideal pharmacotherapy would need to address multiple pathways simultaneously to achieve meaningful clinical benefits. Among the drug candidates explored, testosterone remains the pharmaceutical with the most substantial evidence base regarding its efficacy and safety in improving muscle health. More recently, BIO101, a mas receptor agonist, has emerged as a promising agent with a novel mechanism of action. Bimagrumab (myostatin receptor agonist) deserves an attention as a potential therapeutic for sarcopenic obesity. In contrast, ghrelin receptor agonists and espindolol are therapeutics with potential in muscle loss associated with anorexia/cachexia, but further evidence is required. microRNA mimetics and inhibitors, drug delivery systems for local treatments, gene therapies, and muscle stem cell transplantation appear to be promising novel approaches on the horizon for the treatment of sarcopenia. Combining therapeutics targeting different pathways with conventional interventions, i.e., nutritional support and resistance exercise, holds more potential for a comprehensive sarcopenia management. In this session, we will discuss the most recent landscape and emerging frontiers in the field of sarcopenia treatment.

NSS98

UPDATED JOINT POSITIONS ON PERIOPERATIVE BONE OPTIMIZATION IN ARTHROPLASTY CANDIDATES 2024

R. C. Lopez-Cervantes[1]

[1]Clinica de Fracturas por Osteoporosis, CFO, Hospital de Especialidades San Francisco de Asis de Guadalajara, Guadalajara, Mexico

Osteoporosis and low bone mineral density (LBMD) represent significant yet often overlooked factors in the perioperative management of patients undergoing joint arthroplasty. These conditions contribute to increased periprosthetic bone loss, implant-related complications, and higher revision rates, underscoring the need for an integrated approach to optimize bone health in this patient population. Despite the critical impact of bone quality on surgical outcomes, the routine evaluation and management of bone health remain inconsistent across clinical settings.

The use of antiresorptive and bone anabolic agents has proven effective in mitigating periprosthetic bone loss (PPBL) and reducing implant-related complications after joint arthroplasty. Patients with osteoporosis or bone fragility conditions significantly benefit from these therapies, which preserve periprosthetic bone mineral density (PPBMD), lower revision rates, and minimize non-septic complications. Therefore, routine preoperative assessment of bone health, including bone mineral density (BMD) measurement, is essential to identify candidates for antiosteoporosis treatments. Tailored treatment plans should be based on individualized fracture risk assessments, baseline BMD, and osteoporosis-related factors. Addressing bone health proactively before and after arthroplasty can optimize surgical outcomes, reduce complications, and improve long-term implant survival.

This session presents the latest joint position (FEMECOT, AMMOM,

ACOMM, SCCOT, SECOT, SEFRAOS, SEIOMM) and evidence-based strategies for optimizing perioperative bone health in arthroplasty candidates. Leading experts will discuss the role of antiresorptive and bone anabolic therapies in mitigating periprosthetic bone loss, reducing complications, and improving implant longevity.

NSS99

CURRENT PRACTICES, NEEDS, AND CHALLENGES IN PERIPROSTHETIC BONE MINERAL DENSITY ASSESSMENT: TOWARDS STANDARDIZATION

J. F. Torres-Naranjo[1]

[1]Centro de Investigación Ósea y de la Composición Corporal, CIO, Guadalajara, Mexico

Evaluating bone mineral density (BMD) and periprosthetic bone mineral density (pBMD) in candidates for arthroplasty is crucial for preoperative assessment, postoperative tracking, and enhancing clinical outcomes. Despite its significance, current practices for measuring, interpreting, and utilizing BMD remain inconsistent across both clinical and research environments. There is considerable variability in pBMD measurement protocols, regions of interest (ROIs), and analysis methods, which leads to challenges in creating dependable, evidence-based guidelines. These disparities obstruct comparability among studies and impede the effective incorporation of bone health evaluations into standard clinical care for arthroplasty candidates. This session will delve into the state of current practices, highlighting the variability in pBMD assessment and the challenges that arise from it. A significant focus will be on the need for standardization to enhance precision and reproducibility in longitudinal measurements. For instance, the accuracy of repetitive scans relies heavily on factors such as the scanner's hardware and software, patient positioning during scans, and the consistency of follow-up protocols. Studies have shown significant variability in measured pBMD, with coefficients of variation (CV) ranging from 0.6% under optimal conditions to over 20%. This session will focus on the methodological challenges and collaborative efforts needed to create specific guidelines for pBMD measurement, analysis, and reporting. It will also emphasize the importance of education and training for clinicians and radiology technicians to ensure the consistent application of these protocols. Implementing standardized guidelines can enhance the integration of BMD assessment into routine arthroplasty care. By addressing the gaps in clinical practice, research, and education, standardized pBMD assessments can improve patient outcomes, facilitate comparability between studies, and advance the field of arthroplasty care.

NSS100

CURRENT PRACTICES AND EDUCATIONAL NEEDS IN PERIOPERATIVE BONE OPTIMIZATION FOR ARTHROPLASTY CANDIDATES: SURVEY RESULTS

J. M. Gomez-Acevedo[1]

[1]Mexican Society of Orthopedics and Trauma Research, SMIOT, Zapopan, Mexico

This session presents the findings of a comprehensive survey on current practices, knowledge gaps, and educational needs among orthopedic specialists involved in arthroplasty. The results reveal significant heterogeneity in perioperative bone optimization and highlight discrepancies in the measurement, interpretation, and follow-up of bone mineral density (BMD) in clinical practice.
Key findings includeMost orthopedic surgeons will change their surgical approach if they find bad bone quality. Only around fifty percent of surgeons perform a *Perioperative Bone Optimization (POBO)*. However, most of them state that if they find Bad bone quality during surgery, they initiate POBO or send the patient to an osteoporosis specialist.
Other findings include a lack of standardized protocols for osteoporosis management, limited preoperative BMD assessments, and varying levels of familiarity with antiresorptive and anabolic therapies. These inconsistencies present opportunities to reduce unwarranted variations in clinical care through targeted educational initiatives and standardized guidelines. The session aims to identify actionable strategies for improving perioperative bone optimization, enhancing surgical outcomes, and promoting evidence-based practices among orthopedic specialists by addressing these challenges.

NSS101

ADIPOSE AND BONE TISSUE. A CLOSE RELATIONSHIP

I. Kostoglou-Athanassiou[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Adipose tissue is recognized as an endocrine organ which regulates bone remodeling through the secretion of adipokines and cytokines. En enhanced volume of adipose tissue is linked to low bone mass and fractures, although the detailed interactions between adipose tissue and bone metabolism need further research and study. It is possible and it also is a clinical observation that adipose tissue especially abdominal adipose tissue expands in menopause following estrogen withdrawal and this expansion affects bone remodeling and may induce osteoporosis. The deeper understanding of the relationship between adipose tissue expansion and bone metabolism in a condition of estrogen deficiency may provide novel insights into potential therapeutic targets in osteoporosis.

NSS102

METABOLIC SYNDROME. A PARADIGM OF THE INTIMATE RELATIONSHIP BETWEEN ADIPOSE AND BONE TISSUE

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Metabolic syndrome is characterized by deposition of adipose tissue in the central abdomen leading to abdominal obesity, diabetes mellitus, dyslipidemia and arterial hypertension. The relationship of obesity with bone metabolism is close and may lead to contradictory results as far as bone mineral density is concerned. Obesity is considered to be related to normal bone mineral density by the sheer mechanical effect of the weight on the bone tissue. However, obesity may also have an effect on the bone via the inflammatory mediators adipokines and cytokines produced and lead to disordered bone metabolism and osteoporosis. Therefore, bone metabolism in osteoporosis is a subject which deserves further study.

NSS103

METABOLIC SYNDROME AND OSTEOPOROSIS

Y. Dionyssiotis[1]

[1]Physical Medicine and Rehabilitation Department, National Rehabilitation Center EKA, Athens, Greece

Metabolic syndrome a constellation of symptoms and a phenotype characterized by abdominal obesity, diabetes mellitus type 2, dyslipidemia and arterial hypertension impacts bone metabolism. Its impact reflects the effect of chemical mediators, adipokines and cytokines produced by the adipose tissue on bone tissue. These effects may be detrimental and may lead to osteoporosis. Osteoporosis in the context of metabolic syndrome should be managed by the administration of various agents which have a beneficial effect on bone metabolism. However, metabolic syndrome is also managed by the administration of agents which are used to combat diabetes mellitus type 2, dyslipidemia and arterial hypertension. The effect of these various agents on bone metabolism should also be studied and taken into account when managing osteoporosis in the context of metabolic syndrome.

NSS104

METABOLIC SYNDROME AND DIET. DO THEY AFFECT BONE MASS?

L. Athanassiou[1]

[1]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece

Metabolic syndrome is characterized by abdominal obesity. Abdominal obesity has differential effects on bone mineral density. Its effects are related to the effect of adipokines and cytokines on bone metabolism. However, patients suffering from metabolic syndrome are overweight and dieting is applied to manage the metabolic syndrome and the excess body weight related to it. Dieting may also have a detrimental effect on the bone. This detrimental effect is related to less weight and its negative effect on bone metabolism. However, this detrimental effect may also be related to nutritional defects related to dieting. The effect of dieting on bone mineral metabolism should be considered when planning diet plans in patients with metabolic syndrome.

NSS105

METABOLIC SYNDROME AND DEPRESSION

Y. Athanassiou[1]

[1]Department of Philology, Trinity College, Dublin, Ireland

Metabolic syndrome is characterized by abdominal obesity. Abdominal obesity is related to insulin resistance which is related to increased insulin levels. Insulin has a stimulatory effect on beta receptors on vessels which leads to aggressive behavior. Metabolic syndrome is also related to depression. Depression may lead to metabolic syndrome via the effect of depression on eating. Depression may lead to overeating. Overeating leads to the accumulation of adipose tissue and obesity. Obesity may impact behavior and may also impact neurocognitive function and may lead to depression, thus making a vicious cycle. All these data show that metabolic syndrome should be prevented as its effects are not limited to diabetes mellitus, dyslipidemia, arterial hypertension and disordered bone metabolism but also to disordered neurocognitive function.

NSS106

CHALLENGES OF CLINICAL TRIALS FOR NEW OSTEOPOROSIS MEDICATIONS

E. V. McCloskey[1]

[1]University of Sheffield, Sheffield, United Kingdom

The high morbidity and increased mortality of osteoporosis-related fractures are a large and growing public health concern. Given the ageing of the worldwide population, the number of fractures is predicted to substantially increase in the next decades. Currently, several treatments are approved for osteoporosis based on a favorable benefit-to-risk profile, particularly including reductions in the risk of vertebral, hip, and other fractures. However, initiation and long-term use of these effective therapies have decreased in the past decade as a result of concerns about rare side effects and inconvenient dosing requirements, coupled with persistent problems of underdiagnosis and undertreatment of osteoporosis. There is an urgent need to develop new osteoporosis therapies with improved safety profiles, efficacy, and/or convenience to increase patient and clinician adoption.
Randomized trials required for regulatory approval of osteoporosis therapies with vertebral and/or non-vertebral fractures as primary

or co-primary endpoints require large, very expensive multi-year trials in patients at high risk of fracture. Yet, given that effective anti-fracture medications are available, placebo-controlled trials in high-risk patients are no longer ethical, necessitating either active controls or restricting enrollment to lower-risk patients. Both scenarios lead to larger sample sizes and/or longer trials, increasing the cost of drug development and delaying the time for new therapies to reach patients. Consequently, development of new osteoporosis therapies has essentially stalled, with no new anti-osteoporosis medications currently in Phase III clinical trials. A potential solution to improved assessment and approval of osteoporosis treatments is to replace fracture outcomes in such trials with a suitably qualified surrogate endpoint.

NSS107

EVIDENCE SUPPORTING THE USE OF BMD AS A SURROGATE ENDPOINT FOR FRACTURES

R. Eastell[1]

[1]University of Sheffield, Sheffield, United Kingdom

Surrogate endpoints have more statistical power and are more quickly assessed than clinical endpoints. Thus, we aimed to examine the change in total hip BMD after 24 months of treatment as a surrogate measure to replace the clinical endpoint of fracture in osteoporosis clinical trials. To do so, we established the **S**tudy **t**o **A**dvance **B**MD as a **R**egulatory **E**ndpoint (SABRE). We worked with study sponsors under the Foundation of the National Institute of Health to obtain individual patient data from 53 randomized controlled trials with over 170,000 patients. We focused on BMD as it was available in many patients (about 90,000) and had strong prior evidence of potential as a surrogate. The four key steps in identifying a surrogate are 1) there is biological plausibility, 2) there is an association between low BMD and increased risk of fracture, 3) the change in BMD is associated with reduction in the risk of fracture, and 4) there is a threshold that can be used to operationalize the approach, the surrogate threshold effect. We have evidence for each of the steps. Step 3 required a meta-regression of all the clinical trials with total hip BMD change at 24 months in the active and placebo groups. We found a strong association between the change in BMD against fracture risk reduction for vertebral, all clinical and all fractures, with r2 exceeded the critical value of 0.65 recommended for a valid surrogate endpoint. Thus, we have submitted a final qualification package to the Food and Drug Administration proposing that in future clinical trials, the change in total hip BMD at 24 months would suffice for drug licensing.

NSS108

DESIGN CONSIDERATIONS FOR A FUTURE RANDOMIZED TRIALS WITH A TOTAL HIP BMD ENDPOINT

D. M. Black[1]

[1]University of California, San Francisco, United States

Since 2018, the Study to Advance BMD as a Regulatory Endpoint (SABRE) project has been working with U.S. Food and Drug Administration (FDA) to gain formal qualification for the change in total hip BMD as a surrogate endpoint for fracture in future trials of new osteoporosis treatments. To this end, we submitted the 'final qualification package' to the FDA in 2024 and are expecting to receive a decision from the FDA in early 2025. If the change in total hip BMD is qualified by FDA, the surrogate threshold effect (STE) would guide regulatory drug approval. For example, for all clinical fractures, the STE is 2.04%. Therefore, a drug that showed an average 24-month increase ≥ 2.04% in total hip BMD (active versus control) would be approved. All previously approved osteoporosis therapies that were effective for clinical fractures would have met or exceeded this threshold, providing validity to this approach. If the surrogate is qualified by FDA, we hope to expand the qualification outside of the U.S.

This presentation will discuss design considerations for a future trial with an endpoint of total hip BMD change. Use of the surrogate would apply to trials of postmenopausal women with osteoporosis and/or increased risk of fracture. Our analyses indicate that a trial size of at least 500 women (250 per treatment group) would be required. A somewhat larger sample in the active treatment group might be needed to meet requirements for safety (at least 300 patients exposed ≥ 6 months) established by the International Council for Harmonization of Technical Requirements for Pharmaceuticals for Human Use (ICH). Sequential placebo then active treatment regimen and/or an active control study designs might be considered since we have evidence that results from the studies of romosozumab and abaloparatide are consistent with our proposed approach using BMD as a surrogate endpoint. For safety, the current requirements for pre-clinical studies and assessment of bone quality in humans by bone biopsies would remain as they are. ICH requirements for exposure would need to be satisfied across the Phase 1-3 studies in the development program. In addition, post-marketing safety studies might also be required by regulatory agencies to assess rare safety issues.

NSS109

BONE CONSEQUENCES OF PREMATURE OVARIAN INSUFFICIENCY (POI)

J. Kulak Jr.[1,2,3]

[1]Professor of Obstetrics and Gynecology at Federal University of Paraná, Curitiba, Brazil, [2]Board Member of the National Specialized Committee on Menopause of FEBRASGO, São Paulo, Brazil, [3]Board Member of the Brazilian Menopause Society - SOBRAC, São Paulo, Brazil

The usual age of menopause globally is between 48 and 52 years. Premature ovarian insufficiency (POI), loss of ovarian function occurring before the age of 40 years and affects around 2–4% of women. Long-term health concerns associated with POI include an increase in cardiovascular disease, cognitive dysfunction, and reduced bone mineral density (BMD), as well as reduced overall quality of life and life expectancy, largely due to cardiovascular disease. Peak bone mass is usually achieved during the third decade of life, and estrogen deficiency during childhood to young adulthood can impair optimal peak bone mass. Depending on the age of menopause, women with POI may experience both lower peak bone mass, and earlier menopausal bone loss, predisposing to osteoporosis and fractures. Risk factors for lower BMD in women with POI include lower age of menopause, low vitamin D, low body weight, lack of exercise, delay in diagnosis, poor adherence to menopause hormone therapy (MHT), and low calcium intake. Despite affecting significantly more women than POI alone, there is a relative paucity of data on bone health in women with POI, and studies examining osteoporosis and fracture risk in these women have had mixed results, with some showing increased risk and others showing no difference. International guidelines recommend the use of MHT in women with POI, until the usual age of menopause. MHT has been shown to improve BMD in these women, and, although evidence for fracture reduction in this population is unclear, data extrapolated from studies in postmenopausal women in general has shown significant fracture reduction. Clinical guidelines recommend screening with dual X-ray absorptiometry (DXA) and treatment with MHT for most women with POI to reduce osteoporosis and fracture risk; however, some studies indicate gaps in osteoporosis knowledge, guideline uptake, and management adherence by clinicians and women.

NSS110

THE ROLE OF HORMONE THERAPY IN THE MANAGEMENT OF POSTMENOPAUSAL OSTEOPOROSIS

M. C. Osório Wender[1,2,3,4]

[1]President of Brazilian Federation of Obstetrics and Gynecology Associations -FEBRASGO, São Paulo, Brazil, [2]Vice-president of Brazilian Menopause Society (SOBRAC), São Paulo, Brazil, [3]Full Professor of Obstetrics and Gynecology, Federal University of Rio Grande do Sul (UFRGS), Porto Alegre, Brazil, [4]Past-Head of Obstetrics & Gynecology Service at Porto Alegre Clinical Hospital (HCPA), Porto Alegre, Brazil

Postmenopausal osteoporosis poses a significant global health challenge due to its association with increased fracture risk. Hormone therapy (HT) plays a key role in preventing and treating this condition by reducing bone mineral density (BMD) loss and fracture rates. This presentation examines HT's role in osteoporosis management, supported by key clinical studies and guidelines.

HT effectively prevents BMD loss and promotes bone mass gains. The PEPI trial confirmed its efficacy over three years, while long-term studies like the Nurses' Health Study and WHI trials demonstrated reduced fracture risks, including a 34% decrease in hip fractures with combined estrogen-progestogen therapy. Tibolone, a synthetic steroid, also prevents fractures in postmenopausal women, as shown in the LIFT trial. Early postmenopausal women with estrogen deficiency and high fracture risk benefit most from HT. Emerging evidence suggests that low and ultra-low estrogen doses are as effective in BMD maintenance as conventional doses, with fewer risks. This makes them a safer option for broader use.

Guidelines stress personalized HT use based on individual fracture risk, symptom severity, and patient preferences. The "window of opportunity" in early postmenopause maximizes skeletal and cardiovascular benefits while minimizing risks.

This presentation highlights HT as a pivotal tool for osteoporosis prevention and first-line treatment in symptomatic women at risk of fractures. By tailoring interventions, healthcare providers can optimize skeletal health and enhance quality of life for postmenopausal women.

NSS111

EVALUATION AND MANAGEMENT OF OSTEOPENIA AND OSTEOPOROSIS IN BREAST CANCER SURVIVORS

A. Orcesi Pedro[1,2,3,4,5,6]

[1]Vice-President of National Specialized Committee on Osteoporosis of FEBRASGO, São Paulo, Brazil, [2]Regional Advisory Council – Latin America - International Osteoporosis Foundation, São Paulo, Brazil, [3]Committee of Scientific Advisors - International Osteoporosis Foundation, São Paulo, Brazil, [4]Post Graduate Professor of Department of Obstetrics and Gynecology, University of Campinas - UNICAMP, São Paulo, Brazil, [5]Menopause Society Certified Practitioner – The menopause Society, São Paulo, Brazil, [6]Associate Member of ABRASSO - Brazilian Association of Bone Evaluation and Osteometabolism, São Paulo, Brazil

Breast cancer is the most common cancer diagnosed in women worldwide. Due to earlier detection and advances in treatment, the 5-year survival rate in women with early breast cancer is currently greater than 90%, emphasizing the need to mitigate adverse long-term treatment effects. Patients with nonmetastatic cancer may be at risk for osteoporotic fractures due to baseline risks or due to the added risks associated with treatment-related bone loss

due to hypogonadism from endocrine therapy (ie, oophorectomy, GnRH agonists, chemotherapy-induced ovarian failure, aromatase inhibitors), chemotherapy or other cancer therapy associated medications (ie, glucocoriticoids). Osteoporosis fracture risk assessment may include use of FRAX or other established tools. For those patients with substantial risk of osteoporotic fracture, the clinician should obtain a bone mineral density test. The bone health of all patients may benefit from optimizing nutrition, increasing physical activity, strength training, training to prevent falls, smoking cessation and decreasing alcohol consumption. When a pharmacologic agent is indicated, bisphosphonates or denosumab at osteoporosis-indicated dosages are the preferred interventions. Bone-modifying agents (BMAs) are mainstays in breast cancer and prevent and treat osteoporosis in early-stage disease and reduce skeletal metastases complications in advanced disease. There is some evidence to support that BMA also prevents skeletal metastases and improves overall survival.

NSS112

WHY A CLINICAL PRACTICE GUIDELINE IN A MIDDLE-INCOME COUNTRY LIKE COLOMBIA?

G. Altamar[1]

[1]Specialist in Internal medicine and Geriatrics ; Specialist in Health management ; Professor of Geriatrics – Universidad del Valle ; Colombian Osteoporosis Association (ACOMM) President, Cali, Colombia

Colombia is a country known for its geographical, cultural, and biological diversity. With a growing economy and a diverse population, it has a health system that seeks to guarantee care for its entire population but faces challenges in efficiency and equity. Osteoporosis is a systemic skeletal disease characterized by low bone mineral density and deterioration of bone architecture, resulting in reduced bone strength and, consequently, increased susceptibility to fractures. In Colombia between 2012 and 2018, 249,803 of people over 50 years of age were diagnosed with osteoporosis. In 2015, the direct cost of hip fracture was estimated at USD 4,428.88 per event, USD 5,855.71 for surgical vertebral fracture and USD 1,196.65 for distal radius fracture. However, osteoporosis is not a disease prioritized in public policies, without specific primary prevention programs or a systematized registry of the disease. Understanding this scenario, it has been relevant to have guidelines that allow the approach of patients with osteoporosis, which is why the Colombian Association of Osteoporosis and Mineral Metabolism (ACOMM) developed in 2005 and 2018, two consensuses of experts in the diagnosis and treatment of osteoporosis. Due to the initial acceptance of the consensus and the evolution in the diagnosis and treatment of osteoporosis, the need arose for a Clinical Practice Guideline (CPG) that would synthesize the best available evidence, which would improve the diagnosis and treatment of affected patients, reduce the burden of osteoporosis on the health system and improve the quality of life of patients and their caregivers. Our CPG focuses on adult patients at risk or with primary osteoporosis. Developed by a multidisciplinary group of experts, it is aimed at all health professionals involved in the management of patients at risk of osteoporosis, suspected osteoporosis or confirmed diagnosis, at different levels of health care in Colombia.

NSS113

CHALLENGES IN THE DEVELOPMENT OF CLINICAL PRACTICE GUIDELINES IN A MIDDLE-INCOME COUNTRY

A. Medina[1,2]

[1]Department of Endocrinology. Hospital de San José. Bogotá, Bogota, Colombia, [2]Asistant Professor Universidad Nacional de Colombia, Bogota, Colombia

Clinical practice guidelines (CPGs) are considered an essential tool for physicians, policy makers and patients in disease management; however, there are limitations in the development of CPGs that affect all levels, mainly developing countries.

The validity of CPGs depends largely on evidence. The selection of studies based on content, quality, relevance and timeliness is key to avoid providing an erroneous recommendation, or one based on opinion. The difficulty in accessing scientific evidence or the misinterpretation of evidence also contributes to this problem.

Sometimes, the evidence that comes from developed countries cannot be adapted to some developing countries due to the lack of diagnostic methods or treatments, so the CPG must be adapted to the available resources, or it could not be applied, remaining far from the recommendations of international CPGs for the same disease.

There must be a careful selection of the panel of participants since there is usually unequal participation related to high workloads, lack of time, limited advice to the development group to choose the questions, methodology and schedule. Conflicts of interest (COI) of panel members developing CPGs must be disclosed, and while 78% of CPGs analyzed report COIs, most of them have financial ties to the industry, making recommendations less objective.

The costs to implement guidelines usually come from the government or scientific associations, which in low or middle-income countries are limited and CPGsdevelopment times can be extended.

Most CPGs are published in journals or on the websites of individual countries orhealth organizations, making them difficult for clinicians to access and implement. There are often no strategies or funding to disseminate them, and most guidelines

quickly become outdated after 3 years.
The Colombian Guide to Osteoporosis was advised by a group of epidemiologists and had the rigor of evidence and the participation of the panel, with financial resources from Colombian Osteoporosis and Mineral Metabolism Association (ACOMM).
Conclusion: The main challenges in the development of CPGs in low- and middle-income countries are adapting to the country's needs and resources, overcoming financing difficulties, conflicts of interest, dissemination and access.

NSS114

OPPORTUNITIES WITH THE DEVELOPMENT OF CLINICAL GUIDELINES

M. Chalem[1,2,3]

[1]Fundacion SantaFe Bogota, Bogota, Colombia, [2]Colombian Osteoporosis and Mineral Metabolism Association- ACOMM - Past President, Bogota, Colombia, [3]Colombian rheumatology association – Colombian Rheumatology Association - Past President, Bogota, Colombia

Clinical practice guidelines (CPGs) are developed through a rigorous systematic methodology synthesizing the ever-increasing amounts of published literature into a practical and digestible set of clinical recommendations to be used in a healthcare setting. For a multidisciplinary scientific organization like Colombian Osteoporosis and Mineral Metabolism Association (ACOMM), the development of a Clinical Practice Guideline involves a effort that joint several of its active members with experience and knowledge , complementary to the topic of interest in question: rheumatology, endocrinology, geriatrics, gynecology and menopause, orthopedics, sports medicine , physiatry and family medicine.
The work carried out for the preparation of CPG, with a rigorous methodology and a large and enthusiastic participation, reflects ACOMM's commitment to health research and to the improvement of bone health in our country. Up to next some of the opportunities discovered with the development of clinical guidelines:
- Promote the growth and the visibility the ACOMM between Colombian academic, medical and policy members.
- Reduction of variability in clinical practice, especially in primary care to improve health outcomes with informed clinical decisions to the patients and their caregivers.
- Clinical guidelines could be adapted to meet the individual needs of patients and their specific health conditions because they can facilitate communication and collaboration between health professionals, including doctors, nurses and other specialists.
- Clinical guidelines could be integrated into clinical decision support systems and other technologies to improve their implementation and follow-up.
- Clinical guidelines can be the subject of continuous research and evaluation to improve their effectiveness and relevance.
In the experience of ACOMM, an expert consensus was developed and published in 2018, and it was taken as a basis for the elaboration of this new guideline. The association begun the dissemination by taking advantage of specific events and digital platforms that are ideal for carrying out activities around what is proposed in the guide.

NSS115

OSTEOPOROSIS AND THE SPINE OVERVIEW: KEY STATISTICS AND AN OVERVIEW OF THE NATIONAL SPINE HEALTH FOUNDATION'S KEY PATIENT AND HEALTH CARE PROFESSIONAL INITIATIVES

R. Roy[1]

[1]Chief Executive Officer, National Spine Health Foundation, Reston, United States

Dr. Roy will cover the following key topics:
- Provide an overview on the activities and key programs of the National Spine Health Foundation
- Fractures caused by osteoporosis most often occur in the spine (and in the United States, there are 1.5 million vertebral compression fractures that occur each year)
- The age- and sex-specific prevalence of osteoporosis in patients undergoing spine surgery goes up markedly as people age, particularly in females (from 27.8% for women from age 50-59 to 75.4% for women from age 70-79)
- The efforts that the National Spine Health Foundation is driving to educate patients and health care professionals on the need to identify, diagnose, and treat vertebral compression and spine fractures (both surgically and through anti-osteoporotic medications) including its patient and health care professional "Bone Hub" and medical education platform
- Key messages that are most effective with patients to educate them on the connection between spine and bone health (including prevention of osteoporosis, how it is treated, and why bone health is such an important component of spine health)

NSS116

A SPINE SURGEON PERSPECTIVE ON THE NEED FOR SPINE AND BONE HEALTH OPTIMIZATION

P. Anderson[1,2]

[1]University of Wisconsin School of Medicine, Madison, United States, [2]Co-Chair, National Spine Health Foundation Spine & Bone Health Task Force, Reston, United States

Dr. Anderson will cover the following key topics:
- Gaps in spine surgeon awareness of the need to conduct perioperative spine health optimization before surgery as a crucial step for improving patient outcomes and reducing complications (which includes a thorough bone health assessment) given the high prevalence of osteoporosis in patients undergoing spine surgery
- Why spine surgeons should establish care pathways to systematically identify and diagnose osteoporosis in their practices (which may include the establishment of a Fracture Liaison Service program or other means to ensure patients are assessed before surgery)

- The need for vertebral compression fractures to be treated as equally aggressively as hip fractures, with medications including anabolics
- Opportunities for spine/orthopaedic surgeons to work more effectively with bone health specialists to maximize patient care and improve outcomes
- NSHF's platforms to educate health care professionals on spine and bone health

NSS117

A EUROPEAN PERSPECTIVE ON KEY SPINE SURGEON GAPS IN THE DIAGNOSIS AND TREATMENT OF OSTEOPOROTIC PATIENTS

J. C. Le Huec[1,2]

[1]Member, National Spine Health Foundation European Spine & Bone Health Task Force, Reston, United States, [2]Polyclinique Bordeaux Nord Aquitaine and Bordeaux University, Bordeaux, France

Dr. Le Huec will cover the following key topics:

- Economic and personal impact of vertebral fractures across Europe
- NSHF's key activities regarding its European Task Force (building on the success of NSHF's activities in the United States)
- Opportunities for public and health care professional education in Europe regarding the connection between spine and bone health
- Integrating bone quality assessment into decision making and surgical planning in spine surgery
- How spine surgeons and bone specialists in Europe can more effectively work together to identify, diagnose, and treat patients with osteoporosis prior to spine surgery
- Guidance to national patient and health care professional groups on how to incorporate patient and health care professional messaging around spine and bone health

NSS118

SETTING THE STAGE: UNDERSTANDING THE INTERSECTION OF AGING, CKD, AND OSTEOPOROSIS – KEY CONCEPTS AND CLINICAL APPROACHES

S. Ozturk[1]

[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Nephrology and Istanbul Bone and Musculoskeletal Health Consortium, Istanbul, Turkiye

The aging process increases the risk of osteoporosis by decreasing bone density and deteriorating bone quality. This results in an increased risk of fractures, especially those that can lead to serious consequences such as hip fractures. CKD negatively affects bone health by affecting the body's mineral and bone metabolism. Individuals with CKD have a significantly increased risk of developing osteoporosis, especially in advanced stages. The bone disease associated with CKD is called "CKD-mineral and bone disease (CKD-MBD)" and is characterized by weakened bones, pain, and an increased risk of fractures. When aging and CKD come together, bone loss and the risk of fractures increase even further. This makes early diagnosis and treatment of osteoporosis critical in older CKD patients. Effective management of this triad of health problems requires a multidisciplinary approach. Lifestyle changes (regular exercise, balanced diet, fall prevention), medication therapies, and regular follow-up are important to maintain bone health and reduce the risk of fractures.

NSS119

MANAGING SKELETAL FRAGILITY IN THE CONTEXT OF CKD: PRACTICAL INSIGHTS

R. Keen[1]

[1]Centre for Metabolic Bone Disease, Royal National Orthopaedic Hospital, Stanmore, United Kingdom

Chronic kidney disease (CKD) is associated with the development of a mineral bone disorder (CKD-MBD). CKD-MBD is a systemic disorder which is manifested by either one or a combination of the following: abnormalities of calcium, phosphorus, parathyroid hormone, or vitamin D metabolism; abnormalities in bone turnover, mineralization, volume, linear growth, or strength; vascular or other soft tissue calcification. Persons with CKD have an increased risk of fracture compared to those with normal renal function, and this risk is elevated further in those who are on dialysis. There is also a greater risk of morbidity and mortality.
Dual energy X-ray absorptiometry (DXA) should be used to assess fracture risk in persons aged > 50 years and with CKD 4-5D. DXA may, however, underestimate the actual fracture risk as it does not account for impaired bone quality. Fracture risk will also be affected by the severity of CKD and the duration of dialysis. Ongoing studies are assessing whether arithmetic adjustment for bone quality (i.e. using trabecular bone score), non-kidney retained bone turnover markers, or CKD severity, may improve the fracture risk prediction.
Non-pharmacological interventions include ensuring an adequate dietary intake of calcium and vitamin D stores being replete. Persons with CKD are at increased risk of falls, and exercises should be targeted to improve muscle strength and balance.Pharmacological therapies include antiresorptive and osteoanabolic Most clinical trials of antiresorptive medications have excluded patients with advanced CKD, but the available data are most extensive for bisphosphonates. Subgroup analyses of phase 3 trials have suggested therapeutic benefits of bisphosphonates in patients with CKD 1-3b, as well as in patients who have undergone kidney transplantation, although data on bisphosphonates in CKD 4-5D are extremely limited. Denosumab is a drug with antiresorptive properties that can be used in the treatment of osteoporosis in advanced CKD with less risk of renal toxicity. There is, however, risk of severe hypocalcaemia, which can be prolonged and is more common in patients with advanced CKD and on dialysis. In addition, if Denosumab is stopped with

no follow-on treatment, there is an increased risk of rebound osteoclast activity, a rapid reduction in bone mass and an increased risk of vertebral fractures. Although bisphosphonates may negate this, their use may be precluded in patients with CKD. Low bone turnover is commonly observed in patients with advanced CKD or maintenance dialysis, suggesting that osteoanabolic drugs may play an important role. These drugs include Abaloparatide, Teriparatide and Romosozumab, although there are limited studies that have assessed the use of these in CKD patients. At the end of the course of anabolic treatment, it is generally recommended to have follow-on treatment with an anti-resorptive and this choice may be challenging in patients with advanced CKD. In addition, the increased prevalence of cardiovascular disease in CKD patients may limit the use of Romosozumab. Further studies are needed to explore the safety and efficacy of these drugs for treating CKD-MBD.

NSS120

REAL-WORLD CHALLENGES AND PERSONALIZED STRATEGIES IN DIAGNOSIS AND TREATMENT

G. Bahat[1]

[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Geriatrics and Istanbul Bone and Musculoskeletal Health Consortium, Istanbul, Turkiye

While management of OP is well-defined in guidelines, management and treatment decisions in older complex patients having CKD-MBD and osteoporosis are still challenging. The presentation will include a brief summary of a series of 20 cases with OP and CKD-mineral and bone disorder (MBD) managed by Istanbul Bone and Musculoskeletal Health Consortium. Afterwards, we will focus on a selected case illustrating the need for personalized strategies. Attendees are aimed to gain insights and practical tools to address these complex scenarios effectively.

NSS121

HIV AND IT'S TREATMENTS ON FRACTURE RISK: A SCOPING REVIEW

C. Gregson[1,2]

[1]The Health Research Unit of Zimbabwe (THRU ZIM), The Biomedical Research and Training Institute, Harare, Zimbabwe, [2]Global Health & Ageing Research Unit | Musculoskeletal Research Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom

We will outline findings from a recently completed WHO-commissioned scoping review, on incidence, prevalence, risk factors and prevention of fractures in adults living with HIV in low- and middle-income countries (LMIC), which has identified gaps in the evidence-base, on which to focus in future research programmes. Findings include the evidence for PrEP (pre-exposure prophylaxis) and the association with fracture.

NSS122

FRACTURES E3 FOCUSSING ON VERTEBRAL FRACTURES

[1]MRC Lifecourse Epidemiology Centre University of Southampton, Southampton, United Kingdom, [2]MRC Unit The Gambia at London School of Hygiene and Tropical Medicine, Banjul, Gambia, [3]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [4]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom, [5]The Health Research Unit Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, [6]MRC Unit The Gambia, London School of Hygiene and Tropical Medicine, Banjul, Gambia, [7]Department of Geriatrics, University of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa, [8]Clinical Research Department, London School of Hygiene and Tropical Medicine, London, United Kingdom, [9]Birmingham Women's and Children's NHS Trust, Steelhouse Lane, Birmingham, United Kingdom, [10]MRC International Statistics and Epidemiology Group, London School of Hygiene and Tropical Medicine, London, United Kingdom, [11]Department of Rheumatology, University of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa

To understand the epidemiology of vertebral fractures across Africa, we conducted a community-based prevalence study in The Gambia (urban and rural), South Africa (urban and rural) and Zimbabwe (peri-urban), using iDXA VFA and plain lateral radiographs where iDXA VFA was not available. We recruited 5050 adults age 40 years and older (51% female). Vertebral fracture prevalence, in men and women age 40-54 years was 2-5% and 1-3% respectively, whilst in those age 55-70 years it was 5-7% and 4-9%, and in the older group age 70+ years it was 6-15% and 7-21%. Age, low BMD, glucocorticoid use we strongly associated with VF. In Zimbabwe HIV was associated with prior VF. Overall, prevalence was similar to many European estimates, and as seen elsewhere was associated with back pain. Notably, no individual was taking anti-resorptive medication. We will describe work underway to use these data to aid clinical fracture risk assessment approaches.

NSS123

CLINICAL RISK FACTORS ASSOCIATED WITH FRACTURE RISK IN MIDDLE-AGED MEN AND WOMEN FROM SOWETO, JOHANNESBURG: FINDINGS FROM THE MIDDLE-AGED SOWETO COHORT (MASC)

L. Micklesfield[1]

[1]SAMRC/Wits Developmental Pathways for Health Research Unit, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

Data from the MASC cohort has reported a prevalence of osteoporosis (lumbar spine or total hip) of 25% and 15.7% in women living with HIV and HIV-negative women, respectively. Our longitudinal data have also shown greater menopause-associated bone loss in women living with HIV compared to HIV-negative women; however, it is unknown whether these differences translate to fracture risk, and the fracture risk in South African men of the same age.

We will describe data collected at the most recent time point (2023/2024) from 600 men and women from the MASC cohort and how it has been used to estimate the 10-year probability of a major osteoporotic fracture (MOF) using the South African FRAX tool. We will quantify associations between clinical risk factors such as age, weight, height, smoking status, alcohol consumption, HIV infection, prior fracture, and 10-year probability of MOF in men and women living with and without HIV.

These findings will provide much-needed data on factors associated with fracture risk in an under-represented population who may be at higher risk of osteoporosis and fracture than previously thought.

NSS124

THE INFLUENCE OF HIV ON BONE QUALITY, QUANTITY AND FRACTURE RISK IN MIDLIFE WOMEN: FINDINGS FROM A CROSS-SECTIONAL STUDY IN ZIMBABWE

M. O. Breasail[1], T. Madanhire[2,3,4], K. Ward[5,6], C. Gregson[7,8]

[1]1Department of Medicine, School of Clinical Sciences, Faculty of Medicine, Monash Medical Centre, Nursing and Health Sciences, Monash University, Clayton, VIC , Australia, [2]Population Health Sciences, Bristol Medical School, Bristol, United Kingdom, [3]The Health Research Unit Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, [4]Infectious Disease Epidemiology, Faculty of Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]MRC Lifecourse Epidemiology Centre University of Southampton, Southampton, United Kingdom, [6]MRC Unit The Gambia at London School of Hygiene and Tropical Medicine, Banjul, Gambia, [7]Global Health & Ageing Research Unit | Musculoskeletal Research Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom, [8]The Health Research Unit of Zimbabwe (THRU ZIM), The Biomedical Research and Training Institute, Harare, Zimbabwe

To investigate the effects of HIV on bone health in menopause we conducted a cross-sectional study of women aged 40-60 years (49% with HIV) in Harare, Zimbabwe. We quantified BMD using radial/tibial peripheral Quantitative Computed Tomography (pQCT) scans and DXA, and prior fracture to determine FRAX probabilities of major osteoporotic fracture (MOF).

The 393 women had a mean (SD) age of 49.6 (5.8) years and mean (SD) BMI of 29.1 (6.0) kg/m2. 95% of those with HIV were established on antiretroviral therapy (ART) (85% on tenofovir disoproxil fumarate) and 81% had a viral load <50 copies/mL. BMD T-score ≤ -2.5 was more commonly seen in women living with HIV (WLH) than those without, at both femoral neck (FN) and lumbar spine (LS) (FN, 22 [11.4%] vs 5 [2.5%]; LS, 40 [20.8%] vs 9 [4.5%], respectively). Prior fracture was more prevalent in WLH (any fracture: 27 [14%] vs 14 [7%]); MOF: (14 [7.3%] vs 5 [2.5%]). Nobody reported anti-osteoporosis medication use. Older age, low weight, and HIV infection were strongly associated with lower FN BMD. WLH had a higher 10-year MOF probability, although probabilities were low.

WLH had lower absolute pQCT measures at all sites. Overall, HIV-related deficits were robust to adjustment for age, menopause status, height, and fat mass: WLH had lower trabecular vBMD (radius -7.3 [-12.5; -2.0]%, tibia -5.4 [-9.1; -1.7]%), and cortical vBMD (radius -3.5 [-5.9; -1.1]%, tibia -1.1[-1.6; -0.5]%). Strength estimates were lower in WLH at both radius and tibia. Longer HIV duration was associated with lower radius bone area, BMC, estimates of bone strength, independent of ART duration.

We found that osteoporosis and previous fractures were common and untreated in this relatively young population, particularly in women living with HIV. Trabecular deficits predominate in those women. FRAX-probabilities were low. The approach to consider clinical risk factors in fracture risk prediction tools may need contextual adaptation.

NSS125

EXPLORING THE ROLE OF INFLAMMAGEING IN SARCOPENIA – A QUICK OVERVIEW

J. Dupont[1,2]

[1]Department of Geriatric Medicine, UZ Leuven, Leuven, Belgium, [2]Gerontology & Geriatrics, Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium

Sarcopenia is a muscle disease, characterized by loss of muscle mass and function, leading to 'muscle failure'. It is highly prevalent amongst older adults and can seriously affect the daily life of an older adult, e.g., by limiting the ability to walk and to lift heavy objects like groceries or through difficulties to climb the stairs. One of the major mechanisms behind the onset and progression of sarcopenia is the **chronic low grade inflammatory state related with ageing**, the so-called 'inflammageing'. The concept of inflammageing was originally introduced by Franceschi *et al.* in 2000 and is presumed to play a major role in many age-related diseases, e.g., dementia, cancer, atherosclerosis. However, the

exact mechanisms by which inflammageing causes sarcopenia are not completely clear yet.
Over the past decades, research into the interplay between inflammageing and sarcopenia has increased, with numerous cytokines (e.g., Interleukin-6, Tumor Necrosis Factor-α, IL-1β, and others) being investigated in this context. The growing body of findings is complex and at times contradictory. However, there is accumulating evidence supporting the role of inflammageing as a key driver in the development of sarcopenia, highlighting its potential as a target for therapeutic interventions aimed at counteracting the condition.
This presentation will discuss available data from the **Exercise and Nutrition for Healthy AgeiNg (ENHANce)** study, examining the inflammatory profiles of sarcopenic older adults and their association with functional outcomes (1). Additionally, findings from **the European Male Ageing Study (EMAS)** will be presented, exploring the relationship between inflammatory markers (hs-CRP, WBC, and albumin) and sarcopenia or related traits in middle-aged and older men (2). Finally, **recent advances** in understanding the connection between sarcopenia and inflammageing will be discussed.

NSS126

THE GUT-MUSCLE AXIS IN SARCOPENIA: BRIDGING GUT MICROBIOTA, INFLAMMATION AND DIET

L. Lapauw[1]

[1]Gerontology & Geriatrics, Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium

Sarcopenia, the age-related loss of muscle mass and function, increases the risk of deleterious health outcomes in older populations. Thus, timely diagnosis and treatment optimization for sarcopenia are warranted, which could be attained through in depth insights in its pathophysiology. Multiple factors contribute to sarcopenia (such as chronic low-grade systemic inflammation, anabolic resistance, oxidative stress and habitual dietary intake void of proteins). Additionally, over the past decade, a novel driving mechanism has emerged, namely the gut microbiota (GM) acting through a **gut-muscle axis.**
Healthy GM modulate physiological processes such as gut barrier integrity, suppression of chronic inflammation and enhancement of antioxidative activity, of which some processes are linked to sarcopenia pathophysiology. Thus altered, dysbiotic GM enhance chronic low-grade systemic inflammation, eventually impacting skeletal muscle. Prior research has linked a dysbiotic GM to low muscle mass and function in persons with underlying comorbidity. However, data on the link in primary sarcopenia, when only aging is the evident trigger, is scarce, hampering identification of a **GM signature** of sarcopenia.
Additionally, identification of a GM signature or a surrogate thereof, may be a valuable **diagnostic biomarker** in sarcopenia. Previously, it has been shown that the **intestinal inflammatory marker fecal calprotectin (fCPT)** strongly correlates with dysbiotic GM in persons with Inflammatory Bowel Disease. However, fCPT's potential value as surrogate for GM dysbiosis in sarcopenia diagnosis, has not been investigated.
Currently, non-pharmacological anabolic interventions, such as high-protein diets, are the preferred treatment option for sarcopenia. However, in turn, these high-protein diets do not necessarily beneficially impact GM composition. Furthermore, prior research has investigated effects of interventions restoring dysbiotic GM, such as pre-, pro or symbiotic supplementation on muscle mass, strength. However, these studies often neglected the role of the habitual diet, although known to be a GM modulator.
To address these remaining research gaps, in this symposium we will elaborate upon:
1. Whether there is evidence for the existence of a specific GM signature for sarcopenia, investigating possible associations between specific GM taxa and sarcopenia (-defining parameters).
2. Investigating the value of the gut dysbiosis surrogate fCPT as a biomarker for sarcopenia, alone or in combination with other biomarkers.
3. How GM-altering interventions, such as diet, pre-pro and synbiotics, impact sarcopenia (-defining parameters).
We will present recent findings from a systematic review, meta-analysis and the ongoing Trial in Elderly with Musculoskeletal Problems due to Underlying Sarcopenia – Faeces to Unravel the Gut and Inflammation Translationally (TEMPUS-FUGIT; NCT05008770) to address the above-mentioned gaps.

NSS127

SARCOPENIA AND THE BRAIN: UNRAVELLING THE MUSCLE-BRAIN AXIS IN THE DEVELOPMENT AND TREATMENT OF SARCOPENIA

N. Amini[1]

[1]Gerontology & Geriatrics, Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium

Due to the ageing society, preventing or treating age-related disabilities or diseases is one of the most important public health objectives of this century. Two common key features of the ageing process are **age-related sarcopenia and cognitive decline.**
Emerging research indicates a **potential link between sarcopenia and cognitive decline**, including mild cognitive impairment, Alzheimer's disease and other types of dementia. However, there is paucity of data on the (temporal) association between sarcopenia and its defining parameters (muscle mass, strength and physical performance) and different domains of cognitive functioning. Moreover, preclinical studies suggest that **myokines** could serve as a key molecular mechanism in explaining this relationship, though clinical data remains scarce.
Evidence also indicates that both sarcopenia and cognitive decline may be preventable and reversible by addressing common modifiable risk factors, such as nutritional status and physical exercise. Promising data indicate that resistance exercise training and protein supplementation, can improve sarcopenia and prevent cognitive decline. However, it remains unclear whether combining exercise with protein supplements or omega-3 supplements is more effective than exercise alone for improving both sarcopenia outcomes and cognition.
In this lecture, we will:

- Discuss recent developments in the interrelationship between sarcopenia and cognition, and the potential role of myokines in the muscle-brain axis.
- Discuss whether interventions aimed at improving sarcopenia outcomes, may also have beneficial effects on cognitive functioning in older adults.

We will present recent findings from the Exercise and Nutrition for Healthy AgeiNg (ENHANce) study, a 5-armed triple blinded RCT, in sarcopenic older adults (≥65 years), that aims to assess the effect of combined anabolic interventions (protein supplement, omega-3 supplement and physical exercise) on both physical performance and cognitive performance during a 12-week intervention.References:

NSS128

FIBROMYALGIA AS A SYSTEMIC AUTOIMMUNE DISEASE AFFECTING THE BONE

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Fibromyalgia is a syndrome of persistent widespread pain, stiffness, fatigue, disrupted and unrefreshing sleep, and cognitive difficulties, often accompanied by multiple other unexplained symptoms, anxiety and/or depression, and functional impairment of activities of daily living. It typically presents in young or middle-aged women, but it can affect patients of both sexes and of any age. Fibromyalgia has psychological implications. Basic and clinical investigations have clarified the neurophysiologic basis for fibromyalgia and led to its current classification as a central sensitivity syndrome. It may be considered as a neurosensory disorder characterized in part by abnormalities in pain processing by the central nervous system. Increased understanding of the pathophysiology of fibromyalgia may lead to novel therapeutic advances for the management of the disorder. The disorder is now considered an autoimmune disorder possibly characterized by autoimmunity against the autonomous nervous system. Fibromyalgia affects all organ systems including the musculoskeletal system, which is deeply affected.

NSS129

FIBROMYALGIA IN THE CONTEXT OF AUTOIMMUNE RHEUMATIC DISEASES

L. Athanassiou[1]

[1]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece

Fibromyalgia, a syndrome of persistent widespread pain, stiffness, fatigue, disrupted and unrefreshing sleep, and cognitive difficulties, anxiety, depression, and functional impairment of activities of daily living may occur as a primary disorder in its own right or may occur in the context of systemic autoimmune rheumatic diseases. The presence of fibromyalgia in the context of autoimmune rheumatic disorders, such as systemic lupus erythematosus, rheumatoid arthritis or psoriatic arthritis may aggravate pain and may lead to a severe phenotype of the primary disease. The presence of fibromyalgia in the context of autoimmune rheumatic diseases may lead to difficulties in the management of the diseases as well as to the management of

pain in these affected patients. The presence of fibromyalgia and the associated pain leads to a vicious cycle, aggravates symptoms of the underlying disease and further affects quality of life.

NSS130
FIBROMYALGIA IN THE CONTEXT OF AUTOIMMUNE THYROID DISEASE

I. Kostoglou-Athanassiou[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Fibromyalgia and chronic widespread pain syndromes are among the commonest diseases seen in rheumatology practice. Autoimmune thyroid diseases are common widely prevalent autoimmune disorders and are associated with fibromyalgia and chronic pain. This association is a manifestation of the autoimmune origin of fibromyalgia. It appears that mechanisms of pain related to fibromyalgia and autoimmune thyroid disease are inflammatory mediators, small-fiber neuropathy and central sensitization. The elucidation of pain pathways leads to the application of modern therapeutic agents in the management of pain in thyroid autoimmune disorders. The association of fibromyalgia with thyroid autoimmunity further underscores the autoimmune pathophysiology of fibromyalgia and leads to progress in the elucidation of the origin of chronic pain syndromes.

NSS131
FIBROMYALGIA AND PAIN

I. Sanidis[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Fibromyalgia is a systemic disease which is characterized by chronic pain. Fibromyalgia may occur as a primary disorder or may accompany autoimmune rheumatic diseases. Pain affecting the musculoskeletal system is a main manifestation of fibromyalgia. It is currently thought that fibromyalgia has autoimmune pathophysiology. Therefore, it is thought that molecular pathways related to autoimmunity and inflammation may be responsible for chronic pain, in particular musculoskeletal pain. These recent advances in the elucidation of the pathogenesis of fibromyalgia may lead to therapeutic advances in the management of the disease and in particular in the successful management of pain.

NSS132
FIBROMYALGIA, PAIN AND PSYCHOLOGICAL IMPLICATIONS

Y. Athanassiou[1]

[1]Department of Philology, Trinity College, Dublin, Ireland

Fibromyalgia is a systemic disorder characterized by chronic pain. The disorder may accompany systemic autoimmune rheumatic disorders or may occur as a primary disorder. Fibromyalgia has psychiatric and psychological manifestations such as anxiety and depression. The recent research findings which underline the autoimmune origin and pathophysiology of fibromyalgia further underline the close relationship between autoimmunity and depression. These clinical observations have led to novel therapeutic advancements in the management of pain in the context of fibromyalgia with antidepressive agents. It appears that fibromyalgia is a model disease delineating the relationship of pain and in particular musculoskeletal pain with depression and anxiety and may lead to the elucidation of the pathophysiology of chronic pain.

NSS133
DENOSUMAB: LONG-TERM THERAPY AND DISCONTINUATION

M. McClung[1]

[1]Oregon Osteoporosis Center, Portland, OR, United States

Denosumab is a potent anti-remodeling drug used for the treatment of men and postmenopausal women with osteoporosis and for men and women receiving hormone ablative therapy for non-metastatic prostate and breast cancer. Therapy for 10 years in women with postmenopausal osteoporosis resulted in continued increase in hip bone mineral density (BMD) and persistent or improved reductions in fracture risk. (1) No duration-related adverse events were observed. These findings make denosumab an attractive therapy for the long-term management of patients with osteoporosis. However, in contrast to our experience with bisphosphonates, the discontinuation of denosumab results in a rebound in markers of bone resorption, rapid loss of BMD and vertebral fracture protection and an increased risk of rebound-associated multiple vertebral fractures. (2)These changes have been observed upon discontinuation of denosumab when used for the treatment of osteoporosis in men and postmenopausal women, of glucocorticoid-induced osteoporosis, and to maintain bone health in men or women with non-metastatic cancer receiving hormone ablative therapy. For all patients who discontinue denosumab, regardless of treatment indication, a plan of assessment and management is required to maintain the benefits of the denosumab therapy and to prevent potentially serious consequences of the post-therapy rebound in remodeling.

extension. Lancet Diabetes Endocrinol. 2017;5(7):513-23. 2. Burckhardt P, Faouzi M, Buclin T, Lamy O, The Swiss Denosumab Study G. Fractures after denosumab discontinuation: a retrospective study of 797 cases. J Bone Miner Res. 2021;36(9):1717-28.

NSS134

MANAGING DENOSUMAB DISCONTINUATION IN PATIENTS WITH OSTEOPOROSIS

B. Langdahl[1]

[1]Departments of Endocrinology and Metabolism and of Clinical Medicine, Aarhus University, Aarhus, Denmark

Denosumab treatment leads to a sustained suppression of bone turnover and continuous increase of bone mineral density (BMD) long-term. Upon discontinuation of denosumab a transient overshoot in bone turnover and rapid bone loss occurs. The most plausible mechanism is the accumulation of precursor and recycled osteoclasts that synchronously differentiate when RANKL is no more inhibited, resulting in transient uncoupling with high bone resorption and low osteoblastic activity with low OPG levels. Determinants of greater bone loss with denosumab discontinuation include higher baseline CTX levels, longer denosumab treatment duration, younger age, low BMI and no prior antiresorptive treatment.

The rebound after short-term denosumab treatment (<3 yrs) may be mitigated by oral bisphosphonates, but more certainly by a single zoledronate infusion. The rebound after longer-term denosumab treatment is more difficult to completely overcome. The best proved strategy is multiple infusions of zoledronate during the first 1-2 years after discontinuation, guided by maintaining p-CTX below the premenopausal mean. (1,2) Studies investigating a strategy involving gradual reduction in denosumab doses are ongoing.

After more than 10 years of clinical experience, the efficacy and safety of denosumab in the treatment of post-menopausal osteoporosis is well established. However, preventing the bone turnover overshoot and bone loss related to denosumab withdrawal has emerged as a new challenge. Clinical trials and observational studies have demonstrated that the bone loss and risk of vertebral fractures when discontinuing denosumab can be mitigated by zoledronate, often requiring multiple infusions within the first year.

NSS135

MANAGING THE DISCONTINUATION OF DENOSUMAB IN PATIENTS ON HORMONE ABLATIVE THERAPY FOR NON-METASTATIC CANCER WITH OSTEOPOROSIS

Y. Rhee[1]

[1]Department of Internal Medicine, Endocrine Research Institute, Yonsei University College of Medicine, Seoul, South Korea

Denosumab, a key antiresorptive for postmenopausal osteoporosis, reduces fracture risk by 50% in women on aromatase inhibitor (AI) therapy and is often recommended for its efficacy, ease of use, and tolerance. Spontaneous multiple vertebral fractures (MVFs) after denosumab discontinuation, known as rebound-associated vertebral fractures (RAVFs), have led medical societies to recommend follow-up antiresorptive treatment in postmenopausal osteoporosis.(1) Postmenopausal patients with endocrine-responsive breast cancer treated with adjuvant AIs who stopped denosumab had a significantly higher risk of developing clinical vertebral fractures (hazard ratio [HR] = 2.44; 95% CI = 1.12–5.32) and MVFs (HR = 3.52; 95% CI = 0.98–12.64) compared to patients who stopped placebo. However, this increased risk was only observed in patients who ended AI treatment prior to or more than 6 months after the last dose of denosumab, whereas no difference was seen in those who ended AI treatment within 6 months of stopping denosumab.(2) The use of denosumab often aligns with cancer treatment, requiring careful consideration of alternative antiresorptive therapies or strategies to maintain bone health when discontinuing denosumab.(3)

NSS136

EPIDEMIOLOGICAL FACTS ABOUT OSTEOSARCOPENIA

S. Sabico[1]

[1]Chair for Biomarkers of Chronic Diseases, Biochemistry Department, College of Science, King Saud University, Riyadh, Saudi Arabia

Osteosarcopenia, a geriatric syndrome characterized by concurrent declines in bone density (osteopenia or osteoporosis) and skeletal muscle mass and strength (sarcopenia), poses significant challenges for aging populations. Its dual pathology amplifies the risk of adverse outcomes, including fractures, disability, and mortality, making it a pressing concern in clinical practice. Prevalence estimates vary widely, from 5% to 37%, depending on diagnostic criteria, population demographics, and assessment methods. Osteosarcopenia is more common in postmenopausal women due to hormonal changes but is also increasingly recognized in aging men. The negative consequences of osteosarcopenia are profound, primarily due to the synergistic effects of compromised bone and muscle integrity. The condition significantly increases fracture risk, especially at the hip, spine, and wrist, due to poor bone strength and an increased likelihood of falls. Fractures in osteosarcopenic individuals are associated with prolonged hospitalization, impaired recovery, and functional decline, which collectively elevate the risk of dependency and institutionalization. Moreover, osteosarcopenia is strongly linked to increased mortality. Studies show that individuals with combined osteoporosis and sarcopenia have a higher mortality risk than those with either condition alone. Mechanistically, this elevated risk stems from fracture-related complications, systemic inflammation, and reduced physical activity, which contribute to cardiovascular and metabolic deterioration. Physicians must recognize osteosarcopenia as a significant predictor of mortality and morbidity. Early identification and multifaceted interventions can mitigate these adverse outcomes, improving both longevity and quality of life for affected patients.

NSS137

THE MOLECULAR PATHWAYS OF OSTEOSARCOPENIA

G. Duque[1,2]

[1]Professor of Medicine - Dr. Joseph Kaufmann Chair in Geriatric Medicine, Faculty of Medicine and Health Sciences, McGill University, Montreal, Canada, [2]Principal Investigator - Bone, Muscle, and Geroscience Group - Research Institute of the McGill University Health Centre, Montreal, Canada

Osteosarcopenia, the concurrent decline of bone and muscle mass and function, represents a burgeoning challenge in aging populations worldwide. This symposium will explore the intricate pathophysiological mechanisms underpinning this syndrome, highlighting the interconnected nature of skeletal and muscular systems. Key topics will include the role of inflammatory pathways, hormonal dysregulation, mitochondrial dysfunction, and the impact of mechanical loading on musculoskeletal health. Cutting-edge research on the contribution of bone-muscle crosstalk through myokines and osteokines will be presented, alongside the influence of nutritional deficits, physical inactivity, and systemic diseases.

By examining the shared and distinct etiological factors of osteoporosis and sarcopenia, this symposium aims to provide a comprehensive understanding of the biological underpinnings of osteosarcopenia and its clinical implications. The session will conclude with an overview of emerging therapeutic approaches, from pharmacological interventions to tailored exercise and dietary strategies, aimed at mitigating the functional and metabolic consequences of this syndrome. Attendees will gain insight into translational opportunities for advancing prevention and treatment to improve the quality of life and functional independence of aging individuals.

NSS138

HOW TO TREAT OSTEOSARCOPENIA

N. Veronese[1,2]

[1]Associate Professor in Geriatrics and Internal Medicine, Saint Camillus International University of Health Sciences, Rome, Italy, [2]Professor King Saud University, Riyadh, Saudi Arabia

Osteosarcopenia, a clinical condition characterized by the concomitant presence of osteoporosis and sarcopenia, poses a significant challenge to aging populations. This dual impairment in bone density and muscle mass or function increases the risk of fractures, disability, and mortality, necessitating an integrated and multidisciplinary therapeutic approach. Effective management focuses on addressing the shared pathophysiological mechanisms of osteosarcopenia, including chronic inflammation, hormonal decline, and nutritional deficiencies.Nutritional interventions are of importance, emphasizing adequate protein intake (1.0–1.5 g/kg/day), vitamin D optimization, and calcium supplementation. Emerging evidence supports the role of omega-3 fatty acids and other micronutrients, such as magnesium and vitamin K2, in promoting musculoskeletal health. Resistance and weight-bearing exercises are essential, as they stimulate muscle hypertrophy and enhance bone remodeling. Tailored exercise programs combining strength, balance, and aerobic training improve physical performance and reduce fall risk.Pharmacological strategies target bone loss and muscle function. Bisphosphonates, denosumab, or anabolic agents like teriparatide are indicated for osteoporosis, while selective androgen receptor modulators (SARMs) and myostatin inhibitors are under investigation for sarcopenia. Hormone replacement therapy may benefit postmenopausal women with severe osteosarcopenia. Additionally, sarcopenia-specific pharmacotherapies, such as acetylcholinesterase inhibitors, are gaining attention.Comprehensive management incorporates lifestyle modifications, fall prevention, and regular monitoring to tailor interventions. Early diagnosis and treatment are pivotal in mitigating the synergistic effects of osteosarcopenia on morbidity

and improving patient outcomes. This talk underscores the need for personalized, multidisciplinary strategies to optimize care in this vulnerable population.

NSS139

THE LATAM PAG MATERIALS AND METHODS

P. Clark[1]

[1]Director Clinical Epidemiology Unit, Federico Gomez Hospital, UNAM, Mexico, Mexico

In the past years, several bone-related organizations have explored patients' perceptions, behaviors, and expectations through surveys and patient group discussions. IOF in collaboration with medical societies in Argentina, Brazil, Colombia, Mexico, Panama and Peru set a patient group and carried out a study with the aim of understanding the perception of patients with bone fragility to better understand their osteoporosis diagnosis and treatment pathways as well as assess their information needs.
To this purpose a convenience sample of 20 patients from the six different Latin American countries listed above constituted a focal group. All participants have been diagnosed with osteoporosis and already in treatment at various stages of OP. The study was conducted in two phases: the first phase involved a cross-sectional survey using an instrument developed by the IOF which was modified to meet LATAM needs, and the second phase consisted of a focus group conducted in a hybrid format.

NSS140

KEY FINDINGS AND RESULTS

A. Orcesi Pedro[1]

[1]Post Graduate Professor of Department of Obstetrics and Gynecology, University of Campinas - UNICAMP, São Paulo, Brazil

Both phases of the study gathered relevant information related to the patients' diagnosis and treatment journeys and their perceptions towards the disease. All 20 patients in the sample were diagnosed with osteoporosis by a specialist, either gynecolgist or endocrinologist for more than three years and since then received anti osteoporosis medication. Average time to treatment was reported between 0 to 2 months, and a very low percentage (less than 5%) have interrupted treatment.
Patients indicated a high level of trust in their treating physician, who provided them with relevant information about bone friendly lifestyle. Pharmaceutical companies were also ranked with a high level of confidence by a large percentage of the individuals in the sample (65%). Media and influencers were rated as highly unreliable by the majority of the LATAM group of patients.
During the focal session, patients provided more insight about their journey. Patients shared in first person the different access to diagnosis and treatment a person in risk of osteoporosis experienced at a public vs a private healthcare institution: longer waiting time to get a doctor's appointment, limited access to diagnosis methods and treatment options to name the most relevant ones.
This group of patients showed a significant knowledge about osteoprosis, bone health and sources of information, specifically related to osteoporosis, treatment benefits and potential drug side effects. Own treating physician was rated high as a trustable source of information, in opposition to media and influencers.
Finally, the LATAM patients' group addressed how osteoporosis impacted their daily life. However, none of the participants reported a significant impact of osteoporosis in their quality of life, they all shared great fear about the future. And, even under treatment, they expressed deep concern about falls and loss of independence due to bone fragility.

NSS141

LISTENING TO THE PATIENT'S VOICE

R. C. Lopez-Cervantes[1]

[1]Clinica de Fracturas por Osteoporosis, CFO, Hospital de Especialidades San Francisco de Asis de Guadalajara, Guadalajara, Mexico

I want to shed light on the lived experience of being diagnosed with primary osteoporosis and categorized as being at a very high fracture risk. It captures the emotional and practical journey from diagnosis to treatment and highlights patients' unique daily challenges.
This journey began with the shock and uncertainty that accompany an osteoporosis diagnosis, being a young, previously healthy man working as an orthopedic surgeon treating fragility fracture patients.
For many, as for me, this news felt like an abrupt loss of vitality, lifespan, and independence, shadowed by fears of fractures and their consequences. The doubts are immediate: *What does this mean for my future? Will I still be able to do the things I love? For how long will I still be able to work?* I found myself wrapped up in an overwhelming amount of information, unclear prognoses, and conflicting advice about my lifestyle and activities.
Finding a secondary cause was a long way of forbearance, uncertainty, hope, and fear. On the one, you could bump into something bigger, but at the same time, you might find the cause and the solution for osteoporosis. After an expensive and time-consuming journey that left me with a diagnosis of primary osteoporosis, it was a necessary journey that allowed me to realize the true rival I was facing.
Daily living becomes a careful negotiation. Many healthcare professionals, relatives, colleagues, and self-driven insights come along with how you should or must adapt your life to minimize fracture risk, avoiding activities that were once routine or joyful. There is a persistent uncertainty about what is allowed and what is not: *Which type of exercise? Is a high-calcium diet enough? What if I fall during house chores? Am I able to carry my child? How much axial weight is too much?* This cautious existence often leads to a sense of loss of independence and diminished quality of life. Also, you find out the lack of evidence-based information to solve these questions. And how vague our current patients' lifestyle recommendations are.
Pharmacological treatment brings its own set of concerns.

Including navigating the fear of different side effects, from discomforts to rare but severe complications. Also, I asked myself questions about the long-term efficacy and safety of the prescribed medications. The sense of vulnerability deepens when side effects materialize in some of my own patients, creating a complex balancing act between the necessity of treatment and its physical toll. That made me wait for the initiation of treatment for almost a year.

Another critical dimension of the discussion addresses systemic issues in the healthcare and community landscape. We often lack empathetic communication with our patients, leaving them feeling unheard and unsupported. The need for greater understanding, reassurance, and tailored guidance is palpable. Moreover, the absence of robust patient communities exacerbates feelings of loneliness and a self-driven lifestyle. Peer support is a missing pillar in coping with osteoporosis, depriving patients of shared experiences and encouragement.

Practical barriers, such as the scarcity of osteoporosis-friendly exercise spaces and knowledge professionals, further hinder patients' ability to maintain bone health and physical activity. Accessible, safe environments where individuals can engage in weight-bearing and balanced exercises are urgently needed but remain elusive in many regions.

This experience was a call to action for a more patient-centered approach to managing osteoporosis. We need to build a vast, open, and strong communication between patients and healthcare providers, fostering supportive communities and addressing the practical gaps in daily living. By enhancing empathy and systemic support, the journey with osteoporosis can shift from one defined by fear and restrictions, underscoring the need for holistic care to one of empowerment and proactive care, taking care not just of the patient's bones but the person as a whole.

NSS142

EXERCISE IN OSTEOPOROSIS

A. Yaman[1]

[1]University of Health Sciences, Faculty of Medicine, Etlik City Hospital, Department of PMR, Ankara, Turkiye

Osteoporosis is a prevalent condition characterized by decreased bone mass and deterioration of bone tissue, leading to increased fragility and a higher risk of fractures. Exercise plays a pivotal role in the management and prevention of osteoporosis by enhancing bone health, improving muscle strength, and reducing fall risk. This abstract explores the types, benefits, and mechanisms of exercise in addressing osteoporosis. Weight-bearing aerobic exercises, such as walking, jogging, and dancing, stimulate osteogenesis by promoting mechanical loading on bones. Resistance training, including the use of weights or resistance bands, further strengthens the musculoskeletal system by improving bone mineral density (BMD) and muscle mass. Balance and flexibility exercises, such as yoga and tai chi, contribute to fall prevention by enhancing proprioception and reducing postural instability. The efficacy of exercise in osteoporosis is influenced by factors such as intensity, frequency, and duration. High-impact activities are particularly effective for younger individuals in maintaining bone density, while low-impact and modified exercises are recommended for older adults and those with advanced osteoporosis to minimize fracture risk. Personalized exercise programs, tailored to the patient's age, fitness level, and medical history, are critical for safety and optimal outcomes.

Regular physical activity not only addresses the skeletal aspects of osteoporosis but also improves cardiovascular health, mental well-being, and overall quality of life. This underscores the importance of integrating exercise into comprehensive osteoporosis management strategies. Future research should focus on elucidating the long-term effects of various exercise regimens and optimizing intervention protocols for diverse patient populations.

NSS143

PHYSICAL THERAPY MODALITIES IN OSTEOPOROSIS AND ITS COMPLICATIONS

S. Gümrük Aslan[1]

[1]University of Health Sciences Faculty of Medicine, Gaziler Education and Research Hospital, Dept of PMR, Ankara, Turkiye

Osteoporosis is a systemic skeletal disorder characterized by reduced bone mineral density (BMD) and microarchitectural deterioration, leading to increased fracture risk. Physical therapy modalities are integral to managing osteoporosis and addressing its complications, such as fractures, chronic pain, and reduced mobility. This abstract reviews the role and effectiveness of various physical therapy interventions in improving patient outcomes in osteoporosis. Physical therapy modalities encompass a range of approaches, including therapeutic exercises, electrotherapy, manual therapy, and patient education. Low-intensity pulsed ultrasound (LIPUS) and electrical stimulation have shown potential in promoting bone healing and improving BMD in individuals with fractures. Heat and cold therapies are employed to manage pain and inflammation associated with acute and chronic musculoskeletal complications. Manual therapy techniques and soft tissue mobilization can address musculoskeletal imbalances and improve joint mobility, particularly in patients with vertebral fractures. Patient education on posture correction, body mechanics, and lifestyle modifications complements the physical therapy regimen. Kinesio taping can also be used in posture correction,

The effectiveness of physical therapy modalities in osteoporosis is highly dependent on individualized treatment plans that consider patient age, comorbidities, fracture history, and functional status. Integration of physical therapy into a multidisciplinary approach can significantly improve quality of life and mitigate the complications of osteoporosis. Future research should aim to refine physical therapy protocols and explore novel modalities to enhance bone health and functional outcomes in this population.

NSS144

MICROBIOTA AND DIET IN OSTEOPOROSIS

P. Borman[1]

[1]University of Ankara Medipol, Faculty of Medicine, Department of Physical Medicine and Rehabilitation (PMR), Ankara, Turkiye

Emerging research highlights the critical role of the gut microbiota and dietary factors in the pathogenesis and management of osteoporosis. Osteoporosis, characterized by decreased bone mineral density (BMD) and increased fracture risk, is influenced not only by hormonal, genetic, and lifestyle factors but also by gut health. This abstract explores the interplay between microbiota, diet, and bone health, offering insights into novel therapeutic strategies. The gut microbiota modulates bone health through mechanisms such as the regulation of calcium and vitamin D absorption, production of short-chain fatty acids (SCFAs), and modulation of systemic inflammation. Dysbiosis, characterized by an imbalance in gut microbial composition, has been associated with increased bone resorption and impaired bone formation. Factors contributing to dysbiosis include age, antibiotics, and a Western diet high in fat and sugar. Diet plays a pivotal role in maintaining both microbiota diversity and bone health. Nutrients such as calcium, vitamin D, magnesium, and protein are essential for bone metabolism, while prebiotic and probiotic-rich foods, including fiber and fermented products, support gut health. Emerging evidence suggests that specific dietary patterns, such as the Mediterranean diet, can enhance microbial diversity and provide anti-inflammatory benefits, thereby promoting bone strength. Conversely, diets deficient in nutrients or rich in processed foods can exacerbate gut dysbiosis and bone loss. Interventions targeting the gut microbiota, such as the use of prebiotics, probiotics, and synbiotics, hold promise in mitigating osteoporosis progression. Personalized nutrition strategies, tailored to an individual's microbiota profile, may optimize bone health and reduce fracture risk.

This growing field underscores the importance of a multidisciplinary approach integrating diet, microbiota modulation, and conventional osteoporosis therapies. Further research is warranted to better understand the microbiota-diet-bone axis and to develop innovative, microbiota-targeted therapies for osteoporosis prevention and management.

NSS145

DIAGNOSTICS METHODS FOR STUDYING THE BONE DAMAGE IN CANCER PATIENTS

L.- G. Cui[1]

[1]Department of Ultrasound, Peking University Third Hospital, Beijing, China

Background: The bone health monitoring in cancer patients is crucial due to the significant reductions in bone quality and density they experience. Several cancer-associated factors contribute to bone impairment, including cancer treatments that directly affect the delicate balance of bone remodeling, chronic inflammation, nutritional deficiencies, physical inactivity and bone metastasis. As a result, this population has a risk of fractures, which can compromise both their quality of life and prognosis. Traditional diagnostic methods for assessing bone damage in cancer patients include imaging techniques (X-rays, CT, MRI, bone scintigraphy, ultrasound technologies), biochemical markers of bone metabolism and biopsies.

Objectives: This review aims to explore and compare pro and cons of the current available diagnostic methods for assessing bone damage in cancer patients.

Methods: A comprehensive literature review was conducted on the base of the available published data related to X-ray-based and ultrasound-based diagnostic methods. The review evaluated the efficacy, safety, easy to use, of these technologies in bone health assessment in cancer patients and their capability to measure bone quality and predict fracture risk.

Results: While effective for detecting metastases, structural changes, and metabolic activity, X-ray based methods have limitations, such as low sensitivity for early lesions, lack of specificity (scintigraphy), invasiveness (biopsy), and the use of X-rays, which is generally discouraged in cancer patients due to radiation exposure. X-ray-based methods, while standard, pose radiation risks and are less suitable for frequent monitoring in cancer patients. Ultrasound-based techniques provide a safer, non-invasive option. New generation ultrasound-based technologies, such as Radiofrequency Echographic Multi Spectrometry (REMS), have been recognized as a promising alternative to X-rays. REMS studies highlighted their potential to evaluate bone quality, assess fracture risk, and detect microarchitectural changes with higher sensitivity for early bone alterations compared to X-rays. Furthermore, ultrasound-based devices offer portability and lower costs, making them ideal for frequent monitoring.

Conclusion: Ultrasound-based technologies offer a safe, effective, and patient-friendly option for diagnosing and monitoring bone damage in cancer patients

NSS146

HOW CAN SHORT-TERM MONITORING BE HELPFUL TO ASSESS BONE FRAGILITY IN BREAST CANCER PATIENTS?

E. Bischoff[1], F. Bischoff[2], N. Kirilov[3]

[1]Faculty of Global Health and Health Care, University "Prof Dr Assen Zlatarov", Burgas, Bulgaria, [2]IPSMP Rheumatology, Stara Zagora, Bulgaria, [3]Institute of Medical Informatics, Heidelberg University Hospital, Heidelberg, Germany

Objective: Aromatase inhibitor (AI) therapy in women with estrogen receptor-positive breast cancer (BCs) accelerates bone loss, increasing the risk of osteoporosis and fractures. Effective strategies are essential to prevent fragility fractures. Short-term monitoring of bone fragility in BCs, aiming for early detection and timely intervention to reduce fracture risk is crucial. Current densitometric methods, cannot track changes in BMD over short periods, requiring 1-year between consecutive measurements. Therefore, they are unsuitable for monitoring bone health in BCs.

This study evaluates the potential of radiofrequency echographic multispectrometry (REMS) for short-term monitoring of bone fragility in BCs.

Material and Methods: A review of published studies on REMS technology was conducted to assess whether REMS can effectively monitor bone fragility in the short-term in BCs. The study compares REMS with the gold standard, DXA, both of which assess BMD at axial sites. Key factors like precision, accuracy, ease of use, safety, and cost-effectiveness were evaluated for both methods.

Results: REMS showed higher precision and operator independence, with less than 1% variability. REMS follow-up studies demonstrated a short-term BMD reduction in BCs treated with AI together with a short-term BMD recovery in patients receiving denosumab, at both axial sites (from 6-18 months from treatment starting). REMS indicated strong diagnostic agreement with DXA, showing accuracy in diagnosing osteoporosis. Unlike DXA, which can yield false positives due to artifacts, REMS automatically processes data excluding artifacts. In BCs, particularly those with breast implants used for reconstruction of the breast after mastectomy, REMS could be more reliable than DXA for assessing BMD and fracture risk. REMS also provides a fragility score (FS) that outperformed DXA T-scores in previous papers identifying fragile patients and is available for individuals as young as 20, unlike FRAX, which can be calculated after the age of 40, allowing earlier bone fragility assessment in BCs. Its radiation-free nature enhances safety allows frequent assessments and improves patient adherence.

Conclusion: REMS offers notable advantages over DXA, including higher precision, earlier fragility detection through its FS, and portable design ideal for bedside use in BCs. These features, along with its cost-effectiveness, position REMS as a promising tool for short-term bone health monitoring in this patient population.

NSS147

MANAGEMENT OF BONE FRAGILITY IN PROSTATE CANCER PATIENTS

G. Guglielmi[1]

[1]Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy

Objective(s)

Bone fragility is a significant clinical concern in prostate cancer patients (PCs), particularly those undergoing androgen deprivation therapy (ADT), which increases the risk of osteoporosis and fractures. This highlights the urgent need for early identification of bone damage and short-term monitoring approaches for assessing fragility. This review evaluates current strategies for preventing and managing bone fragility in these patients.

Material and Methods

A recent literature review was conducted on the management of bone fragility in prostate cancer patients, highlighting the impact of hormonal therapies on bone metabolism.

Results

PCs undergoing ADT experience heightened bone fragility due to suppressed testosterone levels. Early detection of bone loss is crucial. Tailored monitoring protocols significantly reduce the risk of severe complications. Recent literature on PCs show the reliability of Radiofrequency Echographic Multi Spectrometry (REMS) technology in assessing bone health in these patients, revealing a significant reduction in lumbar and femoral BMD compared to healthy controls by confirming REMS's effectiveness in the early assessement of osteoporosis, bone fragility, and fracture risk through a simple ultrasound scan of the femur and spine.

Conclusion(s)

Cancer hormonal therapies significantly increase the risk of bone fragility and fractures, Early detection of bone damage and proactive management through short-term monitoring and comprehensive care strategies are needed. Densitometric tools based on REMS technology, coupled with timely interventions, can enhance long-term outcomes and quality of life for cancer patients, facilitating better management of PCs patients, especially those at higher risk due to ADT. This approach meets clinical practice requirements and is essential for the primary prevention of bone fragility.

NSS148

SLEEP DISORDERS AND SARCOPENIA - ASSESSMENT BY POLYSOMNOGRAPHY

O. De Matos[1]

[1]Women's Health Laboratory Coordinator - Physical Education Department - Physical Exercise and Health Graduation Program - Federal University of Technology, Parana, Brazil

A short multicomponent protocol was developed to assess the risk of falls and fractures in frail or pre-frail elderly patients. Questionnaires and polysomnography are to assess sleep quality in the elderly targeted fragmentation of sleep hours and, consequently, have non-restorative sleep quality, leading to sarcopenia and falls. Sleep disturbances progressively affect cognitive functions and neurodegenerative disorders.

Sarcopenia and osteoporosis are manifestations of frailty in adulthood and the combination of both decrease considerably quality of life.

Persistent chronic hypoxia, oxidative stress and inflammatory responses in patients with obstructive sleep apnea syndrome (OSAS) affect the balance of muscle and bone metabolism, thus increasing the risk of sarcopenia and osteoporosis.

Therefore, the activity will address clinical and functional characteristics linked to non-restorative sleep, parameters assessed by Polysomnography and the consequences of the association between sleep disturbances and osteoporosis in the elderly.

TOPICS:

- Multicomponent protocol design
- Sleep functions
- Sleep quality assessment by questionnaire
- Polysomnography characteristics
- Obstructive sleep apnea syndrome (OSAS)

- Relationship between OSAS, sarcopenia and osteoporosis

SARCOPENIA AND OSTEOPOROSIS ASSESSMENT BY DUAL X-RAY ABSORPTIOMETRY (DXA)

B. Muzzi Camargos[1]

[1]Densitometry Unit Coordinator - Rede Materdei de Saúde, Belo Horizonte, Minas Gerais, Brazil

Sarcopenia is a muscle disease that advances with age across lifetime leading to multiple morbid conditions. Sarcopenic patients present with higher risk of fragility fractures independently of lumbar / spine bone densitometry assessment.

More common in older adults, sarcopenia can also present earlier in life. On 2019, the EWGSOP2 Consensus on Sarcopenia defined that a total body Dual X-ray Absorptiopmetry (DXA) acquisition integrates the algorithm used to define sarcopenia. The consensus defines clear cut-offs for DXA measurements of specific variables used for sarcopenia definition.

DXA is a non-invasive and low energy X-ray technique that takes 05 to 10 minutes to perform a total body acquisition scan. From a total body scan, it is possible to evaluate sarcopenia through the Skeletal Mass Index (ASMI) which is the sum of lean mass on arms and legs divided by square high.

The total body DXA acquisition is performed at the same facility that performs spine and hip scans, with minor positioning issues needed. It makes the total body DXA feasible at a favorable cost-benefit.

Sarcopenia is one of the clinical risk factors that influences treatment decision according to American Association of Clinical Endocrinologists / American College of Endocrinology Clinical Practice Guidelines for the Diagnosis and Treatment of Postmenopausal Osteoporosis issued on 2020.

Since sarcopenia is highly correlated with imminent risk of fractures, a total body composition assessment by DXA, performed alongside a regular bone scan, would enhance risk stratification thus influencing treatment decision. Postmenopausal sarcopenic patients, selected by total body DXA acquisition scan, with spine and hip T-scores higher than -3.0, might benefit from an osteoanabolic-first approach.

The available evidence supports the hypothesis that sarcopenia assessed by total body DXA, in non-fractured postmenopausal patients, could influence decision-making towards an osteoanabolic-first approach.

Further research is necessary to define the most cost-effective cutoffs and indices assessed by total body DXA scans useful for fragility fracture prediction.

RESULTS AFTER MULTIDISCIPLINARY TREATMENT IN PATIENTS WITH PRIMARY CHRONIC PAIN, SECUNDARY CHRONIC PAIN AND FIBROMYALGIA

A. A. G. Arias Gassol[1], T. R. A. Rodriguez Araya[1], L. P. Polino[1], X. T. M. Torres Mata[1]

[1]HOSPITAL CLINIC BARCELONA, BARCELONA, Spain

Introduction: Chronic pain is the most prevalent pathology in terms of functional disability in our country. Our Primary Chronic Pain Unit manages patients with a variety of chronic pain conditions, including musculoskeletal, visceral, post-oncological pain. This study aims to compare pain, fatigue and functional capacity before and after a multidisciplinary treatment approach (medical, psychological, physical and occupational therapy), using the Fibromyalgia Impact Questionnaire (FIQ) as the measure for functional capacity.

Background and Objective: To evaluate the differences in pain, fatigue and functional capacity between patients with Primary Chronic Pain (PCP), Secondary Chronic Pain (SCP), and fibromyalgia (FM) before and afeter multidisciplinary treatment.

Patients and methods: A total of 40 PCP patients, 68 SCP patients and 166 FM patients were enrolled. Pain, fatigue and functional capacity were assessed before and after treatment. All patients received a comprehensive treatment plan involving medical, psychological, physical and occupational therapy. Pain Visual Analogue Scale (VAS), fatigue VAS anf functional capacity were the primary variables analyzed.

Results: Baseline pain scores were 6.23 for FM, 6.75 for PCP, 6,58 for SCP. After treatment, pain decreased to 3,57 for FM, 1,43 for PCP, and 1,67 for SCP.

Baseline Fatigue scores were 6,46/10 for FM, 5,30 for PCP, and 3,54 for SCP. After treatment, fatigue improved to 4.03 for FM, 1,59 for PCP and 1,91/10 for SCP.

Functional capacity (FIQ) improved from 66,67 to 32.71 in FM, from 59.45 to 12.81 in PCP and from 66.00 to 14.97 in SCP.

Conclusions:

Multidisciplinary treatment significantly improved pain, fatigue and functional capacity across all patient groups, demonstrating its effectiveness in managing various chronic pain conditions.

Keywords: Primary Chronic Pain; Secondary Chronic Pain, Fibromyalgia; VAS pain ; VAS fatigue; Disability (FIQ)

SARCOPENIA RISK IN WOMEN WITH POSTMENOPAUSAL OSTEOPOROSIS

B. K. Turan[1], A. A. Küçükdeveci[1], Z. Günendi[2], A. Yaman[3], O. Özdemir[4], J. Meray[2], Y. G. Kutsal[4]

[1]Ankara University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Ankara, Turkiye, [2]Gazi University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Ankara, Turkiye, [3]Health Science University, Ankara Etlik City Hospital, Physical Therapy and Rehabilitation Hospital, Ankara, Turkiye, [4]Hacettepe University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Ankara, Turkiye

Objective

Osteoporosis and sarcopenia are disorders of bone and muscle, respectively. Studies reported that these disorders were interrelated. However, this relation was explored in older adults and/or with certain comorbidities. Therefore, the aim of this study was to assess the relation between osteoporosis and risk of sarcopenia in postmenopausal women aged ≤ 70 years.

Material and Methods

This multicenter prospective case-control study included 238 postmenopausal women. Dual-energy x-ray absorptiometry was performed to diagnose osteoporosis. Sociodemographic and clinical factors, risk of sarcopenia (SARC-F), muscle strength (grip strength and five-times sit-to-stand test: 5T-STS), and physical activity levels (International Physical Activity Questionnaire-short form) were compared between osteoporotic and non-osteoporotic participants.

Results

No significant differences were observed between participants with or without osteoporosis regarding risk of sarcopenia, skeletal muscle strength, probable sarcopenia, and physical activity level (Table). Osteoporotic group had lower body mass index (BMI) and protein intake. BMD values at L1-4 and femoral neck were not correlated with grip strength and 5T-STS ($p > 0.05$). The older participants ($p = 0.002$) with lower physical activity levels ($p < 0.001$) were found to have higher risk of sarcopenia.

	Non-osteoporosis (n = 119)	Osteoporosis (n = 119)	p
Age	59 (54-64)	58 (55-63)	0.933[a]
BMI	31 ± 5	27 ± 5.1	**<0.001[b]**
Educational status (> 5 years)	31.9	49.6	**0.006[c]**
Covered clothing (with scarf)	70.6	56.3	**0.022[c]**
Menopause age	47 (43-50)	46 (41-50)	0.495[a]
Number of pregnancies	4 (2-4)	3 (2-4)	**0.020[a]**
Current smoking	11.9	22.7	**0.028[c]**
Protein intake (g/day)	43 (31-53)	38 (29-49)	**0.011[a]**
Risk of sarcopenia (SARC-F ≥ 4)	38.7	48.7	0.117[c]
5T-STS (sec)	14 (11.7-16)	13.9 (11.7-16)	0.986[a]
Grip strength (kg)	22 (17.8-26)	23 (18.2-27)	0.329[a]

Probable sarcopenia (grip strength < 16 kg)	15.3	14.5	0.876[c]
Physical activity level (MET-minutes per week)	792 (248-2226)	908 (380-1782)	0.983[a]

[a] Mann Whitney-U test, median (25th-75th percentiles); [b] Independent T-test, mean ± SD; [c] Pearson Chi-Square test, percentage.

Conclusion

There was no elevated risk of sarcopenia in women with postmenopausal osteoporosis aged ≤ 70 years. Risk of sarcopenia was related to older age and lower physical activity level.

THE STUDY OF VITAMIN D LEVELS IN PATIENTS WITH OBESITY AND OSTEOARTHRITIS

G. N. Koshukova[1], A. A. Zayaeva[1], E. M. Dolya[1], V. B. Kaliberdenko[1], V. A. Fursova[2], N. G. Nikolashina[1], E. R. Kulieva[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]State Budgetary Healthcare Institution of the Republic of Crimea "Republican Clinical Hospital named after N.A. Semashko", Simferopol, Russia

Objective: Among the numerous factors, influencing the intake, synthesis and metabolism of vitamin D, a significant role is given to metabolic disorders like obesity. There are several mechanisms for reducing vitamin D levels in the blood, including the accumulation of 25(OH)D in adipose tissue and decreased synthesis of cholecalciferol in the skin.

Methods: The analysis of the level of vitamin D (intermediate form in its metabolism - calcidiol or 25(OH)D in the blood serum was carried out in 82 patients with obesity and osteoarthritis (27 men, 55 women aged 49-78 years). The normal level of vitamin D was defined as the concentration of 25(OH)D in the blood serum >30 ng/ml, deficiency — 30 to 20 ng/ml and severe deficiency <10 ng/ml. Body mass index (BMI) was calculated for all patients using the A. Obesity was diagnosed with a BMI ≥30 kg/m2. The 46.3% of patients reported regular intake of vitamin D3 at a prophylactic dose of 2000 IU per day.

Results: According to BMI, patients were divided into 4 groups: 25–29.9 kg/m2 – overweight (n=19), 30–34.9 kg/m2 – grade 1 obesity (n=22), 35–39.9 kg/m2 – grade 2 obesity (n=27), 40 kg/m2 and more – grade 3 obesity (n=14). Most patients in groups 1 and 2 (73.7% and 72.7%) had vitamin D deficiency (25.8±2.6 ng/ml and 23.1±2.8 ng/ml), no significant differences were found between the groups. Among patients in groups 3 and 4, vitamin D deficiency was predominant (16.7±4.1 ng/ml and 14.9±3.8 ng/ml), with a significantly higher number of patients ($p<0.05$) with severe vitamin D deficiency. A negative relationship was found between the 25(OH)D level and patients' BMI ($r= - 0.12$, $p=0.04$), which allows us to consider obese patients as a risk group for vitamin D deficiency.

Conclusion: The patients with overweight have a decrease level of vitamin D3, which correlates with the degree of obesity. Thus, it is necessary to identify obese patients as a separate risk group for vitamin D deficiency, determine their serum 25(OH)D levels, and, if a deficiency or deficiency is detected, recommend taking higher doses of cholecalciferol.

P104

THE FEATURES OF OSTEOPOROSIS DEVELOPMENT IN PATIENTS WITH OBESITY AND COMORBID PATHOLOGY

G. N. Koshukova[1], A. A. Zayaeva[1], V. B. Kaliberdenko[1], E. R. Kulieva[1], N. G. Nikolashina[1], G. V. Nikolashin[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]St. Luka Multidisciplinary Clinical Hospital of V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: Osteoporosis (OP) and obesity are two common diseases, each of them has own unique characteristics and health consequences. OP characterized by decreased bone density and an increased risk of fractures, is often associated with factors such as age, gender, genetics, and physical activity level. However, in recent decades it has become apparent that obesity also plays a significant role in the development of this disease.

Methods: An analysis of 67 patients aged from 49 to 76 years (mean age 57.1±8.3 years) with excess body weight and a confirmed diagnosis of OP based on X-ray densitometry of the spine and/or proximal femur were identified. At the same time, 62.7% of patients had a high and very high BMI. Among the concomitant diseases, type 2 diabetes mellitus (DM), arterial hypertension, ischemic heart disease, and osteoarthritis were most often noted.

Results: According to the results, osteopenia was prevailed in patients with a BMI of 25.0-29.9 kg/m², while with a BMI of more than 30.0 kg/m², there was a tendency for bone mineral density (BMD) to decrease with the development of OP. The fractures of the vertebral bodies and femoral neck were diagnosed in 21 patients (31.3%) mostly with a BMI more than 30.0 kg/m. When assessing comorbid diseases, the lowest manifestations of bone pathology were observed in patients with type 2 diabetes, which did not correspond to a higher incidence of fractures of both the vertebral bodies and the femur in this category of patients. Also, OP was noted in individuals with poorly controlled arterial hypertension, which may be associated with hyperactivation of the sympathetic nervous system and the effect on bone resorption. A higher incidence of OP was noted in patients with polyosteoarthrosis in the late stages.

Conclusion: Thus, the significant disorders of bone metabolism were noted in individuals with BMI more than 30.0 kg/m² and with poorly controlled arterial hypertension and in the late stages of polyosteoarthrosis. The obtained results require further more detailed study.

P105

INCIDENCE OF FEMUR FRACTURE IN IRAQ AND THE DEVELOPMENT OF NATIONAL IRAQI FRAX MODEL

A. Abdulbari[1], N. Jassim[2], Y. Motleq[1], I. Frax Group[3]

[1]Ibn Sina Training Hospital, BAGHDAD, Iraq, [2]Baghdad University / college of Medicine, Baghdad , Iraq, [3]MOH, BAGHDAD, Iraq

The development of an accurate, country-specific FRAX model requires a reliable estimation of the incidence rate of major osteoporotic fractures, particularly femur (hip) fractures, which are a critical indicator of osteoporosis risk. This Retrospective study aims to calculate the national incidence rate of femur fractures to support the establishment of a precise FRAX model tailored for our population.

This study documented the incidence of hip fractures in Iraq in order to permit the construction of Iraqi FRAX model. The study to define the incidence of hip fracture was developed in collaboration between doctors from institutes belong to Ministry of Health & Ministry of Higher Education to represent by (Iraqi National FRAX Group).Using data from hospital records, databases, and registries, we identified and analyzed cases of femur fractures over 2022 & 2023.

In this study include all the numbers of hip fractures from all Iraqi governates. Data on hip fracture were collected on Iraqi citizens age 40years and above irrespective of degree of trauma.In both sex, the incidence of hip fracture increased with age as expected. The total incidence of hip fracture in Iraq for 2022 and 2023 Male incidences were higher than females, The incidence in 2023 is higher than in 2022.Mortality rate is higher in male in 2022 & 2023.

This study emphasizes the importance of country-specific data in accurately estimating osteoporosis risk and enhancing preventive strategies through the FRAX tool, ultimately improving patient outcomes and reducing healthcare burdens associated with osteoporotic fractures.

DECODING THE MYSTERY: WHEN RHEUMATOID ARTHRITIS ISN'T WHAT IT SEEMS

A. Abdulbari[1], F. F. Jalil[2], S. M. Talib[3]

[1]Ibn Sina Training Hospital, BAGHDAD, Iraq, [2]MOH, BAGHDAD, Iraq, [3]Baghdad Teaching Hospital, Baghdad , Iraq

Pachydermoperiostosis (primary hypertrophic osteoarthropathy) is a rare familial autosomal dominant disease. Complete form characterized by triad of skin thickening (pachydermia), skeletal manifestation (periostosis and arthritis), and finger clubbing. Pachydermoperiostosis has been associated with many clinical conditions noted in different case reports, and this include; arthritis and osteoporosis. We report a patient who had complete form of this syndrome in association with Osteoporosis and Rheumatoid arthritis mimic .

Keywords: pachydermoperiostosis, hypertrophic osteoarthropathy, rheumatoid arthritis, tofacitinib.

P107

THE RATE OF BONE MINERAL DENSITY LOSS IN ELDERLY WOMEN WITHOUT BASELINE ANTI-RESORPTIVE THERAPY

A. Adamenka[1]

[1]Medical University of Belarus, Minsk, Belarus

Objective: To analyze the rate of age-related bone mineral density (BMD) loss in the central skeleton of elderly women using dual-energy X-ray absorptiometry (DXA).

Materials and Methods: a retrospective observational study was conducted over 36 months at the Republican Clinical Medical Center of Belarus. It included 27 postmenopausal women aged 70 years and older (mean age: 75.3 ± 4.5 years) with osteoporosis, who had not undergone anti-resorptive therapy. BMD was assessed at the lumbar spine and proximal femur using a GE Healthcare Lunar Prodigy DXA scanner (2018). Data analysis was performed with STATISTICA 10.0, using parametric statistical methods.

Results:

Initial BMD Measurements:

- Lumbar spine: 0.96 ± 0.15 g/cm²
- Left femoral neck: 0.75 ± 0.09 g/cm²
- Right femoral neck: 0.73 ± 0.07 g/cm²

Changes Over 36 Months:

- Lumbar spine BMD decreased by 0.5% (0.937 ± 0.145 to 0.915 ± 0.155 g/cm², p=0.001).
- Left femoral neck BMD decreased by 5.2% (0.727 ± 0.095 to 0.695 ± 0.092 g/cm², $p=8.2 \times 10^{-7}$).
- Right femoral neck BMD decreased by 5.9% (0.721 ± 0.066 to 0.710 ± 0.063 g/cm², p=0.0003).

Annual BMD Loss Rates:

- Lumbar spine: 0.17% per year
- Left femoral neck: 1.97% per year
- Right femoral neck: 1.73% per year

Degenerative changes in the lumbar spine were noted in 48.1% of women, with 37.0% presenting vertebral deformities. Artifacts, such as osteoarthritis and femoral head necrosis, affected 3.7% of femoral scans.

Discussion: The significant difference in the rate of BMD loss between the lumbar spine and femoral regions was influenced by artifacts. Degenerative spinal changes, including vertebral deformities and pathological ossification, falsely elevated lumbar spine BMD values. This highlights the importance of considering artifacts when interpreting DXA results.

Conclusions:

1. Over 36 months, the average annual BMD loss rates in postmenopausal women aged ≥70 years were 0.17% in the lumbar spine, 1.97% in the left femoral neck, and 1.73% in the right femoral neck.
2. Artifacts, such as vertebral deformities and degenerative changes, contributed to discrepancies in BMD loss rates be-

tween the spine and femoral regions.
This study underscores the need for accurate interpretation of DXA results, particularly in older women with osteoporosis, to better evaluate BMD changes and the risk of fractures.

P108

VARIABILITY IN BONE MINERAL DENSITY MEASUREMENTS USING RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY COMPARED TO DUAL-ENERGY X-RAY ABSORPTIOMETRY IN A PATIENT WITH PAGET'S DISEASE

A. Asanova[1], E. Pigarova[1], L. Dzeranova[1], N. Tarbaeva[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective: Dual-Energy X-ray Absorptiometry (DXA) is the standard for evaluating bone mineral density (BMD), but emerging technologies, like Radiofrequency Echographic Multi-Spectrometry (REMS), are gaining attention for assessing bone quality without radiation. This clinical case questions whether REMS can be considered a valid diagnostic technique for various patient groups, including those with Paget's disease.
Material and methods: A 68-year-old female (weight 90 kg, height 154.8 cm, BMI - 37.6 kg/m²) two years ago began experiencing left hip joint pain. A year later, a traumatologist diagnosed left-sided coxarthrosis and prescribed NSAIDs, which moderately reduced pain. MRI from May 2024 showed stage III osteoarthritis in the left hip joint, with diffuse irregularity in the left femur, increased bone volume, and increased cellularity. Laboratory results showed alkaline phosphatase - 207 U/L (35-104), B-crosslaps - 0.962 ng/mL (<0.573), total Ca - 2.67 mmol/L (2.15-2.55), P - 1.32 mmol/L (0.81-1.45), PTH -73.1 pg/mL (15-65) and 25(OH) vitamin D -14.7 ng/mL. Paget's disease of the left femur was confirmed by X-ray of the pelvic bones, CT scan, and a whole-body bone scintigraphy showed a monoossal involvement. The patient underwent two different densitometry modalities, REMS and DXA, that showed principal differences at the site of Paget's lesion. According to REMS the BMD at the lumbar spine (L_2) showed osteopenia (-2.3 SD by T-score) with normal at the left femoral neck (-0.4 SD) and the right femoral neck (-0.3 SD).However, DXA at the lumbar spine (-2.5 SD by T-score in L_1-L_3) was consistent with osteoporosis, while the left femoral neck and total femur showed values significantly higher than normal – +6.0 SD and +9.0 SD by T-score, and the right femoral bone indicated a reduction in bone mass to -1.4 SD and -0.8 by T-score, accordingly. The patient was initiated on anti-resorptive therapy with 5 mg intravenous zoledronic acid.
Results and conclusions: REMS is a relatively new method for assessing bone quality and diagnosing osteoporosis. It offers reliable precision, predicts fracture risk and may overcome some DXA limitations. Still, this case highlights the need for further evaluation of REMS's reliability in different patient groups compared to gold standard methods.

P109

A FEMALE PATIENT WITH LIVER INJURY FOLLOWING ZOLEDRONIC ACID INFUSION FOR OSTEOPOROSIS

A. Athanasia[1], Z. Zoe[1]

[1]1Department of Endocrinology, "Hippokration" General Hospital of Thessaloniki, Thessaloniki, Greece, Thessaloniki, Greece

Introduction: Only a small number of cases have documented liver damage following zoledronic acid (ZOL) infusion.
Purpose: Description of a patient with transient hepatotoxicity following ZOL infusion.
Case description: We present the case of a 60-year-old woman with severe postmenopausal osteoporosis and a history of parathyroidectomy due to primary hyperparathyroidism four years before, who experienced temporary liver toxicity following ZOL treatment. Two days after the ZOL infusion, the patient developed a fever reaching up to 38°C, and serum levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT) increased by 3.9, 5, and 1.7 times, respectively, compared to baseline values. Further biochemical and serological testing showed no evidence of any underlying liver or systemic disorder. The levels of ALT, AST, and GGT returned to normal within three weeks after treatment.
Conclusion: Given the limited understanding of ZOL-induced hepatotoxicity and the unclear mechanism, it is essential for clinicians to be aware of this potential risk. Increased vigilance and careful monitoring are crucial to minimizing adverse effects and ensuring patient safety.

LEVERAGING ARTIFICIAL INTELLIGENCE FOR ENHANCED DETECTION OF OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES: A MULTICENTER EVALUATION

A. Ayobi[1], G. Chaix[2], P. Champsaur[2], C. Castineira[1], S. Quenet[1], J. Kiewsky[1], D. Guenoun[2]

[1]Avicenna.AI, La Ciotat, France, [2]Department of Radiology, Institute for Locomotion, Sainte-Marguerite Hospital, APHM, Marseille, France

Objective: Vertebral compression fractures (VCFs) are a prevalent yet underdiagnosed manifestation of osteoporosis, significantly contributing to morbidity and mortality. Despite advancements in imaging, many VCFs remain unreported in routine radiological analyses, delaying critical interventions. This study compares the standard of care against opportunistic screening powered by an AI tool to identify moderate-to-severe VCFs from computed tomography (CT) scans performed for various clinical indications.
Material and Methods: A retrospective, cross-sectional, multicenter study analyzed CT scans from patients aged ≥50 years, collected over two months across four tertiary hospitals from Assistance Publique des Hôpitaux de Marseille (France). Scans

flagged by CINA-VCF Quantix (Avicenna.AI, La Ciotat, France) were reviewed by expert radiologists. Discrepancies between the AI and clinical reports were analyzed to calculate AI false positive rate (FPR), positive predictive value (PPV), overall agreement between AI and experts, and clinical reports' false negative rate (FNR). Additionally, the number of scans needed to screen (NNS) to detect one additional VCF using the tool compared to the standard of care, was computed.

Results: A total of 2224 cases were analyzed and 489 were flagged as positive by the AI. Of these, 312 were confirmed as true positives, yielding a PPV of 63.8% (95%CI: 59.4%-68.1%) and a FPR of 36.2% (95%CI: 32.0%-40.6%). Regarding the clinical reports' FNR, there were 31.1% [27.0% - 35.4%] of fractures identified by the AI but missed in initial reports. Per-vertebra agreement was 95.8% [95%CI: 95.4%-96.3%] with values ranging from 80.3% for L5 to 99.0% for L2. Main causes of FP were Schmorl's nodes, natural L5 deformities and artifacts from surgical materials. The NNS was estimated at 14.6, indicating that analyzing 14.6 scans with AI detects one additional VCF compared to standard practice.

Conclusion: The AI tool demonstrated strong potential to enhance VCF detection, addressing significant gaps in osteoporosis care. While its integration can streamline workflows and improve FNR, human validation remains crucial to mitigate false positives and ensure clinical relevance. Future research should focus on real-time implementation and assessing impacts on patient outcomes and healthcare resource utilization.

P111

URINARY PENTOSIDINE AS A POTENTIAL BIOMARKER OF IMPAIRED BONE HEALTH: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Ghaseminejad-Raeini[1], A. Shirinezhad[1], A. Azarboo[1], A. Mafhoumi[1], M. Islampanah[2], S. Mohammadi[1], A. H. Hoveidaei[3]

[1]School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Student Research Committee, Faculty of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran, Mashhad, Iran, [3]Sports Medicine Research Center, Neuroscience Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective

Urinary pentosidine, an advanced glycation end product (AGE), has been proposed as a potential biomarker for impaired bone health, especially in older adults and those with diabetes. This study aimed to systematically review and meta-analyze the association of urinary pentosidine with bone mineral density (BMD), fracture risk, and osteoporosis.

Methods

A comprehensive search of Embase, PubMed, Scopus, and Web of Science databases was conducted and records were gathered from 1960 to February 2024. Relevant papers were screened and data were extracted by two independent reviewers. Hedges' g standardized mean difference (SMD) and 95% confidence intervals (CI) were calculated to compare urinary pentosidine levels between patients with and without fractures.

Results

A total of 12 studies comprising 5,878 participants were included in the systematic review. The meta-analysis revealed that patients with fractures had significantly higher urinary pentosidine levels compared to those without fractures (SMD [95% CI] = 0.53 [0.39-0.68]; I^2 = 54%; P < 0.01). In patients with vertebral fractures, pentosidine levels were also elevated (SMD [95% CI] = 0.51 [0.32-0.70]; I^2 = 64%; P < 0.01). Additionally, some studies demonstrated that an increase in urinary pentosidine was significantly associated with fracture risk (aHR = 1.20 [95% CI = 1.07-1.33]; P = 0.001) and BMD reduction (β = -0.125 [95% CI = -0.248, -0.002]; P = 0.047). However, other studies showed inconsistent results, particularly regarding the association between pentosidine and BMD or fracture risk in non-diabetic populations (aRR [95%CI] = 1.08 [0.79-1.49]; P = 0.6). Diagnostic accuracy analyses revealed a sensitivity of 71.9% and specificity of 61.2% for urinary pentosidine in predicting vertebral fracture in patients with type 2 diabetes mellitus.

Conclusion

This systematic review and meta-analysis demonstrate that elevated urinary pentosidine levels are associated with an increased risk of fractures and, to a lesser extent, reduced bone mineral density. Its diagnostic accuracy improves when integrated with other clinical markers, such as BMD and bone turnover indices. However, due to the variability in results, further research is needed to standardize pentosidine's use as a reliable biomarker for impaired bone health in clinical practice.

A SYSTEMATIC REVIEW OF THE ASSOCIATION BETWEEN INSULIN RESISTANCE SURROGATE INDICES AND BONE MINERAL DENSITY

A. Ghaseminejad-Raeini[1], A. Azarboo[1], A. Shirinezhad[1], F. Kanaani Nejad[2], N. Zareshahi[1], S. Mohtasham Amiri[3], Y. Tahmasebi[1], A. H. Hoveidaei[4]

[1]School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Anesthesiology and Critical Care Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Shiraz, Iran, [3]Department of Medicine, Islamic Azad University Tehran Medical Sciences, Iran, Tehran, Iran, [4]Sports Medicine Research Center, Neuroscience Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective
The relationship of insulin resistance with bone mineral density (BMD) remains unclear, offering an opportunity for novel indices to shed light on the matter. The aim of this review was to evaluate the association between surrogate indices of insulin resistance and BMD.
Methods
A systematic review was conducted to evaluate observational studies that examined the relationship between insulin resistance surrogate indices and BMD in adults. Databases including PubMed, Web of Science, Scopus, and Embase were searched. Quality assessment was performed using Joanna Briggs Institute (JBI) critical appraisal tools.
Results
This systematic review included 27 cohorts and cross-sectional studies with 71,525 participants to assess the potential link between insulin resistance surrogate indices like HOMA-IR, HOMA-β, TyG, TyG-BMI, TyG-WtHR, and TyG-WC, along with METS-IR, and VAI, and BMD at various sites. There seems to be no link between BMD and the HOMA index, despite being extensively studied in various studies (adjusted β ranging from -0.49 to 0.103). Most literature suggests that a higher TyG index is associated with decreased BMD levels (adjusted β ranging from -0.085 to 0.0124). Despite limited evidence, other insulin resistance indices such as VAI (adjusted β ranging from 0.007 to 0.016), TyG-BMI (adjusted β ranging from 0.002 to 0.415), METS-IR (adjusted β ranging from 0.005 to 0.060), TyG-WtHR (β = 0.012) and TyG-WC (β = 0.0001) have shown a positive association with BMD in a few studies.
Conclusion
This systematic review emphasizes the intricate connection between insulin resistance and BMD. The lack of ability to perform a meta-analysis and the dependence on cross-sectional studies hinder the robustness of the findings, hence necessitating well-designed longitudinal studies.
Keywords: Insulin resistance, Bone mineral density, HOMA-IR, TyG index, VAI, Systematic review, Osteoporosis, BMD, Metabolic health

P113

APPLICATION OF OSTEOPONTIN (OPN) LEVELS AS A BONE TURNOVER BIOMARKER: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Azarboo[1], A. Ghaseminejad-Raeini[1], S. Jalali[1], O. Tabatabaei-Malazy[2]

[1]School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [2]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective: To evaluate the clinical relevance of osteopontin (OPN) as a bone turnover biomarker by assessing its association with osteoporosis, fractures, and bone mineral density (BMD) through a systematic review and meta-analysis.
Material and Methods: A systematic search was conducted across PubMed, Scopus, Web of Science, Embase, and Cochrane Library for studies published up to October 2024, reporting OPN levels in relation to bone health. Eligible studies included cross-sectional, case-control, and cohort designs. Standardized mean difference (SMD) with 95% confidence intervals (CI) was calculated to assess the association between OPN and outcomes. Random-effects models were employed, and heterogeneity was assessed using the I^2 statistic. Subgroup analysis based on study design was conducted. Meta-regression analysis was performed using confounding variables age, female percentage, and body mass index (BMI).
Results: The meta-analysis included 27 studies encompassing 4,062 participants. OPN levels were significantly elevated in patients with osteoporosis when compared with controls (SMD: 0.68 [95% CI: 0.45 to 0.91], $P < 0.001$; $I^2 = 71\%$). Also, when comparing patients with fractures vs. controls, OPN levels were analyzed to be statistically significantly higher (SMD: 0.72 [95% CI: 0.49 to 0.95], $P < 0.001$; $I^2 = 59\%$). According to some of the included studies, OPN levels were inversely associated with BMD. Subgroup analysis confirmed that cohort studies, similar to cross-sectional designs, demonstrated the observed associations between OPN and bone health outcomes. Meta-regression analysis revealed that heterogeneity in the osteoporosis association with OPN was partially explained by age ($P = 0.03$) and female percentage ($P = 0.02$), while BMI did not significantly contribute ($P > 0.05$). Sensitivity analyses confirmed the robustness of these findings.
Conclusion: This study identifies elevated OPN levels as a strong biomarker for increased risk of osteoporosis, fracture, and lower BMD. Moreover, age and female percentage positively influence the association with osteoporosis. However, further research is needed to explore OPN's role in bone health and its potential clinical applications.
Keywords: Osteopontin (OPN); Bone mineral density (BMD); Osteoporosis; Fracture; Biomarker; Meta-analysis

P114

BONE METABOLISM DISORDERS IN BREAST CANCER PATIENTS TREATED WITH AROMATASE INHIBITORS

A. Bacumova[1], L. Sivordova[2], L. Aref'Eva[1], J. Polyakova[2]

[1]Volgograd State Medical University, Volgograd, Russia, Volgograd, Russia, [2]Federal State Budgetary Institution «Zborovsky Research Institute of Clinical and Experimental Rheumatology», Volgograd, Russia

It is known that bone health is largely determined by the level of human sex hormones. The development of diseases or conditions that disrupt the synthesis of sex hormones contributes to bone metabolism disorders and can lead to osteoporosis (OP) and fractures.

The aim of our study was to investigate the prevalence of osteoporosis among patients with breast cancer (BC) receiving aromatase inhibitors (AI) or tamoxifen, depending on the duration of therapy, and the clinical efficacy of Denosumab, Zoledronic acid and Alendronates in the treatment of osteoporosis.

Materials and methods:

The study was performed using a retrospective analysis of outpatient records of 200 patients with BC receiving AI or tamoxifen. Bone density was assessed according to WHO recommendations using dual-energy X-ray osteodensitometry once a year. The level of bone remodeling was assessed by ELISA-test using commercial kits. The level of bone pain was assessed using the Visual Analogue Scale.

Results.

The study included 200 patients from 32 to 67 years old (mean age 53.25 ± 11.17 years). The average duration of the disease was 3.96 ± 1.98 years. The study showed that 22% (44 patients) had bone mineral density (BMD) below the age norm already in the first year of therapy. The incidence of osteopenia and osteoporosis directly correlated with the duration of such therapy: among patients in the fifth year of therapy, the prevalence of osteoporosis was 47% (94 patients) (p = 0.001).

During the study, groups of patients were identified who were prescribed antiresorptive therapy: 27 patients (Group I) - Denosumab (60 mg subcutaneously, once every 6 months); 39 patients (Group II) Zoledronic acid (5 mg intravenously, once every 12 months); 28 patients (Group III) Alendronates 70 mg per week per os. The control group consisted of 106 patients with normal BMD or osteopenia, with a low risk of fractures according to the FRAX index, who were recommended calcium preparations and cholecalciferol without antiresorptive drugs. The analysis showed that all antiresorptive drugs contributed to the preservation of bone density and a decrease in bone pain. In the group without antiresorptive therapy, bone density continued to decrease and bone pain persisted.

Discussion and conclusions:

In the treatment of breast cancer, aromatase inhibitors and tamoxifen are the most important components of the pathogenetic treatment of the disease. However, such therapy leads to accelerated bone resorption and, therefore, contributes to a decrease in bone mineral density and significantly increases the risk of secondary osteoporosis. According to clinical guidelines, antiresorptive therapy is prescribed to patients who already have osteoporosis, low-energy fractures, or a high risk of fractures according to the FRAX index. To date, there are no recommendations for prescribing antiresorptive therapy for the prevention of osteoporosis. However, there is already some scientific data on the effectiveness of preventive antiresorptive treatment [1,2]. Our study also confirmed the need for such therapy in the pathogenetic treatment of breast cancer using aromatase inhibitors or tamoxifen to prevent bone metabolism disorders.

THE KEYSTONE MECHANISM THEORY OF PAIN: MODERNIZED VERSION OF THE BIOPSYCHOSOCIAL MODEL

C. Walker[1], A. Bajaj[2], S. Er[3]

[1]Viatris, Hatfield, United Kingdom, [2]Viatris, Bengaluru, India, [3]Viatris, Turkiye, India

Introduction:

The biopsychosocial model (BPSm) has long been discussed in musculoskeletal research and practice and was proposed as an improvement to the biomedical model (BMM). Its applicability is limited due to its wide range of interpretations in clinical scenarios. The putative conclusions from BPSm were thought to deliver disease insights, but they offer limited tools for validating knowledge claims and are assertions on arguments and conceptual errors. This overarching conceptual framework may have paved the way for newer approaches to authenticate its underlying principles and scientific claims.

Enactive modernization of BPSm:

Convergence of the “humanistic” interpretation (person and relationship-centeredness) and “causation” interpretation (multifactorial contributors to health and illness) of BPSm leads to the recently discussed “Enactive” approach (Enactivism). The foundation of Enactivism lies in phenomenology, pragmatism, and cognitive sciences properly addressing musculoskeletal pain and the correlation of multiple factors in pain origination and maintenance. Listening and validating a person’s experiences as practical, regardless of an outsider's perspective, may foster clinician-patient trust and mitigate stigmatization.

Beyond BPSm- The Keystone approach:

Identifying "keystone" pain mechanisms, which are critical in the

pathophysiology of pain, is essential for understanding complex causal factors, including biological, psychological, and social influences. These keystones, like the central stone in an arch, are built upon multiple upstream factors but are crucial for system integrity. This approach moves beyond reductionism and aims to identify key biomarkers that explain treatment response variability across individuals, notable examples include- static and dynamic quantitative sensory testing (QST), neuroimaging, and psychometry. The keystone mechanism model guides interdisciplinary research to identify and measure key pain mechanisms, aiming to develop composite biomarkers that are clinically feasible, cost-effective, and reliable without compromising sensitivity.

Conclusion:

BPSm may not be used to define diseases, distinguish disease from non-disease states, or identify genuine cause-effect relationships, nevertheless it may be a useful tool to organize and communicate information about the psychosocial determinants of health. The Keystone approach offers a pragmatic balance and is theoretically and practically beneficial for transitioning from treating populations to individual people, overcoming the shortcomings of current treatments, and mitigating the failure to target the right treatment to the right patient.

ORGAN-ON-CHIP MODELS IN OSTEOARTHRITIS (OA) RESEARCH: STRATEGIES AND APPLICATIONS

A. Bajaj[1], C. Walker[2]

[1]Viatris, Bengaluru, India, [2]Viatris, Hatfield, United Kingdom

Introduction:

Despite scientific recognition of Osteoarthritis (OA) as a whole-joint disease, the complexity of the OA pathophenotype is not accurately reflected in current research. Fluidic integration of the joint microenvironment can greatly enhance the existing in vitro OA models, mimicking physiologic tissue environments. These technologies play a transformative role as they enable an accurate depiction of pathogenesis, offering deeper insights into molecular and cellular mechanisms driving the disease, thus accurately resembling joint tissues, and facilitating the study of intricate cellular interactions.

Soluble Tissue Crosstalk in Osteoarthritis:

Mechanical stimulation, multi-tissue, and immune cell interactions work together through micro-engineered devices combining biomaterials, 3D cell cultures, and microfluidics within the internal device architecture to regenerate and nudge the native tissue environment in OA and multiple tissue models. Mechanical stimulation in joint-on-a-chip models mimics knee joint forces, influencing chondrocyte behavior via mechanotransduction. Advances in microengineering use PDMS [poly(dimethylsiloxane)] to apply compressive stress, but challenges exist in strain control, imaging, and shear stress effects. Models like the "microJoint" integrate cartilage, bone, synovium, and sensory neurons, enabling the study of interactions, inflammatory responses, and joint pathogenesis. This model also helps integrate macrophages, monocytes, and endothelial cells, replicating immune cell interactions, such as monocyte extravasation, thus helping to study OA pathogenesis.

Bioengineering Roadmap and Future Prospects:

Joint-on-chips (JOCs) face key challenges in device engineering, replicating joint physiology, and generating useful readouts. Material selection, manufacturing scalability, and integration of functionality impact device design. Improving cell sourcing, near-native and tissue-specific extracellular matrix, mechanical environments, and collagen fiber arrangements and morphology is crucial for more accurate OA modeling. Advancements like organoids, stem cell differentiation, and 3D bioprinting offer promising solutions, while addressing systemic factors and creating "body-on-a-chip" models can further enhance OA research.

Conclusion:

The development of these systems could bridge the gap between in vitro and in vivo studies and help identify effective treatments for OA. Combining the cartilage-on-a-chip system with other musculoskeletal tissues like synovium and subchondral bone will provide a holistic view of tissue-tissue interactions governing OA onset including inflammation, fibrosis, and degradation of joint tissues. However, challenges remain in designing JOCs that replicate the full complexity of joint biology and disease.

P117

ASSESSMENT OF ADHERENCE TO BISPHOSPHONATE THERAPY AMONG PATIENTS WITH POSTMENOPAUSAL OSTEOPOROSIS DURING WARTIME

A. Balian[1]

[1]Rheumatology Department, Khmelnytskyi Regional Hospital, Khmelnytskyi, Ukraine

Objective: To evaluate the adherence to bisphosphonate treatment among patients with postmenopausal osteoporosis during wartime conditions and identify key barriers to sustained therapy.
Methods: A cross-sectional observational study was conducted from March 2023 to November 2024 involving 210 postmenopausal women diagnosed with osteoporosis based on bone mineral density (BMD) (T-score ≤ -2.5). Participants were recruited from regions affected by the ongoing conflict in Ukraine. Adherence to bisphosphonate therapy was assessed using the Medication Adherence Report Scale (MARS-5) and pharmacy refill data. A structured questionnaire evaluated sociodemographic factors, access to healthcare, and psychological stress during wartime. Adherence was defined as taking ≥80% of prescribed doses over the study period. Descriptive and inferential statistics were applied, with subgroup analyses based on geographic location and access to healthcare services.
Results: Only 42.4% (n = 89) of patients demonstrated adherence to bisphosphonate therapy. The most frequently reported barriers were disrupted access to healthcare services (reported by 65% of non-adherent patients), medication shortages (53%), and high levels of psychological stress (48%). Patients residing in conflict zones showed significantly lower adherence rates (26.7%, n = 40) compared to those in more stable areas (62.1%, n = 49; $p < 0.001$). Among adherent patients, the mean MARS-5 score was 20.3 ± 1.4, while non-adherent patients had a mean score of 12.7 ± 2.8 ($p < 0.01$). Multivariate analysis identified disrupted healthcare services (OR: 3.5, 95% CI: 2.1–5.9) and psychological stress (OR: 2.8, 95% CI: 1.6–4.6) as the strongest predictors of non-adherence.
Conclusion: Wartime conditions have a profound negative impact on adherence to bisphosphonate therapy among patients with postmenopausal osteoporosis. With adherence rates below 50%, urgent measures are needed to address barriers such as healthcare disruptions, medication shortages, and mental health challenges. Interventions like telemedicine, mobile healthcare units, and mental health support could significantly improve outcomes in this vulnerable population.

P118

ASSESSMENT OF THE IMPACT OF DEPRESSIVE AND ANXIETY DISORDERS ON TREATMENT ADHERENCE IN PATIENTS WITH KNEE OSTEOARTHRITIS DURING WARTIME

A. Balian[1]

[1]Rheumatology Department, Khmelnytskyi Regional Hospital, Khmelnytskyi, Ukraine

Objective: To investigate the influence of depressive and anxiety disorders on treatment adherence in patients with knee osteoarthritis (OA) under wartime conditions and identify associated risk factors.
Methods: A cross-sectional observational study was conducted between April 2023 and August 2024. The study included 175 patients diagnosed with knee OA based on clinical and radiological criteria (Kellgren-Lawrence grades II-III). Participants were recruited from war-affected regions. Depressive and anxiety symptoms were assessed using the Hospital Anxiety and Depression Scale (HADS), with scores ≥8 indicating clinically significant symptoms. Treatment adherence was evaluated using the Medication Adherence Report Scale (MARS-5), with adherence defined as taking ≥80% of prescribed medications and following lifestyle recommendations. Statistical analyses included descriptive statistics, chi-square tests, and multivariate logistic regression to identify predictors of non-adherence.
Results: Adherence to treatment was observed in only 38.3% (n = 67) of patients. Depressive symptoms were present in 54.9% (n = 96) of patients, and anxiety symptoms in 61.7% (n = 108). Patients with clinically significant depressive symptoms had markedly lower adherence rates (23.9%, n = 23) compared to those without depression (55.6%, n = 44; $p < 0.001$). Similarly, patients with anxiety symptoms showed lower adherence (30.6%, n = 33) compared to non-anxious patients (50.8%, n = 34; $p = 0.02$). Multivariate analysis revealed depressive symptoms (OR: 3.7, 95% CI: 2.1–6.5) and anxiety symptoms (OR: 2.4, 95% CI: 1.4–4.2) as strong predictors of non-adherence, along with disrupted healthcare access (OR: 3.2, 95% CI: 1.9–5.3).
Conclusion: Depressive and anxiety disorders significantly impair treatment adherence in patients with knee osteoarthritis during wartime. With adherence rates below 40%, addressing mental health is critical for optimizing OA management. Integrating mental health screening and support into routine OA care, especially in war settings, could enhance adherence and improve patient outcomes.

P119

EFFECTS OF DENOSUMAB BEYOND THE BONE RESORPTION: THE ROLE OF SERUM IGF1

A. Barbosa[1], M. Fonseca[2], M. Lopes[2], I. Cosme[1], E. Nobre[3], F. Costa[2], E. Alves[2], F. Sampaio[1]

[1]1Multidisciplinary Fracturary Osteoporosis Outpatient Clinic. Hospital Santa Maria, ULS Santa Maria, Lisboa 2 Faculty of Medicine of Lisboa, Lisboa, Portugal, [2]1Multidisciplinary Fracturary Osteoporosis Outpatient Clinic. Hospital Santa Maria, ULS Santa Maria, Lisboa, Lisboa, Portugal, [3]2 Faculty of Medicine of Lisboa, Lisboa, Portugal

Introduction

In some populations, reduced serum IGF-1 levels has been associated to osteosarcopenia. Osteoporosis and sarcopenia share similar risk factors, highlighting muscle-bone interactions, which may result in debilitating consequences, such as falls and fractures. IGF-1 is the main growth factor in the bone matrix, has a predominant anabolic bone effect and regulates the expression of receptor activator of nuclear factor kappa-B ligand (RANKL). Denosumab is a monoclonal antibody that binds RANKL preventing osteoclast differentiation, used in the treatment of osteoporosis because it reduces the incidence of fragility fractures.

Aims

To analyze the variation of IGF-1 levels in patients with severe osteoporosis under denosumab and its relationship with bone turnover markers.

Methods

Retrospective single-center analysis of female patients with osteoporosis and fragility fractures treated with denosumab. Data were obtained from electronic health records and included age at the beginning of denosumab, duration of therapy, IGF-1 and bone turnover markers (BTM) [Procollagen-1 N-terminal Propeptide (P1NP), bone alkaline phosphatase (BALP), C-terminal telopeptide (CTX) and osteocalcin] before treatment and at the time of its interruption or at the last appointment.

Results

The study included 37 female patients. The mean age at the beginning of denosumab was 71,8 ± 11,7 years old, with mean duration of therapy of 37,3 ± 17,0 months. Treatment with denosumab was associated with a statistically significant reduction in all four BTM, with CTX showing the greatest decrease (57,5%), followed by osteocalcin (53,2%), P1NP (48,1%) and BALP (34,3%). IGF-1 levels reduced by 7,5% (mean level before denosumab 100,7 ng/mL, after denosumab 93,2 ng/mL), without attaining statistical significance (p = 0,413).

Conclusions

In this population, the treatment with denosumab led to the expected decrease in all bone turnover markers, with the biggest expression in CTX, in agreement with the inhibition of bone resorption. It also led to a decrease in serum IGF-1, accompanying the BTM trend, but without statistical significance. Although serum IGF-1 levels do not always directly represent bone IGF-1 levels, these preliminary results of a small cohort point to a lack of effect of denosumab on the bone anabolic action of IGF-1 and on its possible muscle-bone interactions.

P120

MORTALITY REVIEW OF HIP FRACTURE PATIENTS OVER A TWELVE-MONTH PERIOD ADMITTED TO A NORTHWEST ENGLAND TEACHING HOSPITAL

A. Bartlett[1], M. Briggs[2], R. Maman[1], J. O'Hare[1], S. Naraen[1], M. Siddiqi[1]

[1]Liverpool University Hospital Group, Liverpool, United Kingdom, [2]University of Liverpool, Liverpool, United Kingdom

Objective: A mortality review to analyse the numbers of patients who experience ongoing deterioration and die during initial admission or within subsequent twelve months after the hip fracture admission.

Material and Methods: Audit of National Hip Fracture Database data for all patients admitted to a Northwest England Teaching NHS Hospital in the year 2022. Supplemented by a retrospective review of mortality data over a 12-month period from date of initial hip fracture.

Results: A total of 945 patients (average age 81 yrs.) were admitted with fractured neck of femur (NOF) over the twelve-month period from January to December 2022, of which 675 (72%) were females. 33 patients received conservative treatment as were deemed not fit for surgery due to multiple medical comorbidities. 26% of all patients died within 12 months of injury. There was no significant difference in death rate (28.3% vs 26.2%) or age (82yrs.vs 84yrs.) between male and female patients. Most deaths (68.6%) occurred within the first 6 months of hip fracture. Of these 30.4% of deaths occurred during the initial admission with fractured hip. Again, there was no difference in age between male and female patients (84vs82). A further 32.3% of deaths occurred on subsequent admission/s to hospital/ hospice with ongoing deterioration/ advancing frailty and progressive co-morbidity up to 12 months following hip fracture.

Conclusion

Our data compares well with the ICCONIC study (1) and shows the high morbidity and mortality in frail elderly patients with NOF. It emphasises the need to initiate supportive care conversations during the initial hip fracture admission in all such patients. Hip fracture admission offers the opportunity for patients to identify care preferences, make informed decisions about care and receive referrals to appropriate services, to ensure quality end of life care provision, in turn, reducing inappropriate readmission to hospital for those near the end of life (2, 3).

A COMPARISON BETWEEN ASYNCHRONOUS AND PHANTOMLESS CALIBRATION METHODS FOR THE OPPORTUNISTIC SCREENING OF OSTEOPOROSIS ON LUMBOSACRAL SPINE CT SCANS

E. Casoni[1], S. Gazzotti[1], R. Sassi[1], E. Schileo[1], M. P. Aparisi Gómez[2], F. Taddei[1], A. Bazzocchi[1]

[1]IRCCS - Rizzoli Orthopaedic Intitute, Bologna, Italy, [2]Auckland District Health Board, Radiology, Auckland, New Zealand, Auckland, New Zealand

Objective
The aim of this retrospective study is to compare the accuracy of several asynchronous and phantomless calibration methods for the opportunistic determination of bone mineral density (BMD) on standard CT scans of the lumbosacral spine.
Material and Methods
Calibration methods were tested on a cohort of 26 patients (mean age = 61.5 years; 46.2% males and 53.8% females) at risk for osteoporosis who underwent CT using a standard spine protocol (tube voltage = 120 kVp, slice thickness = 1.25 mm; no contrast) for non-dedicated indications. Average BMD (mg/cc) was calculated by placement of a region of interest (ROI) in the body of L4. Asynchronous calibration using a dipotassium phosphate (K_2HPO_4) phantom and internal calibration using five reference ROIs (air, subcutaneous adipose tissue, skeletal muscle, cortical bone and blood) or three reference ROIs (air, skeletal muscle, and cortical bone) were compared via linear regression with asynchronous calibration using the ESP phantom, set as gold standard. ROIs were defined manually using ITK SNAP. Results were obtained in both calcium hydroxyapatite (CHA) and K_2HPO_4 units and all measurements were performed using the open-source Ogo library.
Results
The analyses revealed significant correlations ($p < 0.05$) between densities derived from all methods and the standard ESP calibration. The K_2HPO_4 phantom calibration exhibited the highest concordance, with a regression slope of 0.82 and an intercept of 9.90 ($R^2 = 0.998$). By contrast, although correlations remained significant, internal calibration methods had lower concordance, with decreased slope values (0.58 to 0.73) and increased intercept values, from 15.38 using three ROIs ($R^2 = 0.972$) up to 47.72 using five ROIs ($R^2 = 0.907$). In particular, internal calibration using five ROIs appeared to overestimate BMD values as compared to asynchronous calibration via ESP, especially in low density vertebrae.
Conclusion
Asynchronous calibration methods using different phantoms are highly concordant. By contrast, while representing a convenient option for the opportunistic screening of osteoporosis, phantomless calibration methods using internal references materials still yield suboptimal results and require further investigation to achieve comparable outcomes in clinical practice.

P122

CLINICAL CHARACTERISTICS OF PATIENTS WITH CHRONIC POST-TRAUMATIC PAIN: DATA FROM A PROSPECTIVE STUDY

A. Bialik[1], A. Karateev[1], M. Makarov[1], A. Bialik[1], V. Nesterenko[1], E. Bialik[1], S. Makarov[1]

[1]Nasonova research institute, Moscow, Russia

Chronic post-traumatic pain (CPT) is diagnosed when pain persists ≥3 months after injury. This is a serious pathology that significantly reduces the quality of life and ability to work of patients and is one of the predictors of the development of post-traumatic osteoarthritis.
The aim of the study was to evaluate the clinical features of CPTB after knee joint injury (CS).
Materials and methods. The study group included 103 patients (average age – 39.4±12.5 years, 51.5% of women). All patients suffered a CS injury with a diagnosed anterior cruciate ligament and/or meniscus injury and experienced pain of ≥4 on a numerical rating scale (HRH, 0-10) for ≥1 month after the injury. The patients' condition was assessed after 3 and 6 months. The intensity of pain during movement, at rest and at night, and impaired function were determined by heart rate. The questionnaires KOOS, EQ-5D, painDETECT, CSI, pain catastrophization, as well as HADS, FIRST and FACIT were used.
Results and discussion. After 3 months, the number of patients with CPT was 33 (32.0%). After 6 months, these patients had significantly more pronounced symptoms than patients with CS injury without CPTB (control, n=70). In the CPTB and control groups, the median pain during movement was 5.0 [4.0; 6.0] and 1.0 [0.0; 1.0], respectively, p<0.001; pain at rest – 2.0 [2.0; 3.0] and 0.0 [0.0; 1.0], p<0.001; pain at night – 2.0 [1.0; 3.0] and 0.0 [0.0; 0.0], p<0.001; KOOS score – 4.0 [1.0; 5.5] and 2.0 [1.0; 3.5], p<0.001; EQ-5D quality of life – 0.65 [0.52; 0.73] and 0.89 [0.69; 1.0], p<0.001; On the EQ-5D scale, 64.0 [50.0; 70.0] and 80.0 [70.0; 90.0], p<0.001; painDETECT score >12 was observed in 24.2 and 2.9% of cases, p<0.0037; depression ≥11 in 21.2 and 2.9%, p<0.001, anxiety ≥11 – in 24.2 and 4.3%, p=0.0038; CSI ≥40 – in 9.0 and 0%, p=0.03; pain catastrophization ≥30 – in 12.1 and 0%, p=0.005; FIRST ≥5 – in 6.1 and 0%, p=0.358; FACIT<30 – in 15.2 and 2.9%, p=0.004. After 6 months, there were statistically significant differences between the CPTB group.
Conclusion. 3 months after the injury, CS CPTB developed in 32.0% of patients. All of them had moderate/severe pain with impaired function and decreased quality of life, every 5th had symptoms of neuropathic pain, signs of depression and anxiety. Patients with CPTB showed marked changes in all sections of the KOOS questionnaire.

P123

FACTORS ASSOCIATED WITH THE DEVELOPMENT OF POST-TRAUMATIC PAIN IN PATIENTS AT RISK OF POST-TRAUMATIC OSTEOARTHRITIS

A. Bialik[1], A. Karateev[1], M. Makarov[1], E. Bialik[1], V. Bialik[1], V. Nesterenko[1]

[1]Nasonova research institute, Moscow, Russia

The aim of the study was to identify the factors associated with the development of chronic post–traumatic pain (CPT) in patients with knee joint injury (COP).

Materials and methods. The study group consisted of 136 patients (51.5% women, age 38.7±12.4 years) who had suffered a CS injury with damage to the anterior cruciate ligament (ACL) and/or menisci. The inclusion criterion was the presence of pain in CS ≥4 on a numerical rating scale (HRH 0-10) for at least 1 month after the injury. Surgical intervention (PC plastic surgery, meniscus suture, meniscus resection, combined operations) was performed immediately after injury in 48.5% of patients. The incidence of CPTB (persistence of pain during movement ≥4 HRH after 3 and 6 months of follow-up) and factors related to the development of CPTB were evaluated. All patients were advised to use orthoses, exercise therapy, and nonsteroidal anti-inflammatory drugs on an "on-demand" basis.

Results. CPTB was detected after 3 months in 33.1%, and after 6 months in 32.4% of patients. Surgical treatment had no effect on the development of CPTB: odds ratio (OR): 1.241, 95% confidence interval (95% CI): 0.775–1.986 (p=0.474). The risk of CPTB after 6 months. It was statistically significantly higher in women, people with a high body mass index (≥30 kg/m2), initially severe pain (≥7 according to HRH), in the presence of initial signs of depression and anxiety (Hospital Anxiety and Depression Scale score ≥8) and highly probable central sensitization (score according to the Central Sensitization Inventory (CSI, Central Sensitization Inventory) ≥40): OR=2.152, 95% CI: 1.383–3.348 (p=0.002); OR=1.243, 95% CI: 1.054–1.465 (p=0.05); OR=3.567, 95% CI: 1,717–5,708 (p=0.001); OR=2,330, 95% CI: 1,070–5,726 (p=0.0044); OR=2,446, 95% CI: 1,220–4,905 (p=0.016); OR=2,584, 95% CI: 1,101–8,133 (p=0.043) accordingly.

P124

FACTORS DETERMINING THE DEVELOPMENT OF POST-TRAUMATIC PAIN AND POST-TRAUMATIC OSTEOARTHRITIS

A. Bialik[1], A. Karateev[1], M. Makarov[1], S. Makarov[1], E. Bialik[1], V. Bialik[1], V. Nesterenko[1]

[1]Nasonova research institute, Moscow, Russia

Injuries cause a systemic neurohumoral and behavioral response of the body aimed at repairing damaged tissues and correcting biomechanical disorders. However, in many cases, full-fledged repair is impossible: traumatic damage, resulting inflammation and degenerative processes (fibrosis, neoangiogenesis, heterotopic ossification) lead to severe structural changes and a progressive decrease in functional ability. The most common complications of injuries include chronic post-traumatic (PT) pain and PT osteoarthritis (OA). These complications are interrelated: pain (accompanied by stiffness and impaired function), which occurs in 10-50% of people who have suffered a joint injury, may indicate the formation of an early (pre-allergenic) stage of PT OA. The development of typical structural changes in PT OA after 10-15 years is noted after knee joint injury in more than 30% of patients. PT OA of large joints proceeds more aggressively, is more often accompanied by synovitis and requires endoprosthetics on average 10-15 years earlier than primary OA. Early diagnosis of PT OA is based on an analysis of the dynamics of clinical manifestations (primarily PT pain), visualization of early changes in joint structure (magnetic resonance imaging), as well as a study of the level of biomarkers of inflammation and bone-cartilage destruction. Genetic features that determine the chronization of inflammation and pain, as well as disorders of cartilage and bone tissue repair, are considered as additional risk factors for PT OA.

P125

TRABECULAR AND CORTICAL BONE LOSS POST TRANSPLANTATION: ASSOCIATION WITH EARLY BONE TURNOVER CHANGES

A. Bouquegneau[1], F. Jouret[1], L. Seidel[2], C. Ribbens[3], E. Cavalier[4], P. Delanaye[1], O. Malaise[3]

[1]Division of Nephrology-Dialysis and Transplantation, University of Liège (ULiège), CHU Sart-Tilman, Liege, Belgium, [2]Biostatistics and Research Method Center (B-STAT), CHU-ULiège, Liège, Belgium, [3]Department of Rheumatology, University of Liège (ULiège), CHU Sart-Tilman, Liege, Belgium, [4]Department of Clinical Chemistry, University of Liège (ULiège), CHU Sart-Tilman, Liege, Belgium

Background: Bone loss and mineral abnormalities are common after kidney transplantation (KTx), increasing fracture risk and mortality. Traditional bone health assessments rely on biochemical markers of bone turnover and Dual-Energy X-ray Absorptiometry (DXA) to measure areal bone mineral density (aBMD). High-resolution peripheral quantitative computed tomography (HR-pQCT) provides additional insights into bone microarchitecture and volumetric bone density (vBMD) of cortical and trabecular compartments. This study evaluated bone turnover biomarkers, DXA, and HR-pQCT parameters over 1-year post-KTx, and assessed whether 3-month (3m) biomarker changes (Δdelta) predict 1-year (1yr) bone loss.

Methods: 75 patients were included in this prospective study (median age: 60.4 [52.1–65.8]), bone biomarkers (PTH, BALP, P1NP, TRAcP-5b, CTX, sclerostin) were measured at baseline (D0), 3m, and 1yr. DXA assessed aBMD at the lumbar spine (LS), hip, and radius, while HR-pQCT measured volumetric vBMD and bone microarchitecture at the distal radius and tibia.

Results: DXA revealed significant LS and femoral neck (FN) aBMD declines from D0 to 3m ($p < 0.03$), with partial LS recovery by 1yr. At 1yr, 30%, 29%, and 45% of patients showed significant

bone loss at LS, FN, and ultradistal radius (UD) sites (p<0.003). HR-pQCT showed early declines in total (Tt) and trabecular (Tb) vBMD, as well as trabecular bone volume fraction (BV/TV) starting at 3m. Cortical (Ct) vBMD and cortical thickness (CtTh) also began declining at 3m, with significant reductions in all parameters by 1yr. Multivariate analysis identified ΔBALP at 3m as an independent predictor of LS loss at 1yr (OR 1.025; p=0.003). Baseline sclerostin predicted Ct vBMD loss (OR 5.651; p=0.01), and ΔBALP at 3m independently predicted Tt vBMD loss at 1yr (OR 1.283; p=0.0009).

Conclusion: Bone loss after KTx begins rapidly, with trabecular and cortical compartments significantly affected within 1yr. Early changes in biomarkers, particularly BALP and sclerostin, predict future bone loss, highlighting the importance of biomarker and imaging monitoring to identify high-risk patients and improve bone health outcomes.

P126

IMPROVED TRABECULAR BONE SCORE ALGORITHM IN END-STAGE RENAL DISEASE PATIENTS: A COMPARISON WITH HR-PQCT DATA

A. Bouquegneau[1], F. Jouret[1], L. Seidel[2], C. Ribbens[3], E. Cavalier[4], P. Delanaye[1], O. Malaise[3]

[1]Division of Nephrology-Dialysis and Transplantation, University of Liège (ULiège), CHU Sart-Tilman, Liege, Belgium, [2]Biostatistics and Research Method Center (B-STAT), CHU-ULiège, Liège, Belgium, [3]Department of Rheumatology, University of Liège (ULiège), CHU Sart-Tilman, Liege, Belgium, [4]Department of Clinical Chemistry, University of Liège (ULiège), CHU Sart-Tilman, Liege, Belgium

Purpose: Given the high fracture risk, non-invasive evaluation techniques for assessing bone fragility in chronic kidney disease (CKD) are crucial. The trabecular bone score (TBS) may provide valuable insights for treatment and follow-up decisions. A pre-market TBS software (version 4.0 (V4)), featuring an improved algorithm that adjusts for directly measured abdominal soft tissue thickness, is now available for clinical use. This version addresses limitations of earlier versions, such as V3, which relied on body mass index (BMI) as a surrogate for soft tissue thickness. The aim of this study is to assess if TBS can effectively reflect bone microarchitecture in end-stage renal disease (ESRD) patients, using high-resolution peripheral quantitative computed tomography (HR-pQCT) as the criterion, comparing versions V3 and V4 of TBS.

Methods: Seventy-five ESRD patients were included at the time of kidney transplantation (KTx). Areal bone mineral density (aBMD) was measured using dual-energy X-ray absorptiometry (DXA (Hologic)), and TBS was assessed from the L1-L4 region during DXA scans. Volumetric BMD (vBMD) and peripheral bone microarchitecture at the tibia and radius were analyzed using HR-pQCT. We evaluated the absolute differences in TBS between V3 and uncalibrated V4 versions, assessed their correlation, and calculated the intraclass correlation coefficient (ICC) to determine reliability and agreement between the two versions.

Results: In this ESRD cohort, median age was 60.4 [52.1 – 65.8] years old, and 70.7% were male. Mean BMI was 26.2 (± 4.6) kg/m^2, the median TBS score for V3 was 1.316 [1.256–1.401], while the median TBS for V4 was 1.305 [1.236–1.351]. A strong correlation was observed between TBS V3 and V4 (r = 0.85, p < 0.0001). The ICC for V3 and V4 was 0.80 (95% CI: 0.73–0.87), indicating good reliability.

V3 TBS showed only a modest correlation with aBMD at the total hip (TH) level (r = 0.283, p = 0.02), but not at other sites. TBS V4 maintained a negative correlation with age (r = -0.278, p = 0.02), similar to V3, and modest correlations with aBMD at the lumbar spine (LS) (r = 0.511, p < 0.0001), TH (r = 0.452, p = 0.0001), and femoral neck (FN) (r = 0.377, p = 0.001).

TBS V3 correlated modestly with vBMD parameters (r = 0.242–0.508, p < 0.04). Both versions demonstrated a negative correlation between TBS and trabecular separation (Tb.Sp) (r -0.368–0.550, p < 0.001), indicating that higher TBS values are associated with reduced trabecular separation, reflecting a more interconnected trabecular bone microarchitecture. TBS V4 showed higher correlations with trabecular microarchitecture; however, no, correlations were observed with cortical structural parameters (Ct.Po and Ct.Po.Dm) .

Conclusion: The updated algorithm, which adjusts for directly measured abdominal soft tissue thickness, further strengthened associations with trabecular bone microarchitecture. While correlations with cortical structural parameters were reduced.

OSTEOPOROSIS SCREENING IN POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS PATIENTS ON LONG-TERM CORTICOSTEROID THERAPY: A TERTIARY CARE ANALYSIS

A. C. Moniz[1], J. Tremoceiro[1], S. D. Rodrigues[1], D. Melim[1], M. E. Santos[1], L. Gago[1], C. Lopes[1], P. Araújo[1], J. C. Branco[1], M. Costa[1]

[1]Rheumatology, Unidade Local de Saúde de Lisboa Ocidental, Lisboa, Portugal

Objective: To evaluate osteoporosis (OP) screening and treatment in patients with polymyalgia rheumatica (PMR) and/or giant cell arteritis (GCA) on long-term glucocorticoid (GC) therapy.

Materials and Methods: A retrospective longitudinal study was conducted on PMR and/or GCA patients receiving ≥7.5 mg/day of prednisolone or equivalent for ≥3 months in a Rheumatology department from 2018 to 2024. Patients with prior OP diagnosis or treatment and fragility fracture history were excluded. Data collected included demographic and clinical information, FRAX assessment, bone mineral density (DXA scan), vertebral fracture assessment (spinal x-rays), and OP treatment. Screening and treatment were considered appropriate if performed within the first 6 months of GC therapy[1].

Results: We included 57 patients (49.2% PMR, 35.6% GCA, 11.9% both) with a mean age of 78 ± 8 years; 52.5% were female. Within the first 6 months of GC therapy, FRAX was performed in 31.6% of patients, DXA scan in 36.8%, and spinal x-rays in 15.8%. According to the 2022 ACR guidelines[1], 33.3% of patients had very high fracture risk, 12.3% high risk, and 15.8% moderate risk, totaling 61.4% of patients with an indication for treatment. Among those, 65.7% received anti-OP medication within 6 months and 20% after 6 months but during GC therapy; 31.4% never initiated treatment. Calcium and vitamin D supplementation were prescribed within 6 months in 91.2% of patients. Although 7% of patients were low risk and 31.6% not categorizable due to missing data, treatment was initiated in 25% and 38.9%, respectively, based on rheumatologist's opinion. The prescribed drugs were alendronate (38.6%), denosumab (14%), zoledronate (8.8%), risedronate (1.8%), pamidronate (1.8%) and teriparatide (1.8%).

Conclusion: OP screening and treatment in PMR/GCA patients on long-term GC were insufficient, especially in terms of early assessment. While most patients received calcium and vitamin D supplementation, the use of anti-OP medications did not align with recommendations. Improved strategies are needed to enhance OP management in this high-risk population.

P128

PREDICTORS OF BONE MINERAL DENSITY AT THE TOTAL HIP IN OLDER IRISH ADULTS: RESULTS FROM THE TUDA STUDY

A. Carroll[1], K. Mccarroll[1], R. Lannon[1], E. Laird[2], M. Ward[3], H. Mcnulty[3], C. Cunningham[1], D. Fitzpatrick[1]

[1]St James's Hospital, Dublin , Ireland, [2]Atlantic Technological University, Sligo, Ireland, [3]University of Ulster, Belfast, United Kingdom

Objectives

Several factors are known to influence bone mineral density (BMD) including age, sex, body mass index (BMI), genetic, lifestyle (diet, alcohol intake, smoking, exercise levels), vitamin D, medical conditions, and medications. We aimed to explore the predictors of hip BMD in older Irish adults.

Methods

Study participants were from the TUDA study of Irish adults aged >60 years who had total hip BMD measured by DXA. Exclusion criteria encompassed those on anti-resorptives or anabolic agents. Factors known to or with the potential to affect BMD (including medications) were explored in multinomial regression models with significant predictors reported.

Results

2343 participants, 60% female and mean age 69.1 years. Positive independent predictors of total hip BMD were body mass index ($p<0.0001$), diabetes ($p=0.002$), thiazide diuretics ($p=0.001$), statin use ($p=0.017$), while negative predictors were female sex ($p<0.001$), physical frailty ($p=0.005$), current smoking ($p=0.005$), current or long-term steroid use ($p=0.001$) and hyperparathyroidism (PTH >65 pg/ml) ($p<0.001$). Most of the variation (35%) in BMD was explained by three factors (age, sex, and BMI).

Conclusion

Genetics determines up to 70% of peak bone density which of itself may account for about 60% of the risk of osteoporosis in later life. Nonetheless, we identified that just three factors (age, sex, and BMI) account for about a third of the variation in total hip BMD in older adults. Similar to other studies, thiazides and statins were associated with higher BMD. While diabetes was associated with greater BMD, it is known to compromise bone quality and strength and also increase hip fracture risk.

P129

PREVALENCE OF OSTEOPENIA, OSTEOPOROSIS AND NORMAL OR HIGH BONE MINERAL DENSITY IN PATIENTS ATTENDING FOR DXA AT A BONE HEALTH UNIT

A. Carroll[1], K. Mcsherry[1], R. Lannon[1], N. Maher[1], N. Fallon[1], G. Steen[2], C. O'Carroll[1], K. Mccarroll[1]

[1]Bone Health Unit, St James's Hospital, Dublin , Ireland, [2]Bone Health Unit, St James's Unit, Dublin , Ireland

Objectives
Measurement of bone mineral density (BMD) by DXA is recommended for adults with risk factors for low bone mass and in all females aged >65 and males aged >70 years. We aimed to assess the prevalence of osteoporosis, osteopenia and normal or high BMD in patients referred for DXA at our service.
Methods
Patients who had DXA at the total hip and/or lumbar spine were identified. Patients were classified into the diagnostic categories at each site based on T-scores: osteoporosis: mild (<- 2.5 to -2.9), moderately severe (-3.0 to -3.4) and severe (<-3.5), osteopenia (<-1.0 to -2.4), normal BMD (>-1.0 to <+2.4) and high BMD (>+2.5).
Results
BMD data was available for 9003 patients at the spine and 7410 at the total hip. Prevalence at the spine of osteoporosis was: mild (15.6%), moderately severe (12.2%), severe (16.9%), osteopenia (33.7%), normal BMD (20.8%) and high BMD (0.8%). The lowest spine T-score was -7.0 and the highest +6.8. Prevalence at the hip of osteoporosis was: mild (12.3%), moderately severe (5.8%), severe (6.7%), osteopenia (48.7%), normal BMD (26.5%) and high BMD (0.2%). The lowest hip T-score was -6.9 and the highest +4.6.
Conclusion
The majority of patients had low bone mass at the spine (78%) or hip (73%) reflecting the utility of DXA testing. Osteoporosis was less prevalent in the hip versus spine as reported elsewhere. Under 1% had high BMD (more common in the spine) and which in the majority of cases is known to result from osteoarthritic change.

P130

OSTEOARTHRITIS: PERSPECTIVE OF A POPULATION FACING BARRIERS TO ACCESS HEALTH SERVICES IN GUATEMALA

A. Cifuentes Sosa de Yllescas[1], G. Brincker Nicolas[2], R. Rodas Flores[2], V. Molina de León[2], G. López Oliva[2], J. López Rodríguez[2], J. González Licardie de Ancheta[2], B. Lopez Samayoa[3]

[1]Amir Wellness Center - Iniciativa Guatemalteca de Ortobiologicos y Rehabilitacion, Quetzaltenango, Guatemala, [2]Family Medicine Program Clinica San Antonio at Centro Universitario de Occidente, Universidad de San Carlos de Guatemala, Quetzaltenango, Guatemala, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Osteoarthritis (OA) is a prevalent chronic degenerative disease in Guatemala, a country marked by ethnic, cultural, and linguistic diversity. OA is a leading cause of permanent disability, significantly affecting quality of life due to delayed diagnosis and treatment. Access to healthcare is particularly unequal in northwestern regions, where poverty, low education levels, and limited medical resources exacerbate non-biological risk factors for chronic diseases.

Objective This study aimed to characterize the epidemiological, clinical, and therapeutic profiles of OA in Guatemala, focusing on preventive approaches and alternative therapies in diverse populations.

Material and Methods A retrospective, descriptive study was conducted using data from 201 medical records drawn from a population of N=319, calculated with a 95% confidence level (Z=1.96,p=0.5,q=0.5,E=0.05). Patients aged 15 years or older who received intra-articular platelet-rich plasma (PRP) therapy with a follow-up period of over two years were included. The therapy was performed by a specialist trained in arthroscopy, ensuring consistency. Data from 2017–2021 were analyzed using IBM SPSS software.

Results The knee was the most affected joint (81%), with a 1:2 male-to-female consultation ratio. Socioeconomic disparities were significant, and 37% were illiterate. The primary diagnostic method was X-rays analyzed with the Kellgren and Lawrence scale due to cost barriers to advanced imaging.

Table 1. Epidemiological, Clinical, Diagnostic, and Therapeutic Characterization.

Patient Characteristics	**N / (%)**		
Total patients	201 / (100%)		
Ethnic	**Maya**	**Mestizo**	**None**
	68 / (34%)	96 / (48%)	37 /(18%)
Gender (M/F)	72 (36%) / 129 (64%)		
Occupation			
-Housekeeper	76 / (38%)		
-Students	26 / (13%)		
-Others	99 / (49%)		
Age (Range 15-79)	Median 56, Mode 74, Standard deviation 17.41		
Literacy			
Yes	127 / (63%)		
No	74 / (37%)		
Clinical Characteristics			
Affected joint			
-Knee	162 / (81%)		
-Shoulder	31 / (15%)		
-Others	8 / (4%)		

Conclusions Health disparities, such as poverty and low education, impede timely OA diagnosis and treatment in Guatemala. PRP therapy, although emerging as a treatment option, is financially inaccessible for most patients, who primarily rely on anti-inflammatory drugs. Establishing specialized centers and preventive programs is essential to improving outcomes and mitigating the burden of OA in resource-limited settings.

P131

PLATELET RICH PLASMA AS BIOLOGICAL THERAPY IN WESTERN GUATEMALA: BENEFITS, SAFETY, AND TOLERABILITY

A. Cifuentes Sosa de Yllescas[1], R. Rodas Flores[2], G. Brincker Nicolas[2], J. López Rodríguez[2], V. Molina de León[2], G. López Oliva[2], J. González Licardie de Ancheta[2], B. Lopez Samayoa[3]

[1]Amir Wellness Center - Iniciativa Guatemalteca de Ortobiologicos y Rehabilitacion, Quetzaltenango, Guatemala, [2]Family Medicine Program Clinica San Antonio at Centro Universitario de Occidente, Universidad de San Carlos de Guatemala, Quetzaltenango, Guatemala, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

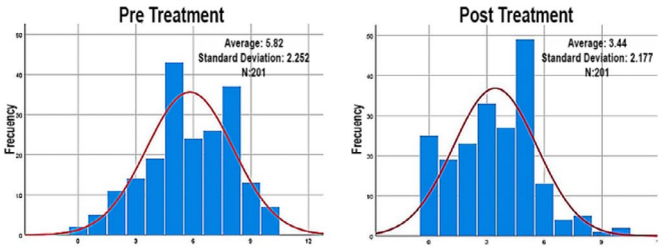
Osteoarthritis (OA) is a degenerative musculoskeletal disease characterized by geographic and population variability, significantly impacting patients physically, psychologically, and economically. Guatemala's ethnic, cultural, and linguistic diversity contributes to variations in OA symptomatology based on age, gender, and ethnicity, particularly in interior regions. Currently, there is no national clinical guideline for non-surgical OA management, and therapies with platelet-rich plasma (PRP) are still emerging.

Objective : This study aims to describe the clinical outcomes of PRP therapy in OA patients before and after treatment.

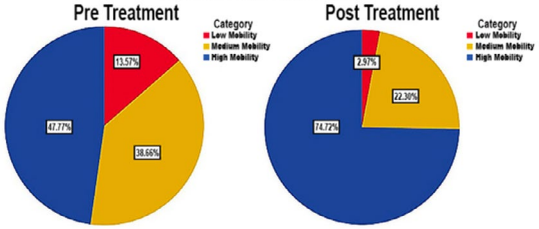
Material and Methods : This retrospective, descriptive study analyzed data from 201 patients meeting inclusion criteria, derived from a population of N=319 with a 95% confidence level (Z=1.96, p=0.5, q=0.5, E=0.05). Patients aged 15 years or older who received intra-articular PRP therapy over a two-year follow-up period were included. The therapy was administered by a trained arthroscopy specialist at the family medicine clinic of the National University of Guatemala, Quetzaltenango campus. Pre- and post-treatment pain scales and mobility function scores were analyzed. Medical records from 2017–2021 were reviewed using IBM SPSS software.

Results : PRP therapy demonstrated a significant reduction in pain, with average pre-treatment scores decreasing from 5.82 to 3.44 post-treatment. Improvements in pain and mobility were noted, particularly among patients classified as Grades I and II on the Kellgren and Lawrence X-ray scale. Patients tolerated the procedure well, with minimal reports of pain or inflammation managed through conservative measures. No adverse or infectious effects were observed during the study period.

Graph 1. Pain Scale Pre and Post-Treatment.



Graph 2. Mobility Function Percentages by Category Pre and Post-Treatment



Conclusions : This study is the first to report on PRP as an alternative therapy for OA in western Guatemala, providing an affordable option for patients unable to access arthroplasty. PRP treatment improved pain and mobility outcomes, particularly in early-stage OA. Patient education and physiotherapy are essential for optimizing results. Expanding access to PRP therapy in Guatemala could significantly enhance OA management, addressing the unmet needs of economically disadvantaged populations.

P132

PLATELET-RICH PLASMA: SEVEN YEARS OF EXPERIENCE IN OBTAINING, PREPARING, AND APPLICATION IN THE WESTERN REGION OF GUATEMALA

A. Cifuentes Sosa de Yllescas[1], R. Rodas Flores[2], G. Brincker Nicolas[2], G. López Oliva[2], V. Molina de León[2], J. González Licardie de Ancheta[2], B. Lopez Samayoa[3]

[1]Amir Wellness Center - Iniciativa Guatemalteca de Ortobiologicos y Rehabilitacion, Quetzaltenango, Guatemala, [2]Family Medicine Program Clinica San Antonio at Centro Universitario de Occidente, Universidad de San Carlos de Guatemala, Quetzaltenango, Guatemala, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Platelet-rich plasma (PRP) is increasingly utilized in osteoarthritis (OA) treatment due to its anti-inflammatory properties and ability to reduce proinflammatory biochemical effects in affected joints. While its bioregenerative mechanisms are not fully understood, PRP demonstrates positive clinical outcomes. In Guatemala, OA is prevalent, but limited healthcare access and economic constraints often preclude surgical interventions like arthroplasty. Despite the emerging use of PRP as an orthobiologic therapy, there is no national protocol standardizing its preparation and application.

Objective

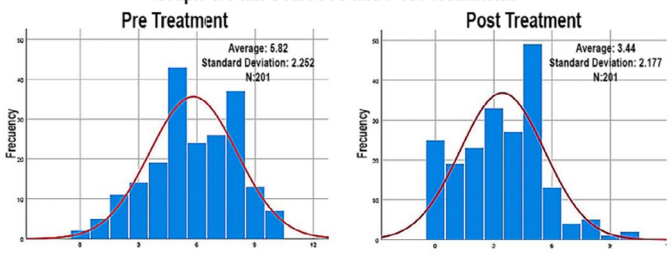
This study aims to describe the PRP preparation process, applica-

tion protocol, and outcomes in OA management.

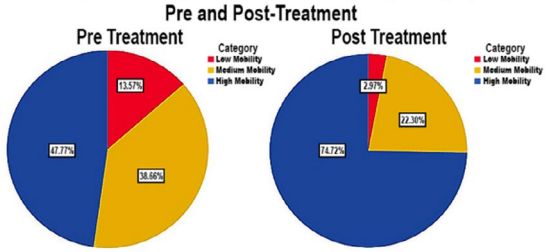
Material and Methods: A retrospective, descriptive study reviewed medical records of 201 patients treated with PRP from 2015 to 2021 at the family medicine clinic of the National University of Guatemala, Quetzaltenango campus. Patients aged 15 years or older, with a follow-up time exceeding two years, were included. PRP was obtained through a standardized protocol: 40 ml of peripheral venous blood was collected, divided into eight 5 ml glass tubes with 3.8% citrate anticoagulant, and centrifuged at 3,200 rpm for 15 minutes. The PRP fraction was extracted under sterile conditions, mixed with 1.8 ml of 10% calcium gluconate as an activator, and prepared for intra-articular injection. Platelet counts and quality were analyzed by trained laboratory personnel.

Results: The protocol yielded 9.5 ml of PRP with platelet levels 2–3 times higher than baseline. Pain scores decreased from a mean of 5.82 (SD: 2.252) pre-treatment to 3.44 (SD: 2.177) post-treatment. Mobility improved in 74.72% of patients based on functional range evaluations.

Graph 1. Pain Scale Pre and Post-Treatment.



Graph 2. Mobility Function Percentages by Category Pre and Post-Treatment



Conclusions: This is the first study in Guatemala to standardize PRP preparation and application for OA treatment. The technique, feasible in conventional clinics, emphasizes controlled antiseptic environments and thorough clinician training. PRP therapy offers a promising, cost-effective alternative for OA management, particularly in resource-limited settings. Further research into platelet quality and therapeutic frequency is recommended to optimize outcomes.

P133

CYTOLOGICAL ANALYSIS OF PLATELET MORPHOLOGY OBTAINED THROUGH PLATELET-RICH PLASMA (PRP) FOR THE TREATMENT OF OSTEOARTHRITIS

A. Cifuentes Sosa de Yllescas[1], P. De León Fajardo[2], R. Rodas Flores[3], G. Brincker Nicolas[3], V. Molina de León[3], G. López Oliva[3], J. López Rodríguez[3], J. González Licardie de Ancheta[3], B. Lopez Samayoa[4]

[1]Amir Wellness Center - Iniciativa Guatemalteca de Ortobiologicos y Rehabilitacion, Quetzaltenango, Guatemala, [2]Department of Clinical Laboratories and Pathology at Roosevelt Hospital, Guatemala, Guatemala, [3]Family Medicine Program Clinica San Antonio at Centro Universitario de Occidente, Universidad de San Carlos de Guatemala, Quetzaltenango, Guatemala, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

The therapeutic application of Platelet-Rich Plasma (PRP) for osteoarthritis has shown promising regenerative potential. However, there is a notable lack of information regarding the morphological characteristics of platelets within PRP in this specific clinical context. Additionally, existing centrifugation methods rarely address their impact on platelet morphology and quality.

Objective:

This study is aimed to describe and analyze the cytological morphology of platelets obtained through a single centrifugation protocol for PRP preparation in patients with osteoarthritis.

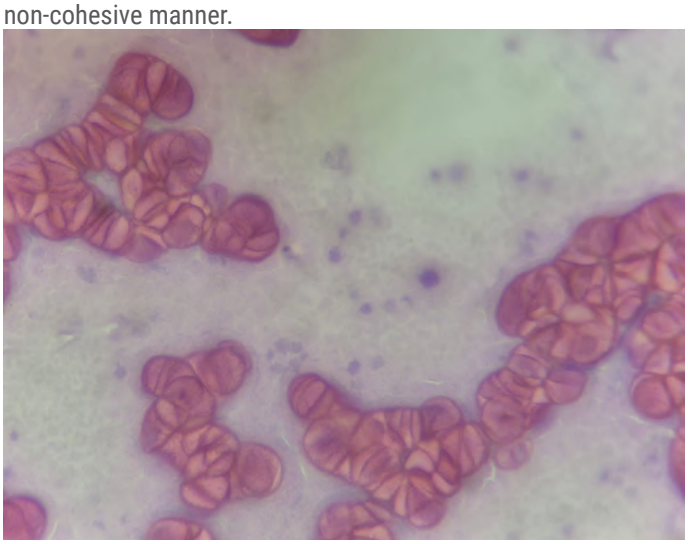
Methods

A prospective observational study was conducted using 54 blood samples obtained from osteoarthritis patients (Kellgren & Lawrence Grades I-III). Blood samples were centrifuged at 3200 rpm for 15 minutes. PRP blood smears were prepared, stained using Hemacolor, and evaluated under optical microscope by a professional histopathologist. Platelet morphology was assessed for size, granularity, membrane integrity, and aggregation. The platelet distribution patterns (scattered or clumped), and morphology (normal, diluted, or damaged) were documented.

Results

Out of the 54 samples analyzed, 83% (45/54) exhibited normal platelet morphology characterized by uniform size, intact membranes, and appropriate granularity, as illustrated in Figure 1. Hemodilution was identified in 15% (8/54) of the samples, leading to lower platelet concentrations, while 2% (1/54) presented damaged platelets with irregular shapes and disrupted membranes. Platelet distribution was predominantly scattered (72%), which is indicative of effective separation during centrifugation, while 15% of the samples showed clumping, potentially reflecting premature activation during processing.

Figure 1. Microscopic image at 100x magnification stained with Hemacolor shows agglomerated red blood cells in the background and multiple basophilic-stained platelets distributed in a non-cohesive manner.



Conclusion

The single centrifugation protocol at 3200 rpm effectively preserved platelet morphology in 83% of the samples, supporting its utility for PRP preparation. This study highlights the critical role of preserving platelet morphology in PRP quality and suggests that further research should be conducted to explore the relationship between platelet integrity and the release of growth factors. Developing standardized methodologies to assess and preserve platelet morphology will be vital to improving PRP preparation and ensuring its regenerative potential. The presence of hemodilution and damaged platelets in a subset of samples reveals areas for optimization in centrifugation protocols.

P134

CKD-MBD MANAGEMENT: RESULTS FROM A NATIONAL SURVEY ON BONE TURNOVER BIOMARKERS PRACTICE AND THERAPEUTIC STRATEGIES AMONG ITALIAN NEPHROLOGISTS

A. Cossettini[1], G. Re Sartò[2], M. Gallieni[3], S. Bianchi[4], L. De Nicola[5], M. Plebani[6], M. Zaninotto[6], L. Cosmai[2], C. Marino[7], A. Aghi[8], G. Tripepi[7], M. Fusaro[9]

[1]Post-Graduate School of Specialization in Nephrology, University of Milano, Milano, Italy, Milano, Italy, [2]Division of Nephrology and Dialysis, Azienda Socio-Sanitaria Territoriale (ASST) Fatebenefratelli-Sacco, Fatebenefratelli Hospital, Italy, Milano, Italy, [3]Department of Biomedical and Clinical Sciences 'Luigi Sacco', Università di Milano, Milano, Italy, Milano, Italy, [4]Department of Internal Medicine, Nephrology and Dialysis Complex Operative Unit, Livorno, Italy, Livorno, Italy, [5]Division of Nephrology, Department of Scienze Mediche e Chirurgiche Avanzate, University of Campania "Luigi Vanvitelli", Italy., Napoli, Italy, [6]QI.LAB.MED, Spin-off of the University, Padova, Italy., Padova, Italy, [7]National Research Council (CNR), Institute of Clinical Physiology (IFC), Italy,, Reggio Calabria, Italy, [8]Independent Researcher, Padova, Italy, Padova, Italy, [9]Department of Medicine, University of Padua, Padua, Italy, Padova, Italy

Background and Objectives: In advanced stages of chronic kidney disease (CKD), the development of a mineral and bone disorder (CKD-MBD) can occur, characterized by laboratory abnormalities in the calcium-phosphorus-parathyroid hormone axis, bone alterations, and extraskeletal calcifications. This condition increases the risk of bone fractures, cardiovascular events, and mortality.

Methods: A national survey was conducted to examine the attitudes of clinicians regarding diagnostic methods and therapeutic strategies for preventing or treating CKD-MBD. From November 2022 to March 2023, 89 members of the Italian Society of Nephrology were asked to respond to 16 closed-ended questions. Data analysis was performed using STATA software.

Results: The survey revealed that laboratories typically fulfill the demand for the most commonly used biomarkers (calcium, phosphorus, and PTH). However, many laboratories do not routinely evaluate other biomarkers, such as FGF23 and bone turnover markers (e.g., bone ALP, P1NP, TRAP-5b). Management of secondary hyperparathyroidism (sHPT) is primarily guided by the KDOQI 2009 (47.2%) and KDIGO 2017 (43.8%) guidelines. PTH levels are measured every three months by 53.9% of clinicians, with 64% considering PTH levels as equally important as ALP levels in predicting fractures. Regarding therapeutic strategies, vitamin D administration (cholecalciferol 27-37.1%, calcifediol 9-12.4%, calcitriol 47.2-53.9%) and its analogues (paracalcitol 21.3-30.3%) were used by our cohort. Antiresorptive agents, such as alendronate (2.2%-23.6%) and denosumab (22.5%-28.1%), were prescribed with varying frequencies across different stages of CKD. Notably, denosumab was widely used across all CKD stages, indicating a confident approach to its use despite the potential risk of hypocalcemia, a known side effect.

Conclusion: Although the survey revealed that the use of biomarkers and bone turnover markers in the management of CKD-MBD is suboptimal, it also highlighted a proactive approach among Italian nephrologists towards the treatment of skeletal fragility in CKD patients.

VITAMIN K DEPENDENT PROTEINS AND BONE QUALITY IN THE FIRST YEAR AFTER KIDNEY TRANSPLANTATION

M. Fusaro[1], A. Aghi[2], M. Gallieni[3], A. Cossettini[4], M. Plebani[5], M. Zaninotto[5], C. Cosma[6], P. Khairallah[7], G. Tripepi[8], T. Nickolas[9]

[1]Department of Medicine, University of Padua, Padua, Italy, Padova, Italy, [2]Independent Researcher, Padova, Italy, Padova, Italy, [3]Department of Biomedical and Clinical Sciences 'Luigi Sacco', Università di Milano, Milano, Italy, Milano, Italy, [4]Post-Graduate School of Specialization in Nephrology, University of Milano, Milano, Italy, Milano, Italy, [5]QI.LAB.MED, Spin-off of the University, Padova, Italy., Padova, Italy, [6]Department of Medicine, University of Padua, Italy, Padova, Italy, [7]Baylor College of Medicine, Houston, Texas, USA, Houston, United States, [8]National Research Council (CNR), Institute of Clinical Physiology (IFC), Italy,, Reggio Calabria, Italy, [9]Chief, Division of Bone and Mineral Diseases, Washington University, School of Medicine, St Louis, MO, USA, St Louis, United States

Objective. Chronic kidney disease (CKD) often leads to mineral and bone disorders (CKD-MBD), which compromise bone quality and increase fracture risk. These bone complications frequently persist after kidney transplantation (K-Tx), primarily due to the lingering effects of pre-existing CKD-MBD. Our aim was to evaluate CKD-MBD biomarkers, bone turnover markers, vitamin K-dependent protein (VKDP) levels, and bone microarchitecture using HR-pQCT at the time of K-Tx (T0) and 12 months post-transplant (T2). The main objective was to establish the association between VKDPs and HR-pQCT-derived bone quality parameters.

Methods. We analyzed data from a cohort of 61 K-Tx patients: mean age 50.9 ± 13.3 years, 67% male, 25 patients (41%) underwent pre-emptive K-Tx, median dialysis duration 12 months (36 patients, 59%), diabetes prevalence 25%, fracture history 32%. The median cumulative total steroid dose was 1194 mg of prednisone equivalent. The following CKD-MBD serum biomarkers and bone turnover markers were measured: 25(OH)D, 1,25(OH)2D, PTH, Bone ALP, P1NP, CTX, cFGF23, Klotho, IGF1, phosphate, calcium. Vitamin K-related proteins included Bone Gla Protein (BGP), undercarboxylated BGP (ucBGP), Matrix Gla Protein, and dephosphorylated-uc MGP (dp-ucMGP). In addition to HR-pQCT of the tibia and radius, DEXA scans of the lumbar spine, hip, and radius were performed at baseline and 12 months post-K-Tx. Spearman correlation (ρ, rho) was assessed between the percentage change in VKDPs, bone biomarkers (PTH, cFGF23), bone turnover markers (P1NP, CTX, Bone ALP), and the percentage change in HR-pQCT parameters of the tibia and radius.

Results. Significant improvements were observed in all CKD-MBD biomarkers and bone turnover markers 12 months post-transplant, except for Bone ALP and Klotho levels. PTH decreased from 100 to 27 ng/L, and CTX from 1524 to 246 pg/ml (**Figure 1**). VKDP levels also showed significant improvement. The prevalence of vitamin K deficiency, based on a cut-off level of uc-BGP ≥ 4.5 ng/ml, decreased from 77% to 32% ($p < 0.01$, Delta % [median and IQR]: -55.22 [-69.50, -24.33]). Using a cut-off level of dp-uc MGP > 500 pmol/L, the prevalence of vitamin K deficiency decreased non-significantly from 97% to 79% ($p = 0.06$). Our findings indicate significant inverse correlations between % Δ uc-BGP and Radius Total Volumetric BMD ($r = -0.37$, $p < 0.05$), Failure Load ($r = -0.51$, $p < 0.05$), and Stiffness ($r = -0.49$, $p < 0.05$). However, correlations between % Δ uc-BGP and Tibial parameters, including Tibial Total Volumetric BMD ($r = -0.08$), Failure Load ($r = -0.11$), and Stiffness ($r = -0.11$), did not reach statistical significance ($p > 0.05$) (**Figure 2**).

Conclusion. Our data confirm an improvement in vitamin K status one year after K-Tx. Additionally, the inverse correlation between ucBGP and bone quality parameters assessed by HR-pQCT underscores the crucial role of BGP in bone health. To our knowledge, these are the first reported data in the literature.

P136

FRACTURE LIAISON SERVICE – PATIENT REPORTED DIGITAL HEALTH REPORT AND FOLLOW UP

A. D. Djuv[1], O. H. Horpestad[1], H. N. Nysted[1]

[1]Stavanger University Hospital, Stavanger, Norway

Objective(s): "Quality register for bone fractures and osteoporosis assessment" (BeinOP) was established in 2021 at the FLS (Fracture Liaison Services) clinic in Stavanger, Norway. Capturing data from structured health record (SHR) to FLS-database was implemented at Stavanger University Hospital (SUH) [1]. To further reduce the FLS nurses` workload both in registration of patients' health prior to FLS assessment and the 3 months follow up of compliance for those starting on oral anti-osteoporosis drug, digital reporting from the patients was warranted. Could the patients report their health information prior to the assessment digitally at home to the health record? Secondly, could a digital home report replace the medical 3 months phone call follow-up?
Methods: Digital patient health reports were developed together with patients' representatives. Software was approved by the Norwegian health authorities. An integration between the national health platform and digital hospital SHR was made. Patients were informed by SMS to login on their smart phone, PC or tablets to the online health status report and deliver it to the hospital SHR. The 3 months follow up were conditioned by the nurse choosing "oral drugs" in the SHR. Patients were included at the FLS-clinic at Stavanger University Hospital in Norway registered in BeinOP database (ID1440) between 01. June 2022-30. September 2024.
Results: 5957 patients were included. 78% were women and median age of 69 years (IQR 61-77). 85% patient replied to the digital health report prior to FLS assessment. 1393 started on per os treatment (alendronate). At the 3 months follow-up the response rate was 37%. Of these, 75% reported to use the drug as prescribed without any side effects, 9% reported side-effects, 4% reported side-effects and had stopped, 5% had never started advised by their dentist and 8% had not yet used the drug prescribed.
Conclusion: The digital patients health report prior to FLS assessment gave excellent response rate. The follow up for the patients after starting p.o. treatment saved telephone calls for the nurses; however, the response rates were low and improvement is in process.
Disclosures: AD has received speaking fees from Amgen and UCB Pharma

Department of clinical sciences, Faculty of veterinary medicine, Université de Montréal, Saint Hyacinthe, Canada, [3]Groupe de recherche en pharmacologie animale du Québec (GREPAQ). Osteoarthritis research unit, University of Montreal hospital research center (CRCHUM)., Saint Hyacinthe, Canada, [4]Parc de la Chapelle, Plescop, France, [5]Groupe d'acoustique de l'Université de Sherbrooke (GAUS) - Department of mechanical engineering, Université de Sherbrooke., Sherbrooke, Canada

Objective: To determine whether sensitisation correlates with deficits in stimulus transmission and integration, or with co-morbidities. The hypothesis was that hypersensitised individuals were at greater risk of nerve conduction damage, sensory changes and cognitive decline.
Material and methods: Healthy (H) and osteoarthritic (OA) adult neutered cats (n=6 H, n=12 OA) and dogs (n=4 H, n=8 OA for nerve conduction) were assessed for peripheral (paw withdrawal threshold, PWT) and spinal (response to mechanical temporal summation, RMTS) sensitisation, with lower values meaning higher sensitisation. Nerve conduction (motor and sensory) of tibial and ulnar nerves was tested under standardised general anaesthesia. Stimulus integration was recorded with somatosensorial (SEP), auditory (AEP) and visual (VEP) evoked potentials under dexmedetomidine sedation. Sensorial perception was evaluated for olfaction (binary behavioural response – repulsion to unpleasant odour) and audition (number of high frequency sound repeated stimuli). Statistical analyses were based on data distribution (α=0.05).
Results: The OA cats or dogs had a decrease by more than 20% for their tibial and ulnar nerve amplitudes and velocities compared to H (P<0.05). The OA cats had higher SEP and AEP latencies and amplitudes (P<0.036), but lower VEP (P<0.046) compared to H. The PWT was positively correlated with nerve conduction velocity (r>0.48, P<0.045) and VEP (ρ=0.747, P=0.004) but negatively with SEP (ρ=-0.428, P=0.037) and AEP (ρ=-0.800, P=0.003) latencies. The RMTS score was positively correlated with VEP latencies (ρ=0.589, P=0.042) and negatively with SEP (ρ=-0.484, P=0.017), smell aversion (ρ=-0.653, P=0.026) and auditory stimulation (ρ=-0.811, P=0.002).
Conclusion: Nerve conduction alterations were reported for OA individuals. Hypersensitised cats were characterised by a decrease

in nerve conduction amplitude and velocity, increase in SEP and AEP latencies. They were more repulsed by unpleasant smell and less sensitive to repeated repulsive sound. Chronic OA pain correlates with transmission alteration up to change in perception of sensory stimuli, raising the concern of its classification and therapeutical management.

P138

HIGH INCIDENCE OF FIBROMYALGIA (FM) MISDIAGNOSED AS AXIAL SPONDYLARTHRITIS (SPA): IMPORTANT INSIGHTS FROM AN ANALYSIS OF 34 PATIENTS IN ALGERIA

A. Djebbari[1], A. Gouder[1]

[1]HMRUC, Constantine, Algeria

Background/Purpose:
Both fibromyalgia (FM) and axial spondyloarthritis (SpA) are associated with pain, though the types of pain experienced differ. Axial SpA is typically marked by inflammatory back pain, whereas FM is characterized by widespread pain throughout the body. In FM patients, sleep disturbances—often resulting from anxiety or depression—can intensify back pain at night, leading it to be mistakenly identified as inflammatory back pain. Consequently, some FM patients are misdiagnosed with axial SpA.

Objectif
The goal of this study is to improve understanding of the modified American College of Rheumatology (ACR) 2010 diagnostic criteria for FM, enhance the diagnostic accuracy for axial SpA, and reduce the incidence of misdiagnosing FM as axial SpA.

Methods
Clinical data were collected from 34 patients diagnosed with primary FM, who had previously been misdiagnosed with axial SpA at tertiary hospitals in Algeria. The re-diagnosis was made using the modified ACR 2010 criteria. Each patient underwent assessment using the Widespread Pain Index (WPI) and Symptom Severity (SS) scale from the modified ACR 2010 guidelines, as well as tests for serous C-reactive protein levels, erythrocyte sedimentation rate (ESR), HLA-B27 status, and imaging of the sacroiliac joints

Results
The cohort consisted of 24 females (70.58%) and 10 males (29.41%), all reporting widespread pain, primarily in the spine. No peripheral arthritis, enthesitis, dactylitis, or limited spinal motion was observed. The median WPI was 5. (range: 3.0-8.0), and the SS score was 8.654 ±1.954. The median C-reactive protein level were 4.31±1.69mg/l. The median ESR was 10.0 (range: 3.0-19.0) mm/1h. HLA-B27 positivity was found in 17.64 % of cases. Ten patients (29.41%, all females) had osteitis condensans ilii detected by CT and MRI, while 15 had normal sacroiliac CT scans, 17 had normal sacroiliac MRI results, and the remaining 11 had normal CT and MRI findings.

Conclusion
The modified ACR 2010 criteria for FM have replaced the tender point count with the WPI and SS scale, and placed more emphasis on anxiety and depression in the diagnostic process. However, in clinical practice in China, FM is still often misdiagnosed as axial SpA, due to two main factors: first, an over-reliance on the tender point counts from the ACR 1990 criteria for FM, and seconde, a failure to prioritize inflammation in the diagnosis of axial SpA. To improve diagnostic accuracy for both FM and axial SpA, it is crucial to thoroughly assess somatization related to anxiety and depression rather than relying solely on tender point counts for FM diagnosis, and emphasize the identification of inflammatory signs in axial SpA diagnosis, such as peripheral arthritis, enthesitis, dactylitis, definitive sacroiliitis on imaging, and elevated inflammatory biomarkers like C-reactive protein and ESR.

P139

OUTCOMES OF ARTHRALGIA IN ALGERIAN PATIENTS WITH PSORIASIS : PREDICTORS OF PROGRESSION TO PSORIATIC ARTHRITIS

A. Djebbari[1], A. Gouder[1], S. Benedjma[2], A. Beguiret[3]

[1]HMRUC, Constantine, Algeria, [2]HCA, Kouba, Algeria, [3]HCA kouba, Kouba, Algeria

Objective The progression from psoriasis (PsO) to psoriatic arthritis (PsA) offers a distinctive opportunity to identify individuals at higher risk of developing PsA, allowing for the implementation of preventive interventions.the aim of this study is to estimate the prevalence of Arthralgia with Psoriasis progression to PsA in a large cohort of Algerian patients and to evaluate the one-year incidence of PsA in those patients by analyzing clinical, laboratory, and imaging factors as predictors.

Methods This prospective cohort study included patients from Algerian PURE 4 cohort , aged 18 years and older with psoriasis and complaining of inflammatory arthralgia. At baseline, data were collected from laboratory tests, X-rays, ultrasound (US) with power Doppler (PD), and clinical interviews. Additional information such as sociodemographic data, clinical assessments (global VAS, joint count, HAQ), and clinical evaluations were also gathered. Evaluators for laboratory, imaging, and clinical assessments were blinded to each other's results. The presence of family history (FH) of PsA were noted. These patients were followed up for one year to determine if they developed PsA. Statistical analysis included descriptive statistics, Chi-square test, Fisher's exact test, Student's T test, and Mann Whitney test, along with a multivariate logistic regression where the dependent variable was the diagnosis of PsA at the one-year follow-up.

Results The study enrolled 66 patients with psoriasis +arthralgia between July 2019 and september 2022. Of these patients, 21 (31.8%, 95% CI: 15-39) developed PsA within one year. The clinical, laboratory, and imaging characteristics of Psoriasis + Arthralgia patients who progressed to PsA were compared to those who did not, as shown in Table 1 (univariate analysis). Among the Psoriasis + Arthralgia patients who progressed to PsA patients, 3 had nail PsO, 11 had synovitis detected by PDUS, 10 had enthesitis, and 7 had Family History of PsA. A longer duration of psoriasis was associated with a higher risk of developing PsA (median years: 12.1 vs. 4.2). Multivariate analysis identified key predictors for progression to PsA: the combination of Family History

of PsA(OR: 4.12; 95% CI: 1.21-7.32), a higher number of tender joints (OR: 3.153; 95% CI: 1.39-6.21), synovitis detected by Power DoplerUS (OR: 9.32; 95% CI: 1.9-21.36), and nail psoriasis (OR: 4.91; 95% CI: 2.3-6.89).

Table 1 characteristics of 2 groups progressed or not to PsA after one years of folow up

Characteristic	Progressed to PsA (n=21)	Did Not Progress to PsA (n=45)	p
Age	42.2	49.3	0.26
Female	10	20	0.12
Nail Psoriasis	3 (14.3%)	7 (13.9%)	0.003
Synovitis Detected by Power Doppler US	11 (52.4%)	5 (11.1%)	0.002
Enthesitis	10 (47.6%)	6 (20%)	0.02
Family History of PsA	7 (33.3%)	2 (4%)	0.001
Duration of Psoriasis (Median years)	12.1	4.2	0.02
PASI	12.3	12.9	0.37
Number of Tender Joints	2.31	0.3	0.03

Conclusion: In our cohort, 31.8 % of patients with Psoriasis+Arthralgia were at risk of developing PsA due to the presence of Family History of PsA and nail involvement at the one-year follow-up. The primary predictive factors for the progression to PsA were ultrasound findings (synovitis), the combination of a higher number of tender joints, and a longer duration of psoriasis.

P140

LACK OF CORRELATION BETWEEN MRI CHANGES AND BASDAI SCORE IN ALGERIAN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Djebbari[1], A. Gouder[1]

[1]HMRUC, Constantine, Algeria

Objective The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is commonly used to assess disease activity in Ankylosing Spondylitis (AS) . BASDAI score greater than 4 is often used as a criterion for initiating anti-TNF therapy. Previous studies have shown a weak correlation between BASDAI scores and MRI findings. This study aimed to evaluate the correlation between BASDAI scores and MRI changes indicative of spondyloarthritis and to compare the clinical and radiological data of AS patients.

Methods A retrospective analysis was conducted on AS patients coming from different departments of the country. Clinical data, including HLA-B27 status, extra-articular manifestations, family history of AS, and CRP levels, were obtained from online systems and clinic letters. The patients' records were reviewed to check if they had undergone an MRI of the sacroiliac joints and had a BASDAI score recorded at the time of MRI. Statistical analysis was performed using the MedCalc calculator.

Results A total of 62 patients were included in the analysis, with a mean age of 43.1 ± 21.6 years (50 males, 12 females). The mean BMI was 26.39, the mean Shober index was 12.6±2.0 .Six (9.6%)patients undergoing peripheral arthritis, however19 patients (31.7%) developpes Extra-articular manifestation (uveitis, colitis,psoriasis) .The mean BASDAI score was 4.3 ± 2.7, and the mean CRP level was 13.21 ± 23.4 (n CRP 5.5). From all population, n = 20 (35.5%) of patients were HLA-B27 positive, 41 patients (66.1%) had inflammatory back pain. Of the 62 patients, 60 underwent a sacroiliac MRI scan, which was reviewed to assess the presence of disease. Two factors were statistically significant when comparing patients with active versus inactive lesions on MRI: high CRP level(p<0.001) (Table 1).

Table 1 : Clinical and imaging characteristics of the 62 patients

Parameter	Value
Total Number of Patients	62
Mean Age (years)	43.1 ± 21.6
Male/Female Ratio	50 males, 12 females
Mean BMI(kg/m^2)	26.39
Mean Shober Index(cm)	12.6 ± 2.0
Peripheral arthritis	6 (9.6%)
Extra-articular manifestation	19 (31.7%)
Mean BASDAI Score	4.3 ± 2.7
Mean CRP Level(mg/l)	13.21 ± 23.4 (Median CRP: 5.5)
HLA-B27 Positive n(%)	20 (35.5%)
Number of Patients with Sacroiliac MRI	60
Factors Statistically Significant for Active vs Inactive Lesions on MRI	High CRP level (p<0.001)

Conclusion Contrary to the literature our data suggest a discordance between the BASDAI score and the severity of inflammation observed on MRI. Only CRP level showed a correlation with MRI-detected disease activity. There were no significant differences in clinical features, including HLA-B27, between patients with active versus inactive MRI findings.

P141

PREDICTIVE FACTORS OF RADIOGRAPHIC PROGRESSION IN EARLY PSORIATIC ARTHRITIS: FINDINGS FROM A SCREENING ALGERIAN COHORT

A. Djebbari[1], A. Gouder[1]

[1]HMRUC, Constantine, Algeria

Objective

Chronic joint inflammation in psoriatic arthritis (PsA) is linked to radiographic damage. Advances in diagnosis and treatment strategy in this rheumatism have not prevented rapid and aggressive structural progression. The goal of this study was to investigate baseline clinical factors that could predict radiographic progression over time.

Methods
Data obteined from the screening PURE 4 Algerian cohort ; a cohort of patients with recently diagnosed PsA. Radiographic changes were measured using the modified Total Sharp/van der Heijde Score (mTSS) for PsA. Univariable and multivariable mixed-effects negative binomial regression analyses were employed to identify baseline predictors of radiographic progression.
Results
The study enrolled 53 patients with early PsA, with radiographs of the hands and feet taken at four time points (baseline, first, second, and third years). The progressive group (n=15) exhibited a higher mTSS at diagnosis compared to the non-progressive group (n=38) (12 [2–26] vs. 1 [0–3]). The progressive group was significantly older (52 [10] vs. 42 [9], p=0.001) and had a higher rate of swollen joints (84% vs. 52%, p=0.023) at diagnosis. Multivariable analysis revealed that age (p=0.001), male sex (p=0.023), and baseline mTSS (p=0.002) were key predictors of radiographic progression. In the progressive group, baseline DAPSA (p=0.006) and swollen joint count (p=0.034) were also significant predictors.

Table 1: Comparison between the progressive and non-progressive groups at diagnosis and significant predictors for radiographic changes over time.

Characteristic	Progressive Group (n=15)	Non-Progressive Group (n=38)	P
Mean mTSS at Diagnosis	12 (2–26)	1 (0–3)	<0.001
Age (Mean ± SD)	52 (10)	42 (9)	0.001
Male (%)	9 (60%)	25 (65.7%)	0.023
Baseline DAPSA (Mean ± SD)	16.23	7.12	0.006
Baseline Swollen Joint Count	6	1	0.034
Baseline Tender Joint Count	8	1	0.002

Conclusion
In patients with early PsA, radiographic progression was minimal under current treatment protocols. The study highlighted that older age and baseline radiographic damage were significant predictors of progression, while female sex appeared to provide a protective benefit. Furthermore, both the disease activity score and the swollen joint count were found to be predictive of radiographic changes over time in those with progressive disease.

P142

RADIOGRAPHIC FINDINGS IN EARLY PSORIATIC ARTHRITIS PATIENTS: LESSONS LEARNED FROM AN 18-MONTH FOLLOW-UP OF ALGERIAN PATIENTS

A. Djebbari[1], A. Gouder[1]

[1]HMRUC, Constantine, Algeria

Objective The duration and severity of joint inflammation in psoriatic arthritis (PsA) significantly impact radiographic outcomes, which can serve as a prognostic factor for the disease's progression.To examine radiographic changes in early psoriatic arthritis (EPsA), defined as less than 2 years from symptom onset.
Methods
Patients with EPsA were assessed by a rheumatologist. Standard clinical and laboratory evaluations were performed, including conventional radiographs of peripheral joints (hands, wrists, feet) and sacroiliac joints. Radiographic changes were categorized as normal, abnormal-not clinically relevant, and abnormal-clinically relevant.
Results
Forty-three patients with EPsA (mean disease duration 1.0 [0.8] years) were included in this study. The most common joint involvement was polyarticular in 26 patients (60.4%), with either symmetric or asymmetric presentation. Distal Interphalangeal (DIP) joint involvement was present in 18 patients (41.8%). Among the 43 patients, radiographic damage was identified in 12 (27.9%) patients, with 6 (50%) showing changes in two joints and 2 (16.1%) in three or more joints. Most of these patients (9 or 75%) experienced joint damage within the first year of symptoms. Radiographic changes observed included new bone formation (often interpreted as degenerative by radiologists), mild-to-moderate joint space narrowing, and both marginal and central bone erosions. Clinically relevant abnormalities were seen in 6 (50%) patients' hands (10 or 71.4% had involvement in both hands), 4 (33.33%) in feet, 3 (25%) in sacroiliac joints, and 2 (16.1%) in wrists.After an 18-month follow-up, 7 (16.6%) of the 43 patients developed new radiographic signs. Radiographic progression, including worsening joint erosion and space narrowing, was seen in 4 (33.33%) of the 12 patients with initial radiographic involvement, while 8 (66.66%) patients had stable radiographic findings.

Table 1: Radiographic Findings in Early Psoriatic Arthritis (EPsA) Patients

Characteristic	Result
Total number of patients	43
Mean disease duration (SD)	1.0 (0.6) years
Most common joint involvement n(%)	Polyarticular (26, 60.4%)
DIP joint involvement n(%)	18 (41.8%)
Radiographic damage n(%)	12 (27.9%)
Number of joints affected n(%)	2 joints (6, 50%), ≥3 joints (2, 16.1%)
Radiographic changes within 1st year of symptoms	9 patients (75%)
Types of radiographic changes	New bone formation, joint space narrowing, bone erosions
Hands n(%)	6 (50%) (10, 71.4% in both hands)
Feet n(%)	4 (33.33%)
Sacroiliac joints n(%)	3 (25%)

Characteristic	Result
Wrists n(%)	2 (16.1%)
Follow-up duration	18 months
New radiographic signs during follow-up n(%)	7 (16.6%)
Radiographic progression during follow-up n(%)	4 (33.33%) with worsening joint erosion and space narrowing
Stable radiographic findings n(%)	8 (66.66%)

Conclusions
Radiographic damage was detected in 27.9% of EPsA patients, with the majority acquiring damage within the first year of symptom onset. The increased frequency of axial and DIP joint involvement aligns with previous studies, which show these as common sites in PsA. Radiographic progression was observed in only 30% of patients, underscoring the importance of early diagnosis and intervention in EPsA

P143

GENDER DIFFERENCES IN CLINICAL AND SONOGRAPHIC MANIFESTATIONS IN ALGERIAN PATIENTS FOLLOWED FOR PSORIATIC ARTHRITIS

A. Djebbari[1], A. Gouder[1]

[1]HMRUC, Constantine, Algeria

Objective
Psoriatic arthritis (PsA) is a complex, multi-domain condition that primarily impacts the musculoskeletal (MSK) system. It occurs in approximately 30% of individuals with psoriasis, with an equal distribution between males and females. Enthesitis is recognized as a central feature of PsA. Evidence suggests that sex may influence the clinical and radiographic presentation of PsA differently. However, research on sex-based differences in ultrasound (US) findings in PsA patients remains limited. To examine sex-related variations in sonographic findings among individuals with psoriatic arthritis (PsA).

Methods
The study comprised consecutive patients diagnosed with PsA according to the CASPAR (Classification for Psoriatic Arthritis) criteria. Participants underwent clinical and physical assessments, followed by an extensive ultrasound (US) examination using both greyscale and Doppler techniques. The US evaluation included 52 joints, 40 tendons, and 14 enthesis points (Modified Madrid Sonographic Enthesis Index [MASEI] plus lateral epicondyles), conducted by a skilled sonographer who was blinded to the clinical information. The US scoring system was based on semiquantitative assessments of synovitis, tenosynovitis, and enthesitis. Enthesitis was categorized into inflammatory lesions (such as hypoechogenicity, thickening, bursitis, and Doppler activity) and structural lesions (such as enthesophytes/calcifications and erosions).

Results
A total of 49 patients were included in the study: 29 males and 21 females. Mean age was 51.23±23.1years, BMI was 29.1±5.3. Males had higher Psoriasis Area and Severity Index (PASI) scores (P = 0.04), long duration of psoriasis (P = 0.03), higher LEI score (P = 0.02) , mean swollen joint counts (P = 0.04), and CRP level (P = 0.02) . The overall US score, as well as the synovitis and tenosynovitis subcategory scores, were comparable between the sexes. However, the total enthesitis score and the inflammatory enthesitis score were significantly greater in males compared to females (P = 0.02 and P = 0.01, respectively). Males also had a higher frequency of hypoechogenicity, thickening, and enthesophytes compared to females (P < 0.03). Multivariate logistic regression analysis showed that male sex was associated with a higher inflammatory enthesitis score on US compared to females (odds ratio 1.96, P = 0.03).

Characteristics	Female, n = 21, Mean (SD)	Male, n = 29, Mean (SD)	P-Value
Age, yrs	51.39 (13.40)	53.22 (12.45)	0.51
BMI	28.23 (4.71)	29.10 (4.32)	0.45
PsO duration, yrs	10.23 (7.21)	12.11 (9.25)	0.03
PsA duration, yrs	10.63 (11.11)	11.86 (11.89)	0.36
TJC	8.19 (9.97)	8.89 (10.10)	0.62
SJC	0.83 (1.76)	1.73 (3.66)	0.04
LEI	1.37 (1.49)	0.76(1.21)	0.02
SPARCC enthesitis	2.17 (3.81)	3.13 (3.21)	0.06
PASI	1.03 (2.12)	2.03 (4.45)	0.04
Pain	6.36 (3.91)	4.23 (2.63)	0.91
CRP, mg/L	6.28 (4.61)	9.13 (8.23)	0.02
DAPSA	19.02 (12.63)	18.36 (14.23)	0.56

Conclusion
In the male sex, this rheumatism appears more severe in terms of skin damage, swollen joints and enthesitis, whereas in terms of ultrasound, enthesitis is more inflammatory in men and is correlated with the clinical evaluation.

P144

CALCIUM ISOTOPES AS A NOVEL BIOMARKER FOR VASCULAR CALCIFICATION IN CKD: IMPLICATIONS FOR OSTEOPOROSIS MANAGEMENT

A. Dosseto[1], A. Fuller[2], A. Borst[2], T. Tacail[3], K. Lambert[2], H. Cheick Hassan[4]

[1]Isochem Solutions, Wollongong, Australia, [2]University of Wollongong, Wollongong, Australia, [3]California Institute of Technology, Pasadena, United States, [4]Wollongong Hospital, Wollongong, Australia

Calcium balance is intricately linked to both bone health and vascular health. In chronic kidney disease (CKD), abnormal calcium

metabolism contributes significantly to the development of vascular calcification, a major cardiovascular risk factor. While osteoporosis is a common comorbidity in CKD, the impact of vascular calcification on bone health remains an area of active investigation.
This study explored the potential of calcium isotope analysis as a non-invasive biomarker for vascular calcification in CKD patients. A cohort of 78 participants, including healthy controls, CKD patients, and those on dialysis, underwent comprehensive assessments, including vascular function tests and serum biomarker analysis.
Results demonstrated significant differences in serum calcium isotope compositions across the groups ($p<0.01$). Receiver operating characteristic (ROC) curve analysis revealed high diagnostic accuracy for serum Ca isotopes in detecting medial calcification (AUC = 0.818, $p<0.01$).
These findings have important implications for osteoporosis management in CKD patients. Accurate assessment of vascular calcification may provide valuable insights into systemic vascular health and may be a useful marker in identifying individuals with CKD at potentially increased risk for adverse health outcomes, including fractures. The use of calcium isotope analysis offers a promising approach for early detection and monitoring of vascular calcification in this vulnerable population. Further research is warranted to investigate the potential interplay between vascular calcification and bone health in CKD, and to explore the clinical utility of calcium isotope analysis in improving osteoporosis management outcomes.

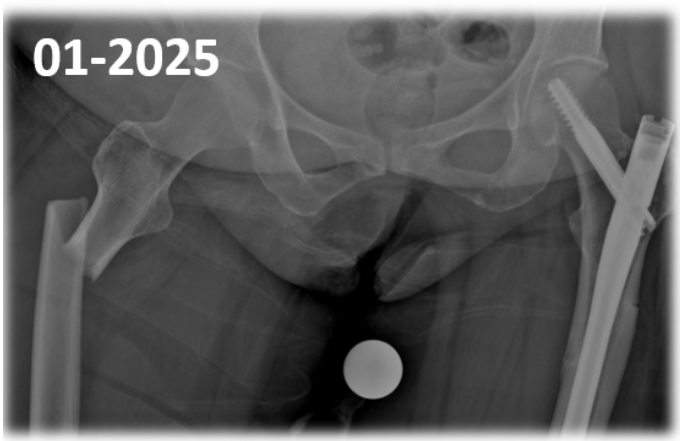
P145

PROPHYLAXIS OR PATIENCE? MANAGING THE UNFRACTURED FEMUR IN ATYPICAL FEMORAL FRACTURES

A. E. Elsalmawy[1], S. Z. Zidan[2], M. S. Sher[1], K. A. Elsalmawy[3], G. D. dos[1], K. P. Patel[1]

[1]southend University Hospital, Southend- on-sea, United Kingdom, [2]Alnoor Specialist Hospital Holly Makkah, Makkah, Saudi Arabia, [3]Alexandria Faculty of medicince, Alexandria, Egypt

A 70-year-old woman with a medical history of asthma, chronic obstructive pulmonary disease , and type 2 diabetes mellitus was diagnosed with osteoporosis 2008 and started on Alendronic acid. Her regular medications included long-term steroids, which likely contributed to increased bone fragility.
She sustained an atypical femoral fracture (AFF) of the left femur April 2024 following a minor fall, which was managed surgically with an interlocking nail. Following this, Alendronic acid was discontinued and denosumab was initiated based on recommendations from a rheumatology multidisciplinary team However, the transition from Alendronic acid to denosumab was not accompanied by close follow-up, which emerged as a critical learning point.
January 2025, the patient presented with an atypical fragility fracture of the contralateral femur, emphasizing the bilateral risk of AFF. The literature indicates that approximately 30% of AFF cases progress to bilateral fractures within one year, particularly in patients with prolonged bisphosphonate use or concurrent glucocorticoid therapy. Unfortunately, there are no clear guidelines for managing contralateral unfractured femurs in AFF. Current management is guided by clinical judgment and varies widely, with options ranging from close monitoring to prophylactic surgical fixation, often depending on surgeon preference.
This case underscores the importance of individualized, multidisciplinary care and highlights critical gaps in evidence-based management strategies for AFF. Specifically, it emphasizes the need for rigorous follow-up during treatment transitions and calls for further research to guide decision-making regarding prophylactic fixation of contralateral femurs in high-risk patients.



P146

UTILIZING CALCIUM ISOTOPE MARKER (CIM) TECHNOLOGY FOR MONITORING DENOSUMAB TREATMENT IN OSTEOPOROSIS

A. Eisenhauer[1], S. Sönnichsen[2], A. Hastuti[3], R. Shroff[4], A. Heuser[1], A. Kolevica[1], A. Lubnow[5], B. Brandt[6], M. Müller[5]

[1]GEOMAR Helmholtz Centre for Ocean Research Kiel, Kiel, Germany, [2]ORTHOPAEDICUM, Kiel, Germany, [3]Department of Pharmaceutical Chemistry, Yogyakarta, Indonesia, [4]UCL Great Ormond Street Hospital and Institute of Child Health, London, United Kingdom, [5]University Medical Center Schleswig-Holstein (UKSH), Department of Orthopedics and trauma surgery, Kiel, Germany, [6]University Medical Center Schleswig-Holstein (UKSH), Department of Clinical Chemistry, Kiel, Germany

Denosumab, a monoclonal antibody targeting RANKL, is a well-established therapy for osteoporosis. Monitoring its effectiveness is essential due to potential side effects, including hypocalcemia, osteonecrosis of the jaw, and atypical femoral fractures. Current patient management involves regular assessments of bone mineral density (BMD) through dual-energy X-ray absorptiometry (DXA) scans. While DXA and bone turnover markers (BTMs) like CTX and P1NP track changes in BMD and overall turnover, they have limited sensitivity to nuanced, time-resolved alterations in bone metabolism. In contrast, Calcium (Ca) Isotope Markers (CIM), which measure naturally occurring variations in stable Ca isotope ratios, e.g. 44Ca/42Ca, in serum (CIM_serum) and urine (CIM_urine), offer a potentially more sensitive and individualized approach for monitoring bone health and therapy responsiveness. In this pilot study, 13 postmenopausal women with DXA-confirmed osteoporosis (T-score range: -2.5 to -3.7) were initiated on standard denosumab therapy. Over a 24-week period, serial measurements of CIM_serum and CIM_urine were obtained at the day of initiation of the denosumab therapy and then at week 1, 2, 4, 8, 12 16, 20 and 24 after therapy initiation alongside traditional indicators including DXA-derived BMD, CTX, P1NP and PTH. CIM thresholds that distinguish net bone Ca uptake from net resorption were applied to evaluate how patients responded over time at an individual level. Baseline CIM values at the start of denosumab therapy (average CIM_serum: -1.09±0.15 ‰ and CIM_urine: 0.00±0.22 ‰) were all below the CIM threshold value of -0.85 ‰ indicating net bone calcium loss before and at the initiation of the denosumab therapy, consistent with advanced DXA determined osteoporosis. Following denosumab administration, all patients showed a significant average increase by +0.4 ‰ in CIM_serum and CIM_urine values after one week. Highest CIM_serum and CIM_urine values were reached in week 4 to 8 (CIM_serum: ~-0.7 ‰) after the start. While an overall improvement was observed among the 13 patients due to denosumab therapy, individual CIM values presented a more nuanced picture. Five patients exhibited rapid increases in their CIM_serum and -_urine values above threshold levels, signalling robust antiresorptive responses and new bone formation. Eight patients showed improvements and bone mineralization, with three demonstrating improved CIM values still below the threshold. Five patients exhibited more modest or transient changes in CIM values. PTH and CIM_serum as well as CIM_urine values were significantly positive correlated (serum: r=+0.65, p<0.001; urine: r=+0.39, p<0.01) emphasizing the interaction of denosumab therapy with renal functionality for bone Ca mineralisation. Overall, our observations suggest that the baseline severity of osteoporosis, as indicated by initial CIM values in serum and urine, influences each patient's response to a standardized denosumab regimen. In contrast, DXA and BTMs provided less granular insights, primarily confirming average group-level gains without elucidating individual variability. CIM provides non-invasive, time-resolved, patient-specific data on bone metabolism changes and may enable early, individualized adjustments of therapy beyond what is possible with DXA and conventional BTMs. Although further validation in larger, controlled cohorts is warranted, these findings highlight CIM's potential to enhance osteoporosis management through personalized treatment monitoring.

P147

CALCIUM ISOTOPE RATIOS IN SERUM INFORM ON SKELETAL CALCIUM BALANCE IN PATIENTS ON DIALYSIS

A. Eisenhauer[1], R. Shroff[2], M. Müller[3], A. Heuser[1], A. Kolevica[1], P. D´haese[4], I. Jochmans[5], E. Cavalier[6], P. Evenepoel[7]

[1]GEOMAR Helmholtz Centre for Ocean Research Kiel, Kiel, Germany, [2]UCL Great Ormond Street Hospital and Institute of Child Health, London, United Kingdom, [3]University Medical Center Schleswig-Holstein (UKSH), Kiel, Germany, [4]University of Antwerp, Laboratory of Pathophysiology, Department of Biomedical Sciences, Wilrijk, Belgium, [5]1. Lab of Abdominal Transplantation, Transplantation Research Group, Departement of Microbiology, Immunology and Transplantation 2. Department of Abdominal Transplantation, University Hospitals Leuven, Leuven, Belgium, [6]Department of Clinical Chemistry, University of Liege, CIRM, Centre Hospitalier Universitaire de Liège, Liège, Belgium, [7]Nephrology Research Group, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium

Dysregulated mineral homeostasis in chronic kidney disease (CKD) can cause bone demineralization and an increased risk of fractures. In both healthy individuals and patients with advanced kidney failure, the ratio of naturally occurring non-radioactive calcium (Ca) isotopes 44Ca/42Ca in serum (Calcium isotope marker: CIM_Serum), serves as quantitative indicator of bone Ca balance (BCaB). Preferential incorporation of the lighter 42Ca isotope into bone elevates CIM_Serum during periods of net bone formation and reduces it when bone resorption predominates. In this study we measured the Ca isotope composition in bone biopsies (CIM_Bone) to determine the sensitivity of CIM_Serum in estimating BCaB. Nineteen patients receiving chronic dialysis (median age 60 years, time on dialysis 3.3 years) underwent Dual Energy X-ray Absorptiometry (DXA) and bone biopsies at the time of kidney transplantation. CIM_Serum and CIM_Bone was measured simultaneously in serum and bone biopsies. After adjustment of all study participants for the uptake of Ca supplements

and renal impairment, we compared the results to those with a control group of ten adults with osteoporosis only. Results show that both CIM_Serum and CIM_Bone were significantly lower in the dialysis patients cohort than in the osteoporosic control. In the osteoporosis group, CIM_Serum correlated strongly with CIM_Bone (p=0.0018, R^2=0.72). A positive, albeit weaker, correlation was also observed in the dialysis group (p=0.005, R^2=0.37). CIM_Serum and CIM_Bone correlated positively with osteoblastic markers BAP and PINP, and inversely with PTH. While only 31% had DXA T-scores below -2.5 defining osteoporosis, CIM_Serum indicated severe bone mineral depletion in 89% of subjects. Histologic analysis revealed that CIM_Bone correlated positively with trabecular thickness and mineralized area, and inversely with osteoid area. Multiple regression analysis identified CIM_Bone (β=0.88, 95% CI -1.31 to -0.29, p<0.001), BALP (β=0.63, 95% CI 0.19 to 0.41, p=0.008), and osteoid area (β=-0.31, 95% CI -1.24 to -0.16, p=0.03) as significant predictors of CIM_Serum, collectively accounting for 87% of its variability. In conclusion, CIM_Serum is a significant and independent predictor of BCaB in dialysis patients, correlating strongly with CIM_Bone provides a comprehensive, real-time assessment of bone health, potentially enhancing the clinical evaluation of CKD-associated bone disease.

P148

A CORRELATION-BASED APPROACH TO PREDICTING DXA USING THE CALCIUM ISOTOPE MARKER (CIM)

A. Eisenhauer[1], A. Heuser[1], A. Kolevica[1], R. Shroff[2], B. Brandt[3], A. Lubnow[4], A. Hastuti[5], M. Müller[4]

[1]GEOMAR Helmholtz Centre for Ocean Research Kiel, Kiel, Germany, [2]UCL Great Ormond Street Hospital and Institute of Child Health, London, United Kingdom, [3]University Medical Center Schleswig-Holstein (UKSH), Department of Clinical Chemistry, Kiel, Germany, [4]University Medical Center Schleswig-Holstein (UKSH), Department of Orthopedics and trauma surgery, Kiel, Germany, [5]Department of Pharmaceutical Chemistry, Yogyakarta, Indonesia

Early detection of osteoporosis onset enhances prospects of success for prophylactic actions in bone fracture prevention. Commonly Dual-energy X-ray absorptiometry (DXA) is applied to quantify bone mineral density (BMD) at a single point in time but does not capture the dynamic rate at which calcium (Ca) is being gained or lost from the skeleton. In contrast, changes in the Ca isotope ratio (44Ca/42Ca), referred to as the Ca isotope marker (CIM) and measured in blood (CIM_serum) or urine (CIM_urine), has been shown to detect alterations in the balance between bone Ca absorption and resorption in near real-time. To evaluate the diagnostic potential of the CIM method in osteoporosis, we retrospectively analyzed data from four clinical studies involving 293 post-menopausal women aged 25 to 81 years, none of whom had kidney failure or vitamin D deficiency (< 25 nmol/L). We compared their CIM_serum and CIM_urine values with the corresponding minimum DXA T-scores of either hip or lumbar spine. The results revealed significant correlations among CIM_serum, CIM_urine, and DXA values, indicating that changes in Ca isotope ratios are closely related to alterations in BMD (CIM_serum/DXA: r^2 = 0.68, p < 0.001; CIM_serum/CIM_urine: r^2 = 0.54, p < 0.001; CIM_urine/DXA: r^2 = 0.43, p < 0.001). Threshold values were defined at −0.85±0.06 ‰ for CIM_serum and 0.23±0.06 ‰ for CIM_urine. Values above or below the confidence interval of these thresholds indicate either bone Ca gain or loss, respectively, in particular the latter pointing toward an increased risk of osteoporosis. Grouped mean DXA values for T-score intervals (Δ=1) ranging from -4 to 3 could be approximated either by second-order polynomials using CIM_serum or CIM_urine (DXA T-score ≈ -10.66·(CIM_serum)² − 0.599·CIM_serum + 6.67, R^2 = 0.35; DXA T-score ≈ -9.95·(CIM_urine)² + 20.18·CIM_urine − 5.21, R^2 = 0.93) or by a multiple linear regression combining both markers (DXA T-score ≈ 6.72·CIM_serum + 13.13·CIM_urine + 1.49, R^2 ≈ 0.98). CIM-derived DXA thresholds correspond to a DXA T-score of approximately -1.2, which is considerably higher than the current osteoporosis diagnostic threshold of -2.5. Post study assessment of osteoporosis related fractures two years after the OsteoGeo study (Eisenhauer et al. 2019, 2024) revealed that all low-trauma fractures were characterized by CIM_serum values below the threshold whereas only one third of the low-trauma fractures occurred in the range at or below the DXA T-score range usually associated with osteoporosis. In conclusion, our results show that CIM values can generally be positively correlated with the corresponding DXA T-score values. The application of the non-invasive CIM procedure therefore represents a significant improvement for early risk detection and therapy monitoring for patients with metabolic diseases of the musculoskeletal system and in particular for osteoporosis.

P149

MAKE A HABIT OF TWO THINGS: TO HELP; OR AT LEAST TO DO NO HARM. GERIATRIC POLYPHARMACY AND HIP FRACTURES

A. Elsalmawy[1], S. Zidan[2], I. Malik[1], M. Mouhsen[1], K. Elsalmawy[3]

[1]southend University Hospital, Southend- on-sea, United Kingdom, [2]Alnoor Specialist Hospital Holly Makkah, Makkah, Saudi Arabia, [3]Alexandria Faculty of medicince, Alexandria, Egypt

Introduction: Falls are a major cause of fractures among older adults, with polypharmacy recognized as a key contributing factor. Furthermore, potentially inappropriate medications (PIMs) and inappropriate polypharmacy have been identified as increasing the risk of falls. This study aimed to evaluate the medications prescribed to older surgical patients with hip fractures to assess the prevalence of polypharmacy and identify PIMs. A secondary objective was to analyze the specific characteristics of medications prescribed to older patients with hip fractures.
Materials and Methods: This retrospective study reviewed clinical data from patients aged 70 years and older who underwent hip surgery at our hospital between November 2022 and November 2024. A log-linear model was applied to investigate the relationship between the number of prescribed medications and the

prevalence of hip fractures.
Results: A total of 200 patient records were analyzed. Of these, 71% of older adults with hip fractures were prescribed five or more medications. The most commonly prescribed categories of PIMs were antihypertensives, anticoagulants, diuretics, and non-steroidal anti-inflammatory drugs. Multivariable analysis demonstrated a significant association between polypharmacy and the occurrence of hip fractures. Notably, anticoagulants and diuretics showed a strong correlation with the prevalence of hip fractures. When considering anticoagulants, compared with warfarin, NOACs (new oral anticoagulants) were associated with lower risks of bone fracture. A positive relationship was also observed between the prevalence of hip fractures and the number of PIM categories prescribed to older patients with hip fractures.
Conclusions: This study highlights the patterns of medication use in older surgical patients with hip fractures. Older adults with hip fractures require special attention, particularly those prescribed multiple medications or several categories of PIMs, especially anticoagulants and diuretics. Identifying and preventing adverse drug reactions (ADRs) in older patients necessitates consistent monitoring and regular evaluation of both prescribed and over-the-counter medications.
ADRs are common contributors to cognitive or functional decline, falls, gastrointestinal bleeding, heart failure, and orthostatic hypotension. Geriatracian should routinely consider the possibility of ADRs in their differential diagnoses and ensure that new medications are prescribed with clear therapeutic objectives. Medications deemed ineffective or unnecessary should be deprescribed. Although standardized tools such as appropriateness criteria and risk prediction models are valuable, they should be viewed as adjuncts to, rather than substitutes for, clinical judgment informed by comprehensive training in geriatric pharmacotherapy.

P150

EFFECT OF HEALTH LITERACY ON ADHRENCE TO OSTEOPOROSIS TREATMENT

A. Fazaa[1], S. Loukil[1], S. Miladi[1], Y. Makhlouf[1], H. Boussaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]RHEUMATOLOGY DEPARTMENT MONJI SLIM HOSPITAL, Ariana, Tunisia

Background: Effective management of osteoporosis requires a holistic approach including pharmacological treatments and lifestyle modifications. Despite the availability of effective therapies, adherence to osteoporosis treatment remains a critical challenge. Many factors can influence treatment adherence, with health literacy identified as one of the key determinants.
Objective : The aim of this study was to assess the effect of health literacy on adhrence to osteoporosis treatment.
Methods: We conducted a cross-sectional study involving patients diagnosed with osteoporosis, recruited from the rheumatology department of Monji Slim Hospital. Sociodemographic data as well as disease-related characteristics were transcribed (medical history, educational level, occupation, marital status, living setting).
Health literacy was assessed using the The European Health Literacy Survey Questionnaire (HLS-EU-Q), a validated tool that measures general health literacy across four key domains: understanding of health information, communication with healthcare providers, decision-making in health, and the ability to navigate the healthcare system. The HLS-EU-Q is scored from 0 to 16. Health literacy levels were classified as inadequate (<8), problematic (9–12), and sufficient (13–16).
Adherence to osteoporosis treatment was evaluated through the Morisky Medication Adherence Scale (MMAS-8): a self-assessment tool designed to evaluate medication adherence behavior that consists of eight questions with a yes or no response format. A significance threshold was set at $p<0.05$.
Results: The study included 28 patients undergoing osteoporosis treatment, with a female predominance (sex ratio M/F =0.08). The mean age was 64± 9 years[45-82]years old and the mean weight was 58± 16 kg[22-88] .
Regarding educational levels, 4% had a university level or higher, 42% had a secondary level, 27% had a primary level, and 27% were illiterate. In terms of occupation, 4% were employed, 73% were unemployed, and 23% were retired. As for marital status, 60% were maried, 4% were single, 28% were widowed, and 8% were divorced.
Seventy-three percent of patients lived in urban areas, while 27% resided in rural settings.
Additionally, 88% of participants reported having a rheumatic disease, and 9% had a history of neoplasia. Fracture-related complications were observed in 17% of patients.
Among the surveyed patients, 31% demonstrated inadequate health literacy, 65% had problematic health literacy, and only 4% had sufficient health literacy.
The mean MMAS-8 score was 4.5± 3 [0-8]. Among the participants, 5% reported high adherence to their treatment, 33% demonstrated medium adherence, and 62% showed low adherence.
Significant associations were observed between adherence and health literacy ($p = 0.047$), weight ($p = 0.034$), and fractures ($p = 0.006$).
Health literacy was significantly associated with educational level ($p=0.023$) and the presence of neoplasia($p=0.04$).
Conclusion:
Healthcare providers should prioritize comprehensive discussions with patients, focusing on enhancing health literacy related to osteoporosis. This approach is essential for improving patient adherence, optimizing treatment outcomes, and ultimately reducing fracture risk.

P151

IMPACT OF PATIENT GLOBAL ASSESSMENT PHRASING ON THE RHEUMATOID ARTHRITIS REMISSION RATES

A. Fazaa[1], M. Ben Messaoud[1], S. Miladi[1], H. Boussaa[1], Y. Makhlouf[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Mongi Slim Hospital, Tunis, Tunisia

Background :
Patient global assessment (PGA) is included in almost all rheumatoid arthritis (RA) composite activity scores and definitions of remission. However, the absence of a standardized PGA formulation may influence disease activity assessments. This study examines how different PGA formulations affect the evaluation of remission in RA.
Methods :
We conducted a cross-sectional observational study on patients with RA (2010 ACR/EULAR criteria). The PGA was measured using five formulations (PGA V1: ACR-EULAR version, PGA V2: CDAI/SDAI version, PGA V3: original DAS version, PGA V4: current DAS version, PGA V5: investigator-formulated version). Composite scores (DAS28 ESR, DAS28 CRP, SDAI, CDAI) were calculated for each patient using each PGA formulation, with PGA V1 serving as the reference.
Results :
Seventy-four patients, 61 women and 13 men, with a median age of 61 years [56.7-67.2], were included. The mean PGA scores varied across formulations, ranging from 41.2 ± 24.9 (PGA V2) to 54.3 ± 28.9 (PGA V4). Correspondingly, composite scores fluctuated. The DAS28 ESR ranged from 4.21 ± 1.37 (PGA V2) to 4.37 ± 1.39 (PGA V4).
The DAS28 CRP ranged from 3.38 [2.49–4.31] (PGA V2) to 3.69 ± 1.51 (PGA V5). The SDAI ranged from 11.7 [7.46–23.6] (PGA V3) to 18.58 [12.27–32.35] (PGA V1). The CDAI ranged from 10.5 [5.87–18] (PGA V2) to 13 [7–17.25] (PGA V3).
The maximum differences in remission rates, depending on the PGA formulation used within the same index (highest minus lowest), were as follows: 5% (CDAI), 5% (DAS28 ESR), 7% (SDAI) and 9% (DAS28 CRP).
Statistically significant differences in remission rates were observed: Between DAS28 ESR V3 and DAS28 ESR V1 (p = 0.035), between CDAI V2 and CDAI V1 (p = 0.045), and between CDAI V3 and CDAI V1 (p = 0.044).
No significant differences were found for DAS28 CRP and SDAI across the various PGA formulations compared to V1.
Conclusion :
Our study indicates that using different PGA formulations can impact the assessment of remission status in RA patients, potentially influencing clinical management decisions. Therefore, standardizing the PGA formulation in clinical practice is essential to ensure consistent and accurate evaluations of disease activity.

P152

VARIABILITY IN PATIENT GLOBAL ASSESSMENT SCORING: IMPACT OF DIFFERENT FORMULATIONS IN RHEUMATOID ARTHRITIS

A. Fazaa[1], M. Ben Messaoud[1], S. Miladi[1], Y. Makhlouf[1], H. Boussaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Mongi Slim Hospital, Tunis, Tunisia

Background :
The Patient Global Assessment (PGA) is a common item in all rheumatoid arthritis (RA) activity scores, but no reference formulation exists. The objective of our study was to analyze the impact of different PGA formulations on how patients rated this scale.
Methods :
We conducted a cross-sectional observational study on patients with RA (2010 ACR/EULAR criteria). Sociodemographic, clinical, biological, and radiographic data were collected. The PGA was measured using five formulations (PGA V1: ACR-EULAR version, PGA V2: CDAI/SDAI version, PGA V3: original DAS version, PGA V4: current DAS version, PGA V5: investigator-formulated version). The differences among the five PGA formulations were evaluated using the following methods: Pearson's correlation coefficients, Bland-Altman plots, paired sample t-tests to compare the mean scores for each formulation, and an analysis of the proportion of patients who scored ≤ 100 mm on each formulation. The first version of PGA was used as the reference.
Results :
Seventy-four patients, 61 women and 13 men, with a median age of 61 years [56.7-67.2], were included. The mean PGA ranged from 41.2±24.9 (PGA V2) to 54.3±28.9 (PGA V4). The formulations showed significative positive correlations (r ranging from 0.436 to 0.743). Bland Altman plots showed low agreement between formulations, with 95% limits of variability ranging from [−45.1 to +44.8 mm] (PGA V3 versus V1) to [−49.2 to +50.8 mm] (PGA V5 versus V1).
The comparison of means across the different PGA formulations revealed that the PGA V2 formulation (CDAI/SDAI version) had the lowest mean (41.8 ± 24.9), with a statistically significant difference (p = 0.000) compared to the reference (PGA V1: ACR-EULAR version).
The comparison of the proportions of patients with PGA values ≤ 100 mm showed a statistically significant difference between PGA V1 and the other versions: PGA V2 versus PGA V1 (p = 0.003), PGA V3 versus PGA V1 (p = 0.006), PGA V4 versus PGA V1 (p = 0.001), and PGA V5 versus PGA V1 (p = 0.006).
Conclusion :
Our study demonstrated that the use of different formulations of the PGA influenced its scoring. A standardized version of the PGA would ensure better patient management.

P153

VARIABILITY IN PATIENT GLOBAL ASSESSMENT FORMULATIONS: INSIGHTS FROM TUNISIAN RHEUMATOLOGISTS

A. Fazaa[1], M. Ben Messaoud[1], H. Boussaa[1], Y. Makhlouf[1], S. Miladi[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Mongi Slim Hospital, Tunis, Tunisia

Introduction: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatism affecting young adults. Accurate assessment of disease activity is crucial for optimizing patient management. The Disease Activity Score 28 (DAS28) is a validated and widely used composite tool for measuring RA activity. One of its components, the Patient Global Assessment (PGA), which lacks standardized formulations.
This study aimed to evaluate the different PGA formulations used by Tunisian rheumatologists for DAS28 calculation.
Methods: A cross-sectional descriptive study was conducted among Tunisian rheumatologists. A self-administered online questionnaire was created and distributed via Google Forms. Participants were asked which PGA formulation they used among five options: PGA1: "Considering all the ways your arthritis has affected you, how do you rate your arthritis today?" (ACR/EULAR version). PGA2: "Considering all the ways your arthritis affects you, how do you evaluate your overall health?" (CDAI/SDAI version). PGA3: "How would you rate your health over the past week?" (Original DAS28 version). PGA4: "How active has your arthritis been over the past week?" (Current DAS28 version). PGA5: "Your disease has highs and lows. When it is very active, there is more pain, morning stiffness, joint swelling, and fatigue. Considering these elements, how would you rate the state of your disease over the past week?" (Investigator-formulated version).
Results: The study population had a mean age of 31.6 years [25–48], with a mean duration of practice of 6.2 years [1–20]. The professional activity was university hospital-based in 73.3% of cases, public hospital-based in 16.7%, and private in 10%. The distribution of PGA formulations used was as follows: PGA4: 43.8%, PGA3: 18.8%, PGA1: 15.6%, PGA5: 15.6% and PGA2: 6.3%. Younger rheumatologists were more likely to use PGA4 (p=0.02). Rheumatologists with less than 5 years of practice predominantly used PGA4 (p=0.01), while those with more than 10 years of practice preferred PGA1 and PGA3 (p=0.03). Hospital-university practitioners favored PGA4 (p=0.008), while private sector rheumatologists predominantly used PGA3 and PGA5 (p=0.04).
Conclusion: This study highlights significant variability in PGA formulations used by Tunisian rheumatologists for DAS28 calculation. These differences may impact the evaluation of disease activity and underscore the need for standardizing PGA formulations to ensure consistent DAS28 assessments. Further research is warranted to explore how these variations influence clinical outcomes and treatment decisions.

P154

SATISFACTION WITH THE DIAGNOSTIC ANNOUNCEMENT AMONG TUNISIAN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Fazaa[1], M. Ben Messaoud[1], H. Boussaa[1], Y. Makhlouf[1], S. Miladi[1], N. Belhadj[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Mongi Slim Hospital, Tunis, Tunisia

Introduction : The announcement of a chronic disease diagnosis is a pivotal moment in establishing a strong doctor-patient relationship. Rheumatoid arthritis (RA) is a chronic and potentially disabling condition. A well-structured diagnostic announcement process can facilitate patient understanding and acceptance of the disease. This study aimed to evaluate patients' perceptions of the diagnostic announcement process in RA and to assess the factors associated with the diagnostic satisfaction.
Methods: This was a cross-sectional study involving patients diagnosed with RA according to the 2010 ACR/EULAR criteria. The quality of the diagnostic announcement was assessed using a 5-point Likert scale (1 to 5, defined as: 1: Not at all satisfied; 2: Slightly satisfied; 3: Satisfied; 4: Moderately satisfied; 5: Very satisfied). Statistical analysis was conducted with a significance threshold set at $p<0.05$.
Results: A total of 100 patients were included, 25 men and 75 women, with a mean age of 58 years [31-80]. The mean disease duration was 36.3 months [3-84]. RA was seropositive in 88.2% of cases and erosive in 49%.
Regarding announcement circumstances, 71% of patients were satisfied with the reception, 20% were moderately satisfied, and 9% were very satisfied. The waiting time was deemed satisfactory by 68% and moderately satisfactory by 20%. The diagnosis was announced in the physician's office in 81% of cases and 69% of patients were alone with the physician.
Concerning physician-related characteristics, 91% of patients reported that the physician introduced themselves at the beginning of the consultation. All patients perceived their physicians as confident, 92% found them empathetic and 89% judged them reassuring. Additionally, 96% of patients considered the time allocated for the announcement sufficient. Regarding communication clarity, 6% found the physician's explanation incomprehensible. In 94% of cases, the diagnosis was precisely stated by naming the disease. The majority of patients (96%) perceived the announcement process as gradual. About 21% of patients reported that their physicians asked if they had questions about the disease.
Satisfaction with the diagnostic announcement was significantly associated with the announcement ($p = 0.012$). A strong positive correlation was observed between satisfaction with the diagnostic announcement and satisfaction with the explanations provided about the disease ($p = 0.000$) as well as the level of understanding of the disease ($p = 0.006$). Additionally, satisfaction with the diagnostic announcement was significantly linked to the accuracy of the diagnostic statement ($p = 0.000$), the naming of the disease ($p = 0.000$), the manner of announcement ($p = 0.000$), the stage of announcement ($p = 0.024$), and the physician's empathetic ($p = 0.000$) and reassuring attitudes ($p = 0.000$).

Conclusion: Our study highlights that precise and well-structured communication, combined with an empathetic and reassuring physician attitude, enhances the patient experience during the diagnostic announcement of RA. These aspects should be considered to optimize medical communication and improve patient outcomes.

P155

KNOWLEDGE OF TUNISIAN RHEUMATOLOGISTS REGARDING TRAVEL FOR PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES ON IMMUNOSUPPRESSANTS

A. Fazaa[1], M. Ben Messaoud[1], S. Miladi[1], H. Boussaa[1], Y. Makhlouf[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Mongi Slim Hospital, Tunis, Tunisia

Introduction: The increasing number of patients with chronic inflammatory rheumatic diseases (CIRD) traveling internationally coincides with the rise in immunosuppressive (IS) treatments. These patients face a heightened risk of infections, making it essential to provide appropriate travel-related advice. This study aimed to assess the knowledge of Tunisian rheumatologists concerning preventive measures and educational points for CIRD patients on IS therapy planning to travel.

Methods: A cross-sectional descriptive study was conducted among Tunisian rheumatologists who are members of a social media group established under the Tunisian Anti-Rheumatic League. A self-administered questionnaire was created and distributed via Google Forms over a four-month period.

Results: Out of 186 contacted rheumatologists, 56 responded (30%). The average age was 48.4 ± 10.5 years, predominantly female (sex ratio = 0.27), with an average of 19 ± 10 years of experience. Fourty-three rheumatologists (77%) consulted at least six CIRD patients on IS therapy per week.

Thirty-four rheumatologists (60.7%) reported being occasionally asked by patients for pre-travel advice. Ten physicians (18%) were aware of specialized travel consultations, yet 34 (60.7%) had never referred patients to such services.

Topics addressed by at least 62.5% of rheumatologists included travel characteristics, exposure risks to certain diseases, travel-related issues concerning CIRD and vaccination. Live attenuated vaccines were considered contraindicated by at least 45% of respondents.

Regarding treatments, 35 rheumatologists (62.5%) did not discontinue IS therapy before administering inactivated vaccines. For live attenuated vaccines, 40 (71%) recommended stopping IS therapy one to six months prior to vaccination, with 32 (57%) advising resumption two weeks post-vaccination. Twenty-three rheumatologists (41%) provided advice on medication storage during travel.

Concerning IS infusions, 50 rheumatologists (89%) agreed to administer them in the destination country if the travel was extended and hygiene conditions were met.

Twelve rheumatologists (21%) offered suggestions to enhance patient management, with six proposing easily accessible guides for patients and five recommending training sessions for rheumatologists on this topic.

Conclusion: A specialized pre-travel consultation is highly recommended for CIRD patients on IS therapy to discuss infectious disease prevention and general precautions. It is crucial for physicians to stay updated with the latest recommendations to provide optimal care.

P156

ANEURYSMAL BONE CYST OF THE CALCANEUS: AN EXCEPTIONAL LOCALISATION

A. Fekih[1], J. Saadana[1], A. Mestiri[1], I. Najjar[1], A. Kharrat[1], I. Bousselmi[1], H. Haj Taieb[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective: Aneurysmal bone cysts are lesions with an unclear origin and pathogenesis. They are commonly found in pediatric populations. Their occurrence in the calcaneus is quite unusual.

Case Report: A 20-year-old male, with no significant medical history, presented with a foot injury. A radiograph revealed a large, cystic lesion in the calcaneus consistent with Lodwick's type IA. Subsequent CT and MRI scans confirmed the presence of multiple intraosseous cavities with a fluid-fluid level and a hypo-intense margin, strongly suggesting an aneurysmal bone cyst.

The patient underwent surgical excision of the cyst followed by bone grafting using autologous iliac crest bone. Histopathological examination confirmed the diagnosis of an aneurysmal bone cyst.

At the 9-month follow-up, the patient was pain-free and radiographic imaging showed complete healing with no evidence of recurrence.

Discussion: Aneurysmal bone cysts of the calcaneus can be discovered incidentally during imaging studies for unrelated reasons. Patients may present with ankle pain, swelling, or a pathological fracture.

The primary differential diagnosis for aneurysmal bone cysts, especially in the calcaneus, is telangiectatic osteosarcoma. Given their similar imaging characteristics, a high index of suspicion is necessary to differentiate between these two entities.

Advanced imaging techniques such as MRI can be invaluable in characterizing the lesion and aiding in the differential diagnosis.

A watchful waiting approach can be considered for small, asymptomatic lesions, especially in young patients.

Surgical excision with curettage and bone grafting is the gold standard treatment.

In certain cases, adjuvant therapies such as embolization may be considered prior to surgery to reduce blood flow to the lesion.

Despite surgical treatment, there is a significant risk of recurrence, estimated to be around 30%. Regular follow-up imaging is essential to monitor for any signs of recurrence.

Conclusion: While most aneurysmal bone cysts are benign, their aggressive local growth potential and the risk of recurrence high-

light the importance of early diagnosis and appropriate management.
Definitive diagnosis is based on histopathological examination of the surgical specimen.
Treatment decisions should be individualized based on the patient's age, symptoms, functional demands, and the specific characteristics of the lesion.

P157

BILATERAL AND SIMULTANEOUS SCAPHOID FRACTURES: A SURGICAL CASE REPORT

A. Fekih[1], J. Saadana[1], I. Najjar[1], A. Kharrat[1], I. Bousselmi[1], H. Haj Taieb[1], A. Mestiri[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Scaphoid fractures are the most common carpal bone fractures, but bilateral, simultaneous fractures are rare.
Case Report:
A 24-year-old right-handed male presented with acute pain in both wrists following a fall. Physical examination revealed tenderness over the anatomical snuffboxes on both sides. Radiographs confirmed bilateral Herbert type B2 scaphoid fractures. The patient underwent bilateral percutaneous screw fixation. At the final follow-up, both fractures had healed, and the patient had regained full wrist motion.
Discussion:
Scaphoid fractures account for 70-80% of carpal bone fractures. Due to subtle initial symptoms, these fractures are often diagnosed late despite advances in imaging. The primary mechanism of injury is a fall onto an outstretched hand. Scaphoid fractures are most common in young, active males who may be reluctant to undergo prolonged immobilization, especially for bilateral fractures.
While recent trends favor internal fixation for bilateral scaphoid fractures to avoid prolonged casting and lost work time, conservative treatment with casting can also yield successful outcomes.
For displaced fractures, open reduction and internal fixation is typically indicated, with the specific technique depending on the fracture pattern and surgeon preference.
It is essential to assess for associated cartilage damage, as this can negatively affect the final outcome. Bilateral scaphoid fractures treated with screw fixation typically heal well with no limitations in wrist motion.
Conclusion:
Bilateral, simultaneous scaphoid fractures are uncommon but require appropriate treatment to ensure healing and a quick return to normal activities.

P158

CHONDROMA OF THE SCAPHOID BONE: A RARE CASE REPORT

A. Fekih[1], A. Kharrat[1], I. Bousselmi[1], H. Haj Taieb[1], A. Mestiri[1], I. Najjar[1], J. Saadana[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Chondromas are benign bone tumors that develop from cartilage-forming cells. They can be solitary or multiple. While chondromas commonly affect the hands, their occurrence in the carpal bones, especially the scaphoid, is relatively rare.
Case Report:
A 19-year-old patient presented with a 6-month history of wrist pain following a minor trauma. Physical examination revealed tenderness over the scaphoid tubercle. Radiographs showed a cortical fracture of the scaphoid within a well-defined, oval-shaped lucency measuring 8 mm in diameter. CT scan further confirmed the presence of an osteolytic lesion with a sclerotic rim. Based on these findings, a diagnosis of a chondroma complicated by a fracture was strongly suspected.
The patient underwent surgery involving removal of the tumor and bone grafting. Post-operatively, the patient was immobilized in a cast for three months. Histopathological examination confirmed the diagnosis of a chondroma.
At the one-year follow-up, the patient was pain-free with full wrist motion, and radiographs showed complete healing.
Discussion:
Chondromas of the scaphoid can be discovered incidentally, often during imaging for unrelated reasons, such as a wrist fracture. Patients may present with a painless mass, localized pain, or vague wrist discomfort.
Chondromas typically appear as radiolucent areas with a sclerotic rim. The overlying cortex is often thinned but intact, except in cases of fracture.
These lesions often have a more aggressive appearance with a "soap-bubble" pattern on imaging.
The histological appearance of chondromas is characteristic, showing a lobular pattern of hyaline cartilage.
The traditional approach involves curetting the lesion and filling the defect with bone graft. In cases of larger or more aggressive lesions, en bloc resection may be necessary.
Autologous bone grafts, such as iliac crest or distal radius, are commonly used to fill the defect and promote healing. Immobilization and early range-of-motion exercises are typically recommended to prevent stiffness.
Conclusion:
With appropriate surgical treatment, the prognosis for chondromas of the scaphoid is excellent, with a low risk of recurrence.

P159

DEGENERATIVE MENISCAL LESIONS: A RETROSPECTIVE STUDY OF 20 CASES

A. Fekih[1], J. Saadana[1], I. Bousselmi[1], H. Haj Taieb[1], A. Mestiri[1], I. Najjar[1], A. Kharrat[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
The concept of degenerative meniscal lesions (DMLs) has evolved significantly since its introduction in 1970. While initially controversial, DMLs are now recognized as a significant clinical entity. This retrospective study aimed to investigate the clinical presentation, surgical management, and short-term outcomes of patients with DMLs.
Material and Methods:
Twenty patients diagnosed with DMLs based on MRI findings were included in the study. All patients underwent arthroscopic knee surgery following the failure of conservative treatment. Intraoperative findings were classified according to the French Arthroscopy Society, and any concomitant cartilage lesions were classified using the Béguin and Locker system.
Results:
The study population comprised predominantly males with a mean age of 51 years. The primary presenting symptom was knee pain without a history of significant trauma. Arthroscopic evaluation confirmed the degenerative nature of the meniscal lesions, with partial meniscectomy performed in two-thirds of cases. At a mean follow-up of 2 years, 15 patients reported improved pain and knee function.
DMLs represent a spectrum of degenerative changes within the meniscus, leading to structural alterations and functional impairment. While MRI plays a crucial role in diagnosis, clinical examination remains essential. Conservative management, including physical therapy and non-steroidal anti-inflammatory drugs, should be the initial treatment approach. Surgical intervention, primarily partial meniscectomy, may be considered in patients with persistent symptoms refractory to conservative care.
However, the long-term impact of meniscectomy on DMLs remains a subject of ongoing debate. Concerns exist regarding its potential to accelerate cartilage degeneration and contribute to the development of osteoarthritis.
Conclusion:
This study highlights the challenges in managing patients with DMLs. While surgery can provide short-term pain relief, its long-term effects and the potential for iatrogenic cartilage damage warrant careful consideration. A multidisciplinary approach, emphasizing conservative management and judicious surgical intervention, is crucial for optimizing patient outcomes.

P160

EVALUATING THE PSYCHOLOGICAL IMPACT OF TOTAL HIP REPLACE: A COHORT STUDY OF 100 PATIENTS

A. Fekih[1], J. Saadana[1], H. Haj Taieb[1], A. Mestiri[1], I. Najjar[1], A. Kharrat[1], I. Bousselmi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Pre-operative screening for psychiatric disorders before total hip arthroplasty and subsequent treatment can lead to improved patient-reported outcomes in individuals undergoing surgery for degenerative coxarthrosis, while potentially reducing healthcare costs.
Our objective is to assess the psychological impact of total hip replacement on patients with degenerative coxarthrosis.
Material and Methods:
This retrospective cross-sectional study included patients who underwent total hip arthroplasty for degenerative coxarthrosis over a four-year period. Data were collected using the Hospital Anxiety and Depression Scale, a 14-item self-report scale assessing anxiety and depression symptoms. A total score of 11 or more indicates clinically significant symptoms.
Results:
A total of 100 patients, predominantly male with an average age of 49, were included in this study. The most common patient complaints were pain (94.9%), limping (49.4%), and reduced walking distance (35.9%, with an average of 200 meters).
Post-operatively, all patients were encouraged to sit up on the first day and 74.4% were able to walk. Rehabilitation was provided to 94.9% of patients for an average of 25 days.
At the one-year follow-up, 79.5% of patients could walk without assistance, while 14.1% needed one cane and 3.8% required two canes.
A statistically significant improvement in the Hospital Anxiety and Depression Scale was observed. Preoperatively, the average depression score was 6.86 ± 2.86, which decreased to 3.85 ± 2.21 postoperatively. This translated to a decrease in the proportion of patients experiencing "certain depression" from 12.8% to 9%.
Similarly, the average anxiety score declined from 8.44 ± 3.06 preoperatively to 4.86 ± 2.66 postoperatively, with the percentage of patients with "certain anxiety" significantly reduced from 28.2% to 5.1%.
Conclusion:
This study demonstrated a significant reduction in anxiety and depression levels following total hip replacement surgery for patients with degenerative coxarthrosis. Pre-operative screening and appropriate treatment for mental health conditions may be a valuable component of comprehensive care for these individuals. The observed improvements in mental well-being can be attributed to various factors, including pain relief, increased functional capacity, and enhanced quality of life.

P161

EVALUATION OF SLEEP QUALITY IN PATIENTS UNDERGOING TOTAL HIP ARTHROPLASTY FOR DEGENERATIVE COXARTHROSIS

A. Fekih[1], J. Saadana[1], A. Mestiri[1], I. Najjar[1], A. Kharrat[1], I. Bousselmi[1], H. Haj Taieb[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Chronic hip pain in patients with degenerative coxarthrosis can significantly affect sleep quality. Our objective is to evaluate sleep quality in patients undergoing total hip arthroplasty for degenerative coxarthrosis using the Pittsburgh Sleep Quality Index (PSQI).

Material and Methods:
This retrospective, descriptive, and analytical cross-sectional study included 100 patients who underwent total hip arthroplasty for degenerative coxarthrosis within a four-year period. Data were collected using the PSQI, a self-reported questionnaire comprising 19 items that generate seven component scores: subjective sleep quality, sleep latency, sleep duration, sleep efficiency, sleep disturbances, use of sleep medication, and daytime dysfunction.

Results:
The mean age of the participants was 49 years, with a male predominance. Preoperatively, the most common functional complaints were pain (94.9%), limping (49.4%), and reduced walking distance (35.9%). The average walking distance was 200 meters. Hip joint involvement was primary in 52.6% of cases and secondary to systemic disease in 47.4%. Coxarthrosis was the primary indication for total hip arthroplasty in 52.6% of cases, followed by osteonecrosis of the femoral head in 21.7%, and dysplasia in 8.9%.

Postoperatively, sleep quality significantly improved, with a substantial decrease in the mean total PSQI score from 7.72 preoperatively to 3.01 postoperatively. The proportion of patients considered "good sleepers" (with a PSQI score ≤ 5) increased significantly from 24.4% to 87.2%.

Our analysis revealed a statistically significant correlation between post-total hip arthroplasty sleep quality, as measured by the Pittsburgh Sleep Quality Index (PSQI), and the patient's preoperative walking distance and subjective range of motion.

This suggests that patients with greater functional limitations before surgery tend to experience more significant improvements in sleep quality following total hip arthroplasty.

Conclusion:
The results of this study support the hypothesis that total hip arthroplasty can effectively alleviate the sleep disturbances commonly associated with degenerative coxarthrosis. To optimize patient outcomes, it is crucial for healthcare providers to discuss patients' pre-operative sleep concerns and expectations, allowing for personalized post-operative care and support.

P162

FUNCTIONAL OUTCOMES FOLLOWING TOTAL HIP ARTHROPLASTY FOR DEGENERATIVE COXARTHROSIS

A. Fekih[1], J. Saadana[1], A. Kharrat[1], I. Bousselmi[1], H. Haj Taieb[1], A. Mestiri[1], I. Najjar[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Total hip arthroplasty has revolutionized the management of chronic and disabling hip conditions, restoring function and improving quality of life. Our objective is to evaluate the functional outcomes of patients undergoing total hip arthroplasty for degenerative coxarthrosis using generic instruments: the Postel-Merle d'Aubigné (PMA) score and the Hip Disability and Osteoarthritis Outcome Score (HOOS).

Material and Methods:
This retrospective, descriptive, and analytical cross-sectional study included 100 patients who underwent total hip arthroplasty for degenerative coxarthrosis over a four-year period. Data was collected through interviews and phone calls using the specific scoring systems.

Results:
The mean age was 49 ± 15.59 years, with a male predominance. Most patients resided in urban areas (81%). The left hip was more commonly affected (60.3%), and preoperative complaints included pain (94.9%), limping (49.4%), and reduced walking distance (35.9%). The majority (64.9%) received metal-on-polyethylene implants, while 35.1% had ceramic-on-ceramic implants.

All patients were mobilized on the first postoperative day. Rehabilitation was provided to 94.9% of patients for an average of 25 days. At the one-year follow-up, 79.5% of patients walked without assistance, 14.1% used one cane, and 3.8% used two canes.

Both the PMA and HOOS scores showed significant improvements postoperatively. The PMA score increased from 7 preoperatively to 14 postoperatively, indicating improved function. The HOOS score also demonstrated significant improvement, with the overall score rising from 35 to 76 postoperatively.

A positive and statistically significant association was found between the post-operative HOOS score and living environment, bearing surface (metal-on-polyethylene vs. ceramic-on-ceramic), age of the patient, time to standing and postoperative PMA score.

Conclusion:
The study clearly demonstrates the significant improvement in functional outcomes following total hip arthroplasty, as measured by both the PMA and HOOS scores. The use of standardized scoring systems allows for a more comprehensive assessment of patient outcomes and facilitates tailored treatment plans.

P163

MANAGEMENT OF PELVIC GIANT CELL TUMOR: AN INTERESTING ALTERNATIVE

A. Fekih[1], J. Saadana[1], I. Bousselmi[1], H. Haj Taieb[1], A. Mestiri[1], I. Najjar[1], A. Kharrat[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Pelvic giant cell tumors present a significant surgical challenge due to their complex location and potential for local aggressiveness. While typically benign, these tumors can exhibit aggressive local growth, often involving the end of long bones and extending into the joint. Less frequently, they arise in flat bones, including the innominate bone of the pelvis. Recent advancements include the introduction of Denosumab, a human anti-RANKL monoclonal antibody, and the utilization of 3D-printed models for enhanced surgical planning.
Case Report:
This report describes the case of a 21-year-old male who presented with a painful swelling on the left side of his pelvis. Physical examination revealed a hard, tender mass in the posterior left pelvis without any neurovascular compromise.
Radiographic imaging, including X-ray, CT scan, and MRI, confirmed a large (9x8x7cm) osteolytic lesion in the posterior-superior aspect of the left ilium, extending into the sacroiliac joint. Pathological examination of the lesion confirmed a diagnosis of giant cell tumor.
A neoadjuvant treatment regimen of nine 120mg doses of Denosumab was administered with appropriate monitoring.
Preoperative planning was significantly enhanced by the use of a 3D-printed model of the pelvis. Surgical resection was performed via a posterior sacroiliac approach. Intraoperatively, the surgical planes were found to be well-defined, facilitating complete tumor removal. To address the resulting pelvic ring instability, reconstruction was performed using single-axis pedicle screws placed in the fourth and fifth lumbar vertebrae and the ilium. A fibular strut graft was utilized to bridge the bone defect. The patient experienced an uneventful postoperative recovery.
Discussion:
Denosumab, this anti-RANKL antibody has emerged as a valuable neoadjuvant therapy for GCTs, contributing to tumor size reduction and potentially improving surgical resectability and reducing recurrence rates.
3D-Printed models provide invaluable tools for preoperative planning, enhancing surgical accuracy, and facilitating better communication within the surgical team.
Conclusion:
The optimal management of pelvic giant cell tumors necessitates a multidisciplinary approach involving oncologists, orthopedic surgeons, and other specialists to develop personalized treatment plans. Close postoperative surveillance is crucial for early detection and management of any potential recurrence.

P164

MANAGEMENT OF PELVIC GIANT CELL TUMOR: AN INTERESTING ALTERNATIVE

A. Fekih[1], J. Saadana[1], H. Haj Taieb[1], A. Mestiri[1], I. Najjar[1], A. Kharrat[1], I. Bousselmi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

The optimal management of pelvic giant cell tumors necessitates a multidisciplinary approach involving oncologists, orthopedic surgeons, and other specialists to develop personalized treatment plans. Close postoperative surveillance is crucial for early detection and management of any potential recurrence.

P165

OSTEOMYELITIS OF THE SUPERIOR PUBIC RAMUS: AN UNCOMMON LOCALISATION

A. Fekih[1], J. Saadana[1], H. Haj Taieb[1], A. Mestiri[1], I. Najjar[1], A. Kharrat[1], I. Bousselmi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Osteomyelitis of the pubic bone is an uncommon condition, accounting for approximately 2% of all hematogenous osteomyelitis cases. Diagnosis can often be challenging, as its presentation may mimic other conditions such as osteitis pubis, pubic symphysis fracture, or non-infectious inflammation.
Case Report:
This report describes a 19-year-old male who presented with ten days of worsening pelvic pain. Initially, he experienced spontaneous pelvic pressure without systemic symptoms like fever or chills. Subsequently, he developed progressively severe pain in his left hip and groin.
Three days prior to presentation, he was evaluated in the emergency department but discharged with pain medication. However, his pain worsened, and he returned to the emergency department with fever at 39°C, tachycardia, pain radiating into the left buttock with inability to bear weight on his left lower extremity.
Laboratory investigations revealed elevated inflammatory markers with a White Blood Cell Count (WBC): 23,300 cells/µL and a C-reactive protein (CRP): 172 mg/L.
Based on these findings, an MRI of the pelvis was ordered, which revealed osteomyelitis of the pubic bone with endopelvic spread. Surgical intervention was performed, including a wedge resection of the infected bone. Tissue cultures subsequently grew Staphylococcus aureus, confirming the diagnosis of osteomyelitis pubis with an abscess extending into the adductor compartment.
The patient received intravenous antibiotic therapy for three weeks followed by an additional three weeks of oral antibiotics. At the four-month follow-up, the patient was pain-free, inflammatory markers had normalized, and a CT scan demonstrated resolution of the osteomyelitis.
Conclusion:
Osteomyelitis of the pubic bone is a rare but potentially life-threatening condition that should be included in the differential diagnosis of patients presenting with acute onset pelvic pain of unknown etiology.
Early diagnostic evaluation, including MRI or CT imaging, is crucial for prompt diagnosis and initiation of appropriate treatment. Definitive diagnosis often relies on microbiological confirmation through a bone biopsy obtained during surgical debridement, aspiration of abscesses or sampling of infected tissues at the site of entry.
Treatment typically involves a combination of surgical debridement to remove infected bone and tissue and prolonged antibiotic therapy for effective eradication of the infection.

P166

RADIUS BIPOLAR FRACTURE: A RARE AND UNIQUE INJURY

A. Fekih[1], J. Saadana[1], A. Dhouib[1], A. Lassoued[1], I. Ben Massaoud[1], R. Dhouibi[1], A. Ltifi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Simultaneous ipsilateral distal radius and radial head fractures, termed "radius bipolar fracture," represent a unique and uncommon injury. Few cases have been reported, and its incidence remains unknown.
Case Report:
A 32-year-old healthy male presented to the emergency department with right elbow and wrist pain following a slip and fall on stairs. He was unable to move the elbow or wrist, though finger movement and sensation remained intact. Radiographs revealed a radius bipolar fracture: a Mason type I radial head fracture and an AO type C1 (C1.3) distal radius fracture.
The patient underwent surgery. Traction with counter-traction facilitated distal radius reduction, followed by percutaneous K-wire fixation. The undisplaced radial head fracture was treated conservatively.
Post-operatively, an above-elbow cast was applied with the forearm in mid-prone position. Elbow mobilization began three weeks post-surgery, followed by cast and K-wire removal and gradual wrist motion. At six-month follow-up, both wrist and elbow demonstrated good range of motion.
Discussion:
Distal radius fractures are often associated with elbow dislocations, but rarely with proximal radius fractures. The most probable mechanism for this injury is a fall on an outstretched hand.
While treatment guidelines exist for individual radial head and distal radius fractures, there are no specific protocols for radius bipolar fractures.
If both fractures require surgical intervention, the order of surgery is crucial. If a radial head replacement arthroplasty is planned, it is recommended to operate on the wrist first. This preserves radial length and prevents radiocapitellar overstuffing or instability. However, if open reduction and internal fixation is performed for the proximal radius fracture, the order of surgery is less critical.
Conclusion:
Currently, no specific treatment guidelines exist for radius bipolar fractures. This case suggests a potential treatment algorithm: prioritize treating the distal radius fracture if open reduction is planned for the radial head. Surgical and postoperative care must address both the elbow and wrist, with a primary focus on preserving radial length to optimize outcomes.

P167

RESULTS OF PERCUTANEOUS PINNING FOR METACARPAL FRACTURES: A SERIES OF 70 CASES

A. Fekih[1], J. Saadana[1], A. Lassoued[1], I. Ben Massaoud[1], R. Dhouibi[1], A. Ltifi[1], A. Dhouib[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Metacarpal fractures are common injuries of the upper extremity. Approximately 25% of these fractures require surgical intervention.
Material and Methods:
This retrospective study analyzed 70 cases of metacarpal fractures treated with percutaneous pinning between 2020 and 2022. Pinning techniques included fasciculated, Iselin, metacarpocarpal, and cruciate methods. Outcomes were assessed based on fracture reduction, healing, return to work, and the presence of complications.
Results:
The study population was predominantly male (88.6%). Right-hand injuries were more common (73%). Most frequent mechanisms of injury were falls on the dorsum of the hand (35%) and punches (25%).
Fifth metacarpal fractures were most frequent (36 cases), with neck fractures (53%) and base fractures (30%) being the most common subtypes.
First metacarpal fractures were the second most common (25 cases), with base fractures accounting for 88% of cases.
Surgery was performed within 24-48 hours in 55 cases. Pinning techniques included fasciculated centromedullary (31 cases), Iselin (22 cases), metacarpocarpal (13 cases), and cruciate (4 cases).
Pins were typically removed after 23 days. With a mean follow-up of 2.5 years, 78% of cases demonstrated favorable outcomes with complete healing and no sequelae.
Minor complications, such as joint stiffness or pin site infection, occurred in a few cases and were successfully managed with rehabilitation and medical treatment.
Patients were able to return to normal activities an average of 20 days after pin removal.
Conclusion:
Percutaneous pinning is an attractive treatment option for metacarpal fractures, offering good results, relative ease of technique, and cost-effectiveness. However, limitations include the potential for rotational malalignment, insufficient absolute stability, pin migration, and pin site infection.

P168

SCAPHOID FRACTURE WITH FRAGMENT EJECTION: A RARE CASE REPORT

A. Fekih[1], J. Saadana[1], I. Ben Massaoud[1], R. Dhouibi[1], A. Ltifi[1], A. Dhouib[1], A. Lassoued[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Scaphoid fractures with fragment ejection are rare injuries in carpal trauma. They are often caused by high-energy mechanisms.
Case Report:
A 38-year-old right-handed construction worker presented to the emergency department following a three-meter fall onto his left wrist. Examination revealed a swollen, immobile wrist with signs of acute carpal tunnel syndrome. A palpable, hard, mobile mass was noted on the anterior aspect of the wrist. Radiographs showed a body fracture of the left scaphoid with a proximal fragment. Emergency surgery revealed a perinervous hematoma and a free proximal scaphoid fragment that had lost its ligamentous attachments. The fracture was reduced and stabilized with a screw, and the scapholunate ligament was repaired. Postoperatively, the patient was immobilized in a volar splint for six weeks, followed by physical therapy. At one-year follow-up, the patient had a painless wrist with near-normal mobility.
Discussion:
Scaphoid fractures with proximal fragment ejection are uncommon and are often associated with trans-scapholunate dislocations. In this case, the anterior and proximal avulsion of the scaphoid fragment was likely due to the high-energy impact and associated ligamentous ruptures.
Several surgical techniques can be used to treat these complex injuries, including scaphoid screw fixation and scapholunate interposition. In this case, we opted for fracture reduction with screw fixation and ligament repair. The literature reports a case of anterior-brachial avulsion of the lunate and proximal scaphoid fragment associated with an open trans-scapholunate-retro-lunate dislocation of the carpe, which was treated with a partial proximal carpectomy, leaving the distal scaphoid fragment in place. This patient achieved a good anatomical and functional outcome at six-year follow-up.
Scaphoid fractures with proximal fragment ejection can lead to complications such as nonunion, avascular necrosis, and carpal instability.
Conclusion:
Scaphoid fractures with proximal fragment ejection are rare but challenging injuries. Stabilization of the fracture with screw fixation and ligament repair offers a viable treatment option and can yield satisfactory anatomical and functional results.

P169

SLEEP DISTURBANCES IN ELDERLY INDIVIDUALS FOLLOWING HIP FRACTURES

A. Fekih[1], J. Saadana[1], R. Dhouibi[1], A. Ltifi[1], A. Dhouib[1], A. Lassoued[1], I. Ben Massaoud[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Sleep disturbances are prevalent among the elderly and pose a significant challenge following hip fractures. These fractures, often a consequence of falls, can disrupt sleep patterns and exacerbate existing sleep problems. Our objective is to investigate the prevalence of sleep disturbances in elderly hip fracture patients and identify associated risk factors.
Material and Methods:
This study included patients who had undergone treatment for a hip fracture. Data collection involved a questionnaire assessing medical history, fall circumstances, time spent on the ground, availability of support, self-esteem, and sleep quality using the Pittsburgh Sleep Quality Index (PSQI).
Results:
The study included 80 patients (56 women and 24 men) aged 59 to 94 years. For 78.9% of these patients, the fracture resulted from their first fall. Slipping was the most common cause of the fall in 47.4% of cases, while syncope accounted for 5.3%. In 15.8% of cases, the patient remained on the ground for more than an hour. A support system was available in 57.9% of cases. Self-esteem was rated as very low in 37.1%, low in 21.1%, and average in 21.1%. Notably, 94.7% of patients reported poor sleep quality, highlighting the significant impact of hip fractures on sleep.
Our results show that most patients experienced their first fall leading to a hip fracture, suggesting that fall prevention is crucial for this population. Moreover, the prevalence of poor sleep quality was high, consistent with previous studies. The limited availability of a support system, reported in only 57.9% of cases, highlights the need for comprehensive care for elderly individuals following a hip fracture.
Conclusion:
Sleep disturbances are a significant concern for elderly individuals following hip fractures. This study highlights the high prevalence of poor sleep quality in this population and emphasizes the importance of comprehensive care that addresses not only the physical but also the psychological and social needs of these patients.

P170

SLIPPED CAPITAL FEMORAL EPIPHYSIS IN ADOLESCENTS: A SERIES OF 20 CASES

A. Fekih[1], J. Saadana[1], A. Ltifi[1], A. Dhouib[1], A. Lassoued[1], I. Ben Massaoud[1], R. Dhouibi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Slipped capital femoral epiphysis is a condition where the head of the femur slips backward relative to the neck.
This study aimed to investigate the clinical and radiological characteristics of slipped capital femoral epiphysis, as well as the various treatment modalities and short-to-medium-term outcomes.
Materiel and Methods:
This retrospective study included 20 patients diagnosed with slipped capital femoral epiphysis over a nine-year period. We used the Loder classification to categorize slips as stable or unstable, and the Carlioz classification to assess the severity of the slip based on the slip angle. Outcomes were assessed using a four-category scoring system.
Results:
The mean age at diagnosis was 14 years for boys and 12.8 years for girls, with a male predominance (85%). A history of minor trauma and obesity was reported in 55% and 50% of cases, respectively. Thirteen cases (65%) were stable, and seven (35%) were unstable. The disease course was acute in 5 cases (25%), chronic in 8 (40%), and acute on chronic in 7 (35%). The slip was classified as stage I in 10 hips (50%), stage II in 8 (40%), and stage III in 2 cases (10%). All patients received medical treatment with analgesics and anti-inflammatory drugs. Surgical treatment involved in-situ pinning in 80% of cases and pre-reduction pinning in 20%. At a mean follow-up of 4 years, outcomes were very good in 8 hips (40%), good in 9 (45%), fair in 1 (5%), and poor in 2 (10%). Complications included pin breakage in one case (5%) and articular impingement in another (5%). Three hips (16%) developed a slip in the contralateral hip after a mean of 1 year and 4 months.
Conclusion:
Slipped capital femoral epiphysis is no longer a rare condition and should be considered in overweight adolescents. The etiology remains unclear. Treatment varies depending on the severity of the slip. Early diagnosis and appropriate management are crucial for optimal outcomes.

P171

SUBACUTE OSTEOMYELITIS: A DIAGNOSTIC AND THERAPEUTIC CHALLENGE

A. Fekih[1], J. Saadana[1], A. Dhouib[1], A. Lassoued[1], I. Ben Massaoud[1], R. Dhouibi[1], A. Ltifi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective: Subacute osteomyelitis can present with subtle and often misleading features, leading to diagnostic delays. Characterized by insidious onset and a relatively indolent course, it frequently involves the metaphyseal region of long bones.
Case Report: A 12-year-old child presented to the orthopedic emergency department with a five-week history of inflammatory knee pain. There was no history of trauma, and the child was otherwise healthy.
Physical examination revealed a localized swelling adjacent to the anterior tibial tuberosity, a restricted and painful range of motion of the knee, a tenderness to palpation over the proximal tibial metaphysis and absence of fever or skin inflammation
Laboratory investigations showed: White Blood Cell Count (WBC): 10,000 cells/µL and C-reactive protein (CRP): 171 mg/dL
Plain radiograph of the knee demonstrated a rounded, well-defined lytic lesion with surrounding sclerosis in the proximal tibial metaphysis. Magnetic Resonance Imaging (MRI) revealed a central fluid-filled bone lesion with a "target" appearance, characteristic of a Brodie's abscess.
Surgical debridement of the abscess was performed and culture of the abscess fluid yielded Staphylococcus aureus.
Intravenous antibiotics were administered for one week, targeting Staphylococcus aureus (oxacillin and ciprofloxacin). This was followed by a four-week course of oral antibiotics.
The patient experienced a favorable postoperative course with a significant reduction in inflammatory markers. At the one-year follow-up, the patient had made a full recovery with complete resolution of the infection on radiographic evaluation.
Conclusion: Brodie's Abscess is a chronic form of osteomyelitis typically presents insidiously, often with a delay in diagnosis (median of 12 weeks). It predominantly affects young males and commonly involves the tibia and femur.
MRI is the gold standard for diagnosing osteomyelitis, particularly in children, as it provides superior soft tissue contrast and better delineation of bone marrow involvement compared to plain radiographs.
Other imaging modalities, such as bone scintigraphy combined with CT, can offer high diagnostic accuracy, but may not be readily available in all settings.
Staphylococcus aureus remains the most common causative organism.
A multi-modal approach is typically required, including surgical debridement to remove infected bone and tissue, and prolonged antibiotic therapy to eradicate the infection.

P172

SURGICAL TREATMENT OF PROXIMAL HUMERUS FRACTURES: A COMPARATIVE STUDY OF PLATE FIXATION VERSUS INTRAMEDULLARY NAILING

A. Fekih[1], J. Saadana[1], A. Lassoued[1], I. Ben Massaoud[1], R. Dhouibi[1], A. Ltifi[1], A. Dhouib[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective: Proximal humerus fractures are common, particularly in the elderly. Only 15-20% require surgical intervention. The optimal surgical approach remains controversial, with intramedullary nailing (Kapandji technique) and plate fixation being the primary contenders.
Material and Methods: This retrospective study analyzed 90 cases of proximal humerus fractures treated over an eight-year period. Functional outcomes were assessed using the Constant Score. Radiographic outcomes were evaluated based on the criteria of the 1997 SOFCOT symposium.
Results: The study included patients aged 16 to 73 years, with an average age of 43 years. Women were slightly more prevalent.
Extra-articular fractures comprised 64.4% of cases, including 38 surgical neck fractures (42.2%) and 20 subtuberosity fractures with associated greater or lesser tuberosity fractures (22.2%).
Articular fractures accounted for 35.6% of cases, including two anatomical neck fractures (2.2%) and 30 greater tuberosity fractures (33.3%).
Forty-two patients underwent intramedullary nailing (Kapandji technique), while 48 received plate fixation.
Early surgical intervention (within four days) was associated with better functional outcomes. Plate fixation demonstrated significantly higher mean Constant scores (86.3) compared to intramedullary nailing (75.4).
Radiographic union was achieved more rapidly with plate fixation. However, there was no significant difference in the time to radiographic union between the two techniques.
Conclusion: 80-85% of proximal humerus fractures can be managed conservatively. Surgical intervention is indicated for unstable or severely displaced fractures.
While various surgical techniques exist, this study suggests that plate fixation may offer superior functional and radiological outcomes compared to intramedullary nailing.

P173

SYNOVIAL SARCOMA OF THE MIDFOOT: A RARE CASE REPORT

A. Fekih[1], J. Saadana[1], I. Ben Massaoud[1], R. Dhouibi[1], A. Ltifi[1], A. Dhouib[1], A. Lassoued[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Synovial sarcoma is a rare and aggressive soft tissue sarcoma, accounting for 8-10% of all soft tissue sarcomas. While typically diagnosed in young adults (median age 35), it can occur across a wide age range (5-85 years) with a slight male predominance.
This tumor commonly arises near joints and tendons, with the extremities being the most frequent sites of involvement. Pulmonary metastases are the most common mode of distant spread.
Case report:
This report describes a 52-year-old male who presented with a one-month history of painful swelling in his left midfoot. Initially, an infectious etiology was suspected due to his rural background and the presence of fever.
Plain radiograph of the foot demonstrated a lytic lesion involving multiple tarsal bones and the CT scan revealed an extensive bone destruction of the midfoot with involvement of the hindfoot and forefoot. Additional MRI was used to better delineate the extent of bone involvement. This osseous invasion of this magnitude is uncommon in synovial sarcoma.
Histological examination of a biopsy specimen confirmed the diagnosis of a high-grade monophasic synovial sarcoma.
Given the extensive bone involvement, mid-leg amputation was performed.
Postoperatively, the patient received chemotherapy with ifosfamide and anthracyclines, as synovial sarcoma demonstrates moderate sensitivity to these agents.
The patient recovered well from surgery and was fitted with a prosthetic limb. At the one-year follow-up, he was satisfied with his prosthetic function and reported no complications or evidence of tumor recurrence on follow-up MRI.
Conclusion:
Synovial sarcoma should be considered in the differential diagnosis of any unexplained soft tissue mass, particularly in patients with risk factors.
Advanced imaging techniques, such as MRI and CT scan, are essential for accurate staging and surgical planning.
Surgical resection remains the cornerstone of treatment, often requiring wide local excision or limb-salvage procedures.
Adjuvant therapies, such as radiation therapy and chemotherapy, may be considered based on tumor characteristics and patient risk factors.
While significant improvements in survival have been observed in recent decades (5-year survival rates of 59-75%), long-term follow-up is crucial as recurrence can occur years after initial treatment

P174

WHAT IS THE THERAPEUTIC APPROACH FOR A MALUNION OF A BIMALLEOLAR FRACTURE ?

A. Fekih[1], J. Saadana[1], R. Dhouibi[1], A. Ltifi[1], A. Dhouib[1], A. Lassoued[1], I. Ben Massaoud[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba Unviersity Hospital, Monastir, Tunisia, [2]Physical Medecine Department, Tahar Sfar University Hospital, Mahdia, Tunisia

Objective:
Malunions following bimalleolar fractures can have severe consequences for the ankle joint. They often result from inadequate reduction or treatment of the initial fracture.
Case Report:
A 21-year-old male presented with a displaced bimalleolar fracture of the left ankle following a road traffic accident. Initial management involved open reduction and internal fixation (ORIF) with a plate and screws for the fibula and a screw for the tibia. Post-operative recovery was uncomplicated.
However, 60 days later, the patient returned with an ankle deformity following a weight-bearing incident. Radiographs revealed a varus malunion of the ankle with hardware failure. Revision surgery included an ankle arthrolysis, debridement of the non-union site, and stabilization with a plate and screws.
At the latest follow-up, the patient had achieved solid bone union with good ankle mobility and no pain during walking.
Discussion:
Bimalleolar fractures disrupt the bimalleolar fork while preserving the weight-bearing function of the tibial plafond. Displaced fractures are typically treated surgically to restore optimal joint anatomy. This approach minimizes the risk of complications associated with this type of fracture.
Any excessive pain on weight-bearing after a fracture, even within the expected healing timeframe, should prompt a thorough radiographic evaluation. Clinically, patients may complain of instability, malalignment, or difficulty weight-bearing.
The Skinner test can be a useful tool to assess the transverse alignment of the talus. An intra-articular malunion is diagnosed when a solid bony union exists but there is a persistent deformity that alters the joint surface, leading to abnormal weight-bearing and/or instability of the tibiotalar joint.
There is no single, standardized approach to managing intra-articular malunions. Surgical approaches are carefully planned based on the specific deformity and any previous incisions. Generally, surgery involves three steps: repositioning the talus, correcting the malunion with an osteotomy (bone cut) and/or grafting, and internal fixation to maintain the correction.
Conclusion :
Any pain on weight-bearing after an ankle fracture should raise suspicion of an intra-articular malunion. Radiographic findings may be subtle. Early detection allows for timely corrective osteotomies before the development of arthritis, which can complicate conservative management.

P175

RELATIONSHIP BETWEEN HEALTH LITERACY SKILLS AND WALKING BEHAVIOR TO PREVENT OSTEOPOROSIS AMONG HEALTHY VOLUNTEERS

A. Fezaa[1], I. Jabrouni[1], S. Miladi[1], H. Boussaa[1], Y. Makhlouf[1], K. Ben Abdelghani[1], A. Laater[1]

[1]Rheumatology Department , Mongi Slim Hospital, La Marsa, Tunisia

Introduction :
Health literacy is essential for adopting health-promoting behaviors, such as walking, which helps prevent osteoporosis. Improving health literacy enables individuals to understand health information and make informed decisions to reduce their risk of osteoporosis.
This study aims to determine the relationship between health literacy and the adoption of walking behaviors among healthy volunteers.
Methods :
A questionnaire based on the short version of the HELIA-SF (Health Literacy Instrument for Adults-Short Form) was administered to 33 volunteers to assess their health literacy.
The HELIA-SF is a 9-item validated questionnaire originally developed in German, designed to assess health literacy in adults. It measures the ability to comprehend and apply medical information, with higher scores indicating better health literacy.
Walking behavior was assessed as the average number of hours walked per week. Demographic data were collected using self-administered questionnaires.
Results :
The study included 33 volunteers (22 females and 11 males) with a mean age of 34.7 ± 11.8 years. Twenty-four participants (72,7%) had a university-level education, while 9 participants (27,3%) had a secondary-level education.
Nineteen participants reported walking, with an average of 1.39 ± 1.98 hours per week.
The mean health literacy score was 3.8 ± 1.01, with 63.6% classified as having good literacy, 27.3% as having moderate literacy, and 6.1% as having poor literacy.
A significant correlation was observed between health literacy and educational level ($p < 0.001$).
No significant correlations were found between walking behavior and health literacy ($p = 0.13$), age ($p = 0.52$), or educational level ($p = 0.58$).
Conclusion :
No significant relationship was found between health literacy and walking behavior. However, the strong link between health literacy and education highlights the need for targeted interventions to enhance health literacy and encourage preventive behaviors like walking to reduce osteoporosis risk.

P176

APPLICATION OF FRAX-BRAZIL 2.0 IN WOMEN WITH GYNECOLOGICAL MALIGNANT NEOPLASIA

C. Buhl[1], B. Catelo[1], A. Figueirêdo[1], L. Vay[1], L. Sá[1], A. Ferreira[1], C. Nunes[1], A. Pedro[1], L. Baccaro[1], C. Nassar[1], F. Fagionato[1], A. Santana[1], G. Mariuci[1], A. Matsubara[1], A. Azevedo[1], L. Costa-Paiva[1]

[1]University of Campinas, Campinas, Brazil

Objective: To compare the risk of osteoporotic fractures between women with and without a history of gynecological cancer.
Methods: A prospective study with climacteric women with and without gynecological cancer. Participants were included in a 1:1 ratio, matched by age/menstrual pattern. Data were collected in a tertiary hospital between 11/2022 and 12/2024. The dependent variable was the fracture risk score, calculated using FRAX-Brazil 2.0 and classified according to the recommendations of the National Osteoporosis Guideline Group (NOGG), calculated with and without bone mineral density (BMD). The study was approved by the national Ethics Committee.
Results: 188 women, with a mean age of 51.4 (±7.6) years, were included. 48.9% had a history of gynecological cancer. In the FRAX analysis without BMD for the risk of major osteoporotic fractures, 99 (52.7%) were classified as low risk, 79 (42%) as intermediate, 3 (1.6%) as high, and 7 (3.7%) as very high. No differences in risk were observed when comparing women with and without cancer ($p=0.27$). 33 women (17.5%) underwent BMD testing. In the FRAX analysis with BMD for the risk of major osteoporotic fractures, 27 (81.8%) were classified as low, 5 (15.2%) as high, and 1 (3%) as very high. No differences in risk were observed ($p=0.61$). In the FRAX analysis with BMD for hip fracture risk, 25 (75.8%) were classified as low, 5 (15.2%) as high, and 3 (9%)as very high. No differences in risk were observed ($p=0.73$). From the 79 women that were classified as intermediate risk in the analysis without BMD, only 17 (21.5%) underwent the test. Of these, 4 (23.5%) were reclassified to high risk for major osteoporotic fracture and 6 (35.3%) were reclassified to high/very high risk for hip fracture.
Conclusion: A history of gynecological cancer did not influence the risk of fractures. Approximately 35% of women with intermediate risk in the FRAX assessment may not receive the correct treatment if they do not undergo BMD testing.

P177

THE LONG TERM RESULTS OF TREATMENT AND REHABILITATION OF MULTIPLE SCLEROSIS PATIENTS

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Methods: Long term results of treatment of multiple sclerosis were studied. The dynamic monitoring of 110 patients over the period of 1 to 1.5 years following the successful inhospital treatment of MS was carried out. Clinical methods, CT and MRI of cerebrum and spinal cord, and a patented radioimmunobiological assay of the myelinotoxic activity (MTA) of blood serum were used. Results: Four groups of patients were distinguished: group 1 (36 patients; 32.7%) – patients with low MTA level (4.56*0.7 units) after successful hormone therapy. No rehabilitation was required out afterwards. Group 2 included 41 patients (37.3%) with low MTA level (3.76*0.81) after hormone and corrector therapy; a rehabilitation course was carried out at a later stage. Group 3 consisted of 22 patients (20.0%) that required long term immunomodulating therapy due to a higher rate of demyelinisation (MTA = 19.2*0.43). The remaining 11 patients (group 4, 10.0%) with moderate rate of demyelinisation (16.4*0.52) were prescribed general health improvement therapy and rehabilitation based on intensive motional activity and physical exercise. Conclusions. Hormone therapy helps to reduce the demyelinisation rate to acceptable level within 2 to 4 month. The subsequent rehabilitation helps to achieve the extended remission period. However, long time after treatment of acute MS the hormone therapy is not justified.

P178

DIFFERENTIAL DIAGNOSIS AND TREATMENT OF MYOTONIC AND MYOFASCIAL SYNDROMES OF NECK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objectives: The dynamic monitoring of 195 patients with myotonic and myofacial syndromes of neck pain was done against the control group of 45 people.
Methods: MRI of cervical and vertebrocranial areas of spinal column, electromyography of 7 to 9 relevant muscles, finding of the "key" muscle and the overall computer aided assessment of osteomuscular, cardiorespiratory and oxygen transport system disorders. Results: Clinical and electromyographic criteria for diagnosis of myotonic and myofascial syndromes of neck pain were identified based on the occurrence rates. The role of major system disorders in pathogenesis of neurological manifests of neck pain was studied. New therapeutic approaches to stopping pain and myotonic syndromes were developed; the effectiveness of early rehabilitation measures was demonstrated. The prevailing myotonic syndromes were identified which were the musculus obliquus capitis inferior syndrome (in 68, or 39.4% patients); superscapular area syndrome (33% of patients); musculus scalenus anterior and musculus scalenus medius syndromes (18.9%); musculus pectoralis minor syndrome (9.7%).
Hypodynamia caused system disorders were noted in 78.3% patients including excessive body mass and fat content; reduced blood circulation rate and heartbeat volume and the pronounced decrease of PWC170. The most informative spondylographic findings were reduced thickness of posterior areas of intervertebral disks from CI to CVII (52.3 to 77.9% of patients), cervical lordosis impression (76.4%) and uncovertebral arthroses (58.2%).
Conclusions: The most seriously affected ("key") muscles in neck pain patients were found. Diagnosis and treatment strategies for neck pain patients were developed

P179

TECHNICAL MEANS OF REHABILITATION FOR PATIENTS WITH LOW BACK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Background and Aims: 78 patients with myotonic (MT) syndrome Methods: Patients went through the clinical estimation of neurologic status, manual testing of muscles, CT and MRI of back bone lumbar department, interferential and needle electromyography of the most damaged muscular groups, dosed loading veloergometry, revasography of feet, and shins. Results: Medical-rehabilitation complex on damaged extremity was approbated in 27 patients with MT syndrome. The complex included oral reception of katadolon (100 mg 3 times a day for 10days), tractions on Fintrac-471 table (with force from 3 to 55 kg, a course of 8-10 sessions) and also acupuncture with use acupuncture points of general action with vascular autonomic nervous system orientation (G14, MJ6, E36, RP6, TR5, V40) and locally-segmented points on the most damaged muscular groups (AT60, VB30 with deep introduction to piriform muscle; VB 34, VB41, F3). Conclusions: After treatment damaged extremity pain has completely disappeared in 19 patients, pain essentially decreased and increased tolerance of physical activity in 6 patients. It is established, that katadolon shows not only analgesic and neuroprotective, but also myorelaxing action on muscles of pelvic girdle and feet in patients with acute and chronic pain syndrom.

DIFFERENTIAL DIAGNOSIS AND TREATMENT OF MYOTONIC AND MYOFASCIAL SYNDROMES OF NECK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objectives
The dynamic monitoring of 195 patients with myotonic and myofacial syndromes of neck pain was done against the control group of 45 people.
Methods
MRI of cervical and vertebrocranial areas of spinal column, electromyography of 7 to 9 relevant muscles, finding of the "key" muscle and the overall computer aided assessment of osteomuscular, cardiorespiratory and oxygen transport system disorders.
Results
Clinical and electromyographic criteria for diagnosis of myotonic and myofascial syndromes of neck pain were identified based on the occurrence rates. The role of major system disorders in pathogenesis of neurological manifests of neck pain was studied. New therapeutic approaches to stopping pain and myotonic syndromes were developed; the e□ectiveness of early rehabilitation measures was demonstrated. The prevailing myotonic syndromes were identified which were the musculus obliquus capitis inferior syndrome (in 68, or 39.4% patients); superscapular area syndrome (33% of patients); musculus scalenus anterior and musculus scalenus medius syndromes (18.9%); musculus pectoralis minor syndrome (9.7%).
Hypodynamia caused system disorders were noted in 78.3% patients including excessive body mass and fat content; reduced blood circulation rate and heartbeat volume and the pronounced decrease of PWC_{170}. The most informative spondylographic findings were reduced thickness of posterior areas of intervertebral disks from CI to CVII (52.3 to 77.9% of patients), cervical lordosis impression (76.4%) and uncovertebral arthroses (58.2%).
Conclusions
The most seriously a□ected ("key") muscles in neck pain patients were found. Diagnosis and treatment strategies for neck pain patients were developed.

P181

TECHNICAL MEANS OF REHABILITATION FOR PATIENTS WITH LOW BACK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Background and Aims
78 patients with myotonic (MT) syndrome
Methods
Patients went through the clinical estimation of neurologic status, manual testing of muscles, CT and MRI of back bone lumbar department, interferential and needle electromyography of the most damaged muscular groups, dosed loading veloergometry, revasography of feet, and
shins.
Results
Medical-rehabilitation complex on damaged extremity was approbated in 27 patients with MT syndrome. The complex included oral reception of katadolon (100 mg 3 times a day for 10 days), tractions on Fintrac-471 table (with force from 3 to 55 kg, a course of 8-10 sessions) and also acupuncture with use acupuncture points of general action with vascular autonomic nervous system orientation (G14, MJ6, E36, RP6, TR5, V40) and locally-segmented points on the most damaged muscular groups (AT60, VB30 with deep introduction to piriform muscle; VB 34, VB41, F3).
Conclusions
After treatment damaged extremity pain has completely disappeared in 19 patients, pain essentially decreased and increased tolerance of physical activity in 6 patients. It is established, that katadolon shows not only analgesic and neuroprotective, but also myorelaxing action on muscles of pelvic girdle and feet in patients with acute and chronic pain syndrom.

PATHOGENESIS OF COGNITIVE NEUROSIS-LIKE DISORDERS IN PATIENTS WITH INITIALLY CHRONIC VIRAL ENCEPHALITIS

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Methods: brain MRI, research of cerebrospinal fluid and its dinamic, definition of a spectrum of 20 basic amino acids in blood serum and liquor
Results: 126 patients with initial chronic viral encephalitis were surveyed. The most significant and informative appeared the decrease in free amino acids: serine (5,12±0,15mg/l; P< 0,01), glycine (6,59±0,2mg/l; P< 0,001), histidine (5,11±0,12mg/l; P< 0,05), alanine (12,93±0,12mg/l; P< 0,001), arginine (5,62±0,09mg/l; P< 0,001), tyrosine (5,08±0,09mg/l; P< 0,001), meteonin (2,19±0,12mg/l; P< 0,001), phenylalanine (3,36±0,14mg/l; P< 0,001), lysine (6,94±0,17mg/l; P< 0,001), leucine (4,64±0,14mg/l; P< 0,001), threonine (6,2±0,14mg/l; P< 0,001), glutamic acids (2,99±0,16mg/l; P < 0,001) at simultaneous increase in concentration of tryptophan (7,36±0,12mg/l; P < 0,001). Among the connected amino acids in CMЖ the reliable increase, in comparison with control group healthy participants was observed, glycine (11,44±0,13mg/l; P < 0,001), histidine (6,12±0,11mg/l; P< 0,001), methionine (5,86±0,07mg/l; P < 0,01), lysine (19,42±0,16mg/l; P < 0,001), leucine (18,94±0,14g/l; P< 0,01), threonine (18,94±0,14mg/l; P < 0,001), glutamic acids (9,69±0,17mg/l; P < 0,001).
Conclusion: In pathogenesis of cognitive neurosis like disorders in patients with initial chronic viral encephalitis the great importance has the decrease in content of the majority

free and bonded amino acids in cerebrospinal fluid and blood serum (alanine, glycine, glutamic acids, leucine, methionine, threonine, tryptophan, phenylalanine) at simultaneous increase of tryptophan, that it must be considered atcarrying out of therapeutic actions.

P183

SOME ASPECTS OF REHABILITATION FOR PATIENTS WITH LOW BACK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objectives: Examination of 78 patients with myotonic (MT) syndrome of lumbar osteochondrosis. Methods
Patients went through the clinical estimation of neurologic status, manual testing of muscles, CT and MRI of back bone lumbar department, interferential and needle electromyography of the most damaged muscular groups, dosed loading veloergometry, revasography of feet, and shins.
Results: It was established for the first time, that among MT-syndrome patients 54 (69,2 %) an associated damage of two or more muscles prevailed. The most damaged ("key") muscles appeared to be gastrocnemius muscle (43; 55,1 %), gluteus medius (42; 53,82 %), quadriceps femoris (36; 46,2%), rectus abdominis and external oblique (32; 41,1 %), peroneal muscle (29; 37,2 %), piriform muscle (29; 37,2 %), lumbar quadrate muscle (28; 35,9 %), gluteus maximus (19; 24,3 %), gluteus minimus (16; 20,5 %), adductor (14; 17,9 %) and abductor (9; 11,5 %) thigh muscles.Medical-rehabilitation complex on damaged extremity was approbated in 27 patients with MT syndrome. The complex included oral reception of katadolon (100 mg 3 times a day for 10 days), tractions on Fintrac-471 table (with force from 3 to 55 kg, a course of 8-10 sessions) and also acupuncture with use acupuncture points of general action with vascular autonomic nervous system orientation (G14, MJ6, E36, RP6, TR5, V40) and locally-segmented points on the most damaged muscular groups (AT60, VB30 with deep introduction to piriform muscle; VB 34, VB41, F3)
Conclusion: After treatment damaged extremity pain has completely disappeared in 19 patients

P184

IMMUNOLOGICAL DISORDERS IN MULTIPLE SCLEROSIS PATIENTS WITH THE PRESENCE OF FOOD ALLERGY

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Background and Aims
102 multiple sclerosis patients 19 to 33 years old were examined against the control group of 20 healthy people.
Methods
MRI and immunological studies
Results
All patients on the level of IgE in blood serum of 20 basic food products are divided into four groups: the first (13 pers, 12.7%) with the absence of IgE in serum, second (29 pers., 28.5%) with the presence of IgE (threshold 0,35-0,69 IU / ml); third (45 pers., 44.1%) with a moderate increase in IgE (0,70-3,49 IU / ml); 4 st (15 pers., 14.7%) with a significant increase in IgE (3,50-17,49 IU / ml) in serum. Patients first group without clinical signs of apparent exacerbation of MS were observed in blood eosinophilia, and the brain MRI revealed hyperintense foci in a single T-2W mode, indicating the absence of active demyelinating process.
Patients with the second group with a slow chronic course of MS were determined by individual eosinophils (18.1%), indicating that they have a weak allergic reaction. Identification of individual hypo-and hyperintense lesions on brain MRI evidence of chronic course of demyelinating process in the presence of rare clinical exacerbations was seen by us as secondary progressive MS. In the third group investigated the apparent worsening of the process of clinical signs detected a moderate increase in serum IgE (45 pers., 44.1%) in the presence of explicit eosinophilia (11.8%).
Conclusions
Markers of exacerbation of MS is the simultaneous moderate increase in serum IgE eosinophilia, and the appearance of new lesions on MRI brain.

REHABILITATION TECHNOLOGY OF PATIENTS WITH SYMPTOMATIC EPILEPSY

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

OBJECTIVE:220 patients with symptomatic epilepsy were examined.
MATERIAL-METHODS: Neurological examination, MRI, EEG.
RESULTS: Prepared technology rehabilitation of patients with symptomatic epilepsy caused by organic diseases of the central nervous system. The technology is intended for use by inpatient and outpatient o□ces rehabilitation, medical and rehabilitation expert committees, clinics, health resorts organizations in order to improve the outcome of the disease, prevent the development of disability or reduced the severity of violations, Disability formed under disability. The technology includes: selection of the object and the subject of rehabilitation of rehabilitation; expert-rehabilitation diagnostics; evaluation of rehabilitation potential, rehabilitation prognosis; medical examination (with evaluation categories and the degree of Disability, the risk of disability); formation and practical implementation of individual rehabilitation programs; evaluation of the e□ectiveness rehabilitation and formation of further rehabilitation of the route.
CONCLUSION: With the formation of medical rehabilitation measures provided by the integrated use therapy, medical physical training, medication correction, physical therapy, dietetics, the organization "School of the patient."

IMMUNOLOGICAL DISORDERS IN MULTIPLE SCLEROSIS PATIENTS WITH THE PRESENCE OF FOOD ALLERGY

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Background and Aims: 102 multiple sclerosis patients 19 to 33 years old were examined against the control group of 20 healthy people.
Methods: MRI and immunological studies
Results: All patients on the level of IgE in blood serum of 20 basic food products are divided into four groups: the first (13 pers, 12.7%) with the absence of IgE in serum, second (29 pers., 28.5%) with the presence of IgE (threshold 0,35-0,69 IU / ml); third (45 pers., 44.1%) with a moderate increase in IgE (0,70-3,49 IU / ml); 4 st (15 pers., 14.7%) with a significant increase in IgE (3,50-17,49 IU / ml) in serum. Patients first group without clinical signs of apparent exacerbation of MS were observed in blood eosinophilia, and the brain MRI revealed hyperintense foci in a single T-2W mode, indicating the absence of active demyelinating process. Patients with the second group with a slow chronic course of MS were determined by individual eosinophils (18.1%), indicating that they have a weak allergic reaction. Identification of individual hypo-and hyperintense lesions on brain MRI evidence of chronic course of demyelinating process in the presence of rare clinical exacerbations was seen by us as secondary progressive MS. In the third group investigated the apparent worsening of the process of clinical signs detected a moderate increase in serum IgE (45 pers., 44.1%) in the presence of explicit eosinophilia (11.8%).
Conclusions: Markers of exacerbation of MS is the simultaneous moderate increase in serum IgE eosinophilia, and the appearance of new lesions on MRI brain.

SEVERE OSTEOPOROSIS IN A CASE WITH MULTIPLE RISK FACTORS AND RECENT TOTAL LEFT HIP ARTHROPLASTY

A. Gherle[1], M. Cevei[1], D. Stoicanescu[2], F. Andronie Cioara[1], M. S. Deac[1], R. Mihut[1]

[1]UNIVERSITY OF ORADEA, FACULTY OF MEDICINE AND PHARMACY, ORADEA, Romania, [2]University of Medicine and Pharmacy "Victor Babes", Timisoara, Timisoara, Romania

Objective: To monitor the functional status of a patient with multiple risk factors and severe osteoporosis, with recent total left hip arthroplasty and determining the effectiveness of rehabilitation interventions, such as physical therapy and gait training programs.
Material and methods: A 68-year-old woman presented herself in our outpatient unit for: gait difficulties; pain in the left foot; right coxalgia; dorsalgia. The patient's medical history includes severe osteoporosis since 2020, chronic venous insufficiency; flat foot and hallux valgus bilateral; facet joint syndrome lumbar and a recent total left hip arthroplasty in 05.2024. For assessing bone mineral density (BMD) we used DXA. We assessed patient's grip strength using Jamar dynamometers at the first evaluation and the last evaluation. Walking ability and speed were assessed using 10m walking test and TUG(Time Up and Go) test at the time of the first evaluation and during last evaluation. She underwent complex rehabilitation therapy in our facility for 10 days including hydrokinetotherapy, individual kinetotherapy, LASER terapy, electromechanotherapy- Deep Oscilation.
Results and discussions: The muscle strength at last evaluation improved compared to the value measured at the first evaluation (26 kg vs 20 kg) reflecting enhanced upper body strength and overall functional capacity, which is essential for mobility and reducing fall risk. There was a slight improvement of gait speed at the last evaluation compared to first evaluation (1.8 m/s vs 1.05 m/s). TUG test revealed as well improvement at the final evaluation vs first evaluation(11.6 s vs 15.4). demonstrating improved balance, mobility, and reduced risk of falls DXA scores measured during the 2 weeks period of physical therapy were as follows: T-Score left hip: -3.5; T-Score right hip: -3.7; T-score lumbar spine: -3.8.
Conclusions: DXA high scores confirmed severe osteoporosis in this case emphasizing the need for continued management, including pharmacological treatment and preventive strategies. The results underline the importance of individualized, comprehensive rehabilitation programs in patients with severe osteoporosis, and long-term osteoporosis management is recommended to maintain and further improve functional independence while minimizing fall risk and associated complications.

P188

DETECTING PATIENTS WITH OSTEOPOROSIS USING NATIONWIDE CLAIM DATA IN IRAN

A. Golestani[1], M. Farshbafnadi[1], S. Bostani[1], M. Rezaee[2]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Orthopaedics Department of Orthopedics, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran

Objective: Claim data are large-scale datasets offer valuable information for various epidemiologic applications. One application is the detection of patients by health systems, which can be used to estimate disease burden and formulizing individualized follow-up strategies. However, prescription data in many developing countries, including Iran, often lacks specific diseases diagnosis. This study aimed to develop a decision rule using prescription data from a public insurance organization in Iran to identify patients with osteoporosis.
Methods: This study utilized prescription data from the Iran Health Insurance Organization (IHIO) from 2014 to 2017 across 24 of 31 provinces of Iran. The IHIO is one of the largest public

insurance providers in Iran that covers approximately 50% of the population. Only prescriptions for patients aged ≥ 18 years without any missing values were included. Based on literature review and expert consultation, medications including G03XC01 (raloxifene), H05AA (parathyroid hormones and analogs), H05BA (calcitonin preparations), and M05BA (bisphosphonates) were selected as medication with potential usages for osteoporosis treatment. The drug prescription score and the generalized extreme studentized deviate test (GESDT) were used to develop decision rules.

Results: A total of 112,532,876 prescriptions from 14,785,795 patients (56.2% female) were evaluated. Medications potentially related to osteoporosis were prescribed 816,217 times. The exploratory analysis resulted in a decision rule that identified patients receiving at least one prescription for H05AA or H05BA as having osteoporosis. Receiving bisphosphonates were included in the decision rule unless prescribed by hematologists or radiotherapists, because their prescription could possibly be due to bone cancer treatment. Applying this rule identified 405,975 patients (2.75%) as having osteoporosis, with 109,085 (0.74%) diagnosed in the last year of the study. The prevalence of osteoporosis was higher in females (4%) compared to males (1%) and increased from 0.31% in the 18–24 age group to 5.65% in those aged 50–59 and 7.6% in those ≥ 75, peaking at 8.6% in the 60–74 age group. Prevalence varied by province, ranging from 1.4% in Hormozgan and Sistan and Baluchestan to 5% in Isfahan.

Conclusions: Previous studies indicated a prevalence of osteoporosis of 38% in women and 25% in men aged ≥ 50 in Iran (1). However, the prevalence detected through our prescription-based method was under 9% for above 50 years old age groups, suggesting underdiagnosis and undertreatment. Identifying patients with their initial prescriptions enables health systems to implement targeted follow-ups and strategies to prevent disease progression.

P189

DECOMPOSITION ANALYSIS OF FALL INCIDENCE CHANGES IN THE NORTH AFRICA AND MIDDLE EAST REGION FROM 1990 TO 2021

A. Golestani[1], Y. Azizpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Falls represent a significant public health concern due to their substantial impact on morbidity and quality of life. The North Africa and Middle East (NAME) region, characterized by rapid population growth and demographic shifts toward aging, offers a unique context to examine long-term trends in fall incidence. This study aims to understand the drivers of these changes over the past three decades, providing insights to inform targeted prevention strategies.

Methods: Data on fall incidence by year and sex were obtained from the Global Burden of Diseases (GBD) 2021 repository. Estimates were reported with 95% uncertainty intervals (95% UIs). Decomposition analysis was conducted under two scenarios: (1) applying 1990 age-specific incidence rates to the 2021 population to isolate the effect of population growth, and (2) applying 1990 age-specific rates while accounting for changes in age structure and sex distribution. Differences between observed and estimated cases in these scenarios were attributed to population growth, population aging, and changes in age-specific incidence rates.

Results: From 1990 to 2021, the total fall incidence in the NAME region increased by 106.0% (95% UI: 93.7 to 119.5), rising from 6.9 million (6.0 to 8.1) to 14.3 million (12.7 to 16.2). However, the age-standardized fall incidence rate per 100,000 population showed a smaller increase of 19.3% (15.4% to 23.7%) during the same period, from 1,911.8 (1,692.7 to 2,192.1) to 2,281.7 (2,042.5 to 2,564.7). In 2021, the highest age-standardized rates per 100,000 population were observed in Qatar (3,371), the United Arab Emirates (3,463), and Oman (3,054), while the lowest rates were reported in Afghanistan (1,243), Egypt (1,314), and Yemen (1,459). Decomposition analysis revealed that the increase in fall incidence was primarily driven by population growth (83.7%) and changes in age-specific incidence rates (30.6%), while population aging contributed negatively (-8.4%). Most countries followed a similar pattern, with population growth as the dominant factor. However, some countries, such as Qatar and Saudi Arabia, exhibited distinct patterns (Table 1).

Conclusions: Fall incidence in the NAME region has significantly increased, primarily due to population growth and changes in age-specific rates, while population aging has had a negative contribution. Despite progress in controlling falls among older adults, the region's growing population necessitates improved and targeted prevention strategies for all age groups.

Table 1. Decomposition analysis of fall incidence between 1990 to 2021 in North Africa and Middle East and its countries.

	New cases		Expected new cases		Contribution of each factor			
location	1990	2021	Population growth	Population growth + Aging	Population growth (%)	Population aging (%)	age-specific Incidence rate change (%)	Overall change (%)

P190

MORBIDITY ATTRIBUTABLE TO LOW BONE MINERAL DENSITY SHOULD TAKE PRIORITY OVER ATTRIBUTABLE MORTALITY IN THE NORTH AFRICA AND MIDDLE EAST REGION

A. Golestani[1], Y. Azizpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Low bone mineral density (LBMD) is a significant risk factor for morbidity and mortality, particularly in older adults. This study estimates the burden of LBMD and evaluates potential life expectancy gains from eliminating this risk to guide policymaking in the North Africa and Middle East (NAME) region.

Methods: The Global Burden of Disease Study 2021 was used as the data source for death, years of life lost (YLL), years lived with disability (YLD), and disability-adjusted life years (DALYs) attributable to LBMD from 1990 to 2021. The burden attributable to LBMD was incorporated in the population-attributable fraction for the estimation of deaths and DALYs and was presented with 95% uncertainty intervals (95% UIs). The effect of LBMD on life expectancy was estimated via cause-deleted life tables, which were computed hypothetically by considering the years of life that would be saved by lowering the levels of LBMD to the theoretical minimum risk exposure level (TMREL) (1).

Results: From 1990 to 2021, DALYs attributable to LBMD increased from 390.8 thousand (95% UI: 328.4 to 449.0) to 798.5 thousand (661.0 to 940.0). Deaths attributable to LBMD rose from 9,106.7 (7,683.8 to 10,245.2) to 17,730.7 (14,883.1 to 20,211.1). However, age-standardized rates per 100,000 population decreased for DALYs (from 226.2 [189.4 to 261.2] to 167.6 [139.0 to 197.2]) and deaths (from 6.4 [5.4 to 7.4] to 4.5 [3.8 to 5.1]). The YLD age-standardized rate per 100,000 remained stable at approximately 80 between 1990 and 2021, whereas the YLL rate declined from 141.8 to 93.8. This resulted in an increase in the YLD-to-YLL ratio from 0.6 to 0.8. Life expectancy gains from removing LBMD as a risk factor were minimal across all countries and age groups, adding approximately 0.03 years overall, with percentage increases remaining below 1% even in older populations (Figure 1).

Conclusions: The rising YLD-to-YLL ratio and minimal gains in life expectancy from eliminating LBMD highlight the effectiveness of interventions in reducing mortality. However, the remaining burden is predominantly related to morbidity. Policymakers should prioritize strategies aimed at reducing the morbidity associated with LBMD rather than focusing solely on mortality reduction.

Figure 1. Changes in life expectancy by age in North Africa and Middle East region and its countries in 2021 if low bone mineral density (LBMD) had been lowered to the theoretical minimum risk exposure levels.

P191

ASSOCIATION OF FRACTURES DUE TO FALLS WITH SOCIO-DEMOGRAPHIC INDEX (SDI) AT THE GLOBAL LEVEL

A. Golestani[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Bone fractures represent a significant global public health concern due to their associated disability. Falls are the leading cause of fractures. Analyzing the burden of fractures and their subtypes attributable to falls in relation to the socio-demographic index (SDI) provides valuable insights for policymakers to design targeted interventions.

Methods: Data on the prevalence, incidence, and years lived with disability (YLDs) of fractures and their subtypes due to falls, as well as SDI values for different regions, were extracted from the Global Burden of Disease Study (GBD) 2021 data repository. Results were reported with 95% uncertainty intervals (95% UIs). Locally estimated scatterplot smoothing (LOESS) regression was employed to evaluate the association between SDI and fracture

burden metrics.

Results: Between 1990 and 2021, the absolute number of fractures due to falls increased significantly: incidence rose from 67.2 million (95% UI: 57.1–79.6) to 100.5 million (87.9–114.3), prevalence grew from 158.2 million (138.0–178.9) to 275.8 million (243.6–307.3), and YLDs rose from 8.9 million (6.0–12.5) to 15.3 million (10.3–21.6). However, age-standardized rates per 100,000 population showed a declining trend: incidence decreased by 7.0%, prevalence by 9.8%, and YLDs by 12.1%. Fracture patterns remained consistent across years and locations (Figure 1). The most prevalent and disabling fractures due to falls were those of the patella, tibia, or femur (approximately 66% and 70%, respectively), followed by hip fractures (16% and 10%). However, the proportion of other fractures, particularly fractures of the radius and/or ulna, increased for incidence, reaching approximately 21%. The burden of fractures due to fall—incidence, prevalence, and YLDs—was strongly associated with SDI, with a significant positive correlation (r = 0.75) (Figure 2). Prevalence exhibited the strongest association with SDI, with a coefficient of 9060.9.

Conclusions: While global age-standardized rates of fracture incidence, prevalence, and YLDs due to falls declined slightly from 1990 to 2021, absolute numbers increased substantially, underscoring the growing burden. The high prevalence and YLDs associated with fractures of the patella, tibia, or femur and hip are particularly concerning due to their severe consequences, necessitating targeted preventive measures. The positive association between SDI and fracture burden highlights the need for policymakers in high-SDI regions to prioritize strategies aimed at reducing falls and their impact.

Figure 1. The proportion of different subtypes of fracture due to fall in different location in 1990 and 2021.

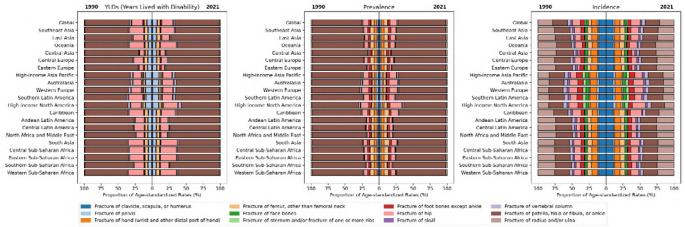

Figure 2. The association of different burden measures of fracture due to fall with socio-demographic index (SDI).

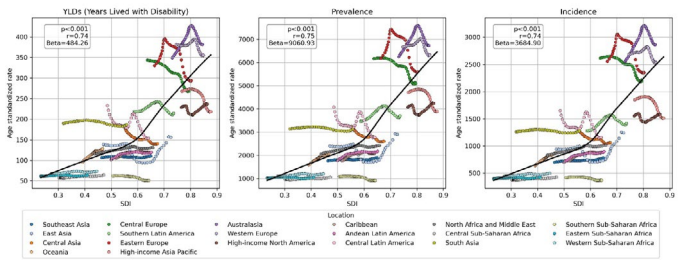

P192

SERUM CHOLESTEROL AS A MODIFIABLE CARDIOVASCULAR RISK FACTOR AMONGST PATIENTS ON ROMOSOZUMAB TREATMENT

A. Gupta[1]

[1]glangwili hospital, Carmarthen, United Kingdom

Introduction: Romosozumab is a potent and effective anabolic treatment for patients at very high fracture risk. Cardiovascular(CV) safety concerns were raised from ARCH trial in the Romosozumab group when compared to the Alendronate group. Osteoporosis patients are elderly and many have associated cardiovascular risk factors some of which are modifiable thereby having potential to modify romosozumab potential CV side effects

Objective: the aim of study was to measure lipid profile of patients who were started on Romosozumab and to modify elevated levels of high cholesterol >4 mmol/L)and LDL (>1.8 mmol/L).

*Methods:*Setting-single-centre specialist osteoporosis clinic in a teaching hospital in UK) Subjects- high fracture risk patients who have qualified for Romosozumab. Intervention- Serum lipid profile was measured before and at the end of one year romosozumab treatment and patients with elevated levels were advised atorvastatin 20 mg or 40 mg(if already on statin) /day via letter to GP.

Results: 27 patients have not finished injromosozumab course. Out of 20patients completed Romosozumab, average age of 69years (range 65 to 80).All were postmenopausal females. The average baseline 5-year fracture risk was 18.1% ± 8.6% for MOP fractures and 8.8 ± 5.4% for hip fractures. The baseline 5-year cardiovascular risk (QRISK-3)was7.8 ± 4%. The most common cardiovascular risk factors were hypertension (35%), history of smoking (4%), current smoking (2%), diabetes mellitus Type 2 (5%).Serum total cholesterol >4 mmol/L (range 4.1 to 8.2) in 19/20 and LDL > 1.8 mmol/L (range 2 to 5.2)in 17/20 patients. 19 patients advised cholesterol lowering drug out of which 2 had intolerance, others completed 12 months. At the end of one year romosozumab treatment, the serum cholesterol and LDL levels were significantly lower –mean TC 4.8 and LDL was 1.1. No patient suffered any adverse CV event during study period.

Conclusion: Patients suitable for romosozumab had a high fracture risk but also have cardiovascular risk factors. Given the substantial benefits of romozosumab on fracture risk reduction, patient's CV risk status can be easily modifiable thereby reducing any suspected CV side effect of romosozumab. Prescribing physicians should assess and treat modifiable CV risk factors such as hypertension, smoking, diabetes, obesity and hypercholesterolaemia and not exclude potential patients who could have huge fracture risk reduction benefits.

P193

REAL WORLD EXPERIENCE OF ROMOSOZUMAB IN A TERTIARY SPECIALIST CLINIC

A. Gupta[1]

[1]glangwili hospital, Carmarthen, United Kingdom

Objective: This study aimed to investigate the real-world experience of 12 months of romosozumab treatment on acceptability, tolerability, BMD increase and identify factors that predict the rate of BMD increase after 12 months of romosozumab treatment.

Methods:setting-tertiary centre clinic. We prospectively investigated 52 patients commenced on 12-month romosozumab treatment for osteoporosis with a high risk of fractures at a hospital in UK. Data on BMD, fragility fracture before and during the treatment was collected. Reasons for any discontinuation, patient feedback and nursing staff experience was recorded.

Results –average age 64 yrs (Range 60 to 80 yrs) All females. Amongst 52 patients with high fracture risk eligible and offered Romosozumab treatment, 1 refused, 27 still ongoing 20 completed one year course. 155 high risk patients could not be started on treatment as males(12) (not licenced), high QRISK score(55) patient refusal (3) ,patients with frailty/comorbidities/cognitive impairment(85), fracture more than 2 yrs before (delayed presentation to clinic)(40).
34 patients were naïve and not received antiresorptive treatment before. After 1 year of treatment, the lumbar spine BMD increased by 14.6%, and femoral neck BMD increased by 5.1%. There were superior BMD gains when romosozumab is given to treatment-naïve patients before antiresorptive drugs. Patients with lower BMD before receiving romosozumab were more likely to have increased BMD with romosozumab treatment. No patient suffered a fragility fracture during treatment. The drug was well tolerated by all except one patient discontinued after 3 doses due to rash. Patient and nursing feedback was very good.
Conclusion, our real world study demonstrated the effectiveness,-acceptability and safety of the 12-month romosozumab treatment for osteoporosis on both hip and spine BMD in patients at high risk of fractures which supports results of randomised trials. Majority of patients who were offered Romosozumab accepted advice. A large percentage of high fracture risk patients are being denied the benefits of this potent osteoporosis drug due to suspected CV safety concerns and strict NICE criteria. These findings support the CV safety and tolerability of romosozumab in eligible patients. Anabolic-first approach is needed for maximum benefits and strategies are needed for early identification and referral of this cohort.

P194

HOW COMMON IS VITAMIN D DEFICIENCY IN HIGH RISK POPULATION?

A. Gupta[1], D. R. Biswas[2]

[1]glangwili hospital, Carmarthen, United Kingdom, [2]royal glamorgan hospital, Pontypridd, United Kingdom

Objectives: Vitamin D deficiency is defined as a risk factor for osteoporotic fractures but the prevalence in the subgroup of frail older hospitalized patients is not clear. We sought to investigate the prevalence and predictors of vitamin D deficiency in frail older hospitalized patients.
The aim of this study was to evaluate serum levels of 25-hydroxyvitamin D (25OHD) in high fracture risk hospitalised patients with or without fragility fractures
Methods: we measured the serum 25OHD levels of 45 patients admitted with vertebral fractures, 87 patients with hip fractures, 35 patients with Parkinsons disease , 220 patients with frailty to evaluate the prevalence of vitamin D insufficiency. Those who were receiving antiosteoporosis therapy including vitamin D were excluded. Serum 25 (OH)D concentrations < 29.9 nmol/L and between 30 and 49.99 nmol/L were classified as deficient and insufficient, respectively, whereas concentrations ≥50 nmol/L were considered as desirable. A stepwise binary logistic regression model was performed to assess the simultaneous effects of age, gender and comorbidities on the prevalence of low vitamin D concentration.
Results: Mean age of the cohort was 83.6±8.0 years (72% females) only 5% had desirable serum concentrations ≥50 nmol/L , 25% had concentrations in insufficiency range 70% were in deficiency range. Vitamin D deficiency and insufficiency was prevalent in high fracture risk patients (71%) and more common in female patients (78%). Univariate logistic regression analysis showed age, gender, bone mass index (BMI), femoral neck BMD, calcium, and vitamin D levels were significantly different between patients with fragility fractures and the control group. 25OHD levels was not significantly associated with their underlying diseases, such as diabetes mellitus, hypertension or stage of chronic kidney disease but were significantly lower in patients with recurrent falls and frailty. The other markers, albumin, alkaline phosphatase, PTH were not significantly associated with 25OHD levels.
Conclusion: In the group of frail older hospitalized patients without previous vitamin D supplementation, the prevalence of inadequate vitamin D concentrations is extremely high. Vitamin D insufficiency is likely to be an important risk factor for fragility fractures as well as patients with recurrent falls and frailty in both men and women but more pronounced in females. Therefore, usefulness of the routine measurement of vitamin D status before initiating of supplementation appears to be questionable in this patient group. Further studies to evaluate possible routine supplementation of Vitamin D (simple and cheap intervention) to derive its benefits in this high risk group is needed.

P195

WHAT IS KNOWLEDGE ATTITUDE AND PRACTICE TOWARDS OSTEOPOROSIS ?

A. Gupta[1], R. B. Biswas[2]

[1]glangwili hospital, Carmarthen, United Kingdom, [2]royal glamorgan hospital, Pontypridd, United Kingdom

Objective: To identify the level of knowledge, attitude, and practice (KAP) toward osteoporosis amongst nurses and medical students at a teaching hospital in United Kingdom.
Methods: A cross-sectional design was adopted in this study. A convenience sample of 150 trained nurses working in medical and orthopaedic wards and 150 medical students (Year 4 and 5) were given a self administered questionnaire. The assessment tool used in the current study contained 35 items, measuring KAP amongst a cohort of teaching hospital nurses and students toward osteoporosis. Part 1-demographic details. Part 2 –knowledge amongst participants. Part 3 attitudes towards osteoporosis Part 4- their practice. The correlation Pearson test and regression test were used to analyze data using Statistical Package for Social Sciences.
Results: The total KAP scores were 25, 38, and 20 respectively amongst nurses and 45, 58 and 65 amongst medical students. These results revealed that nurses have a moderate level of KAP toward osteoporosis with better scores amongst medical students.
Conclusions: nurses who regularly deal with high risk osteoporosis patients showed a moderate KAP and had major gaps on knowledge, their attitudes and clinical practice towards osteoporosis. Their training and education needs to be improved as an effective step to reducing the growing incidence and impact of osteoporosis. Medical students had higher scores possibly due to better training programs. The lack of KAP can have a serious and growing impact on the health sector and patients' health in terms of cost, healthcare resources, and social impact. Nurses and medical students can play a valuable role in educating patients on bone fractures/osteoporosis, its risks, and prevention, as well as in helping them with nutrition, drug and lifestyle recommendations.

P196

OSTEOPOROSIS AS A MANIFESTATION OF LYSINURIC PROTEIN INTOLERANCE

A. Halasheuskaya[1], A. Pachkaila[2]

[1]Belarusian State Medical University, Minsk, Belarus, [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

Objective: To present a case of severe osteoporosis in a child with lysinuric protein intolerance. Lysinuric protein intolerance (LPI, OMIM: 222700) is a rare autosomal recessive disorder caused by mutations in the SLC7A7 gene. The pathogenesis is based on impaired transport of cationic amino acids (lysine, arginine, ornithine) in the intestine and kidneys. This disease does not show a correlation between phenotype and genotype and is highly variable in its clinical manifestations.
Case report: We present a 17-year-old girl who was followed up in our clinic for 5 years for idiopathic osteoporosis. She was first admitted to us at the age of 12 years with back pain that developed after a 3-month course of prednisolone for the treatment of unspecified recurrent encephalopathy. The patient's medical history included 2 left femur fractures (at 1 year 8 months and at 2 years), chronic pyelonephritis, hepatosplenomegaly, short stature, normochromic anemia, elevated ESR, elevated ferritin and LDH levels, and an aversion to protein-rich foods. Blood amino acid analysis did not reveal any diagnostically significant abnormalities. MRI showed multiple compression fractures of the thoracic and lumbar vertebrae. Dual-energy X-ray absorptiometry revealed low bone mineral density (BMD) in the lumbar spine (Z-score -4.7 SD) and the whole body excluding the head (Z-score -2.8 SD). The patient took cholecalciferol, alfacalcidol and calcium carbonate, but without significant changes. She was prescribed bisphosphonates (pamidronic acid) at the age of 15. During treatment with bisphosphonates, a significant increase in BMD was observed in the lumbar spine (Z-score -2.4 SD) and the whole body excluding the head (Z-score -2.4 SD) and a decrease in the degree of vertebral deformation in the thoracic and lumbar spine. At the age of 17, whole exome sequencing, performed to identify the cause of osteoporosis, revealed a heterozygous mutation in the SLC7A7 gene. Thus, it was not until the age of 17 that LPI was diagnosed.
Conclusion: The presented case highlights the importance of maintaining a high index of suspicion for LPI in patients with unexplained fractures and idiopathic osteoporosis and demonstrates the utility of whole exome sequencing for the diagnosis of rare diseases with unusual presentations, where early intervention can significantly impact the clinical course and outcome.

P197

THE PREVALENCE OF OSTEOPOROSIS IN BOSNIAN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Hasanović[1], S. Mehmedagić[2]

[1]DEPARTMENT OF ANATOMY, FACULTY OF MEDICINE, UNIVERSITY OF SARAJEVO, SARAJEVO, Bosnia & Herzegovina, [2]CLINIC FOR HEART, BLOOD VESSELS AND RHEUMATIC DISEASES, UNIVERSITY CLINICAL CENTER SARAJEVO, SARAJEVO, Bosnia & Herzegovina

Objective: The aim of this study was to determine the frequency of osteoporosis and to analyze the risk factors in rheumatoid arthritis (RA) patients.
Matherial and Methods: A total of 126 patients with rheumatoid arthritis, treated between January 2024 to October 2024 at the Clinic for heart, blood vessels and rheumatic diseases of the University Clinical Center in Sarajevo with bone mineral density (BMD) results were included in this study. The patients were divided into two groups according to bone mineral densitometry (BMD) status, osteoporotic and non osteoporotic. The data were collected from medical records of each patients and association between osteoporosis and related risk factors were recorders. The differences were tested using chi-square and Mann-Whitney

tests. The level of statistical significance was set at p<0,05.
Results: Of the 126 patients with RA, 117 women (92,86%) and 6 men (7,14%), 47 patients (37,29%) were in the osteoporotic group (T score ≤-2.5 SD in L2-L4 in the lumbar spine or in the femoral neck). The mean age of the patients was 63,45±9,52 years and the patients were significantly older in the osteoporotic group 64,12±10,10, compared to patients without osteoporosis 53,21±8,51 (p<0,01). The average BMI of the patients with osteoporosis was significantly lower (27,84±7,50 kg/m²) compared to patients without osteoporosis (32,45±4,30 kg/m²) (p<0,01). RA patients with osteoporosis had a higher frequency of fractures that those in other group, especially fractures of the femur (p<0,01).
Conclusion: A large percentage of our patients with rheumatoid arthritis had osteoporosis. Old age, low BMI, menopause were the main risk factors for osteoporosis.
Keywords: osteoporosis, rheumatoid arthritis, prevalence, risk factors

P198

VITAMIN D STATUS IN BOSNIAN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS

A. Hasanović[1], A. Lakota-Žiga[2], A. Kapetanović[2]

[1]DEPARTMENT OF ANATOMY, FACULTY OF MEDICINE, UNIVERSITY OF SARAJEVO, SARAJEVO, Bosnia & Herzegovina, [2]Public Institution Health Centre of Sarajevo Canton, Sarajevo, Bosnia and Herzegovina, Sarajevo, Bosnia & Herzegovina

Objective: The aim of this study was to investigate the serum vitamin D levels in Bosnian postmenopausal women with diagnosed osteoporosis, and the associations of serum 25(OH)D level with bone mineral density (BMD).
Material and Methods: Assessment of 25-hydroxyvitamin D (25(OH)D) was performed in 132 Bosnian postmenopausal women with a diagnosis of postmenopausal osteoporosis. Bone mineral density (BMD) measured on the lumbar spine (L1-L4), femoral neck were obtained by dual-energy X-ray absorptiometry (DXA). The differences were tested using chi-square i Pearson correlation coefficient. The level of statistical significance was set at p<0,05.
Results: Among 132 examined postmenopausal women aged > or =50 years for vitamin D level, deficiency of vitamin D was found in 116 (87,88%) of patients. Average 25(OH)D serum concentrations was 44,25 nmol/L. Our results has shown the deficiency of vitamin D in 87,88% of the examinees with postmenopausal osteoporosis, and positive correlation of the level of 25 (OH) D and bone mineral density (BMD) or T score on lumbar spine (L1-L4) (p<0,05) and a significantly lower initial concentration of 25 (OH) D with the examined with prior bone fractures (36,92±12,22) opposed to those without fractures (53,82±18,15) (p<0,01). Patients with diagnosed postmenopausal osteoporosis have reduced levels of vitamin D, which is an important factor in reduced bone density and bone fractures.
Conclusions: This study showed the vitamin D deficiency in Bosnian postmenopausal women with osteoporosis and the relationships between vitamin D and BMD. The results contribute to a more comprehensive understanding of how vitamin D may impact bone health.
Keywords: osteoporosis, vitamin D status, postmenopausal women, bone mineral density

P199

RETROSPECTIVE COHORT STUDY OF INTRAOSSEOUS VANCOMYCIN FOR SURGICAL TREATMENT OF NATIVE SEPTIC ARTHRITIS

A. Hsu[1], F.-C. Kuo[1], Y.-C. Hsu[1]

[1]Chang-Gung Memorial Hospital, Kaohsiung, Taiwan

Background
The use of intraosseous (IO) vancomycin in arthroplasty has been a recent topic with promising results in primary hip and knee replacement surgery. It has also been established in recent literature to yield increased local drug perfusion and penetration for revision surgeries in lowering the risk of periprosthetic joint infection (PJI). We utilize intraosseous vancomycin administration for patients that are presented with native septic arthritis and analyze the safety and outcomes compared to a conventional treatment protocol.
Methods
We performed a retrospective comparative study on native septic arthritis from either direct joint inoculation or hematogenous infection. A diagnosis of septic arthritis was reached with a synovial WBC cell-count greater than 50,000 cells/mm3. We evaluated preoperative and postoperative serum lab, organism, and antibiotics profile. All patients underwent arthrotomy of the infected joint. The control group (n=30) underwent radical debridement followed by rigorous irrigation. The IO group (n=15) received additional IO vancomycin. Systemic treatment of organism-specific intravenous antibiotics was given post-operatively for a minimum of two weeks as according to treatment guidelines.
Results
Comparative analysis was performed for the matched cohort. There was a trend towards earlier decrease of CRP and ESR to no statistical difference. The prevalence of adverse effect was similar between the two groups, while the development of AKI was lower in the IO group, but without statistical significance.
Conclusions
Use of IO vancomycin in native septic arthritis is a novel surgical strategy with scarce literary documentation. We found the outcome of IO vancomycin to be promising and with safe results. A larger cohort study via this technique may yield statistical significance in the increased potency of IO organism eradication properties.

SCREENING FOR SARCOPENIA IN OSTEOPOROTIC AND OSTEOPENIC POSTMENOPAUSAL WOMEN USING RECTUS FEMORIS ULTRASONOGRAPHY AND BIOIMPEDANCE

M. M. Bartelick[1], A. I. Gasparik[1], I. M. Pascanu[1]

[1]George Emil Palade University of Medicine, Pharmacy, Science and Technology, Targu Mures, Romania

Objectives: Osteosarcopenia is characterized by decreased muscle mass and function in patients with low bone mineral density. When osteoporosis and sarcopenia are present concomitantly, they form a "hazardous duet" leading to increased frailty, fractures, and mortality (1). Recent studies have aimed to find a readily available, low cost and efficient method to evaluate muscle mass (2). Our study aims to investigate how muscular ultrasound parameters compare to bioimpedance in postmenopausal women with osteopenia or osteoporosis.

Materials and methods: We evaluated muscle function and quantity in 40 osteoporotic and 22 osteopenic women presenting to the Endocrinology Department of Targu Mures County Hospital. Handgrip strength (HGS) and gait speed (GS) were used to evaluate muscle strength and function with cut-off values of HGS <18kg, GS <0.8m/s. We estimated appendicular skeletal muscle mass (ASMM) from bioimpedance using the equation by Kyle et al (3). Rectus femoris muscle thickness (MT), cross-sectional area (CSA), and pennation angle were measured using ultrasound and compared to estimated ASMM and ASM/height^2 using a cut-off value of 5.5kg/m^2 based on EWGSOP2 criteria.

Results: 62 women were included in our study with a mean age of 66.5 ±7.3. 25.8% of women had low muscle strength and 7.8% had sarcopenia. Osteoporotic women had significantly lower rectus femoris CSA (4.7 cm^2 vs. 5.6 cm^2, p=0.02) and MT (1.41 cm vs 1.56 cm, p=0.016) compared to osteopenic women, also after adjusting for BMI. Women with low HGS had lower rectus femoris pennation angle (10.3° vs 11.6°, p=0.01). MT and CSA were moderately correlated to estimated ASMM.

Conclusion: The findings of our study suggest that assessing muscle quantity with ultrasound may effectively indicate overall muscle mass. Sarcopenia is often underdiagnosed, significantly affecting the quality of life of older adults. Incorporating muscle ultrasound into routine clinical practice could play a pivotal role in earlier detection and improving outcomes in sarcopenia.

PREDICTIVE SCORING SYSTEM FOR INDEPENDENT WALKING DISABILITY AT THREE MONTHS AFTER FRAGILITY HIP FRACTURE SURGERY: A MULTICENTER STUDY

P. Chanthanapodi[1], A. Jarusriwanna[2], N. Kitcharanant[3], J. Patumanond[2], S. Lawanaskol[4], A. Laoruengthana[2], P. Atthakomol[3], S. Chiewchantanakit[3], S. Jacktong[5], T. Sanpunya[5]

[1]Sawanpracharak Hospital, Nakhon Sawan, Thailand, [2]Faculty of Medicine, Naresuan University, Phitsanulok, Thailand, [3]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, [4]Chai Prakan Hospital, Chiang Mai, Thailand, [5]Phrae Hospital, Phrae, Thailand

Objectives: Loss of independent walking ability after hip fractures in older adults increases morbidity and mortality. This study developed a scoring system to predict the risk of independent walking disability at 3 months postoperatively in patients aged ≥60 years with fragility hip fractures.

Materials and Methods: A prospective observational cohort study analyzed 767 patients aged ≥60 years with intertrochanteric or femoral neck fractures treated at eight hospitals in 2024. Multivariable logistic regression identified predictors, which were converted into a 17-point scoring system stratifying patients into low-, moderate-, and high-risk groups. Bootstrap internal validation assessed predictive performance.

Results: Among participants, 15.5% (119/767) had independent walking disability at 3 months. Nine predictors were identified, including age, Charlson Comorbidity Index, pre-fracture walking status, ASA classification, serum albumin, Barthel Index, operative type, postoperative complications, and hospital stay (Table 1). The scoring system achieved 81% accuracy (AuROC=0.8124). Patients scoring 0-5 (low risk) had a 1.8% risk of walking disability, suggesting routine follow-up; scores of 6-15 (moderate risk) indicated 19.5% risk, requiring home visits; and scores of 16-17 (high risk) showed a 63.6% risk, recommending home ward care.

Conclusions: This scoring system enables accurate risk stratification for walking disability, guiding personalized rehabilitation and targeted interventions, particularly for high-risk patients needing home ward care.

Table 1. The clinical predictors and scoring system

Predictors	OR	95% CI	*p*-value	Coefficient	Score

EFFECTS OF DISCONTINUING DIFFERENT ANTIRESORPTIVE REGIMENS ON MEDICATION-RELATED OSTEONECROSIS OF THE JAW IN PATIENTS UNDERGOING DENTAL PROCEDURES: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

A. Jarusriwanna[1], K. Ruksakiet[2], W. Sadaeng[2], A. Laoruengthana[1], T. Sang-Ngoen[2], T. Dhippayom[3]

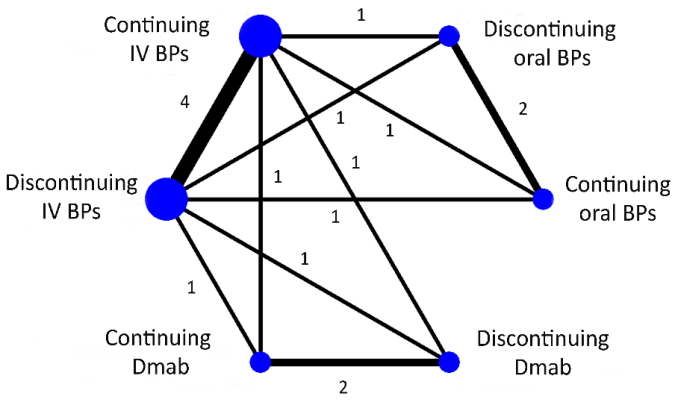
[1]Faculty of Medicine, Naresuan University, Phitsanulok, Thailand, [2]Faculty of Dentistry, Naresuan University, Phitsanulok, Thailand, [3]Faculty of Pharmaceutical Sciences, Naresuan University, Phitsanulok, Thailand

Objectives: Controversy exists on whether a drug holiday is necessary for patients on antiresorptive medication for osteoporosis or bone metastasis and undergoing dental procedures to lower the risk of medication-related osteonecrosis of the jaw (MRONJ). This study evaluated the effects of discontinuing different antiresorptive regimens on MRONJ in these patients.

Material and Methods: Publications from PubMed, EMBASE, Cochrane Library, and EBSCO Open Dissemination were searched from inception to September 2023, following PRISMA guidelines, and the review was registered in PROSPERO. Eligibility criteria included clinical studies on the effects of continued and discontinued antiresorptive medications for osteoporosis or bone metastasis in patients undergoing dental procedures. The involved antiresorptive agents were oral bisphosphonates (BPs), intravenous (IV) BPs, and denosumab (Dmab). The primary outcome was the occurrence of MRONJ assessed by clinical and radiographic findings. Quality assessment was investigated using the risk of bias in non-randomized studies of interventions (ROBINS-I) tool for the non-randomized studies and the risk of bias in randomized trials (RoB 2) tool for the randomized controlled trials (RCTs). Risk ratios (RRs) with 95% confidence interval (CI) were estimated using a random-effects model.

Results: Of the 2,590 records identified, 6 studies (n=717) were included (see Figure for the network geometry). Quality assessment evaluated by risk of bias was moderate in 4 studies and low in 2 studies. Discontinued use of oral BPs had a lower MRONJ risk than discontinuation of IV BPs (RR=0.05; 95% CI 0.00-0.83) and continuation of IV BPs (RR=0.03; 95% CI 0.00-0.46). Continuing oral BPs also resulted in a lower MRONJ risk compared to both discontinuation and continuation of IV BPs, with RR=0.04 (95% CI 0.00-0.67) and RR=0.03 (95% CI 0.00-0.37), respectively. No significant difference was found between continuation and discontinuation of oral BPs, along with other comparisons.

Conclusions: A drug holiday may not be necessary before dental procedures for oral BPs. Temporary discontinuation of IV BPs or Dmab is also unlikely to reduce MRONJ risk compared to continued medication.



P203

THE NEW SHARED GENETIC CONTRIBUTION OF OBESITY AND OSTEOPOROSIS

Armita Kakavand Hamidi[1], Mahsa Mohammad Amoli[2]

[1] Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran.[2] Metabolic Disorders Research Center, Endocrinology and Metabolism MolecularCellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran.

Background: The relationship between obesity and osteoporosis is complex and inconsistent. Genetic factors may influence the effects of obesity on the odds of incident osteoporosis.
Objective: We aim to evaluate if a common genetic factor causes obesity and osteoporosis that can be assessed through blood samples.
Material and Methods: We searched the gene expression omni (GEO) for datasets evaluating the gene expression of obese *vs.* normal weight and individuals with high peak bone mass (PBM), an important determinant of osteoporosis, versus subjects with low PBM. The datasets were analyzed using affy and limma packages in R. The up-regulated differentially expressed genes (DEGS) in each dataset were retrieved and the community between three lists was obtained through a Venn diagram. The shared genes were enriched in Enrichr and Enrichr-KG.
Results: Two genes named CCNL1 and MALAT1 were upregulated in all datasets. These genes are involved in TNF-alpha Signaling via NF-kB according to MSigDB Hallmark 2020. Other pathways enriched significantly were Increased Brain Apoptosis (MP:0014178), Brain Inflammation (MP:0001847), and Abnormal Nervous System Physiology (MP:0003633). Also, CCNL1 which is a new genetic factor that is shown in both osteoporosis and obesity is related to the regulation of transcription by RNA polymerase II as its biological process (GO:0006357) and is regulated by transcription factors like HES7, ZNF75A, HOXA2, ZNF304 and MAPK9 from ARCHS4 all co-expressed with kinases.
Conclusion: Although some studies indicated that obesity protects against osteoporosis others illustrated divergent results as an association between obesity and low body mass density (BMD). In this study, we showed that obesity and high PBM have shared underlying genetic identifiers as overexpression of CCNL1 and MALAT1 have been detected in both conditions which might be the reason for the greater risk of fracture in obese subjects. CCNL1 and MALAT1 might mimic the role of leptin in decreased bone formation through the central nervous system in obese patients.

P204

RELATIONSHIP BETWEEN BODY MASS INDEX AND BONE MINERAL DENSITY AT LUMBAR SPINE AND FEMORAL NECK IN BOSNIAN POSTMENOPAUSAL WOMEN

A. Kapetanović[1], S. Sarić[1], A. Hasanović[2], E. Mešanović[3], G. Bajić[4], M. Zonić-Imamović[5]

[1]Public Institution Health Centre of Sarajevo Canton, Sarajevo, Bosnia & Herzegovina, [2]University of Sarajevo, Sarajevo, Bosnia & Herzegovina, [3]University Vitez, Vitez, Bosnia & Herzegovina, [4]Pan-European University Apeiron, Banja Luka, Bosnia & Herzegovina, [5]University Clinical Center Tuzla, Tuzla, Bosnia & Herzegovina

Objective: This study aims to investigate the relationship between body mass index (BMI) and bone mineral density (BMD) at different skeletal sites in Bosnian postmenopausal women.
Material and Methods: A total of 200 postmenopausal women from Bosnia and Herzegovina (BiH) participated in the study. The participants were divided into two study groups (those with osteoporosis at the lumbar spine and those with osteoporosis at the hip) and two control groups (those without osteoporosis at the lumbar spine and those without osteoporosis at the hip). BMD was measured at the lumbar spine and proximal femur using Dual-Energy X-ray Absorptiometry (DXA). BMI was calculated by dividing weight (in kilograms) by height squared (in meters) (kg/m²).
Results: There was no statistically significant difference in age between the groups. However, a significant difference in BMI was observed between the study and control groups. The average BMI was significantly lower in women with osteoporosis at the lumbar spine (21.48±0.73 kg/m²) compared to those without osteoporosis at the lumbar spine (29.69±1.47 kg/m²), $p<0.01$. Similarly, women with osteoporosis at the hip had a significantly lower average BMI (21.51±0.79 kg/m²) than those without osteoporosis at the hip (29.14±1.87 kg/m²), $p<0.01$. BMI was positively correlated with BMD at the lumbar spine ($p<0.01$; $r=0.792$) and femoral neck ($p<0.01$; $r=0.929$).
Conclusions: The findings of this study indicate that a lower BMI is associated with an increased risk of osteoporosis at both the lumbar spine and the hip in postmenopausal women living in BiH. Conversely, a higher BMI is linked to increased BMD in this population.
Keywords: BMI, BMD, Bosnian postmenopausal women

P205

FREQUENCY OF PERIPROSTHETIC FRACTURES IN TOTAL HIP ARTHROPLASTY BETWEEN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

A. Khramov[1], M. Makarov[1], S. Makarov[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Surgical treatment of patients with rheumatoid arthritis (RA) is associated with an increased risk of complications due to the presence of an inflammatory process, prolonged intake of glucocorticoids (GC), disease-modifying and genetically engineered biological drugs, reduced physical activity, functional disorders and severe osteoporosis. All this contributes to an increased risk of intraoperative complications, including periprosthetic fractures.
Objective: to conduct a comparative analysis of periprosthetic fractures, which included intraoperative fractures of the large and small trochanter, as well as the acetabulum, during total hip arthroplasty (THA) in patients with RA and osteoarthritis (OA).
Material and methods: 1173 hip replacement operations were performed in patients with RA and OA in the period from 2004 to 2023 (OA – 709, RA – 484).
Results: A total of 41 (3.49%) periprosthetic fractures were diagnosed during THA. Of these:
- 23 (4.96%) fractures occurred in patients with RA;
- 18 (2.54%) in patients with OA.
In most cases, osteosynthesis with intraosseous sutures, circular sutures with wire or plate was performed for the treatment of periprosthetic fractures (61.8%), and Wagner's long revision leg was also used. Osteosynthesis was performed more often in patients with OA (66.7%), less often in patients with RA (43.5%).
Statistical analysis of the data revealed a significantly higher number of complications in the group of RA patients ($p=0.0288$). Significant differences were also obtained in the analysis of each type of complications ($p<0.05$).
Conclusion: obtained results confirmed that the risk of periprosthetic fractures was 2 times higher in RA patients than in patients with OA. Therefore, these patients require a special approach, which includes in the competent medical perioperative treatment of osteoporosis and careful handling of bone and surrounding soft tissues during the operation.

P206

CORRELATION OF POSTMENOPAUSAL OSTEOPOROSIS WITH BMD, SKIN COLOR AND LEVEL OF EDUCATION

A. Kollcaku[1], J. Kollcaku[2], A. Kapaj[3]

[1]Mother Teresa University Hospital Center, Tirana, Albania, [2]Public Health Service Polyclinic, No. 3, Tirana, Albania, [3]Pharma Company, Tirana, Albania

Objectives: the study aimed to assess the correlation of postmenopausal osteoporosis with body mass index, level of education, and skin color in Albanian women.
Material and methods: it was a cross-sectional study with a total of 4115 Albanian women. All subjects are asked about their level of education, skin color, and body mass index calculated for all women enrolled in the study. Bone mineral density was measured using Achilles ultrasound.
Results: Overall, 299 (6.2%) postmenopausal women were diagnosed with osteoporosis and 793 (16.6%) with osteopenia. By using Kendal's correlation coefficient we found a negative correlation between osteoporosis and level of education ($r=-0.101$, $p<0.001$) and a positive correlation between osteoporosis with white skin color ($r=0.0032$, $p<0.027$). We found a negative correlation between osteoporosis and body mass index ($r=-0.0033$, $p<0.009$) also.
Conclusions: estrogen decrease plays an important role in developing osteoporosis in postmenopausal women. There is a correlation between postmenopausal osteoporosis and white skin color, low body mass index, and low levels of education.

P207

OSTEOPOROSIS AND EARLY MENOPAUSE

A. Kollcaku[1], J. Kollcaku[2], V. Duraj[1]

[1]Mother Teresa University Hospital Center, Tirana, Albania, [2]Public Health Service Polyclinic, No. 3, Tirana, Albania

Objectives: The study aimed to assess the correlation between early menopause, before age 45, and osteoporosis.
Material and methods: It was a cross-sectional prospective study with 4115 Albanian women participation. All subjects were asked about the age of menopause and were measured for bone mineral density, using Achilles ultrasound device.
Results: Overall, 6.2% of women were diagnosed with osteoporosis. 36.1% of total menopausal women have had menopause before age 45. The regression analysis model demonstrated that postmenopausal women had 69% more chances to have osteoporosis versus the others (OD=1.69; 95%CI=1.45-1.77). A significant statistical correlation was found between early menopause and osteoporosis (OR=1.83, 95%CI=1.02-4.25).
Conclusions: This study provides useful evidence of correlations between osteoporosis and early menopause.

P208

DETERIORATION OF BONE QUALITY PARAMETERS AFTER CYTOTOXIC TREATMENT WITH TAXANES

A. Kurth[1], A. Müller[2], K. Gazis[3], P. Augat[4], P. Hadji[5]

[1]Orthopaedic Institute Dres. Baron & Colleagues and JW Goethe University, Frankfurt, Frankfurt/Main, Germany, [2]Gynecology Munich-Gauting, Munich, Germany, [3]Medical Service Center, Zwenkau, Germany, [4]Biomechanics Institute, BG Unfallklinik Murnau, Murnau, Germany, [5]Frankfurt Center of Bone Health and Endocrinology, Frankfurt/Main, Germany

Chemotherapy-induced osteoporosis is an iatrogenic side effect of many antineoplastic treatments. Chemotherapy-driven estrogen loss is postulated to drive bone loss, but significant data suggests the existence of an estrogen-independent mechanism. Direct negative effects of cytotoxic treatment (e.g. Docetaxel) on bone have been reported anecdotally, but little information is available in the literature.

The aim of the present study was to investigate the effects of widely used chemotherapy on bone after simulated osteoporosis. M&M: 56 SD rats were divided into three groups. All animals underwent sham ovariectomy (sham-ovx) or ovariectomy (ovx) at 6 months of age. The sham group and one ovx group received placebo therapy, the other ovx group received docetaxel (10mg/kg bw) intraperitoneally for 6 cycles with an interval of 3 weeks. A DXA measurement of L5 (Hologic QDR 4500+, animal software) was performed before the first cycle, 15 weeks after ovx and 10 weeks after the last cycle of chemotherapy. 10 weeks after the last cycle, the animals were killed. The spinal column and both femora were obtained. PQCT and µ-Scope (Stratec, Germany) of the proximal femur a, µCT of LWK 5 (Skyscan- Bruker, USA)

Results

Discussion: Based on the data collected in this study using various methods of bone quality assessment, it is clear that chemotherapy-induced osteoporosis cannot be explained solely by the negative effect on the ovaries. Compared to normal bone, a significant loss of bone mass and trabecular architecture has been shown after OVX, which has already been shown before. If estrogen-deficient osteoporosis is already present, as in the case of simulated osteoporosis caused by OVX, the cytotoxic agent docetaxel can lead to a further loss of bone mass and architecture. A direct negative effect on the bone must therefore be assumed.

P209

FREQUENCY AND DETERMINANTS OF SUBCLINICAL ATHEROSCLEROSIS IN GOUT

A. L. Barbulescu[1], C. D. Parvanescu[1], C. E. Bita[1], S. C. Firulescu[1], B. A. Trasca[1], S. C. Dinescu[1], F. A. Vreju[1]

[1]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Objective. The study aimed to reveal the presence of subclinical carotid atherosclerosis in a group of gout patients by US examination and to explore potential correlations with various disease-related variables.

Material and methods. This observational, prospective study included 65 consecutive patients diagnosed with gout, assessed at the Rheumatology Clinic, Emergency County Hospital Craiova, along with 40 healthy controls. Ultrasound examinations were conducted using an Esaote MyLab system with a high-frequency linear probe (10–18 MHz). Musculoskeletal ultrasound (MSKUS) assessments were performed to evaluate elementary lesions of MSU crystal deposits as defined by OMERACT. Inflammation was evaluated based on local power Doppler (PD) signal, graded on a semiquantitative scale from 0 to 3. Carotid arteries were bilaterally examined for increased IMT and atheroma plaques following the Mannheim consensus.

Results. A CCAIMT greater than 0.9 mm was observed in 19 patients (29.23%), a statistically significant difference compared to controls (7 patients, 17.5%; p = 0.0428). Carotid plaques were detected in 23 patients (35.38%) during ultrasound examination, a significantly higher prevalence than controls (19 patients, 29.23%; p = 0.002). Multivariate logistic regression identified SUA (OR = 2.103; p = 0.0002), age (OR = 1.051; p < 0.001), disease duration (OR = 1.740; p = 0.0039), and LDLc (OR = 1.003; p = 0.0029) as independent factors associated with increased IMT in patients with gout. Similar results were obtained regarding carotid plaques. MSKUS performed on all patients yielded significant findings. The presence of deposits was associated with a higher risk of thickened IMT, with similar results observed for double contour sign, aggregates, and tophi. A statistically significant association was noted for the presence of deposits (p = 0.002). Regarding carotid atheroma plaques, identifying deposits, double contour sign, aggregates, tophi, and PD signal was linked to a higher risk.

Conclusions. Our findings confirm that carotid ultrasound is a readily accessible imaging technique that provides valuable predictors of atherosclerotic status.

AN OBSERVATIONAL ANALYSIS OF METABOLIC SYNDROME AND CARDIOVASCULAR RISK IN PATIENTS WITH PSORIASIS

A. L. Barbulescu[1], R. C. Dascalu[1], C. E. Bita[1], S. C. Dinescu[1], F. A. Vreju[1]

[1]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Objective. The study aimed to assess the prevalence of metabolic syndrome (MetS) in a cohort of psoriasis (PsO) patients and examine its association with subclinical atherosclerosis, as evaluated by carotid ultrasound.
Material and methods. We conducted an observational study involving 54 patients with psoriasis (PsO) admitted to the Dermatology Department of the Emergency County Hospital in Craiova, Romania, between August 2023 and January 2024, along with 40 control subjects. Results. The criteria for MetS were met by 35 of the psoriasis patients (64.81%) compared to 11 of the controls (27.5%), with a statistically significant difference (p=0.0003). When examining the components of MetS, significant differences were found in total cholesterol levels and waist circumference. Carotid ultrasound results showed an increased intima-media thickness (IMT) of over 0.9mm in 19 PsO patients (35.18%), significantly higher than in the control group. Additionally, carotid plaques were more prevalent in psoriasis patients (37.03%) compared to controls (17.5%, p=0.001). We also observed that patients with MetS had significantly higher average IMT values than those without MetS. The prevalence of carotid plaque was notably higher in psoriasis patients with MetS. In the PsO group, IMT was positively correlated with age, MetS, blood glucose levels, disease duration, and PASI score. However, only age and MetS remained independent predictors of carotid IMT after conducting multiple linear regression analysis (p=0.02 for age, p=0.001 for MetS).
Conclusion. Our findings support a strong association between metabolic syndrome and psoriasis, highlighting the increased cardiovascular risk in psoriasis patients, particularly those with MetS. These factors might offer deeper insights into the mechanisms driving the increased cardiovascular risk.

INFLUENCE OF POOR SLEEP QUALITY ON MUSCLE MASS AND STRENGTH IN OLDER ADULTS AT RISK OF FALLS

A. Lacoski[1], P. Stinghen[1], A. L. Coutinho[1], M. L. Cloque[1], B. Maoski[1], O. De Matos[1]

[1]Federal University of Technology-Parana, Curitiba, Brazil

Objective: The main objective of this study was to verify the influence of poor sleep quality on the loss of strength and muscle mass in older adults at risk of falls.
Methods: 94 participants were divided according to the sleep quality questionnaire as normal (N=50) and poor (N=44) sleep quality , dual energy x-ray absorptiometry (DXA) was used for total lean mass (TLM), appendicular skeletal mass (ASM/H²), bone mineral density (BMD). The performance tests was used handgrip strength (HGS), Short physical performance battery (SPPB) and Chair stand test (CST). For statistics, descriptive analysis, Mann-Whitney test for independent samples, Spearman correlation and Linear regression analysis were used.
Results: Total lean mass and performance tests show lower values compared to the normal sleep group. The correlation test was performed only in the poor sleep quality group. This group presented moderate and statistically significant between TLM and HGS, LBMD and FBMD. ASM presented moderate and significant statistical with SPPB, LBMD and CST. The influence of TLM was 54.5% on HGS, 27% in LBMD and 22% in FBMD.
Conclusion: We conclude that poor sleep appears to negatively affect muscle quality and physical performance, especially muscle strength in older adults, increasing the risk of falls. Therefore, we consider it important to verify the cause of non-restorative sleep in this population.

P212

THE RELATIONSHIP BETWEEN BODY MASS INDEX AND HIP FRACTURES IN OLDER IRISH ADULTS

A. Lynch[1], R. Lannon[1], N. Maher[1], N. Fallon[1], G. Steen[1], C. O'Carroll[1], A. Carroll[1], D. Fitzpatrick[2], K. Mccarroll[1]

[1]Bone Health Unit, St James's Hospital, Dublin, Dublin, Ireland, [2]Mater Miscericaordiae University Hospital, Dublin, Dublin, Ireland

Objective
Higher body mass index (BMI) is associated with greater bone mineral density (BMD) which may protect against fracture at weightbearing sites such as the hip. However, increased adiposity is also associated with adipocytokines that are known to adversely affect bone quality. We aimed to investigate the relationship between BMI and hip fracture prevalence in patients attending out bone health clinic.
Material and Methods
We extracted data for analysis from our bone health clinic database. We then explored the cross-sectional association between those who were underweight (BMI < 18.5 kg/m²), overweight (BMI 25 – 30 kg/m²) and obese (BMI >30 kg/m²) and the prevalence of hip fracture adjusting for age and sex. The reference group for comparison was normal weight (BMI 18.5 – 25.0 kg/m²).
Results
There 5128 patients in analysis and 1093 (21.3%) had a history of hip fracture. Those who were underweight were more likely to have a hip fracture (OR 1.49, CI 1.13 – 1.95, p=0.001). Conversely, being overweight was associated with a reduced risk (OR 0.68, CI 0.58 – 0.80, p=0.001) which the risk reducing further with obesity (OR 0.61, CI 0.50 – 0.75, p=0.001).

Conclusion
Low body mass was associated with a 49% increased risk for hip fracture while the risk reduced by 32% in those who were overweight and 39% in obesity. This is likely to be explained by an increased BMD in patients with greater weight. It has also been hypothesized that fat tissue around the hip might attenuate the impact on falling which might reduce fracture risk. While obese patients may have a lower risk of hip fracture, they have a higher risk of complications post hip fracture repair.

P213

ULTRASOUND GUIDED RADIOFREQUENCY ABLATION FOR KNEE OSTEOARTHRITIS: ADVANCING PAIN MANAGEMENT SOLUTIONS

A. M. Abdalla[1], F. I. Abdelrahman[2]

[1]Faculty of Medicine, Damietta University , Department of Rheumatology and Rehabilitation, Damietta, Egypt, [2]Faculty of Medicine, Zagazig University, Department of Rheumatology and Rehabilitation, Zagazig, Egypt

Background: Knee osteoarthritis (KOA) is a chronic degenerative disease in the knee joint that commonly occurs in elderly patients. Among the various symptoms of knee osteoarthritis, pain is the leading limiting factor of physical activity and remains the major reason for knee joint replacement [1]. Radiofrequency ablation (RFA) of the genicular nerves is a minimally invasive technique that has been approved for efficacy as a treatment for the pain of chronic KOA [2]. Genicular nerve blocks under ultrasound guidance and subsequent RFA was later introduced and has been demonstrated to be as effective as fluoroscopicguided RFA, without the risk of radiation exposure, and to be less time consuming [3].
Objective: To evaluate the effectiveness of radiofrequency ablation (RFA) of genicular nerves guided by ultrasound in pain relief in patients with KOA.
Methods: Prospective observational study included 58 patients who had suffered from chronic knee joint pain for more than 6 months and grade III–IV KOA according to the Kellgren-Lawrence classification system. The patients underwent ultrasound-guided radiofrequency ablation of genicular nerves after showing a positive response to a diagnostic block. The target nerve selection principle was as follows: the superomedial genicular nerve (SMGN) branch and inferior medial genicular nerve
(IMGN) branch of the saphenous nerve and the superolateral genicular nerve (SLGN) branch of the femoral nerve . RFA at 80oC was performed for 120 seconds per nerve. Outcome assessments were performed at baseline and at 4 and 12 weeks post treatments using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC).
Results: Total of 101 knees of 56 patients underwent genicular nerve RFA. 16 knees were grade III KOA while 85 knees were grade IV KOA. 45 of the patients were bilateral and 11 were unilateral. The mean age of the patients was 65.11± 8.74, 44 of them were females while 12 were males. The mean of body mass index (kg/m2) was 27.61 ± 3.03. The mean of disease duration was 7.31 ± 3.01 years. There was significant improvement from baseline to post treatment in pain and physical function domains of the WOMAC with no significant improvement from baseline to post treatment in the stiffness domain. There was also significant improvement from baseline to post treatment in total WOMAC score. Mean of WOMAC scores at baseline, 4 weeks posttreatment and 12 weeks posttreatment in terms of pain (22.8 ±3.4, 11.9 ±1.4,12.5 ±1.6 respectively P<0.01), physical function (46.4 ± 2.63, 27.76 ± 3.3, 28.35 ± 3.17 respectively with p = 0.05).
and total score (62.71 ± 4.28, 34.69 ± 3.54, 36.09 ± 3.36 respectively with P<0.01) but not stiffness (3.5 ±0.88, 3.08 ±0.91, 3.18 ± 0.76 respectively P=0.336 , 0.273 respectively).
Conclusions: RFA of genicular nerves can significantly alleviate pain and improve functional outcomes in knee osteoarthritis patients.

COMORBIDITIES IN RHEUMATOID ARTHIRITIS

A. M. Bumbea[1], D. Matei[1], R. Traistaru[1], A. Musetescu[1], V. S. Caimac[1], B. S. Bumbea[2]

[1]University of Medicine and Pharmacy, Craiova, Romania, [2]County Emergency Hospital, Targu Mures, Romania

Objectives: Rheumatoid arthritis has a complex pathogenic mechanism, with a wide variety of antibodies, with multiple actions. In this context, we propose to highlight the complexity of this disease as a cofactor of increased risk in many other pathologies.
Material and method: we evaluated a group of 45 patients with rheumatoid arthritis with evolution over 5 years in synthetic remissive therapy, patients with biological therapy were not included in this study. All patients were evaluated in terms of disease activity using the DAS 28 composite index, the degree of disability using the Barthel questionnaire, the degree of osteoporosis using the T score, pulmonary radiological evaluation, cranian CT scan in patients with a history of stroke, evaluation of biological constants: blood test, transaminases, creatinine, urinealysis, urine culture.
Results: after the evaluation, we found that more than half of the patients presented predominantly urinary infections, a third of the patients presented cardiac disease - ischemic heart disease, arterial hypertension, less than 20% presented anemic syndrome, only one patient developed lung neoplasm, 3 patients have ischemic stroke.

Conclusions: our study on a small cohort of patients highlights comorbidities that require additional therapy, which shows that both, the disease and the treatment for polyarthritis, can be an inducing factor of other pathologies. More studies on larger cohorts are needed to highlight the types of comorbidities that may appear during the evolution and therapy of patients with rheumatoid arthritis.

P215

THE ADVANTAGES OF USING THE BTS G-WALK SYSTEM IN THE STAGE EVALUATION OF THE RESULTS OF PHYSICAL-KINETIC THERAPY ADDRESSED TO PATIENTS WITH POST-TRAUMATIC KNEE DYSFUNCTION

V. S. Caimac[1], A. M. Bumbea[1], R. Traistaru[1], B. S. Bumbea[2]

[1]University of Medicine and Pharmacy, Craiova, Romania, [2]County Emergency Hospital, Targu Mures, Romania

Objectives: assessment of the usefulness of the initial and stage assessment using the 6-minute walk test - within the BTS G – Walk system for the assessment of the effects on pain and walking obtained by association within the 14-day conservative therapeutic program dedicated to patients diagnosed with post-traumatic knee dysfunction , of physical therapeutic means.

Material and method: We organized a prospective, observational, randomized study on a group of 31 patients with Morton's neuritis. The patients were randomly divided into a control group (15 patients) who received only specific medication (group 1) and a study group - group 2- (16 patients), who additionally received physical therapy (where short, laser, orthotics, massage, physical therapy). Patients were evaluated initially and after 14 days of treatment. The monitored parameters were: pain (using visual analogue scales), joint balance, manual muscle testing, and to evaluate the functionality of the lower limb we used the 6-minute walking test - within the BTS G-Walk system.

Results: The score values for the functional parameters improved: the VAS pain score value decreased by 35.3% in group 2, compared to 24.1% in group 1 ($p=0.000053$); knee flexion range of motion improved (32.5% in group 2 vs. 19.1% in group 1) and locomotion improved more in patients in group 2 (41.3%) compared to group 1 (28.4%). The results had statistical significance ($p<0.05$).

Conclusions: The obtained results highlight the relief of pain and the improvement of functional parameters in the study group, certifying the effectiveness of the applied physical means of treatment. These findings motivate the continuation of the study for a longer period and a larger number of patients.

P216

FIBROMYALGIA A DISEASE OF THE MODERN AGE

A. M. Bumbea[1], R. Traistaru[1], V. S. Caimac[1], B. S. Bumbea[2], A. N. Bumbea[2], A. Musetescu[1]

[1]University of Medicine and Pharmacy, Craiova, Romania, [2]County Emergency Hospital, Targu Mures, Romania

Objectives: fibromyalgia is an increasingly common diagnosis in medical offices. Many musculoskeletal pathologies are recently accompanied by fibromyalgia syndromes. The presence of increasing stress changes the patient's profile and psycho-emotional status, which leads to a re-evaluation of the pain perception threshold.

Material and method: we included in the study a number of 80 patients with lumbar and cervical discopathy and spondylosis and osteoarthritis, aged between 45 and 70 years. All patients were evaluated using the WPI Widespread Pain Index and the SS Severity Scale score, the VAS visual analog scale for pain. All patients followed a physical and kinetic program adapted to the pathology.

Results: at the initial examination we obtained scores that confirm fibromyalgia in 65% of the patients, and after a month of kinetic treatment the score dropped to 50%.

Conclusions: fibromyalgia is much underdiagnosed, in the current context of predominantly sedentary activity, against the backdrop of stress and sleep impairment. Involvement of patients in controlled physical kinetic programs could reduce the occurrence of fibromyalgia and the increase in pain perception threshold.

P217

ENDOTHELIAL AND PLATELET IMPAIRMENTS IN PRIMARY HYPERPARATHYROIDISM AND HYPOPARATHYROIDISM

A. M. Naciu[1], A. Nusca[2], F. Piccirillo[2], G. Tabacco[1], A. D'Amico[3], A. M. Di Tommaso[1], G. Sterpetti[1], M. M. Viscusi[2], F. Bernardini[2], M. Forte[4], L. D'Ambrosio[3], G. Frati[3], C. Nocella[5], N. Napoli[1], R. Carnevale[3], S. Sciarretta[3], F. Grigioni[2], A. Palermo[1]

[1]Unit of Metabolic bone and thyroid disorders, Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy, Rome, Italy, [2]Cardiology Unit, Fondazione Policlinico Universitario Campus Bio-Medico of Rome, Rome, Italy, [3]Department of Medical and Surgical Sciences and Biotechnologies, Sapienza University of Rome, Latina, Italy, [4]IRCCS Neuromed, Pozzilli, Italy, [5]Department of Clinical Internal, Anesthesiology and Cardiovascular Sciences, Sapienza University of Rome, Rome, Italy

Objective. Both primary hyperparathyroidism (PHPT) and chronic hypoparathyroidism (HypoPT) are associated with the onset and development of cardiovascular diseases (CVDs). Endothelium is a recognized target tissue of PTH and there is an increasing body of evidence that PTH affects functional and structural properties of arteries. However, the molecular mechanisms underlying the effects of parathyroid disorders on endothelial dysfunction and platelet aggregation, two main determinants of CVDs, are not

completely understood.
Aim. To evaluate the effects of PHPT and HypoPT on oxidative stress, endothelial and platelet function.
Material and methods: in a monocentric, cross-sectional study we enrolled hypoPT patients treated with calcium and calcitriol, PHPT subjects and age-matched controls. All patients underwent a biochemical examination including calcium-phosphorus metabolism, inflammation markers, circulating levels of markers of oxidative stress, endothelial function, and platelet activation. Moreover, we evaluated brachial artery endothelial function (flow-mediated dilation-FMD), common carotid intima-media thickness (ccIMT), diastolic function and global strain measures with ultrasound.
Results. These are the results of this project that included 120 subjects (40 hypoPT, 40 PHPT and 40 age- and sex-matched control subjects). HypoPT and PHPT patients showed increased oxidative stress markers as compared to control subjects (p<0.001). Among patients with parathyroid disorders, those with PHPT demonstrated the highest reduction of nitric oxide (p<0.001 versus HypoPT and controls) and FMD (p<0.001 and p=0.001) and a marked increase of IMT (p<0.001 and p=0.001). We also observed an increased platelet aggregation in patients with parathyroid disorders, with the highest values in PHPT patients (p<0.001, PHPT vs controls; p=0.006, HypoPT vs controls; p<0.001, PHPT vs HypoPT), along with increased levels of soluble P selectin and thromboxane B2.
Conclusions. PHPT and HypoPT patients have increased atherothrombotic risk due to endothelial and platelet function alterations. Our results suggest that PTH may influence platelet reactivity. Further research is needed to determine if personalized antiplatelet therapy is necessary in subjects with parathyroid disorders.

P218

IMPAIRED NEURAL PLASTICITY MECHANISMS IN HYPOPARATHYROIDISM

A. M. Naciu[1], A. Palermo[1], G. Tabacco[1], M. Cereghino[1], E. Sargentini[1], F. Motolese[2], G. Musumeci[2], V. Di Lazzaro[2], F. Capone[2]

[1]Unit of Metabolic bone and thyroid disorders, Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy, Rome, Italy, [2]Unit of Neurology, Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy

Objective: Chronic hypoparathyroidism (hypoPT) is characterized by low serum calcium levels, accompanied by low or inappropriately normal levels of parathyroid hormone (PTH). The conventional treatment involves the use of activated vitamin D and/or calcium supplements. Many hypoPT patients experience symptoms that indicate a decline in their quality of life. These symptoms often include physical issues (such as fatigue, increased susceptibility to fatigue, muscle spasms, pain, and paresthesia), cognitive symptoms (such as "brain fog", difficulty concentrating, slow processing speed, executive function, auditory memory, and visual memory), and emotional struggles. Transcranial magnetic stimulation (TMS) is a powerful tool to evaluate, in vivo, cortical excitability and brain circuits functioning.
Purpose: we aimed to investigate cortical excitability, circuit functioning, and plasticity propensity in hypoPT in comparison with controls.
Material and Methods: we enrolled hypoPT treated with calcium and calcitriol and age-matched controls. All subjects underwent a biochemical examination including calcium-phosphorus metabolism. Moreover, cognitive status was evaluated using the validated Telephone-based Mini-Mental State Examination (itel-MMSE). Participants without significant cognitive impairment underwent transcranial magnetic stimulation (TMS), assessing cortical excitability (motor evoked potentials-MEP), circuit functioning (short-latency afferent inhibition and short intracortical inhibition), and plasticity via intermittent theta burst (iTBS) protocol. MEP amplitude was measured before and after iTBS and compared between patient and age-matched healthy control group. A patient subgroup had TMS recordings repeated after initiating PTH treatment [3 subjects on PTH(1-34) and 3 subjects on Palopegteriparatide].
Results: these are the results of this project that included 44 subjects (32 hypoPT and 12 controls). HypoPT patients had significantly lower PTH and calcium levels (p<0.001) and higher phosphorus levels (p<0.001) than controls. MEP amplitude changes after iTBS differed significantly between patients and controls (-0.02 mV vs 0.33 mV, p:0.03). Patients undergoing PTH replacement therapy showed MEP amplitude responses similar to controls (-0.3 mV vs 0.3 mV, p:0.04). No other statistically significant differences were observed in TMS parameters.
Conclusion: our findings suggest that hypoPT present a functional impairment of neural plasticity mechanisms. PTH replacement therapy seems to restore this impairment, but we believe that further comprehensive studies are needed.

P219

CONSENSUS ON ADVANCEMENTS IN MUSCULOSKELETAL REHABILITATION AND PHYSIOTHERAPY: INSIGHTS FROM A VIRTUAL SYMPOSIUM OF 623 EXPERTS ON EVIDENCE-BASED PRACTICES

A. Maiya[1], Z. Veqar[2], S. Shah[3], C. Mehta[4]

[1]Manipal College of Health Professions, Manipal, India, [2]Centre for Physiotherapy and Rehabilitation Sciences, Jamia Millia Islamia, Delhi, India, [3]Rita A Patel Institute of Physiotherapy, CVM University, Anand, India, [4]Aquamax Rehab and Wellness, Mumbai, India

Introduction: This study aimed to establish a consensus on emerging evidence and advancements in rehabilitation and physiotherapy within the Indian healthcare setting. By focusing on contemporary clinical developments, the symposium aimed to develop agreement on best practices, guide future directions, and create contextually relevant approaches for physiotherapists in India.

Methods: The virtual symposium, *Vital Musculoskeletal Learning & Insights of New Innovations in Physiotherapy*, held on 8th September 2024, celebrated World Physiotherapy Day. It included four core panelists and 623 physiotherapists from diverse regions, collectively representing over 7,500 man-years of clinical experience. A structured, evidence-based questionnaire with 17 questions was developed, focusing on contemporary innovations. Participants rated statements using a 5-point Likert scale. Statistical analysis was performed using GraphPad 10.3.0, with consensus defined as a weighted score exceeding 100.
Results: Key findings include: 71.5% strongly agreed that YouTube is unreliable for shoulder joint mobilization techniques (Weighted Score: 124.5); 77.6% agreed on the effectiveness of the Laser Shoe in reducing neuropathic pain in diabetes patients (Weighted Score: 123.5); 50.9% strongly agreed that core exercises improve balance, mobility, and quality of life post-Total Knee Arthroplasty (Weighted Score: 123.0); 44.8% strongly agreed that aquatic therapy enhances postural balance and muscle strength in chronic stroke patients (Weighted Score: 122.8); 69.3% strongly agreed that diaphragmatic breathing combined with core exercises improves pain and disability in chronic low back pain (Weighted Score: 122.7); and 41.8% strongly agreed that Diclofenac diethylamine 2.32% gel applied twice daily is effective for acute ankle sprains (Weighted Score: 121.8). The overall mean response scores were: Agree: 53±20 (95% CI 43 to 63), Strongly agree: 46±21 (95% CI 35 to 57), $p<0.0001$.
Discussion: The symposium successfully established consensus on key advancements in rehabilitation, including core exercises, aquatic therapy, and emerging technologies like the Laser Shoe. Strong agreement was noted on the effectiveness and convenience of Diclofenac diethylamine 2.32% gel. These findings emphasize the importance of evidence-based approaches in physiotherapy, offering valuable insights into effective interventions that enhance patient outcomes. The consensus supports tailored rehabilitation strategies for the Indian healthcare context, guiding clinical practice and future research.

P220

IMPACT OF HOUSEHOLD CHARACTERISTICS ON PATIENT OUTCOMES POST HIP FRACTURE: A RETROSPECTIVE OBSERVATIONAL STUDY IN LONG-TERM RHEABILITATION FACILITIES

A. Medioli[1], C. Cucchetti[1], S. Orsucci, L. Gallicchio[1], Y. Condolino Gambertoglio, P. Contini[1], N. Lowbadi[1], G. Civardi[1]

[1]Clinca Sant'Antonino, Piacenza, Italy

Objective
Hip fracture is common in older people and has significant health and care implications. Objective of the study is to verify whether household characteristics have influenced the clinical outcome upon discharg in hip fracture patients in long-term rehabilitation.
Material and Methods
In a retrospective observational study in a long- term care 3054 patients,from1/1/21 to 30/6/24, were analysed. We selected 518 patients with hip fracture correlating them with the number of days of hospitalization and the outcame dimmission: return home, return home with hiring a paid carer, activation of home nursing service, other hospital, retirement home, emergency room, voluntary resignation or death.The caregiver profile which was divided in : daughter/son and others During the entrance interview with the care giver , a hypothesis of discharge outcome was made with the care giver which was correlated with the actual discharge destination upon discharge
Results:
The average age in the cluster analyzed is 81.1. The sample analyzed is 70,2% female and 29.8% male. The average hospital stay is 31.125. Our data show how caregiver characteristics change discharge outcomes. Significantly increasing the days of hospitalization if the caregiver is not a first-degree relative.The expected discharge method also changes based on the type of caregiver. the caregivers were divided into: first degree relatives (daughters and sons) and others. Caregivers represented by sons and daughters had a significantly lower average hospital stay than other caregivers 25.45 days versus 36.8 with a standard deviation 8.025. The discharge method changes significantly based on what was assumed at the time of admission based on the type of caregive. The type of discharge was divided into home, home with assistance, acute hospital, nursing home, hospice, emergency room voluntary discharged. First degree relatives are more efficient with regard to actual discharge rather than planned discharge with a standard deviation 6.71.
Conclusions:
The data analyzed confirm that impact of household characteristics is statistically significant both with regard to the average hospital stay and the patient's expected discharge.Collecting data regarding the type of caregiver is important from the moment the patient enters the facility in order to better share the patient's journey

P221

OSTEOGENESIS IMPERFECTA-CASE REPORT

A. Miceva-Trajkova[1], G. Andonov[1], M. Miceva[2]

[1]General Hospital Strumica, Strumica, Republic of North Macedonia, [2]PZU Dr. Micev, Strumica, Republic of North Macedonia

A heritable disease in which bones fracture easily, often with no obvious cause or minimal injury.
In this case we observe mother and daughter suffering from OI - the mother is 32 years old, disabled since she was 3 years old, with 128 fractures so far, 60% damaged hearing, HA, 60 surgeries, problems with breathing and on the other side, a 9-year old daughter, with 6 fractures so far, spondylolysthesis and by this moment, only pain in the ears. Both have blue sclera, triangular face, muscle weakness. The disease in both patients is confirmed with genetic testings and radiological studies, bone densitometry and laboratory by MANU. The treatment is non-specific. It is a multidisciplinary, involving medical, orthopaedic, physiotherapy and rehabilitation specialists. Bisphosphonates, vitamin D and calcium, several surgeries for correction of bone deformities. In the most common forms, people with OI have a gene that

carries incorrect instructions in one copy of the gene for making collagen, a substance that makes bones strong. The gene causes the body to not make enough collagen or the collagen does not work properly and this leads to weak bones that break easily. In most cases, patients with OI inherit this gene from one parent or in other forms, a mutation in gene from both parents. The disease can be in dominant or recessive form. It is still not clear, will the test that are by this moment performed only on laboratory mice, also be performed on patients in future. Maybe in future we should give more accent and make the OI community more knowledgeable about OI genetics and the concept of gene therapy.
Overall, OI is a condition that requires ongoing management, but with appropriate care, many patients with OI can lead active lives.

P222

CASE REPORT – HUNGRY BONE SYNDROME IN CASE OF MULTIPLE MYELOMA

K. Rupwane[1], A. Dutta[1], A. Mithal[1]

[1]Max Superspeciality Hospital, Saket, Delhi, Delhi, India

We present the case of prolonged hypocalcemia in a 76-year old man, with prior history of type 2 diabetes, chronic kidney disease(CKD stage 2), and multiple myeloma (MM) diagnosed one month ago with multiple lytic lesions. Prior to current presentation, the patient received 2 doses of denosumab- first (60 mg) for hypercalcemia with acute kidney injury (1 month back; lead to the diagnosis of MM) and second (120 mg) along with the first chemotherapy dose. He was diagnosed to have asymptomatic hypocalcaemia, during the second chemotherapy session. Labs revealed albumin-corrected calcium: 7.1 mg/dL (8.4-10.2), creatinine: 3.7 mg/dL (0.2-1.2), magnesium 1.4 mg/dL (1.8-2.6), phosphate: 2.9 mg/dL (2.5-5), 25-hydroxy vitamin D: 45.3 ng/mL (30-50). Trousseau and Chvostek signs were negative, but EKG showed QTc prolongation(520 ms).
He received intravenous calcium gluconate after endocrinology reference and was discharged on calcium carbonate 1000 mg TID and calcitriol 0.25 mcg TID. Due to Hypocalcemia (6.1-7.9 mg/dL), hypophosphatemia (3-3.4 mg/dL at CKD4-5) and hypomagnesemia (1-1.7 mg/dL) persisted during follow-up despite up-titrating calcitriol (0.5 mcg TID) and supplementing magnesium (100 mg/day). This prompted further investigations: parathyroid hormone (PTH; 252.2-315.8 pg/mL), alkaline phosphatase (ALP; 221-307IU/L), 24-hour urinary calcium: 34.2 mg/g creatinine, C-terminal telopeptide of type I collagen (CTX; 970 pg/mL), and procollagen type 1 N-terminal propeptide (P1NP; 199.6 ng/mL). In the patient, prolonged hypocalcemia, hypophosphatemia, hypomagnesemia, and elevated CTX, P1NP, ALP confirmes the diagnosis of hungry bone syndrome (HBS). After gradual biochemical improvement (Table 1), serum calcium normalized to 8.4 mg/dl and doses of calcium and calcitriol were reduced.

Conclusion

HBS can cause prolonged hypocalcemia due to rapid remineralization of diseased bone following profound osteoclast suppression. This case highlights a rare occurrence of HBS after denosumab in MM, emphasizing the need for monitoring in similar patients.

THE ASSOCIATION BETWEEN THE DURATION OF DM AND BLOOD SUGAR CONTROL WITH OSTEOARTHRITIS SEVERITY AMONG PATIENTS ATTENDING THE ORTHOPEDIC CLINICS AT KING ABDULLAH MEDICAL CITY, MAKKAH, SAUDI ARABIA

A. Aladraii[1], A. Mohammed[1]

[1]Orthopedic department, king Abdullah medical city, Makkah, 24246, Saudi Arabia, Makkah, Saudi Arabia

Background: Osteoarthritis (OA) has become the most common chronic condition affecting the knee. Evidence suggests a possible link between diabetes mellitus (DM) and the amplification of OA symptoms and severity.
Objectives: The aim of this research is to determine the association between the duration of diabetes mellitus (DM) and blood sugar control, with the severity of knee osteoarthritis (KOA).
Material and Method: A retrospective cross-sectional study design was used with a sample size 211 diabetic patients with knee osteoarthritis who attended the orthopedic clinic at King Abdullah Medical City (KAMC). The collection of data encompassing age, gender, medical history associated with diabetes mellitus, and knee osteoarthritis was collected from patient medical records, and the grading of knee osteoarthritis severity was determined through the application of the Kellgren and Lawrence system.
Results: There was a good positive correlation between HbA1c and the severity of osteoarthritis (r = 0.015). The severity of knee osteoarthritis was higher among the patients who had diabetes for >10 years.
Conclusion: Research found a strong link between high HbA1c levels and the severity of knee osteoarthritis. Long-term diabetes patients had more severe osteoarthritis symptoms. Based on the study findings, we recommend implementing educational programs on osteoarthritis awareness for individuals with diabetes.

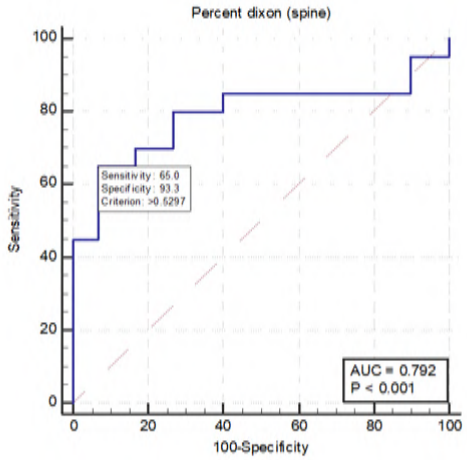
P224

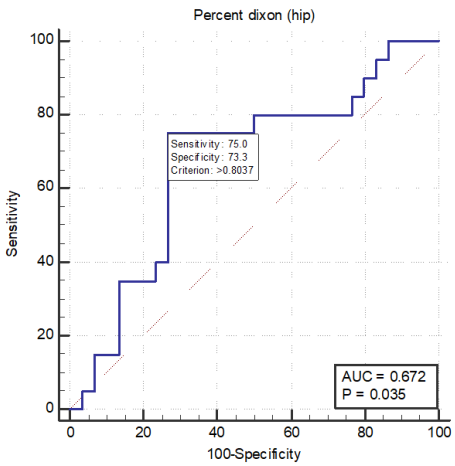
DIXON MRI FOR ASSESSMENT OF BONE MARROW FAT FRACTION IN TYPE 2 DIABETES

A. Mousa[1], R. Ramadn[1], A. Wafa[1], N. Tharwat[1]

[1]Mansoura University, Mansoura, Egypt

Objective: Diabetes is associated with increased fracture risk. As evidence that other components besides the mineral component may be important in the evaluation of bone strength. Dixon MRI can be used to quantify bone marrow fats by assessing the fat fraction (FF) in bone marrow.
Material and methods: This case control study was carried out at Mansoura Specialized Medical Hospital, Endocrinology Outpatient Clinic, and radiology department Mansoura University. It included 38 premenopausal females and ≤50 years males patients with type 2 diabetes and 30 normal healthy age, sex, and BMI matched population. Sagittal and Coronal Dixon MRI were carried out at lumbosacral spines and both hips respectively.
Results: FF measured by Dixon MRI at spines but not at hips was significantly higher in diabetics than controls and was significantly correlated with fat fraction at hip and age of patients. ROC curve analysis showed that FF >0.5297 at spine, (with sensitivity of 66% and specificity of 93.3%) and >0.8037 at hip (with sensitivity of 75% and specificity of 73.3%) can differentiate increase bone marrow fat in diabetes from control group.
Conclusion: Higher bone marrow fat in diabetes could be identified as a potential marker for diabetes-related skeletal fragility that can be used as potential therapeutic target .





P225

ULTRASOUND-BASED EVALUATION OF SHOULDER COMPLICATIONS IN TYPE 2 DIABETES MELLITUS: A RETROSPECTIVE ANALYSIS

S. Ochea[1], A. Florescu[1], C. Criveanu[1], S. Dinescu[1], C. Bita[1], A. Ananu[1], A. Cojocaru[1], A. Musetescu[1]

[1]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Objectives: To evaluate the prevalence and characteristics of structural alterations in the rotator cuff among diabetic patients.
Methods: This retrospective observational study analyzed data

from patients admitted to the Rheumatology department between April 2022 and December 2024. The patients considered eligible were previously diagnosed with T2DM using ADA 2018 criteria, had been undergoing long-term treatment with oral anti-diabetic drugs and reported subjective complaints of chronic pain and functional impairment of the shoulder. The shoulder involvement was assessed using musculoskeletal ultrasonography with a 12MHz linear probe.
Results: A total of 100 patients were included (64 females, 36 males). The mean age was 66,4 and the average HbA1c was 7,4 % (range: 4.7-11.2%). The vast majority of participants were overweight, with only six having a normal body mass index. The most affected tendon was the supraspinatus, as follows: 71% of the subjects exhibited intra-tendinous calcifications (p=0,002, 95% confidence intervals (CI) 0,033-0,149), 50 % had a full-thickness supraspinatus tendon tear (p=0,03, CI: 0,004-0,135), 49 % had a partial tear and 40% had insertional enthesophytes. The second most injured tendon was the subscapularis, with the most prevalent lesions being full-thickness tears (11%) and calcifications (30%). Only 21 participants exhibited involvement of the infraspinatus. Subacromial-subdeltoid bursitis was also present in 38% of the individuals.
Conclusions: Although changes in the musculoskeletal system are not among the most common complications of diabetes mellitus, the impact on the patients' quality of life is particularly significant in terms of limited mobility and functionality, chronic pain and total discomfort. The present study demonstrates that a significant percentage of the T2DM patients encounter rotator cuff pathology, with the supraspinatus being the most frequently affected site. Ultrasonographic screening could be a useful tool for early detection and management of the musculoskeletal impairments in diabetes mellitus.
Mușetescu AE et al. Life. 2022; 12(4):470.

CYSTIC LUNG DISEASE IN PRIMARY SJÖGREN'S SYNDROME- AN UNDERDIAGNOSED ENTITY: A SERIAL CASE REPORT

A. Cojocaru[1], A. Florescu[1], C. Criveanu[1], S. Dinescu[1], C. Biță[1], A. Vreju[1], S. Ochea[1], A. Mușetescu[1]

[1]University of Medicine and Pharmacy of Craiova, Craiova, Romania

Objective: Combined pulmonary fibrosis and emphysema is a rare phenotype of diffuse interstitial pneumopathy identified in primary Sjögren's syndrome (pSS), which usually consists of pan-lobular pulmonary emphysema of the upper lobes and basal interstitial features similar to usual interstitial pneumonia. We present a case series with this particular pulmonary phenotype.
Material and Methods: We analyzed 6 patients aged between 43 and 66 years (5 women, 1 man) diagnosed with pSS for several years, who had associated atypical lung damage in evolution.
Results: The patients presented clinical symptoms of sicca syndrome, fatigue, inflammatory pain in the small joints of the hands and feet, without significant respiratory symptoms or radiographic changes, high titers of anti-SS-A, anti-Ro52 antibodies and RF in all cases, anti-SS-B antibodies- 3 cases, C3 hypocomplementemia- 3 cases, C4- 2 cases, hypergammaglobulinemia, persistent inflammatory biological syndrome, intense inhomogeneous aspect of the glandular parenchyma, multiple hypoechoic areas >2mm and hyperechoic bands, with positive Power Doppler signal at ultrasonography of the salivary glands and a positive result for lymphocytic sialadenitis on lip biopsy. One of the patients presented hematological damage with severe thrombocytopenia-5000/mmc. HRCT revealed a cystic aspect of the lung parenchyma characterized by the presence of numerous panlobular and/or subpleural emphysema bubbles, with thin walls, located predominantly in the upper lobes and basal or diffuse fibrotic lesions. DLCO showed a quantified reduction in 2 of the patients (70%, 62%), without significant plethysmographic changes.
Conclusions: Emphysema is a rare manifestation of pSS, usually not visualized on chest X-ray, and awareness of this association may lead to an earlier diagnosis and allow early initiation of immunosuppressive treatment. In patients with seropositivity for anti-SS-A and anti-Ro52 antibodies, clinical screening and lung function tests are necessary for monitoring and should include chest HRCT especially if there is a reduction in DLCO.

OSTEOPOROSIS IN A WOMEN WITH A RARE BLOOD DISORDER

T. Stratigou[1], G. I. Lambrou[2], A. Samartzi[3], M. Tzanela[1], A. N. Tsartsalis[3]

[1]Department of Endocrinology Diabetes and Metabolism, European and National Expertise Center for Rare Endocrine Disorders, "Evangelismos - Polykliniki" General Hospital, Athens, Greece, [2]National and Kapodistrian University of Athens, Choremeio Research Laboratory, First Department of Pediatrics, Athens, Greece, [3]Department of Endocrinology Diabetes and Metabolism, Naval Hospital of Athens, Athens, Greece

Objectives
Secondary osteoporosis is a common clinical entity. It is also common in patients with hematological diseases such as β-Thalassemia Major, multiple myeloma and hemophilia. The pathophysiological mechanism causing bone loss is still under investigation
Patient a method
We report a case of osteoporosis in a 65 -year- old women with a myelodysplastic syndrome with mutation in SF3B1 (Exon 15, c. 2098A>G) and JAK2 (Exon 14, c.1849G>T). Patient received Denosumab for 5 years, however, she performed vertebrae fractures in lumbar spine (L3, L4, L5). Consequently, she received alendronate for one year and she also performed vertebrae fractures in thoracic spine (T9 and T12). Finally, she received zolendronic acid iv once per year with calcium and vitamin D.

Results
Two years of zolendronic acid resulted in improvement in Bone Mineral Density and patient has not new osteoporotic fractures.
Conclusions
Zolendronic acid is very effective treatment for protection of osteoporotic fractures and it appeared to be more effective than other bisphosphonates and denosumab, so that could first line treatment in these patients. This result is in agreement with administration of other hematological disorders in reducing osteoporotic fractures
Key words: osteoporosis, bone mineral density, zolendronic acid

P228

VARIATIONS IN POST-OPERATIVE FOLLOW-UP OF PATIENTS UNDERGOING ARTHROPLASTY FOR OSTEOARTHRITIS

A. Naraen[1], P. Shrinivasan[1], A. Naraen[2], R. Pydisetty[1]

[1]Mersey and WestLancs NHS Trust, Prescot, United Kingdom, [2]Leeds Teaching Hospitals, University of Leeds, Leeds, United Kingdom

Introduction: There were wide variations in follow-up protocols for knee and hip osteoarthritis patients treated with arthroplasty in the Mersey and West Lancs (MWL) NHS Trust, after being discharged. Following the results, the investigation was taken across the united Kingdom and beyond.
Objective: To regularize and improve the arthroplasty follow-up service.
Inclusion: Patients undergoing primary arthroplasty
Exclusion: Revision arthroplasty, infected, dislocated joint replacements, peri-prosthetic fractures.
Methods: With the help of Google Forms, a questionnaire was sent across to all the Orthopaedic consultants of MWL NHS Trust. The response was then analyzed. The questionnaire was then forwarded to Orthopaedic colleagues in various centres across the world.
Results: There was a wide variation observed in both the timing and types of radiographs requested at follow-up clinics.
Conclusion: We reviewed the follow-up recommendations by various Orthopaedic associations.
Discussion: We suggest an economic and safe protocol for review of arthroplasty patients in Follow-up clinics.

P229

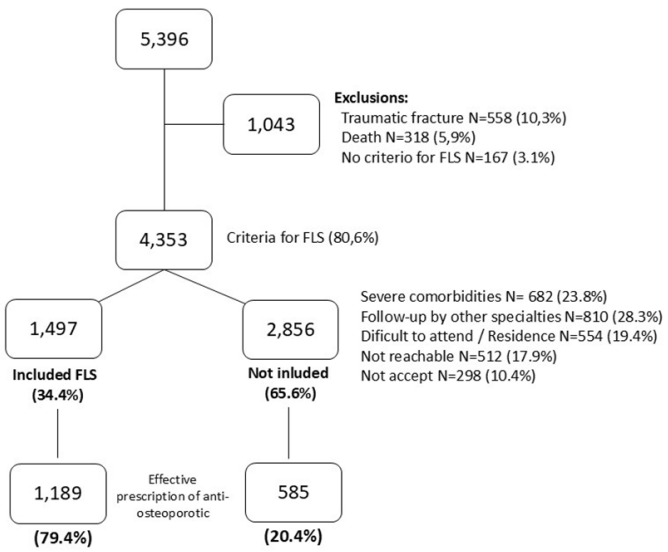
IMPACT OF THE FLS MODEL ON PATIENTS WITH MAJOR FRACTURE IN GRAN CANARIA; 2018-2022 EXPERIENCE

A. Naranjo[1], C. Sarmiento[2], A. Molina[1], S. Fuentes[1], L. Caceres[1], S. Ojeda[1]

[1]Hospital Dr. Negrin, Las Palmas, Spain, [2]Universidad de las Palmas de Gran Canaria, Las Palmas, Spain

Introduction: The Fracture Liaison Service (FLS) is the most effective model for secondary prevention.
Objectives: To analyze THE impact of the FLS unit on the prevention of new fractures.
Methods: Patients >50 years were attended at the emergency department for fractures of the proximal femur, proximal humerus, distal forearm, pelvis or vertebra during the period 2018-2022 were included. A file was constructed containing demographic data, type of fracture, inclusion in the FLS and the initiation of treatment to prevent new fractures. A sample of patients not treated at the FLS was selected for estimating the prophylaxis of fractures under standard care management.
Results: A total of 5,396 patients were included, 74.2% women, with a mean age of 74 years. After excluding 558 traumatic fractures (10.3%), 318 (5.9%) deaths, and 167 (3.1%) cases due to a lack of criteria, the sample of potential patients who were candidates for FLS was 4,353. This represented 80.6% of the initial sample, of which 1,497 patients (34.4%) were attended at the unit. Factors independently associated with referral to the FLS were younger age (OR 0.97; 95% CI 0.97-0.98), female sex (OR 2.24; 95% CI: 1.91-0.98). 2.61) and humerus fracture (OR 1.34; 95% CI: 1.16-1.55). Treatment to prevent fractures was verified in 1,189 patients (79.4%) in the FLS group and in 585 (20.4%) of those with fragility fractures who were not included. At the healthcare level, the services provided by the FLS resulted in an increase of treated patients from 20% in standard care to 41% with the FLS model.

		Assessed by the FLS		
	total	No	Yes	%
Hip	1,541	1,068	473	30.7
Distal forearm	1,220	732	488	40.0
Humerus	904	524	380	42.0
Vertebra	400	276	124	31.0
Pelvis	288	256	32	11.1



Conclusions: In terms of treatment initiation to new fractures prevention at the healthcare level the FLS achieved a two-fold increase. The high incidence of fractures and the progressive aging of the population underlines the effectiveness of the FLS secondary prevention model.

P230

SUBTROCHANTERIC FEMORAL FRACTURES (ATYPICAL OR NOT) AND PREVIOUS TREATMENT WITH BISPHOSPHONATE

A. Naranjo[1], A. Molina[1], S. Fuentes[1], L. Caceres[1], S. Ojeda[1]

[1]Hospital Dr. Negrin, Las Palmas, Spain

Introduction: The subtrochanteric femoral fracture requires special attention in a *Fracture Liaison Service* (FLS) unit to screen for atypical fracture.
Objectives: To analyze the characteristics of the subtrochanteric fracture in a FLS.
Methods: Patients >50 years were attended for fragility fracture of the proximal femur during the period 2022-2024 were included. The type of fracture and fracture risk factors as well as previous treatment for osteoporosis were analyzed. For atypical femoral fracture we applied ≥4 of the following major criteria (Shane et al. J Bone Miner Res. 2014): 1) No or minimal trauma; 2) line begins laterally and is basically transverse; 3) may progress to complete with medial spicule; 4) not comminuted or minimally comminuted; and 5) periosteal thickening in external cortex.
Results: A total of 390 patients were included, 82.8% women, mean age 79 years. 192 (49%) fractures were of the femoral neck, 142 were pertrochanteric (43%) and 30 (7%) were subtrochanteric. The table shows the characteristics of the patients. The subtrochanteric fracture was associated with a higher body mass index and previous treatment with bisphosphonate. Multivariate analysis resulted in OR 1.124 (95% CI 1.045-1.209; *p*=0.002) for BMI and OR 2.811 (95% CI 1.146-6.895; *p*=0.02) for previous bisphosphonate. In patients with subtrochanteric fracture, 6 had received alendronate, 1 risedronate and 1 denosumab. One patient (previous alendronate) met criteria for atypical femoral fracture (0.25% of the whole sample, 3.3% of subtrocanteric type and 2.1% of patients with previous treatment with bisphosphonate or denosumab). None of the patients had a contralateral femoral fracture during the average follow-up of 24 months.

	All patients (n=390)	Subcapital or pertrocanteric hip fracture (n=360)	Subtrocanteric hip fracture (n=30)	p
Female, N (%)	323 (82.8)	297 (82.5)	26 (86.6)	0.56
Age, mean (SD)	79.0 (9.3)	78.9 (9.4)	80.0 (7.4)	0.50
Assessment during admission, N (%)	248 (63.6)	240 (66.6)	22 (73.3)	0.45
Years of education <8, N (%)	311 (79.7)	284 (78.8)	27 (90)	0.14
Risk factors, N (%)				
Body mass index, mean (SD)	25.9 (5.0)	25.8 (4.7)	28.7 (5.3)	<0.001
Previous fragility fracture	99 (25.3)	86 (23.9)	11 (36.6)	0.12
Parent hip fracture	69 (17.7)	63 (17.5)	6 (20)	0.73
Current smoker	45 (11.5)	42 (11.6)	3 (10)	0.78
Glucocorticoids	30 (7.7)	26 (7.2)	4 (13.3)	0.22
Rheumatoid arthritis	13 (3.3)	12 (3.3)	1 (3.3)	0.99
Secondary osteoporosis	76 (19.5)	68 (18.8)	8 (26.6)	0.30
Alcohol	15 (3.8)	14 (3.8)	1 (3.3)	0.63
Previous densitometry, N (%)	100 (25.6)	89 (24.7)	11 (36.6)	0.15
Femoral neck T score, mean (SD)	-2.1 (1.0)	-2.2 (1.0)	-2.0 (1.1)	0.36
Previous bisphosphonate or denosumab, N (%)	47 (12.0)	39 (10.8)	8 (26.6)	0.01

Conclusions: Subtrocanteric femoral fractures are associated with higher BMI and the use of bisphosphonate or denosumab. Atypical fracture is rare, accounting only 3% of subtrocanteric type.

P231

ADHERENCE TO ROMOSOZUMAB VERSUS PTH ANALOGUES IN PATIENTS WITH VERY HIGH RISK OF FRACTURE

A. Naranjo[1], A. Molina[1], S. Fuentes[1], L. Caceres[1], S. Ojeda[1]

[1]Hospital Dr. Negrin, Las Palmas, Spain

Introduction: Adherence to treatment to prevent fractures is a key point in the management of osteoporosis, especially in those with high risk of fracture. The introduction of romosozumab (RMZ) and abaloparatide (ABL) in Europe leads us to consider whether the patient profile and adherence are similar to teriparatide (TPT).
Objectives: To analyze the characteristics of patients prescribed anabolics in a reference hospital and their adherence to treatment.
Methods: Patients from the FLS unit and monographic clinic who were prescribed an anabolic (TPT, ABL, RMZ) in the last 5 years were analyzed. Demographic data and fracture risk factors, densitometric values, BMI and previous treatment for osteoporosis were collected. An expert nurse instructed the patients for subcutaneous administration of the drug. The criterion for including a patient was having at least one electronic prescription of anabolic. Adherence was assessed by dispensing in the pharmacy, recording the reason for suspension if applicable.
Results: 131 patients were included, 51 treated with TPT, 28 with ABL and 52 with RMZ (table). None of the patients in the RMZ group had high cardiovascular (CV) risk or a history of CV events. Vertebral fracture was the most frequent fracture, 72% in the TPT group, 70% in the ABL group and 67% in the RMZ group.
Adherence at 6 months was >85% with TPT, ABL and RMZ. Adherence at 12 months was 73.5% with TPT and 81.5% with RMZ (p=0.14). Adherence to the complete treatment regimen was 48%

with TPT and 81% with RMZ (p<0.01) (figure).
The reason for suspension was an adverse effect in half of the cases of TPT, ABL and RMZ, while in the rest of the cases the reason was the patient refusal.
Conclusions: The profile of patients with anabolic treatment is consistent with current guidelines. Adherence at 6 months is similar for TPT, ABL and RMZ, but adherence to full treatment is significantly higher for RMZ.

OSTEOPOROSIS IN RHEUMATOID ARTHRITIS: COMPARATIVE INSIGHTS INTO SEROPOSITIVE AND SERONEGATIVE SUBTYPES

A. Nistor[1], E. Russu[1], L. Chislari[1], E. Deseatnicova[1], L. Groppa[1]

[1]State University of Medicine and Pharmacy Nicolae Testemitanu, Chisinau, Moldova

Background: Rheumatoid arthritis (RA), a systemic autoimmune disease, is classified into seropositive (SPRA) and seronegative (SNRA) subtypes, with osteoporosis (OP) being a significant comorbidity. SPRA is characterized by serological markers like rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA), whereas SNRA lacks these markers, complicating early diagnosis and intervention.
Objective: This study aimed to compare OP prevalence, clinical manifestations, and systemic complications in SPRA and SNRA patients, with a focus on bone health and inflammatory markers.
Methods: A total of 100 RA patients (50 SPRA, 50 SNRA) meeting ACR/EULAR 2010 criteria underwent comprehensive clinical and paraclinical evaluations, including disease activity (DAS28), bone mineral density (BMD) assessment via dual-energy X-ray absorptiometry (DXA), and systemic complication analysis. Quality

of life was assessed using the Health Assessment Questionnaire (HAQ).

Results:

• Osteoporosis prevalence: OP was more frequent in SPRA (48% vs. 30% in SNRA, $p < 0.05$), particularly in patients with high inflammatory activity. Vertebral fractures were observed in 18% of SPRA patients compared to 6% in SNRA.

• Bone Mineral Density (BMD): SPRA patients had significantly lower BMD at the lumbar spine (T-score: -2.8 ± 0.4) and femoral neck (-2.6 ± 0.3) compared to SNRA (-2.2 ± 0.5 and -2.0 ± 0.4, respectively, $p < 0.05$).

• Inflammatory burden: SPRA had higher DAS28 scores (7.25 ± 0.99 vs. 6.78 ± 0.19, $p < 0.05$) and elevated CRP and ESR levels, correlating with greater bone loss.

• Quality of life: SNRA patients reported better HAQ scores (1.68 ± 0.08 vs. 1.92 ± 0.07 in SPRA, $p < 0.05$), reflecting less functional disability.

Conclusions:

Osteoporosis is a prevalent and severe comorbidity in RA, particularly in SPRA patients due to greater systemic inflammation and disease activity. Early OP screening and management are critical, especially in SPRA, to prevent fractures and improve patient outcomes. Enhanced diagnostic criteria for SNRA, combined with vigilant BMD monitoring, can mitigate long-term complications and optimize care for RA patients.

P233

TNFAIP3, TNFA, TNFAIP3, CTLA-4, BAFF, KCNS1 AND STAT4 POLYMORPHISMS ASSOCIATED WITH NON-RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS SWITCHING BETWEEN BDMARDS AND JAKI

A. M. Lila[1], A. O. Bobkova[2], A. E. Karateev[2], I. A. Guseva[2], E. Y. Samarkina[2]

[1]V.A. Nasonova Research Institute of Rheumatology, Department of Rheumatology Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Moscow, Russia, [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Genetic single nucleotide polymorphisms (SNPs) may determine response to biologic disease-modifying antirheumatic drugs (bDMARDs) and Janus kinase inhibitors (JAKi) in rheumatoid arthritis (RA). The aim of this study was to determine the association between polymorphisms of TNFAIP3 (rs10499194), TNFA (rs1800629), CTLA-4 (rs231775), TNFSF13B (BAFF) (rs9514828), KCNS1 (rs734784) and STAT4 (rs7574865) genes and poor response to switching between bDMARDs and JAKi in RA patients who failed previous bDMARDs/JAKi.

Materials and Methods. The study group consisted of 94 patients with RA (85.1% female, 47.2 ± 13.8 years of age) with moderate/high activity (DAS28-CRP - 5.38 ± 0.90) in spite of bDMARD/JAKi therapy. All patients were switched to bDMARD/JAKi with different mechanisms of action, including 12 (12.8%) to TNFi, 27 (28.7%) to iIL-6, 46 (48.9%) to rituximab and 9 (9.6%) to JAKi. RA activity was assessed by DAS28-CRP, SDAI and CDAI indices after 6 months. Two groups were identified: responders (achievement of remission or low activity DAS28-CRP < 3.2, SDAI < 11, CDAI < 10) and non-responders (maintenance of moderate/high activity according to the indices). All patients underwent polymerase chain reaction genotyping for SNPs in the above genes.

Results. There were 47 (50%) patients each in the bDMARD/JAKi responder and non-responder groups. Carriers of the variant T (TT+CT) allele of the TNFAIP3 SNP (rs10499194) and the T (GT+TT) allele of STAT4 (rs7574865) independently increased the risk of non-response to bDMARDs/JAKi (TT+CT vs. CC: odds ratio (OR) =2. 84 [95% confidence interval (CI): 1.23-6.56]; p=0.013; OR=3.18 [95% CI: 1.36-7.46]; p=0.007, respectively). The presence of T minor alleles of the BAFF gene SNP (rs9514828) and the G (AG+GG) KCNS1 gene (rs734784) were independently associated with a reduced risk of treatment failure (CC vs. CT+TT: OR=0.25 [95% CI: 0.10-0.66]; p=0.004; OR=0.29 [95% CI: 0.12-0.74]; p=0.008, respectively). For the TNFA gene SNP (rs1800629) the multiplicative model (G vs A) was statistically significant (OR=3.12 [95% CI: 1.1-9.03] p=0.037), for the CTLA-4 gene (rs231775) the superdominant model (AA+GG vs AG: OR=2.6 [95% CI: 1.14-6.25] p=0.022).

Conclusions. The genes TNFAIP3 (rs10499194), BAFF (rs9514828), KCNS1 (rs734784) and STAT4 (rs7574865) were identified as four genetic predictors of treatment failure when switching between bDMARDs and JAKi.

***Keywords**: inefficiency, SNPs, gene, TNFAIP3 (rs10499194), TNFA (rs1800629), BAFF (rs9514828), KCNS1 (rs734784), STAT4 (rs7574865), bDMARDs, JAKi, switching.*

P234

CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS WHO REQUIRE SWITCHING BETWEEN BDMARDS AND JAKI IN REAL CLINICAL PRACTICE

A. M. Lila[1], A. O. Bobkova[2], A. E. Karateev[2]

[1]V.A. Nasonova Research Institute of Rheumatology, Department of Rheumatology Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Moscow, Russia, [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

The purpose of this study is to evaluate clinical features and pharmacotherapy in RA patients who needed bDMARDs/JAKi switching.

Materials and Methods. 103 patients with RA hospitalized to the Research Institute of Rheumatology (Moscow, Russia) were consecutively enrolled to this study. All patients met the ACR criteria for RA and required switching (changing bDMARDs or JAKi to another drug class) due to non-response, adverse events (AE), or intolerance. The majority were women – 85.4%, mean age 46.9±13.7 years, median of disease duration – 11.0 [6.0-16.5]. The examined patients were RF - positive - 78.6%, ACPA-positive - 71.8%, median SJC (swollen joint count)– 6.0 [4.0-9.0], PJC (painful joint count) – 11.0 [7.0-15.5], PtPGA (VAS) - 70,0 [60.0-80.0], PhPGA (VAS)

– 70.0 [60.0-70.0], CRP (mg/l) – 14.6 [4.05-33.15], ESR (mm/h) – 36 [14-64]. The inflammatory activity of RA was assessed using mean DAS28-ESR – 5.87±1.11, DAS28-CRP – 5.42±0.90, median CDAI - 32 [23.5-37.5] and SDAI – 32.5 [25.6-42.0] and corresponded to high disease activity. According to case histories 77.7% of patients used csDMARDs, more often methotrexate – 32.0% and leflunomide - 30.1%, less frequently sulfasalazine and hydroxychloroquine - 11.7% for each drug. The majority were taking glucocorticoids (GCs) – 62.1% and NSAIDs – 80.6%. At the time of inclusion to the study, all patients were switched to another therapy according to recommendation. Thus, rituximab was prescribed to 44.7%, iIL-6 - 30.1%, TNFi - 14.6%, JAKi - 9.6% and abatacept - 1%. Patients were divided into 3 groups: Group 1 - patients who required the first switch (n=50), Group 2 - second switch (n=39), Group 3 - ≥3 switches of bDMARDs/JAKi therapy.

Results. At the same time, PJC and PtPGA were significantly higher in groups 2 and 3. Patients in group 2 and 3, compared with group 1, showed a distinct trend to higher activity level on DAS28-ESR (P=0.052) and DAS28-CRP (P=0.057), and a significant difference on CDAI (P_{1-2}=0.01 and P_{1-3}=0.013) and SDAI (P_{1-2}=0.015 and P_{1-3}=0.011). Standard activity indices (DAS28, CDAI and SDAI) were higher in group 3 than in group 2, but this difference was not statistically significant (Figure 1). The frequency of AEs was significantly higher in group 3, compared with groups 1 and 2 (P1-3=0.027, P2-3=0.016). We analyzed therapy of bDMARDs/tsDMARDs for the period before hospitalization. Among all patients included to the study, 41 (39.8%) had previously used TNFi, 23 (22.3%) - JAKi, 17 (16.5%) - iIL-6, 11 (10.7%) - rituximab, and 11 (10.7%) - abatacept. In group 1, 50% of patients had previously used TNFi while there were no such patients in group 3 (p=0.003). In group 3, iIL-6 were more frequently used - 50% of patients versus 14.0% and 7.7% in groups 1 and 2, respectively (P1-3=0.006, P2-3=0.002). At the same time, new therapy after switch differed significantly. Most frequently prescribed for switch were rituximab, in 46 patients (44.7%) and iIL-6, in 31 patients (30.1%). Significantly less frequently - TNFi in 15 (14.6%) and JAKi in 10 (9.6%) patients.

Conclusion. The group of patients with repeated switching of bDMARDs/JAKi therapy was characterized by a higher PJC, higher PtPGA and disease activity indices (DAS28, CDAI and SDAI), than the group of patients with first switch of bDMARDs/JAKi. The most common bDMARDs for the first switch were TNFi, but for repeated switching (group 3) patients were no longer prescribed TNFi. iIL-6 and JAKi were most frequently used to continue treatment.

OSTEOPOROSIS AND FRACTURES AMONG OLDER ADULTS IN THE MUNICIPAL HEALTH PROGRAM OF XOCHITEPEC, MORELOS, MEXICO

A. Ortega[1], H. Rangel[2], A. Rivera[3], M. Romero[2], Y. Hernandez[3], C. Martinez[2], E. Zuñiga[3], R. Flores[3], G. Nogueda[4], A. Ledesma[5]

[1]Latin American University, Cuernavaca, Mexico, [2]National Institute of Public Health of Mexico, Cuernavaca, Mexico, [3]Health Directorate of the Municipality of Xochitepec, Morelos, Mexico, [4]University of the Valley of Cuernavaca, Morelos, Mexico, [5]National Autonomous University of Mexico, CDMX, Mexico

Introduction: Osteoporosis is a disease characterized by decreased bone density. Factors such as age, sex, genetics, calcium and vitamin D deficiency, and lack of exercise contribute to its development.

Objective: To determine the prevalence of older adults with osteoporosis and their history of fractures.

Methodology: This was a cross-sectional descriptive study conducted among older adults in Xochitepec, Morelos, from August to December 2022. A non-probabilistic sample of 278 participants from the Municipal Comprehensive Care Program was used. After obtaining informed consent, data collection was conducted through a survey with validated and standardized instruments focused on geriatric syndromes, health habits, and nutritional status. Statistical analyses were performed using R software (version 4.4.2; R Core Team, 2025).

Results: A total of 278 older adults participated, with a mean age of 67.3 years and a standard deviation of 7.35 years. The prevalence of osteoporosis was 8.6%, of which 79.2% were women. Fifteen respondents did not answer. However, the association between osteoporosis and sex was not statistically significant (p-value = 0.3555 > 0.05). The most prevalent ages for osteoporosis were 62 and 63 years, with this variable showing statistical significance (p-value = 0.0193 < 0.05). Among older adults with osteoporosis, 29.2% reported experiencing fractures in the past year. Additionally, a statistically significant association was found between osteoporosis and type 2 diabetes (p-value = 4.204e-07 < 0.05).

Conclusion: The findings of this study justify the implementation of prevention strategies in the municipality of Xochitepec, Morelos. These interventions aim primarily to prevent fractures that negatively impact the quality of life of older adults.

IDENTIFICATION OF NOVEL LOCUS ASSOCIATED WITH TRABECULAR BONE SCORE IN OLDER ADULTS: THE BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

M. Bidkhori[1], M. Akbarzadeh[2], N. Fahimfar[3], B. Larijani[4], I. Nabipour[5], A. Dehghan[6], K. Holakouie-Naieni[1], A. Ostovar[3]

[1]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Science, Tehran, Iran, Tehran, Iran, [2]Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, Iran, [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [4]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, [5]The Persian Gulf Marine Biotechnology Research Center, The Persian Gulf Biomedical Sciences Research Institute, Bushehr University of Medical Sciences, Bushehr, Iran, Tehran, Iran, [6]Department of Biostatistics and Epidemiology, MRC-PHE Centre for Environment and Health, School of Public Health, Imperial College London, London, United Kingdom, Tehran, Iran

Objective: This study aimed to identify genes related to Trabecular Bone Score (TBS) in the elderly population of Bushehr, a southern province of Iran.
Material and Methods: A Genome-Wide Association Study (GWAS) was performed on TBS in 2,071 participants of the Bushehr Elderly Health (BEH) program, a population-based cohort study. We investigated the association of more than 9.1 million Single Nucleotide Polymorphisms (SNPs) with the mean TBS of the lumbar spine from L1 to L4, using a Mixed Linear Model (MLM)-based GWAS. Adjustments were made for age, sex, and the first 10 principal components. The genotype data were analyzed using the GCTA version 1.91 and PLINK version 2.
Results: One locus on chromosome 2 (2p14) showed a statistically significant relationship with TBS L1-L4. There was a relationship between rs77405433-A on LINC02934, a long noncoding RNA, with TBS L1-L4 (β= -0.074, P= 4.9×10^{-9}).
Conclusion: One SNP of LINC02934 was associated with TBS. There is no direct evidence associating LINC02934 to bone health. Future studies could provide insights into its potential role in osteoporosis and bone quality.

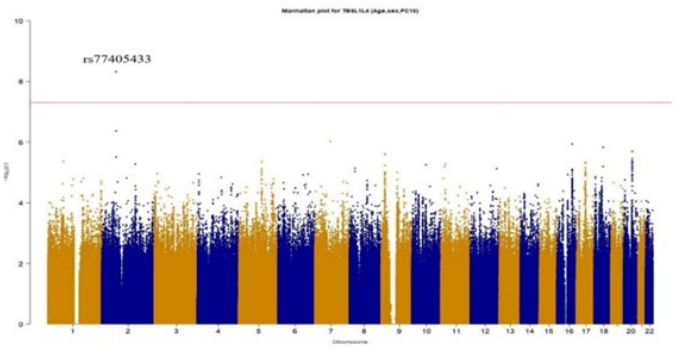

Fig. 1 Manhattan plot of the results from the GWAS of trabecular bone score L1-L4

BONE MINERAL DENSITY IN CHILDREN WITH INFLAMMATORY BOWEL DISEASES

A. Pachkaila[1], A. Halasheuskaya[2]

[1]Minsk Regional Children's Clinical Hospital, Minsk, Belarus, [2]Belarusian State Medical University, Minsk, Belarus

Objective: To evaluate mineral bone density (BMD) in children with inflammatory bowel diseases.
Material and Methods: The study included 64 (34 girls, 30 boys) children with inflammatory bowel diseases aged 2 to 18 years (median age – 13.5 (11.1; 15.6) years) who were examined at the Republican Center for Pediatric Osteoporosis. Crohn's disease was detected in 38 of the examined patients, ulcerative colitis – in 26 patients. Total body less head (TBLH) BMD and lumbar spine (L1-L4) BMD were measured by means of Dual-energy X-ray absorptiometry (DXA). In accordance with the ISCD 2019 Pediatric Official Positions low bone mineral density for chronologic age was defined when BMD Z-scores were less than or equal to -2.0 SD.
Results: The median L1-L4 BMD in the cohort of examined patients was 0.644 (0.535; 0.812) g/cm^2, median TBLH BMD was 0.742 (0.656; 0.842) g/cm^2. The median BMD Z-score (L1-L4) was -1.3 (-2.3; -0.6) SD, median BMD Z-score (TBLH) was -0.6 (-1.2; 0.3) SD. Low BMD was registered in 34,3% (22/64) of children, including 14 patients with Crohn's disease and 8 patients with ulcerative colitis. BMD Z-scores from -1.9 to -1 SD were detected in 26,5% (17/64) of patients. Secondary osteoporosis in accordance with the ISCD 2019 Pediatric Official Positions was diagnosed in 7 of the examined patients due to the presence of vertebral fractures.
Conclusion: Low bone density was found in every third patient, and osteoporosis – in every ninth patient with inflammatory bowel disease. The obtained results determine the need to optimize measures to prevent bone mineralization disorders in children with Crohn's disease and ulcerative colitis.

P238

FEASIBILITY OF MEASURING CLINICALLY MEANINGFUL CHANGE IN FRAILTY USING THE FIT-FRAILTY APP ON A SLOW-PACED REHABILITATION UNIT

A. Papaioannou[1], A. Relan[1], G. Ioannidis[1], M. Conroy[1], P. Hewston[1], J. Crawford[1], J. Lee[1], L. O'Malley[1], M. Wang[1], M. Sidhu[1], T. Woo[1], S. Keen[1], B. Misiaszek[1], T. D. Desinghe[2], E. Rubenschuh[2], S. Warcholak[2], S. Mcleod[2], S. Tariq[3], C. Kennedy[1]

[1]McMaster University, Hamilton, Canada, [2]Hamilton Health Sciences, Hamilton, Canada, [3]University of Toronto, Toronto, Canada

Objective(s): Most frailty tools are discriminative however, there is a need for feasible, evaluative measures to understand treatment response. The Fit-Frailty App is a comprehensive assessment of frailty considering medical history, nutrition, function, psychosocial, cognition, and physical performance domains. An overall score is calculated using a frailty index with items validated in large cohorts including the Canadian MultiCentre Osteoporosis Study. This study aimed to evaluate the feasibility of measuring clinically meaningful change in frailty following slow-paced rehabilitation.
Material and Methods: We recruited a convenience sample of 52 older adults admitted to a slow-paced rehabilitation unit in Hamilton, Canada. Research assistants administered the Fit-Frailty App within 3 days after admission and 3 days before discharge. Feasibility outcomes were evaluated based on a framework adapted from Thabane et al. The threshold for clinically meaningful change proposed by Theou et al. is >0.03.
Results: Between March and September 2024, n=125 were admitted, n=62 were screened, and n=52 consented (58% female, mean age=80.1±8.9 years, mean length of stay=55.7±24.9 days). Fracture was the most common primary diagnosis (29%), and sarcopenia was highly prevalent (94%). The mean user experience rating was high (8.8±1.5 on a 10-point Likert scale). Clinically meaningful change in frailty scores was captured in 32 of the 40 who completed follow-up. Those who improved meaningfully were more likely to be discharged home (78%) compared to those who did not (38%).
Conclusion(s): The Fit-Frailty App can be feasibly implemented on slow-paced rehabilitation units to measure change in frailty. Monitoring treatment response may support successful discharges and prevention or management of related outcomes such as osteoporosis and fractures.
Acknowledgments: This work was supported by EPIC-AT, McMaster Institute for Research on Aging, and the Hamilton Health Sciences Foundation.

USE AND CLINICAL PROFILE OF THE PATIENT UNDER TREATMENT WITH ROMOSOZUMAB

A. Perez Martin[1], C. Palacios Fernandez de Arroyabe[1], A. Perez Guijarro[1], J. I. Gutierrez Revilla[2], M. J. Agueros Fernandez[1], V. J. Ovejero Gomez[3], J. R. Lopez Lanza[1], J. Bustamante Odriozola[1], P. Villacampa Menendez[1], A. N. Ruiz Perez[1], J. Aranda Simon[1], J. L. Hernandez[4]

[1]Isabel II Health Center, Santander, Spain, [2]Division of Pharmacy, Hospital Sierrallana, Torrelavega, Spain, [3]Surgery Department, Hospital Marques Valdecilla, Santander, Spain, [4]Internal Medicine Department, Hospital Marques Valdecilla, Santander, Spain

Objective(s): Romosozumab is an anti-sclerostin monoclonal antibody recommended in patients with a high risk of fracture. The work analyzes the clinical profile, management and use of romosozumab in patients treated for any cause in an region of Spain.
Material and Methods: Retrospective observational study of all prescriptions made in Cantabria (591.481 population) (Spain) until January 2024, without exclusion criteria. Sociodemographic, risk factor, diagnostic and follow-up variables were collected.
Results: 33 subjects were analyzed, with a mean age of 68,39±14,1 years, 96.97% women (one male); As risk factors were found early menopause (21.2%), family history of fracture (18.2%), use of corticosteroids (18.2%), falls (12.1%), gait disorders (9.1%), tobacco (9.1%), dementia (6.1%). 12.1% of subjects had secondary osteoporosis, mainly hyperparathyroidism (6.1%), hyperthyroidism (3%) and hypogonadism (3%). 90.6% of the subjects had a previous diagnosis of osteoporosis. They had a vitD level of 38,66±8,1 ng/mL, and PTH of 83,3±41,5 pg/mL, 6.1% had poor digestive tolerance, 3% poor adhesion, 100% had polymedication, 2,78±1,8 subjects had vertebral fractures, non-vertebral fracture had 48.5%, mainly hip (24.2%). By diagnostic service, internal medicine (56,2%) and rheumatology (34,3%) are the most frequent and by follow-up, internal medicine (56.2%) and rheumatology (35.2%).
Conclusion(s): Romosozumab is used in patients with a very high risk of fractures, coinciding with what is recommended by clinical guidelines. The profile is a 68-year-old woman, on multiple medications with multiple vertebral fractures and other risk factors such as early menopause. Hip fracture is present in 25% of cases. The internist is the main initial prescriber and the one who does the most follow-up afterwards.

[1]Isabel II Health Center, Santander, Spain, [2]Division of Pharmacy, Hospital Sierrallana, Torrelavega, Spain, [3]Surgery Department, Hospital Marques Valdecilla, Santander, Spain, [4]Internal Medicine Department, Hospital Marques Valdecilla, Santander, Spain

Objective(s): Teriparatide is an osteoforming drug recommended for patients with a high risk of fracture. The work analyzes the clinical profile, management and use of teriparatide in patients treated for any cause in a region of Spain.
Material and Methods: Retrospective observational study of all prescriptions made in Cantabria (591.481 population) (Spain) during the year 2023, with no exclusion criteria. Sociodemographic, risk factor, diagnostic and follow-up variables were collected. Of the total of 618 patients, 1 in 9 was selected by simple random sampling.
Results: 66 subjects were analyzed, with an average age of 71.48±10.3 years, predominantly female (90.9%); 84.8% had a previous fracture, 71.2% had vertebral fracture (average of 2.71±1.7) and non-vertebral had 19.7%, mainly hip fracture (6.06%), being 45.5% of them in the last year; 90.9% had other risk factors (corticosteroids 21.2%, falls 18.2% (1.5±0.6 mean)). They had a vitD level of 28.38±10.4 ng/mL, and PTH level of 50.6±25.5 pg/mL. They had a poor drug tolerance 4.5%, poor adherence 6.1% and second osteoporosis 10.6%, mainly rheumatoid arthritis (57.1%). 84.8% of subjects had previously dexa (osteoporosis 67.9%, osteopenia 30.4%). They started treatment mainly in internal medicine (35.3%), rheumatology (35.3%) and primary care (16.7%).
Conclusion(s): Teriparatide is used in patients with a very high risk of fractures, coinciding with recommendations of clinical guidelines. The profile is a 70-year-old woman with multiple vertebral fractures and other bone risk factors. Hip fracture is present in 6% of cases. 4.5% presented poor tolerance. Only 67.9% presented osteoporosis in the densitometry. The internist and rheumatologist are the main initial prescribers.

P241

ANALYSIS OF ADHERENCE TO DENOSUMAB TREATMENT DURING THE COVID-19 PANDEMIC. WERE THERE DIFFERENCES BASED ON CONTRIBUTION TO THE COST OF THE DRUG?

A. Perez Martin[1], J. R. Lopez Lanza[1], J. Bustamante Odriozola[1], J. I. Gutierrez Revilla[2], M. J. Agueros Fernandez[1], A. Perez Guijarro[1], J. M. Olmos[3], V. Martinez-Taboada[4], V. J. Ovejero Gomez[5], P. Villacampa Menendez[1], J. L. Hernandez[3], R. Lopez Videras[1], J. Aranda Simon[1]

[1]Isabel II Health Center, Santander, Spain, [2]Division of Pharmacy, Hospital Sierrallana, Torrelavega, Spain, [3]Internal Medicine Department, Hospital Marques Valdecilla, Santander, Spain, [4]Rheumatology Division, Hospital Marqués Valdecilla, Santander, Spain, [5]Surgery Department, Hospital Marques Valdecilla, Santander, Spain

Objective(s): We aimed to analyze whether the SARS-CoV-2 pandemic has led to a decrease in Dmab adherence of the population based on contribution to the cost of the drug
Material and Methods: All patients who should have required the administration of a dose of Dmab in Cantabria (591481 population) (Spain), during the lockdown period (March to June 2020) were assessed. Sociodemographic variables, risk factors for osteoporosis, data on Dmab administration, and the reason for drug withdrawal were collected. Personal financial contribution to the price of the drug was classified as reduced (<40%) and normal (>40%)
Results: 2948 patients should have received a new dose of Dmab during the lockdown months, but 537 (18.2%) discontinued the drug. When analyzing the data on the withdrawal of denosumab from pharmacies, a decrease of 12.44% was observed in March compared to the same month of the previous year, -7.18% in April, -4.08% in May and +10.77% in June; this represents -12.93% in the study period from March to June. Table 1 contains general, clinical and sociodemographic variables of the non-compliant group. Significant differences were only found with respect to the existence of previous osteoporosis treatment and vertebral and non-vertebral fractures.

Table 1: Variables of the non-compliant group classified by contribution to the cost

		Normal contribution (n=65) %	Reduced contribution (n=472) %	Sig p<0,05
Age (years)		59.92±4.8	78.02±9.05	--
Sex (%)	Male	4.6	9.5	NS
	Female	95.4	90.5	
Secondary osteoporosis (%)		30.8	69.2	NS
Corticosteroid use (%)		12.3	12.9	NS
Cause of withdrawal (%)	Patient´s own decisión	69.2	64.4	--
	Postponed by nursing	20	13.6	--
	Physician	9.2	11.3	--
	Death	0	8.9	--
	Odontologist	1.5	1.9	--
Previous osteoporosis treatment (%)		35.4	51.5	p<0,05
Previous vertebral fracture (%)		12.3	34.8	p<0,05
Previous non-vertebral fracture (%)		15.4	28.4	p<0,05

Conclusion(s): There was a non-negligible percentage of patients who did not receive the dose of Dmab on time during the lockdown period. The main reason for withdrawal was the patient's own decision, It should be noted that the reduced contribution group, mostly retired, is older and therefore has more fractures and risk factors.

P242

PARTICULARITIES OF FRAILTY SYNDROME OF THE ELDERLY FROM THE REPUBLIC OF MOLDOVA

G. Soric[1], A. Popescu[1], A. Popa[1], A. Botezatu[1], N. Bodrug[1], A. Negara[1]

[1]Scientific Laboratory of Gerontology, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova

The aim of the work was the evaluation of clinical and paraclinical particularities of frailty syndrome of the elderly from the Republic of Moldova.

Material and methods. The descriptive epidemiological study included 613 respondents (72.76±0.26 years), aged≥65 years, evaluated according to clinical examination, Complex Geriatric Assessment(CGA) - Katz, Lawton, Tinetti, MMSE, SGD, FS screening - Fried criteria, functionality - SPPB, Charlson Comorbidity Index(CCI), as well as laboratory investigations. The results were analyzed in Soft Statistica 7.

Results. The study data revealed the following results, according to FS screening criteria – frail elderly - 47.53%, pre-frail elderly - 29.39%, robust elderly - 23.07%; according to CGA the general group – Katz – 10.50±0.09, Lawton – 12.70±0.16, Tinetti – 20.62±0.27, MMSE – 25.14±0.16, DGS - 5.63±0.15, SPPB - 7.77±0.14 pt.; frail elderly group – Katz – 9.70±0.12, Lawton – 10.89±0.23, Tinetti – 17.56±0.36, MMSE – 24.09±0.20, DGS – 7.58±0.18, SPPB – 5.81±0.17, MNA – 21.56±0.21 pt.; pre-frail elderly group – Katz – 11.32±0.07, Lawton – 13.97±0.18, Tinetti – 22.22±0.31, MMSE – 25.67±0.23, DGS – 4.90 ±0.21, SPPB – 8.91±0.18, MNA – 24.49±0.20 pt.; robust elderly group – Katz – 11.22±0.18, Lawton – 14.96±0.17, Tinetti – 24.23±0.39, MMSE – 27.01±0.30, DGS – 2.13±0.21, SPPB - 7.77±0.14, MNA – 10.02±0.21 pt. According to CCI - general group – CCI - 4.22±0.08, CCI frail elderly group - 4.73±0.10, CCI pre-frail group – 3.91±0.11, CCI robust group – 3.64 ±0.17. In the general group, cardiovascular pathology - 96.25%, osteoarticular - 74.25% and digestive - 41.61% prevailed; for frail elderly group - osteoarticular - 89.21% and neurological 95.43% pathology; for pre-frail group - cardiovascular pathology – 97.31% and neurological – 96.64%; for robust elderly group - cardiovascular – 93.38% and neurological pathology – 91.73%. The laboratory parameters revealed: serum albumin – minimum value 23 g/l, creatinekinase - max. 347 U/L, 25-OH-Vitamin D value min. 4.98 ng/ml, parathormone max. 229 pg/ml, high-sensitivity PCR - 0.27-12.9 mg/L. Charlson mean values correlated with low autonomy - Katz(Rr=0.45; p<0.05), Lawton(r=-0.54; p<0.05), SPPB(r=-0.47 ; p<0.05), correlations were established between Charlson and Fried criteria: general weakness (Rr=0.31; p<0.05), reduced walking speed (Rr=0.49; p<0.05), weight loss (Rr=0.41; p<0.05).

Conclusions. The results of the study revealed the functional status as one of the most affected aspects against the background of the altered physical condition, such as the frailty syndrome.

P243

STUDY OF OSTEOSARCOPENIA CORRELATED WITH FRAILTY SYNDROME OF THE ELDERLY FROM THE REPUBLIC OF MOLDOVA

G. Soric[1], A. Popescu[1], L. Suveica[2], A. Popa[3], A. Botezatu[1], N. Bodrug[1]

[1]Aging and Age Study Laboratory, Discipline of Geriatrics and Occupational Medicine, Department of Internal Medicine, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova, [2]Department of Family Medicine, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova, [3]Aging and Age Study Laboratory, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova

Background. The aging process involves a series of age-related musculoskeletal physiological changes, which represent an important indicator of health status, with a significant impact on the autonomy of the elderly.

The purpose of the study was to evaluate the prevalence of osteosarcopenia and its association with the frailty syndrome in the elderly.

Material and Methods. The descriptive epidemiologic study included 613 elderly (73.16±0.24 years), who were examined according to clinical evaluation, laboratory and complex geriatric assessment (AGA). Based on the Fried Criteria, 3 comparable groups were formed: frail elderly - 304 (49.59%), pre-frail elderly - 177 (28.87%) and robust elderly - 132 (21.53%). Osteosarcopenia was diagnosed according to EWGSOP2 2018 criteria for sarcopenia and WHO criteria for osteoporosis.

Results. The weight of osteosarcopenia constituted 30.51% of patients from the general group, the highest was determined in the frail elderly - 47.37% vs pre-frail - 20.34% vs robust - 5.30% (p<0.05). A greater number of frail elderly, compared to pre-frail and robust, met the criteria for osteosarcopenia: SARC-F – 5.81±0.13 pt. vs. 3.81±0.15 pt. vs. 1.74±0.18 pt., p=0.001; dynamometry – 18.77±0.64 kg vs 17.72±0.76 kg vs 15.88±0.75 kg, p=0.003; MMT - 49.31±1.27 kg vs 53.23±1.62 kg vs 55.21±1.5 kg, p=0.001; physical performance SPPB – 5.80±0.16 pt. vs. 8.91±0.18 pt. vs. 10.02±0.21 pt., p=0.0001; T-score -2.61±0.06 DS vs 2.28±0.07 DS vs 1.51±0.79 DS, p=0.002. The prevalence of osteoporosis by study groups was higher for the frail elderly group 57.81%, then pre-frail 43.14% and robust 40.50%. The osteosarcopenia syndrome correlated with the severity of the frailty syndrome (r=0.50; p=0.05), with decreased autonomy (ADL, r=-0.59; p=0.05; IADL, r=-0, 63; p=0.05), presence of depression - DGS, r=0.42; p=0.05 and with MMSE cognitive disorders, r=-0.42; p=0.05. The value of 25-OH-Vitamin D per study group was: frail elderly – min value. 4.6 ng/ml, max. value 35.47 ng/ml; pre-frail elderly - min. value 4.98 ng/ml, max. value 60.59 ng/ml; robust elderly - value min. 20.17 ng/ml, max. value 86 ng/ml.

Conclusion. The osteosarcopenia syndrome was more frequently determined for frail elderly patients with a major impact on both autonomy - cognitive and emotional status.
Key-words: osteosarcopenia, frailty, elderly.

P244

EVALUATION OF FRAILTY SYNDROME ON THE BACKGROUND OF POLYPATHOLOGY IN THE ELDERLY FROM THE REPUBLIC OF MOLDOVA

G. Soric[1], A. Popescu[1], A. Popa[2], A. Botezatu[1], N. Bodrug[1], A. Negara[3]

[1]Aging and Age Study Laboratory, Discipline of Geriatrics and Occupational Medicine, Department of Internal Medicine, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova, [2]Aging and Age Study Laboratory, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova, [3]Discipline of Geriatrics and Occupational Medicine, Department of Internal Medicine, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova

Background. The aging process involves a multitude of physiological changes determined by age, which may overlap with physiopathological ones, including polypathology.
The purpose of the study was to evaluate the impact of risk factors of frailty syndrome(FS).
Materials and methods. Descriptive epidemiological study included 613 elderly (73.16±0.24 years), who were examined according to clinical examination, laboratory and complex geriatric assessment (CGA) - Katz, Lawton, Tinetti, MMSE, DGS, FS screening - Criteria Fried, SPPB, multimorbidity – Charlson Comorbidity Index (CCI), nutritional status - MNA. Based on the Fried Criteria, 3 comparable groups were formed: frail elderly – 304 (49.59%), pre-frail – 177 (28.87%) and robust – 132 (21.53%).
Results. All the elderly included into the study had polypathologies. The study data revealed the following results, according to FS screening criteria: frail elderly - 47.53%, pre-frail elderly - 29.39% and robust elderly - 23.07%. According to the CGA, the frail elderly showed the lowest scores: Katz – 9.70±0.12, Lawton – 10.89±0.23, Tinetti – 17.56±0.36, MMSE – 24.09±0.20, DGS – 7.58±0.18, SPPB – 5.81±0.17, MNA – 21.56±0.21 pt., being followed by pre-frail and robust elderly with lower scores. The clinical examination data revealed the following pathologies, for frail elderly group it prevailed - osteoarticular pathology - 89.21% and neurological - 95.43%; pre-frail elderly group - cardiovascular pathology – 97.31%, neurological – 96.64% and osteoarticular pathology – 80.53%; robust elderly group – cardiovascular pathology – 93.38%, neurological – 91.73% and osteoarticular – 75.20%. The mean number of concomitant diseases was 4.62±0.12 diseases. According to CCI: CCI frail elderly group – 4.71±0.12, CCI pre-frail elderly group – 3.83±0.12, CCI robust elderly group – 3.57±0.18 pt. The frail elderly presented mainly low physical activity, fatigue, decreased walking speed, low weight. The administered treatment determined iatrogenic pathology 39.83% of cases. According to MNA - 40% of the participants were at risk of malnutrition, 22% were malnourished and 38% had a normal nutritional status (MNA - 21.20±0.24).
Conclusion. The results of the study highlight the impact of the frailty syndrome on the functional and clinical status of the elderly, revealing the prevalence of polypathologies, the increased risk of malnutrition and the deterioration of physical capacity.
Key-words: frailty syndrome, pathology, elderly.

P245

THE IMPACT OF ALBANIAN URBAN LYRIC MUSIC ON PATIENTS WITH OSTEOARTHRITIS OF THE VERTEBRAL COLUMN

A. Pulaj[1], E. Rapushi[2]

[1]European University of Tirana (UET), Tirana, Albania, [2]UH-C"Mother Theresa", Tirana, Albania

Background: Osteoarthritis of the vertebral column is a progressive degenerative disease that affects the middle age. Osteoarthritis of the vertebral column represents a significant degree of disability of these patients in their daily life.
Objective: To evaluate the effect of the Albanian urban lyric music on patients with osteoarthritis of the vertebral column.
Material and methods: 123 patients (86 women, 69.9% and 37 men, 30.08%) diagnosed with osteoarthritis of the vertebral column in stage 2-3-4 according to Thomson were included in the study. The average age of the group studied was 57±3.2 years. The assessment of the degree of pain was made according to VAS and the patients were assessed for their pain level at the beginning and end of the study. All patients were referred to listen to 30-45 minutes a day of Albanian urban lyric music by Albanian singers such as Tefta Tashko Koço, Marije Kraja, Jorgjie Truja and music from pianist Lola Gjoka, for 30 days. During the study period, the patients were not treated with painkillers or physiotherapy.
Results: VAS measured at the beginning of the study for the study group resulted mild (2-3) in 18 patients, moderate (5-6) in 75 patients and severe (7-8) in 30 patients. At the end of the study period (after 30 days) VAS resulted mild (1-2) in 59 patients (P=0.001), moderate (4-5) in 64 patients (P=0.001).
Conclusion: This study demonstrated the efficacy of the Albanian urban lyric music by these Albanian singers and pianist, on pain caused by degenerative osteoarthritis of the vertebral column. Albanian urban lyric music therapy in these patients improved motivation, availability and the approach to the experience of pain.

P246

DENOSUMAB FOR PAGET'S DISEASE: A SYSTEMATIC REVIEW ON A RENAL-FRIENDLY ALTERNATIVE

C. Moniz[1], A. Teodósio Chícharo[2], A. R. Cruz-Machado[3]

[1]Faculty of Medicine of Lisbon, Lisbon, Portugal, [2]Unidade Local de Saúde do Algarve, Rheumatology Department, Lisbon, Portugal, [3]Unidade Local de Saúde de Santa Maria, Rheumatology Department, Lisbon, Portugal

Objective Review the literature addressing the use of denosumab (Dmab) for the treatment of Paget's disease of bone (PDB).
Material and Methods A systematic literature review was conducted using PubMed, SCOPUS and Web of Science databases until 30-11-2024. PICO criteria were Population - adult-onset PDB; Intervention - Dmab; Comparator (if any) – placebo or bisphosphonates (BP); Outcomes - reduction in alkaline phosphatase (ALP) levels and in pain, and treatment-related side effects. All types of studies were included.
Results After screening 123 articles, 12 were included. A total of 13 patients were found to have PDB and received Dmab. The patients' median age was 74 [40-91] years and 7 (53.8%) were male; 3 (23.1%) had associated Giant Cell Tumor (GCT-PDB). Eleven cases reported high ALP levels at baseline. Dmab regimen varied from 60-120mg SC every 3-12 months. In 6 cases, the choice of Dmab was related to renal impairment (Chícharo et al., 2024 [Abstract]; Eatz et al., 2022; Kostine et al., 2017; Kuthiah, 2018; Schwarz et al., 2012). Two patients received it after poor response or tolerance to BP (Farias & Zanchetta, 2014; Reid et al., 2016); and one other due to osteopenia, prior to PDB diagnosis (Kamalumpundi et al., 2023). In one case, the rationale for choosing Dmab was unclear (Pal & Bhadada, 2022). Regarding GCT-PDB, Dmab was administered after unsuccessful therapy with BP in 2 cases (Cosso et al., 2010; Tanaka et al., 2017) and concurrently with BP in the other case (Verma et al., 2016). Nine studies (10/13 patients) reported a reduction in ALP. In isolated PDB cases, the mean ALP reduction was 60.7% (±22.7) after a median of 3 months (IQR 5). In patients with PDB-GCT, reduction in tumor size was described in all patients after a median of 2.5 months (IQR 5.5). Out of the 12 patients that had symptomatic pagetic lesions, 11 (91.7%) experienced pain improvement. Hypocalcemia was reported in 3 (23.1%) patients, with 1 case requiring ICU admission (Kostine et al., 2017).
Conclusion Dmab demonstrated a favorable safety and efficacy profile in the treatment of PDB. It seems a reasonable therapeutic option for those who have a formal contraindication to BP or in GCT-PDB. This data displays an unmet need for guidelines addressing treatment of PDB in patients with CKD.

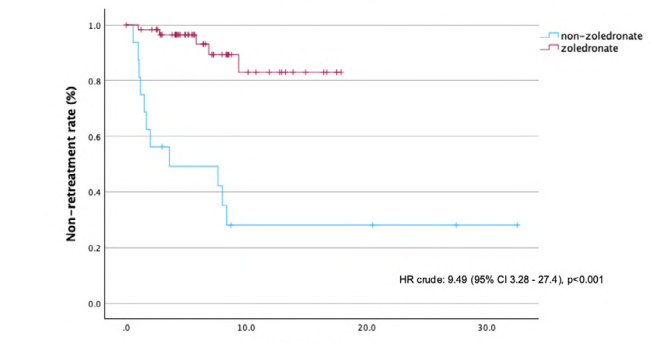
PAGET'S DISEASE OF BONE: CLINICAL AND EPIDEMIOLOGICAL CHARACTERIZATION OF THE POPULATION OF A PORTUGUESE TERTIARY CENTER

R. Pereira da Costa[1], A. R. Lopes[1], C. Ochôa Matos[1], A. Travessa[2], D. Dias[3], C. Tenazinha[1], S. Fernandes[1], R. Barros[1], A. R. Cruz-Machado[1], J. C. Romeu[1]

[1]Rheumatology Department, Unidade Local de Saúde Santa Maria, Centro Académico de Medicina de Lisboa, Lisboa, Portugal, [2]Genetic Department, Unidade Local de Saúde Santa Maria, Centro Académico de Medicina de Lisboa, Lisboa, Portugal, [3]Genetic Department, Unidade Local de Saúde Santa Maria, Centro Académico de Medicina de Lisboa, Lisboa, Portugal;, Lisboa, Portugal

Objectives To characterize the clinical and demographic profile of a Paget's Disease of Bone (PDB) cohort.
Material and Methods Retrospective observational study of 80 PDB patients.
Results Most patients were female and born in rural areas. Diagnosis was between 1974 and 2021, with a mean age of 63±12 years. Eleven patients had PDB family history. The bones most affected were pelvis (75%), sacrum (25%) and femur (25%). Polyostotic disease was present in 51% of patients and associated with higher baseline alkaline phosphatase (ALP, U/L) (200 [167] vs 149 [124], p=0.035), P1NP (ng/mL) (196 [188] vs 115 [76], p=0.015) and CTx (ng/mL) (0.7±0.3 vs 0.6 [0.3], p=0.031). Polyostotic patients had a higher frequency of skull (22% vs 3%, p=0.029), pelvis (88% vs 62%, p=0.007), vertebrae (37% vs 5%, p<0.001), femur (39% vs 11%, p=0.003), and sacrum (37% vs 13%, p=0.014) involvement. In multivariate analysis, affection of vertebrae (OR 279 [10-7671], p<0.001), femur (OR 151 [7-3132], p=0.001), pelvis (OR 101 [7-1432], p<0.001), sacrum (OR 62 [5-738], p=0.001) and skull (OR 48 [1-2056], p=0.044) were associated with polyostotic PDB. First line treatment was zoledronate (ZOL) in 75% of patients, followed by pamidronate (10%), alendronate (5%), calcitonin (4%), risedronate and denosumab (1.3%). Three patients did not undergo treatment and 13 were treated with ≥2 drugs. ZOL was the most used drug (89%). We observed a reduction in the number of patients with elevated ALP (p=0.002) and in the value of ALP, P1NP and CTx (p<0.001) between baseline and 6-12 months after last treatment. Sixteen patients underwent retreatment. Mean drug survival of first treatment with ZOL was 16 years (95% CI 14-18) and 12 years (95% CI 5-18) in the group treated with another drug (Figure 1). Drug survival was significantly lower in the latter, with a higher rate of retreatment (crude HR 9.49 (95% CI 3-27); log-rank p<0.001). When adjusted for age at diagnosis, smoking, baseline ALP and calcium levels, first line treatment with a drug other than ZOL remained associated with lower drug survival (adjusted HR 10.10 (95% CI 2-48); p=0.004).
Conclusion This is the largest Portuguese PDB cohort, noting high prevalence in rural areas and high biochemical remission rates after treatment. ZOL first-line therapy was associated with higher drug survival and lower retreatments rates.

Figure 1 - Drug survival curve of first treatment in patients treated with ZOL (zoledronate) as first line and in patients treated with other drugs other than ZOL as first line (non-zoledronate)



P248

OSTEOPOROSIS RELATED TO ZINC DEFICIENCY IN ACRODERMATITIS ENTEROPATHICA – A RARE MANIFESTATION OF A RARE DISORDER?

F. Costa[1], A. R. Cruz-Machado[1]

[1]Serviço de Reumatologia, Unidade Local de Saúde de Santa Maria, Centro Académico de Medicina de Lisboa, Lisboa, Portugal

Objectives To present the case of a young female with acrodermatitis enteropathica (AD) and early onset osteoporosis related to zinc deficiency and to highlight the importance of these nutrient in bone metabolism.

Material and methods AD is an autosomal recessive disease resulting from a mutation in the gene SLC39A4 on chromosome 8q24.3 which encodes the zinc transporter. This mutation impairs zinc absorption in the gastrointestinal tract. Zinc is fundamental in several processes, particularly in bone health, where it prevents bone resorption and stimulates bone formation. [1]

AD usually manifests in early childhood as a scaly erythematous rash (usually in perioral and anogenital areas), alopecia and diarrhea amongst other symptoms.

Treatment consists of lifelong zinc supplementation which is expected to resolve the mentioned manifestations. However, frequent monitoring and zinc dose adjustments, particularly in certain periods of physiological stress (such as pregnancy), might be necessary. [2]

Results Here we present a case of a 34-year-old female patient who was diagnosed with AD during childhood, when she begun zinc supplementation with complete resolution of clinical symptoms. During adulthood she lost follow-up and zinc levels were not monitored, despite maintaining supplementation.

After her first pregnancy at the age of 24, she started complaining of progressive dorsal and lumbar pain. Bone densitometry (at 34 years old) revealed a Z-score of -2.4 at the lumbar spine and -0.8 at the femoral neck. CT scan of dorsal and lumbar spine showed loss of height in multiple vertebral bodies from D6-D11, particularly in D9 with a loss greater than 30%. The patient had no other risk factors that justified early onset osteoporosis, therefore, it was presumed to be related to zinc deficiency with suboptimal monitoring of zinc levels throughout adult life.

Conclusion Zinc deficiency needs to be considered in young patients with early onset osteoporosis without other risk factors.

P249

REAL-WORLD EFFECTIVENESS OF ANTI-RESORPTIVE AGENTS ON TRABECULAR BONE SCORE IN PATIENTS WITH EARLY BREAST CANCER UNDERGOING AROMATASE INHIBITORS

A. R. Hong[1], J. Y. Park[1], J. H. Yoon[1], H. K. Kim[1], H. C. Kang[1]

[1]Chonnam National University Medical School, Gwangju, South Korea

Objective: Anti-resorptive agents, including denosumab and bisphosphonates, are effective in managing aromatase inhibitor (AI)-induced bone loss in patients with breast cancer. This study aimed to evaluate the real-world effectiveness of denosumab and bisphosphonates on bone quality, assessed by the lumbar spine trabecular bone score (TBS).

Methods: This retrospective study included 161 patients with early breast cancer undergoing AI therapy between December 2018 and November 2024. Patients were treated with either denosumab (n=96) or bisphosphonates (n=65). Bone mineral density (BMD) at the lumbar spine (L1–L4), femoral neck, and total hip, as well as lumbar spine TBS, were measured at baseline and after 12 months of treatment.

Results: The mean age of the patients was 62.8 ± 7.3 years, and the mean body mass index was 23.4 ± 3.3 kg/m², with no significant differences between the denosumab and bisphosphonate groups (P=0.366 and P=0.342, respectively). The median time interval from AI initiation to the start of anti-resorptive therapy was 14.9 months (interquartile range 8.9 -30.0 months), which was comparable between the two groups (P=0.882). Baseline BMD at the lumbar spine, femoral neck, and total hip, as well as TBS, were similar between the two groups (all P>0.05). After 12 months of treatment, lumbar spine BMD increased by 6.65 ± 6.49% in the denosumab group and 3.57 ± 5.01% in the bisphosphonate group. Denosumab showed greater efficacy in improving lumbar spine BMD (P<0.001). Femoral neck BMD increased by 3.57 ± 5.54% with denosumab and 1.58 ± 3.69% with bisphosphonates, with denosumab demonstrating superior efficacy (P=0.007). Additionally, denosumab showed better efficacy for improving total hip BMD than bisphosphonates (3.12 ± 5.61% vs. 1.11 ± 5.20%; P=0.035). Changes in lumbar spine TBS after 12 months were 1.64 ± 3.98% in the denosumab group and 0.67 ± 4.25% in the bisphosphonate group, with no statistically significant differences between the two groups (P=0.140).

Conclusion: Both denosumab and bisphosphonates may increase BMD in patients with early breast cancer undergoing AI therapy, with denosumab demonstrating superior efficacy. Additionally, both agents help maintain stable TBS over 12 months, mitigating the negative effects of AIs on bone quality.

P250

ASSOCIATION OF GENETIC MARKERS WITH CLINICAL AND LABORATORY INDICATORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Rudenka[1], A. Buglova[1], E. Rudenka[1], G. Babak[2], V. Samokhovec[3], K. Kobets[4], P. Marozik[4]

[1]Belarusian State Medical University, Minsk, Belarus, [2]Republican Center for Medical Rehabilitation and Balneotherapy, Minsk, Belarus, [3]1st city clinical hospital, Minsk, Belarus, [4]Institute of Genetics and Cytology of the National Academy of Sciences of Belarus, Minsk, Belarus

Rheumatoid arthritis (RA) is a multifactorial disease influenced by both genetic and environmental factors. Identifying individual genetic predictors of increased risk for RA complications, such as osteopenia and osteoporosis, can enable treatment adjustments and reduce adverse effects.

Objective: This study aimed to identify the most significant polymorphic variants of genes associated with clinical and biochemical indicators in patients with RA, particularly focusing on the prediction of complications such as osteopenia and osteoporosis.

Material and Methods: The study included 262 participants, comprising 128 healthy controls and 176 patients diagnosed with RA. All participants underwent outpatient examination at the 1st Minsk City Hospital, Belarus, after providing informed consent. Clinical data collection involved medical history analysis, anthropometric measurements, and assessment of systemic manifestations. Bone mineral density (BMD) was evaluated using dual-energy X-ray absorptiometry (DEXA). Genetic analysis targeted polymorphisms in the following genes: IL19 (rs587776843), ATIC (rs4673993, rs2372536), ABCB1 (rs1128503, rs1045642), ABCG2 (rs2231142), AMPD1 (rs17602729), ITPA (rs1127354), ADORA2A (rs5760410, rs2236624), TLR4 (rs4986790), HLA-E (rs1264457), NR3C1 (rs258751), ATP5F1E (rs1059150), KLRD1 (rs2302489), GLCCI1 (rs37973), CRHR1 (rs1876828), ESR1 (rs1801132), PRL (rs7739889), IL6 (rs1800795), and CALCR (rs1801197). Genotyping was performed via real-time polymerase chain reaction (PCR).

Results: The genotyping revealed significant associations of specific gene variants with decreased BMD and susceptibility to RA. Key findings include:

- The *ESR1* rs1801132 C/C genotype was significantly associated with reduced femoral neck BMD in RA patients (0.76±0.01) compared to controls (1.02±0.01, p=0.048).
- The *PRL* rs7739889 A/A genotype was linked to lower femoral neck BMD in patients (0.77±0.02) compared to controls (1.12±0.13, p=0.033).
- Similar associations were observed for the *CALCR* rs1801197 A/A and *IL6* rs1800795 C/C genotypes, with femoral neck BMD values of 0.76±0.01 and 0.77±0.02, respectively, in patients, versus 1.03±0.02 in controls (p=0.025 and p=0.038).
- Polymorphisms in *TLR4* (rs4986790), *HLA-E* (rs1264457), and *IL19* (rs587776843) were significantly associated with an increased risk of RA development.

Conclusion: The study demonstrates that genetic markers such as *ESR1* rs1801132, *PRL* rs7739889, *CALCR* rs1801197, and *IL6* rs1800795 are associated with decreased BMD in RA patients. Additionally, polymorphisms in *TLR4*, *HLA-E*, and *IL19* are linked to RA susceptibility. These findings highlight the potential of genetic profiling to enhance personalized medicine approaches in the prevention and management of RA and its complications.

P251

A CASE REPORT OF BLAU SYNDROME

A. Rudenka[1], A. Buglova[1], G. Babak[2], T. Tiabut[1]

[1]Belarusian State Medical University, Minsk, Belarus, [2]Republican Center for Medical Rehabilitation and Balneotherapy, Minsk, Belarus

Introduction: Blau syndrome (BS) is a rare autosomal dominant, auto inflammatory granulomatous disease, which is caused by a gain-of-function mutation in the Nucleotide Binding Oligomerization Domain Containing 2 (NOD2) gene. Clinical manifestations of BS develop in early childhood, and are characterized with the triad of arthritis, uveitis and dermatitis; however, patients with BS do not necessary have all of these three manifestations in their lifetime.

Case description: Patient K, female, born in 1980. Upon admission in 2024, she complained of pain and swelling in the knee joints, subfebrile temperature, deformation and limited movement in the small joints of the hands, feet, and contractures of the elbow joints (fig.1). She was 3 years of age when she developed arthritis mainly targeting both ankles. Later, the joint syndrome progressed with involvement of the joints of the feet, hands, knees and wrists. The disease had a wave-like character; periods of exacerbation were accompanied by severe stiffness and fever. She was diagnosed with Juvenile idiopathic arthritis and was treated with glucocorticoids, NSAIDS, sulfasalazine. In adulthood, she is seen by a rheumatologist with a diagnosis of seronegative rheumatoid arthritis and receives methotrexate. In 2009 at the age of 29 she gave birth to a son. The boy was 1 year of life when he developed skin rash, fever and later polyarthritis and bilateral uveitis. In 2018 attention was drawn to the characteristics of the patient's arthritis, early onset, concomitant manifestations (skin rash, uveitis), the absence of a significant increase in acute phase markers throughout all years of observation, as well as the characteristics of joint damage in the mother. Upon further examination, a mutation in the NOD2 gene was detected in the mother and son. Blau syndrome was diagnosed, methotrexate therapy was prescribed. However, the patient developed severe deformities (fig. 2).

Discussion: BS is a very rare disease, which should be considered in the differential diagnosis of childhood arthritis and uveitis. Timely diagnosis including genetic analysis is necessary to prescribe therapy such as immunosuppressants and biologics.

OSTEOMETABOLIC PROFILE OF PRIMARY HYPERPARATHYROIDISM: PRELIMINARY RESULTS OF A MONOCENTRIC RETROSPECTIVE STUDY

A. Russo[1], P. Amadori[2], V. Racanelli[1]

[1]Internal Medicine Division, Santa Chiara Hospital, Provincial Health Care Agency (APSS), Trento, Italy, [2]Unit of Primary Care, Provincial Health Care Agency (APSS),Trento, Italy

Primary Hyperparathyroidism (PHPT) is an endocrine disorder which has a high impact on the osteoarticular system.
Objective To describe clinical, biochemical and osteometabolic features of patients affected by primary hyperparathyroidism evaluated in Endocrinological Outpatient of a Secondary Centre and to explore the main differences between fragility fractured and not fractured patients.
Methods Clinical, laboratory and radiological data of patients with PHPT evaluated from January 2023 to December 2024 were obtained by reviewing medical records.
RESULTS
A total of 103 patients (Mean Age 65.5 ± 11.5, Female 81.5%, Male 18.5%), were enrolled in this study. At the time of presentation 24 (23.3%) had nefrolitiasis, 49 (47.5%) were affected by osteoporosis, 32 (31 %) by osteopenia, and 27 (26.2%) reported in clinical hystory almost one fragility bone fracture (verterbral, femoral, non vertebral non femoral). 28 patients (27.1%) fell into normocalcemic while 75 (72.9%) into hypercalcemic primary hyperparathyroidism. We divided the patients into two groups : group 1 with fragility fractures and group 2 without fragility fractures. The mean BMI of group 1 was 23.2 ± 4.2 kg/m^2, whereas group 2 was 25.4 ± 4.3 kg/m^2 ($p<0.05$). In group 1 the percent of patients with Bone Mineral Density (BMD) in osteoporosis range was significantly higher for all sites than group 2 (Vertebral = 56.5% vs 33.3 %, Total Femur 47.8% vs 13.1%, Femoral Neck 50% vs 20.9 % , $p < 0.05$). Group 1 and Group 2 had comparable median calcium corrected for albumin (10.6-IQR 0.9 vs 11.06-IQR 1.38 mg/dl), mean phosphate (2.82 ± 0.07 vs 2.64 ± 0.05 mg/dl), median PTH (101; IQR 75 vs 141; IQR 94.4 pg/ml) and mean vitamin D (30.03 ± 9.78 vs 27.05 ± 10.2 ng/ml) level at presentation.
Conclusion In this our preliminary study fractured PHPT patients presented at a lower BMI than non fractured ones. Patients with fracture showed BMD in the range of osteoporosis in a significantly higher percentage than patients without fracture at all measured sites. There was no statistical difference in PTH, calcium corrected for albumin, phosphate and vitamin D levels, percent of patients with nephrolitiasis and normocalcemic profile between the two groups.

P253

MINERAL METABOLISM COMPENSATION AND FRAGILITY FRACTURES IN POST-SURGICAL HYPOPARATHYROIDISM: A CROSS-SECTIONAL STUDY

A. Russo[1], P. Amadori[2], V. Racanelli[1]

[1]Internal Medicine Division, Santa Chiara Hospital, Provincial Health Care Agency (APSS), Trento, Italy, [2]Unit of Primary Care, Provincial Health Care Agency (APSS),Trento, Italy

INTRODUCTION
Permanent post-surgical hypoparathyroidism is a complication of thyroidectomy (about 3%) characterized by reduced calcium levels due to inadequate PTH production. The treatment is based on calcium salts and active vitamin D integration and the adequate control of mineral compensation is essential to avoid osteometabolic complications. The disease's impact on fracture risk has yet to be determined and published data are still inconsistent (1).
OBIECTIVE
To describe the cohort of patients with postsurgical hypoparathyroidism in a 6-year observation period (from January 2017 to December 2022) and the distribution of fragility fractures in relation to the functional profile of mineral metabolism and therapy at the latest clinical evaluation available.
METHODS
103 patients (Age at diagnosis 49.1 ± 15.5 years, F = 78.6%, M= 21.4%) were enrolled in the study and data on body mass index (BMI), therapy, fragility fracture's history and mineral metabolism

(total and corrected for albumin calcium, phosphate, creatinine, 25-OH vitamin D, PTH, TSH) at the latest evaluation were collected. The patients were divided in 2 groups: Group 1 with fragility fractures and Group 2 without fragility fractures.

RESULTS

88 patients (85.4%) were taking calcium salts, 98 (95.1 %) were taking vitamin D active analogues. 14 patients (13.6 %) reported fragility fractures (vertebral, femoral, non vertebral non femoral). The comparison between the two groups showed that patients with fractures had higher calcium-phosphate product values (38.4 ± 4.94 vs 33.7 ± 5.7 mg^2/dl^2, p= 0.006) and higher phosphate values (4.50 ± 0.77 vs 3.90 ± 0.70 mg/dl , p= 0.012). No differences were found for all the other parameters analysed.

CONCLUSION

In our population, although with the limitations of a retrospective study, fractured patients with post-surgical hypoparathyrodism have a worse mineral metabolism than the unfractured ones, in particular higher levels of phosphate and, consequently, higher levels of calcium-phosphate product.

PRP THERAPY IN OA KNEE- MY EXPERIENCE (A SERIES OF 490 CASES – 545 KNEES)

A. S. Bhatia[1]

[1]Dr Bhatia's Bone & Joint Care Clinic, Chandigarh, India

ABSTRACT

PRP THERAPY IN OA knee- MY EXPERIENCE (A series of 490 cases – 545 KNEES)

INTRODUCTION

Osteoarthritis (OA) is a major source of disability, pain, and economic burden worldwide. Genetic, biochemical, and mechanical factors are responsible for the complex multifactorial epidemiology of the disease. Abnormal joint biomechanics, age, gender, joint injury, and high body mass index (BMI), along with a strong genetic basis, are associated with OA development. Presently, OA is the eighth-most common disease in males world over and the fourth most common disease in females [1].

Previously, OA was believed to be caused by the mechanical degradation of cartilage. But now the understanding is , this a complex of , mechanical, chemo- inflammatory , the pathophysiology is complex inter play leading to the production of matrix metalloproteinases (MMPs), nitric oxide (NO), and prostaglandins (PGs), leading to matrix degradation [2]. The catabolic effects of interleukins secreted by chondrocytes, mononuclear cells, osteoblasts, and synovial cells interfere with the activity of growth factors and reduce the synthesis of aggrecan, which is the key constituent of the matrix providing resilience to cartilage [3]. Interleukin-1β (IL-1β), the pro inflammatory cytokine, is a major protagonist in inducing arthritic changes, as evident by its increased levels in the synovial fluid of affected joints [4-5].

Intra-articular injection of platelet-rich plasma (PRP) has been broadly considered for cartilage repair, as it could enhance matrix synthesis thanks to the properties of its growth factors (mostly platelet-derived growth factor (PDGF) and transforming growth factor-beta (TGF-beta) [6-8].To evaluate the efficacy of PRP intra-articular injections in OA knee patients . A series of 123 patients with different grade of OA. Assessing the recovery on VAS and WOMAC scale.

Methodology

08ml of patient's blood taken in two tubes containing 0.5 ml of Sodium Citrate (38%w/l). Centrifuged at the 4000 rpm for 20 min. Let sample rest for about 5 minutes, about 05 to06 ml of PRP is extracted. Patient shifted to operation theatre. After proper skin sterilisation and knee draping. This PRP is injected into the knee joint. 2nd injection of PRP repeated after one month. For the last 250 patients augmented with Sodium hyaluronate Injection (30mg /2ml). The patient's progress is assessed after the second injection. First case done 5yrs. Back and last case included 6month back(today-11.05.2024) . Recovery assessed with VAS and WOMAC scale. Four aspects of WOMAC sore taken into consideration – 1) Pain at night, 2) rising from sitting, 3)walking on flat surface, , 4) performing light domestic duties

Results

In the series of 490 cases – 545 KNEES taking into consideration the severity of OA as per K& J classification - Grade 2 (minimal) moderate joint reduction, Grade 3 (moderate) severe joint space reduction with sub chondral sclerosis, Grade 4 (severe) large osteophytes, marked narrowing of joint space, severe sclerosis and definite deformity of bone ends. BMI of the patient, age of the patient showed– 1) Pain at night- 85 to 100%, 2) rising from sitting 86 to 100%, 3) walking on flat surface 85 to 95%, 4) performing light domestic duties70 to 96%, across various Grade of OA (Grade 2 to 4). Patients were also instructed for regular exercises to strengthen their thigh muscles and life style changes to bring their body weight in permissible levels as per their height.

Conclusion

PRP therapy in moderate to severe OA knee showed good to excellent results in improving pain during rest, pain free walk, climbing stairs. Patients who do not want TKR is worth trying. Up to 5yrs follow patients are happy and pain free.

ESTROGEN RECEPTOR SIGNALING MODULATES NEURO-OSTEOGENIC AXIS FOR OSTEOPOROSIS SUPPRESSION

A. S. Brah[1], J. K. Kubi[1], K. M. C. Cheung[1], K. W. K. Yeung[1]

[1]Department of Orthopaedics and Traumatology, Li Ka Shing Faculty of Medicine, The University of Hong Kong (HKU)., Hong Kong, Hong Kong SAR China

Background
Estrogen-deficiency-induced postmenopausal osteoporosis is a bone-related disease characterized by reduced bone quality and strength, resulting in increased bone fragility among the aged population. Osteoporotic fractures continue to pose a significant socioeconomic burden on healthcare systems and patients. Estrogen receptor signaling plays a crucial role in the development of estrogen-deficiency-associated osteoporosis. Estrogen receptors ERα, ERβ, and GPR30 are significantly expressed by osteoblasts and osteocytes bone cells. The subsequent activation of these receptors by estrogenic stimuli modulates estrogen receptor signaling which helps maintain bone health. Femur bones are densely innervated by sensory nerves that release neurotrophic factors that play a critical role in maintaining bone homeostasis. Even though estrogen receptor signaling and sensory nerve activities promote bone formation it is unclear whether estrogenic modulation of sensory nerves on long bones influences bone formation in normal and osteoporosis conditions.
Objective: The current study assessed how estrogen receptor (ERα) signaling modulation could enhance peripheral sensory functions to suppress osteoporosis development.
Method: In this study, an ovariectomy(OVX)-induced osteoporosis model was established in C57BL/6N female mice aged 8-10 weeks. The experimental groups were sham control, OVX control, and 30μg/Kg Estradiol (E2). All mice received intraperitoneal injections three times per week for 4 weeks. Micro-computed (μCT) scan was taken before the ovariectomy and weekly after the ovariectomy to assess bone growth.
Results: The Estradiol treatment significantly suppressed osteoporosis development by improving bone mineral density (BMD), trabecular thickness (Tb.th), and number (Tb.N) in comparison with the OVX control group. The estradiol treatment also significantly increased the expression of osteogenic markers OCN, ALP, and RUNX2. Interestingly, the estradiol treatment also upregulated the co-expression of the estrogen receptor alpha (ERa), GAP43, and MAP2 neuronal markers on the periosteum of the femur bones.
Conclusion: The activation of estrogen receptor alpha (ERα) by estradiol in periosteal sensory nerves can enhance positive neuro-osteogenic modulation to trigger new bone formation and anti-osteoporosis activity in OVX mice. Thus, targeting estrogen receptor signaling for improved neuro-osteogenic activities can serve as a new therapeutic strategy for osteoporosis prevention.

IMPACT OF GENDER-AFFIRMING HORMONE THERAPY ON PATIENTS WITH GENDER DYSPHORIA: A CASE SERIES

J. Vargas[1], A. Sierra Osorio[1], A. Medina[1], W. Rojas[1]

[1]hospital san jose bogota colombia, Bogota , Colombia

Objective: To describe changes in bone mineral density in a gender dysphoric population receiving gender affirmation therapy. Materials and Methods: This case series included seven transgender individuals (three FTM, four MTF) who initiated GAHT at our endocrinology clinic. BMD measurements (lumbar spine, femoral neck, total hip) were obtained using dual-energy X-ray absorptiometry (DXA) at baseline and after one year of GAHT. Descriptive statistics were used to analyze the data.
Results : We describe changes in bone mineral density in 7 transgender patients . Three of the 7 patients were transgender men (female to male FTM) and 4 were transgender women (male to female MTF). The entire population received gender-affirming hormone therapy over a one-year period. The average age in the FTM group was 49 years, and in the MTF group, 47 years. FTM Group: Lumbar spine BMD: Baseline: 1.176 g/cm2, One-year: 1.198 g/cm2,Femoral neck BMD: Baseline: 0.883 g/cm2, One-year: 0.892 g/cm2, Total hip BMD: Baseline: 0.973 g/cm2, One-year: 0.975 g/cm2. MTF Group: Lumbar spine BMD: Baseline: 1.510 g/cm2, One-year: 1.110 g/cm2, Femoral neck BMD: Baseline: 0.936 g/cm2, One-year: 1.013 g/cm2. Total hip BMD: Baseline: 0.948 g/cm2, One-year: 0.962 g/cm2. The FTM group demonstrated a

slight increase in BMD at all sites over the one-year follow-up period. In contrast, the MTF group exhibited significant variability, with some individuals experiencing BMD loss.
Conclusion: This case series provides preliminary data on the impact of GAHT therapy on bone mineral density in transgender individuals. While the FTM group demonstrated a slight increase in bone mineral density, the MTF group showed significant variability in patients who were not adherent to therapy. These findings emphasize the importance of ongoing bone health monitoring in transgender individuals receiving GAHT therapy, particularly in the MTF population. Further research with larger sample sizes and longitudinal follow-up is critical to fully understand the long-term effects of GAHT therapy on bone health and to develop appropriate strategies to optimize bone health outcomes in this population.

P257
LOW BONE MINERAL DENSITY IN FERTILE WOMEN AND YOUNG MEN WITH SYSTEMIC SCLEROSIS

A. Sorokina[1], N. Toroptsova[1], O. Dobrovolskaya[1], N. Demin[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective(s): to study the frequency of low bone mineral density (BMD) and factors affecting it in fertile women and men < 50 years with systemic sclerosis (SSc)
Material and Methods: The study included 84 patients with SSc according to the criteria of ACR/EULAR 2013: 68 (81.0 %) fertile women and 16 (19.0 %) men under the age of 50 (median age - 37.0 [32.0; 44.0] years). BMD was measured at lumbar spine, femoral neck and total hip by dual energy X-ray absorptiometry (DXA). Low BMD was diagnosed if the Z-score was less than -2.0 SD. To identify the factors associated with low BMD, a logistic regression analysis was performed.
Results: 17 (20.2 %) patients had low BMD, including 14 (20.5%) women and 3 (18.8 %) man. Univariate logistic regression revealed that low BMD was associated with duration of SSc (OR 1.12; 95% CI [1.02; 1.23]; p = 0.013), joint contractures (OR 3.44; 95% CI [1,05; 11,29], p = 0,039), duration of glucocorticoids (GCs) taking (OR 1.18; 95% CI [1.06; 1.32], p = 0.003) and cumulative dose of GCs (OR 1.07; 95% CI [1.03; 1.12], p = 0.002), body mass index (BMI) < 25 kg/m^2 (OR 6.85; 95% CI [1.41; 33.29], p = 0.017). Multivariate analysis demonstrated the association between low BMD and BMI < 25 kg/m^2 (OR 6.68; 95% CI [1.27; 35.17], p = 0.025), duration of SSc (OR 1,13 95% CI [1,02; 1,26], p = 0,018) in young patients with SSc.
Conclusion(s): 20.2% of young patients with SSc had low BMD, which was associated with BMI and disease duration.

P258
FACTORS AFFECTING BONE MINERAL DENSITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Sorokina[1], N. Toroptsova[1], N. Demin[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective(s): To study the frequency of osteoporosis (OP) and related factors in patients with systemic sclerosis (SSc).
Material and Methods: 200 patients with SSc (median age 52.0 [40.0; 63.0] years) were included: 160 (80.0%) women and 40 (20.0%) men. BMD was measured by DXA. In postmenopausal women and men ≥ 50 years OP was diagnosed with T- score at any region ≤ -2.5 SD, in fertile women and men < 50 years - with Z-score <-2.0 SD. To identify the factors associated with OP, a logistic regression analysis was performed.
Results: OP was detected in 62 (31.0%) persons. In univariate analysis the presence of OP was associated with age, duration of SSc, duration of proton pump inhibitor use, joint contractures, acroosteolysis, low diffusing capacity of the lung for carbon monoxide, interstitial lung disease, glucocorticoids (GCs) use > 3 months, GCs cumulative dose, current dose of GCs, duration of GCs taking, anti-topoisomerase I positivity, body mass index (BMI) < 24 kg/m^2, female gender. Multivariate analysis confirmed association between OP and BMI < 24 kg/m^2 (OR 2.86 95% CI [1.49; 5.49], p = 0.001), age (OR 1,05; 95% CI [1,02; 1,07], p < 0.001), duration of SSc (OR 1.07; 95% CI [1.02; 1.11]; p = 0.004), joint contractures (OR 2,08; 95% CI [1,03; 4,19], p = 0,040) and anti-topoisomerase I positivity (OR 2,23; 95% CI [1,13; 4,39], p = 0,019).
Conclusion(s): 31% of examined patients with SSc had OP. BMI < 24 kg/m^2, age, duration of SSc, joint contractures and anti-topoisomerase I positivity increased the risk of OP.

P259
RISK FACTORS OF FRAGILITY FRACTURES IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Sorokina[1], N. Toroptsova[1], O. Dobrovolskaya[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective(s): to evaluate the frequency and factors associated with of fragility fractures in patients with systemic sclerosis (SSc)
Material and Methods: 200 patients (80,0% women; median age - 52.0 [40.0; 63.0] years) with SSc according to the criteria of ACR/EULAR 2013 were included. The history of low-energy nonvertebral fractures and vertebral fractures according to spine X-ray morphometry was assessed. To identify the factors associated with fragility fractures, a logistic regression analysis was performed.
Results: 42 (21%) patients had fragility fractures: 18 (9.0%) - ver-

tebral and 24 (12.0%) - nonvertebral fractures. Univariate analysis revealed the association between fragility fractures and age (OR 1.08; 95% CI [1.05; 1.11], p < 0.001), duration of SSc (OR 1.06 95% CI [1.02; 1.10], p = 0.004), modifed Rodnan skin score (OR 1.09; 95% CI [1.02; 1.19], p = 0.018), glucocorticoids (GCs) use > 3 months (OR 2.93; 95% CI [1.09; 7.88], p = 0.031), duration of GCs use (OR 1.06; 95% CI [1.01; 1.11] p = 0.009), cumulative dose of GCs (OR 1.02; 95% CI [1.01; 1.03], p = 0.004), glomerular filtration rate (OR 0.98; 95% CI [0.97; 0.99], p <0.001), body mass index (BMI) < 23 kg/m^2(OR 4.76; 95% CI [1.41; 16.67], p = 0.012), bone mineral density of lumbar spine (OR 0,13; 95% CI (0,02; 0,92), p = 0,040). Multivariate analysis confirmed the association between fragility fractures and age (OR 1.08; 95% CI [1.03; 1.14], p <0.001), modifed Rodnan skin score (OR 1.12; 95% CI [1.01; 1.24], p = 0.025) and GCs use > 3 months (OR 5.05; 95% CI [1.31; 19.37], p = 0.017).

Conclusion(s): We found out that 21% of SSc patients had a history of fragility fractures. The risk of fragility fractures was increased with age, modifed Rodnan skin score and GCs use > 3 months.

THE VERTAIDO PROJECT (VERTEBRAL FRACTURE AI DETECTION FOR BETTER OSTEOPOROSIS CARE): IMPLEMENTATION OF AI-SCREENING IN CLINICAL ROUTINE – FIRST MONTH DATA

A. Spangeus[1], E. Baldimtsi[2], M. Lindblom[3], C. Salzlechner[4], T. Bjerner[5], M. Woisetschläger[5]

[1]Dept Activiy and Health, Linköping University Hospital/ Dept HMV, Linköping University, Linköping, Sweden, [2]Dept Activity and Health, Linköping University Hospital / Dept HMV, Linköping University, Linköping, Sweden, [3]Department of Radiology, Linköping University Hospital, Linköping, Sweden, [4]Department for Research and Development, IB Lab, Vienna, Austria, [5]Department of Radiology, Linköping University Hospital / Dept HMV, Linköping University, Linköping, Sweden

Objective: Vertebral fractures are significantly underdiagnosed in routine clinical practice. Opportunistic screening using CT scans could enhance detection rates. This study aims to implement an MDR approved AI-screening tool (FLAMINGO, IB Lab) within a clinical Fracture Liaison Service (FLS), thereby integrating radiology with clinical care.

Materials and Methods: In this prospective study, the AI-screening tool was incorporated into clinical care, linking radiology workflows to a FLS. All patients over 50 years of age undergoing thoracic and/or abdominal CT scans for non-skeletal reasons (e.g. pneumonia, malignancy, kidney stones) at a medium-sized hospital, serving approximately 250,000 inhabitants, were included.

Results: During the first month, a total of 1,249 CT scans (1,127 unique patients) were screened using the AI algorithm, with 19% flagged as positive (238 CT scans [216 unique patients]). Radiologist confirmation indicated that 71% of these were true positives (169 CT scans [148 unique patients]). In the FLS triage, 74 of these 148 patients (50%) were referred for further osteoporosis investigation and treatment. The remaining patients were already known and under correct treatment (30%) or were terminally ill or had deceased shortly (during 3 months) after the CT (20%). In total, 6.5% of all patients originally screened were finally referred for a vertebral fracture that was new or had not been handled correctly before.

Conclusion: The implementation of the AI-screening tool (FLAMINGO, IB Lab) within the clinical FLS demonstrated significant potential to increase the detection of vertebral fractures and to enhance subsequent investigation and treatment of osteoporosis.

THE PAEDIATRIC ACL NATIONAL AUDIT (PANA) STUDY

A. Subramanian[1], B. Gompels[1], D. Hide[1], D. Collins[2], F. Bradshaw[1], S. Castagno[1], W. Nbuyato[2], I. Liew[1], C. Gupte[3], N. Nicolaou[4], S. Mcdonnell[1]

[1]Division of Trauma and Orthopaedic Surgery, Department of Surgery, University of Cambridge, Cambridge, United Kingdom, [2]PANA Group Collaborators, England, United Kingdom, [3]Department of Surgery & Cancer, Imperial College London, London, United Kingdom, [4]Department of Orthopaedics, Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom

Objectives

Paediatric anterior cruciate ligament (ACL) injuries are becoming increasingly common and pose significant management challenges. Without proper treatment, these injuries can lead to joint instability, increasing the risk of early-onset osteoarthritis and long-term functional impairments. The Paediatric ACL National Audit (PANA) Study aims to assess UK practices regarding adherence to BOAST guidelines for managing paediatric ACL injuries. Additionally, it seeks to identify opportunities to improve care for skeletally immature patients and standardise treatment to improve long-term musculoskeletal outcomes.

Methods

The Paediatric National ACL Audit (PANA) was a collaborative audit of 22 hospitals in England, Wales, and Scotland. It measured adherence to BOAST best practice guidelines for treating and diagnosing paediatric ACL injuries. Data were collected by orthopaedic surgeons and trainees using a secure online questionnaire regarding the service provision of centres managing ACL injuries in skeletally immature patients, including diagnostic imaging protocols, rehabilitation, post-operative follow-ups, and surgical techniques.

Results

Our analysis revealed significant differences in adherence to BOAST guidelines for managing ACL injuries among paediatric patients, with 65% of centres surveyed reporting the use of acute knee pathways and 68% utilising locally collaborative imaging pathways. Furthermore, our analysis revealed variability in post-operative monitoring, with approximately 59% of centres surveyed performing radiological growth monitoring and only

30% reporting functional outcomes post-operation. Additionally, re-rupture rates were found to be reported by fewer than 50% of surveyed centres, and adherence to rehabilitation protocols was implemented in 74% of surveyed centres.

Conclusion

The rising occurrence of ACL injuries in children underscores the need for standardised care delivery and reporting. Following the release of the BOAST guidelines in 2022, this nationwide audit has found discrepancies in practices throughout the UK. A multidisciplinary team (MDT) to standardise practice and promote best practices is essential for improving patient care and long-term musculoskeletal outcomes in this population.

P262

A STUDY OF MINERAL LEVELS IN ADULT PATIENTS WITH OSTEOGENESIS IMPERFECTA.

D. Valeeva[1], K. Akhiiarova[1], B. Yalaev[2], R. Khusainova[2], A. Tyurin[1]

[1]Bashkir State Medical University, Ufa, Russia, [2]Endocrinology Research Centre, Moscow, Russia

Background: Osteogenesis imperfecta (OI) is a rare monogenic connective tissue disorder characterized by fragility of bones and recurrent fractures. In addition to the hereditary component, there are a number of factors that influence the course of the disease, the contribution of which is poorly understood, in particular the levels of some minerals.

Methods: A cross-sectional study was conducted involving 45 with OI and 45 healthy individuals. The concentrations of minerals (calcium, copper, inorganic phosphorus, zinc, and magnesium) and bone mineral density (BMD) were evaluated in all the participants.

Results: The concentrations of minerals in all the groups were within the reference values. In the OI overall, magnesium and copper were elevated, and phosphorus and zinc were lower. Type I exhibited higher concentrations of magnesium and copper and the lowest phosphorus; type III was associated with lower zinc, type IV with lower calcium and higher copper, and type V with the lowest phosphorus. OI overall was associated with lower BMD values. A correlational analysis in the OI group showed that the number of fractures correlated with BMD in absolute values but not with the Z-score.

Conclusions: The obtained data emphasize the importance of the levels of minerals in the pathogenesis of connective tissue diseases, in particular OI. As in the results of previous studies, the levels of minerals were within the population norm, which probably requires the development of individual criteria for the content of substances in this category of patients.

P263

DYSREGULATION OF ANGIOPOIETIN-LIKE PROTEINS TYPES 3 AND 6 IS ASSOCIATED WITH OBESITY IN PATIENTS WITH PSORIATIC ARTHRITIS

N. V. Golovina[1], A. V. Aleksandrov[2], L. N. Shilova[1], V. A. Aleksandrov[2], I. Y. Alekhina[3], N. V. Aleksandrova[4]

[1]Volgograd State Medical University, the Department of Hospital Therapy, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, VolgogradState Medical University, Volgograd, Russia, [3]Stavropol State Medical University, the Department of Hospital Therapy, Stavropol, Russia, [4]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Psoriatic arthritis (PsA), a type of arthropathy, combines immunometabolic disorders and lipid abnormalities and inflammatory manifestations due to the action of proinflammatory cytokines and adipokines.

Purpose of the study:

To evaluate the relationship of angiopoietin-like proteins types 3, 4 and 6 (Angptl 3,4,6) with obesity in patients with PsA.

Materials and Methods.

45 PsA patients (men 44.4%, women 55.6%) were under observation. The group of patients with abdominal obesity without arthropathies included 30 healthy individuals aged 22 to 53 years (18 women and 12 men).

All patients underwent clinical and laboratory examination, which also included determination of serum levels of Angptl types 3, 4, and 6 by enzyme immunoassay.

Results and Discussion.

Abdominal obesity is one of the most common chronic diseases that involves the accumulation of excess fat in the torso and internal organs. Obesity of various degrees was found in 37.8% of PsA patients. Angptl3 and Angptl6 content in obese patients (group 1) was significantly higher than in overweight patients (group 2) and in PsA patients without obesity (group 3) (Kruskal-Wallis test; p=0.002 and p=0.024, respectively), Angptl4 levels had no intergroup differences (p>0.05) (Table).

Table. Angptl content of types 3,4 and 6 in PsA patients depending on obesity

Показатели	Group 1 Obese patients (n=17)	Group 2 Overweight patients (n=14)	Group 3 Patients with normal body weight (n=14)
Angptl3, pg/mL	1276 ± 292 #	1074 ± 313	840 ± 306
Angptl4, pg/mL	414 ± 215	396 ± 156	341 ± 128
Angptl6, pg/mL	5,6 ± 1,7 #	7,2 ± 5,3	4,1 ± 1,7

Note: # – p<0.05.

The performed regression analysis labeled body mass index (BMI) as an independent predictor of Angptl6 concentration increase (F=8.6, β=0.408, p=0.005). We can assume the inclusion of different mechanisms involved in the dysregulation of Angptl types 3 and 6 in patients with obesity and arthropathies.

Conclusions.
Serum Angptl concentrations are variable in patients with arthropathies according to their different metabolic phenotypes. It is obesity that becomes the main destabilizing factor, which is accompanied by increased levels of Angptl types 3 and 6, in PsA patients in the presence of various metabolic disorders.

P264

PRESENCE OF CAGA-ASSOCIATED HELICOBACTER PYLORI INFECTION AFFECTS THE EFFICIENCY OF ERADICATION THERAPY IN RHEUMATOID ARTHRITIS

N. V. Aleksandrova[1], L. N. Shilova[2], V. A. Aleksandrov[3], E. A. Zagorodneva[4], A. V. Aleksandrov[4]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Volgograd State Medical University, the Department of Hospital Therapy, Volgograd, Russia, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Volgograd State Medical University, Volgograd, Russia, [4]Volgograd State Medical University, the Department of Laboratory Diagnostics, Volgograd, Russia

Rheumatoid arthritis (RA) patients with CagA-associated Helicobacter pylori (H. pylori) infection tend to have more severe clinical manifestations of the disease. The virulence factor of H. pylori, cytotoxin-associated gene A (CagA), is able to influence the efficiency of eradication therapy.
Purpose of the study:
To evaluate the efficiency of eradication therapy in RA patients with CagA-associated H. pylori infection.
Materials and Methods.
40 women with RA and confirmed chronic H. pylori infection (DAS28-ESR 3.96±0.56 points) were examined. The efficiency of H. pylori eradication therapy was confirmed in 62.5% of RA patients. Patients were divided into two groups: group 1 - 22 RA patients with CagA-associated H. pylori infection (CagA+), group 2 - 18 RA patients with negative total antibodies to CagA H. pylori (CagA-).
Results.
The dynamics of laboratory parameters reflecting inflammatory and immunologic changes in patients with RA (before the start of eradication therapy and 4-6 weeks after its completion) showed a decrease in the levels of RF, CRP, IL-6, TNF-alpha, anti-CCP, angiopoietin-like protein type 3 (for all parameters $p<0.05$) in group 2 (CagA-), and in patients from group 1 (CagA+) there was a decrease only in CRP and IL-6 ($p<0.02$), which, still, is an important confirmation of the decrease in the activity of inflammation after eradication of H. pylori.
The success rate of H. pylori eradication in the short term in CagA+ RA patients (group 1) was lower than in patients from group 2 (CagA-) ($p=0.033$). It was also noted that the combination of high titers of anti-citrullinated antibodies (> 60 IU/mL) and CagA-associated H. pylori infection in RA patients was accompanied by more rare positive eradication results ($p=0.009$) within the established time frame.
Conclusions.
The efficiency of eradication depends on the presence of chronic variant CagA-associated H. pylori infection and the level of antibodies to citrullinated proteins. This should be taken into account when choosing a therapeutic intervention against H. pylori in this group of RA patients.

P265

ASSESSMENT OF FACTORS INFLUENCING CHRONIC POSTOPERATIVE PAIN AFTER LARGE JOINT REPLACEMENT IN RHEUMATOID ARTHRITIS

V. N. Khlaboshchina[1], A. V. Bobkova[1], E. Y. U. Polishchuk[1], V. A. Nesterenko[1], V. E. Byalik[1], A. A. Byalik[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the effect of a number of clinical and psychological factors on the persistence of chronic postoperative pain for one year after hip and knee replacement in patients with rheumatoid arthritis.
Material and Methods: The study consistently included patients with rheumatoid arthritis who were admitted to the rheumoorthopaedic department from May 2022 to May 2024 for routine total knee/hip replacement. All patients were examined by a rheumatologist before surgery with an assessment of the disease activity according to DAS28-CRP, and were also asked to fill out the following questionnaires: Health Assessment Questionnaire (HAQ), painDETECT, Hospital Anxiety and Depression Scale (HADS), Pain Catastrophizing Scale.
Results: A total of 134 patients were recruited, 111 women (82.8%) and 23 men (17.2%). The average age was 56.7±13.7 years, the average duration of the disease was 14.9±10.8 years (Me [25‰;75‰] was 13.0 [7.0;20.0] years). The majority of patients had the stage II or III according to the Steinbroker's classification (33 and 34 patients, respectively). 20.1% showed signs of osteonecrosis. On average, signs of moderate disease activity were observed before surgery (DAS28-CRP was 3.5±0.8). 71.6% and 23.1% of patients received and conventional and biological disease-modifying antirheumatic drugs, respectively. After 12 months, 16.7% of patients continued to complain of pain in the area of the operated joint in the absence of infection or instability of the prosthesis components. The likelihood of pain retention correlated with the following factors ($p < 0.05$): female gender, depression according to HADS, high disease activity (DAS28-CRP is more than 5.2), neuropathic component of pain according to painDETECT, a tendency to catastrophize pain (more than 21 points on the scale of catastrophic pain). The duration of the disease or the severity of joint destruction were not significantly associated with the likelihood of chronic pain one year after the surgery.
Conclusion: Factors such as female gender, the presence of neuropathic pain, depression, and a tendency to catastrophize pain can contribute to the persistence of chronic pain in patients with rheumatoid arthritis after total knee and hip arthroplasty.

P266

TO THE QUESTION OF DENTAL HEALTH IN HIV-INFECTED PATIENTS

O. P. Galkina[1], A. V. Grokhotova[1]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: The dentofacial system is an integral component of the human musculoskeletal system. According to the literature data, the processes occurring in the facial bones are similar to those in the supporting system bones. The most pronounced manifestations of this interrelation are observed in the periodontal tissues and the teeth themselves. Some researchers consider teeth to be derivatives of the skeletal system. In recent years, particular attention has been drawn to the patient dental health in the post-COVID period. **Study objective** – to conduct a qualitative and quantitative characterization of the carious process in HIV-patients who have recovered from *COVID-19*.
Methoods: A total of 95 HIV-patients aged 35-44 years were examined. Of which, 59 patients had a confirmed history of *COVID-19* (study group, SG), while the comparison group (CG) consisted of 36 HIV patients who had not had coronavirus infection. The caries prevalence and intensity were determined using the DMF-index (Decayed, Missing, Filled teeth).
Results: Caries prevalence reached 100% in both study groups. The DMF-index did not differ significantly between the two groups and amounted to 22,45±2,5 in the SG and 18,52±3,22 in the CG. However, qualitative analysis of the values for the DMF components showed significant differences (p<0,05) between the groups. The values for decayed, filled, and extracted teeth in the SG were 10,97±3,49, 5,71±4,08 and 5,77±2,42, respectively, compared to 6,03±2,75, 9,29±3,73 and 3,19±1,85 in the CG. Notably, patients in the SG reported "active loss of fillings" (complete or partial) both during and after *COVID-19* illness.
Conclusion: Among HIV-infected patients exposed to *COVID-19*, the number of filled teeth decreases, while the number of decayed teeth increases due to the loss of fillings. This issue requires further investigation, particularly from the perspective of correlating changes in both the immune system and the musculoskeletal system.

P267

HISTOMORPHOMETRIC INDICATORS OF THE PROXIMAL EPIPHYSEAL CARTILAGE OF TIBIAE IN JUVENILE RATS DURING 90-DAY CAFFEINE OVERCONSUMPTION AND CORRECTION WITH MEXIDOL

A. V. Gutsenko[1], I. A. Belik[1], N. A. Mosyagina[1]

[1]FSBEI HI St. Luka LSMU of MOH of Russia, Lugansk, Russia

Objective. Changes in the structure of proximal epiphyseal cartilage (PEC) of tibiae in male rats at juvenile age under excessive caffeine administration and correction with mexidol for 90 days.
Materials and Methods. The experiment involved 72 male rats with initial body weight 130-140 g. In the first group there were animals that received distilled water. In the second group animals received caffeine intragastrically in dosage 120 mg/kg/day. In the third group animals received caffeine in the same way as animals from the second group and additionally subcutaneously injected mexidol in dosage 50 mg/kg/day.
Results. In the second group there was a narrowing of the PEC, width of the osteogenesis zone in comparison with the first group on 90 days of the experiment by 6.42% and 7.83%. Also, on 90 days, the width of proliferating cartilage and destruction zones lagged behind the values of the first group by 7.02% and 6.28%, and the width of indifferent and definitive cartilage zones - by 6.17% and 5.19%.The specific number of osteoblasts and primary spongiosa decreased from the values of the first group on 90 days of the experiment by 7.19% and 5.33%. At the same time, the content of intercellular substance in PEC in juvenile rats exceeded the values of the first group by 5.84%. The width of the osteogenesis zone of the third group exceeded the values of the second group at 90 days of the experiment by 5.89%, and the specific number of primary spongiosa and osteoblasts - by 5.13% and 5.98%. Also, by 90 days of the experiment the values of the second group were higher: the width of the zone of indifferent, proliferating and definitive cartilage - by 4.96%, 4.82% and 3.78% and the width of the zone of destruction - by 4.64%.
Conclusion. In juvenile male rats, excessive administration of caffeine was accompanied by inhibition of bone-forming function of the PEC of tibiae. When mexidol was administered, the detected changes were restored.

P268

BONE MINERAL DENSITY IN PATIENTS WITH MAFLD AND TYPE 2 DIABETES MELLITUS

A. V. Klimchuk[1], M. G. Nikolashin[1], S. Kulanthaivel[2], S. A. Khamidova[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India, [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Purpose of this study is analyzis of bone mineral density (BMD) in patients with metabolic-associated liver disease (MAFLD) and type 2 diabetes mellitus.
Methods: The study involved 100 patients of the State Healthcare Institution of the Republic of Crimea "N.A. Semashko Republican Clinical Hospital" with type 2 diabetes mellitus, including 56 patients with MAFLD and 44 patients without MAFLD. Age 58±6 years. Diagnostic criteria for MAFLD: the presence of fatty liver degeneration according to abdominal ultrasound, the presence of excess weight. Excess weight was defined as BMI ≥25 and <30 kg/m2. Exclusion criteria: liver cirrhosis, active viral hepatitis, autoimmune liver disease, liver tumors. BMD was measured using dual-energy X-ray absorptiometry at the lumbar spine and hip.
Results: Among patients with MAFLD, 42 (75%) had decreased BMD, of which 18 patients had BMD consistent with osteoporosis and 24 patients had osteopenia. Among patients without MAFLD, 19 (43%) had decreased BMD, of which 16 patients had osteope-

nia and 3 patients had osteoporosis.
Conclusion: Patients with type 2 diabetes with MAFLD are more likely to have decreased BMD than patients with type 2 diabetes without MAFLD.

P269

BONE MICROARCHITECTURE DISORDER IN POSTMENOPAUSEAL WOMEN WITH TYPE 2 DIABETES MELLITUS WITH NORMAL BONE MINERAL DENSITY

A. V. Klimchuk[1], A. A. Zayaeva[1], M. G. Nikolashin[1], S. Kulanthaivel[2], S. A. Khamidova[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India, [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Purpose of the study is estimation of the trabecular bone index TBS (Trabecular Bone Score) in postmenopausal patients with type 2 diabetes mellitus (T2DM) with normal bone mineral density (BMD).
Methods: The study involved 87 patients – postmenopausal women with type 2 diabetes mellitus (T2DM) aged 60±9 years. The HBA1 level was 7.2±0.3%. BMD, TBS were assessed by dual-energy X-ray absorptiometry (DXA). Exclusion criteria: risk factors for secondary osteoporosis, decreased BMD according to the T-score.
Results: 59 women (67.8%) had decreased TBS values (≤ 1.31). Among women with decreased TBS values, 41 women were obese (BMI ≥30 kg/m2), 16 women were overweight (BMI ≥25 and <30 kg/m2). Among the examined patients, there were 28 women (32.2%) with normal TBS values (≥1.35), of which 4 were obese and 12 were overweight.
Conclusion: Postmenopausal women with type 2 diabetes mellitus and normal BMD against the background of obesity were more likely to have impaired bone microarchitecture.

P270

BONE MICROARCHITECTONICS IN FEMALE PATIENTS WITH TYPE 2 DIABETES MELLITUS TAKING GLUCOCORTICOIDS IN POSTMENOPAUSE

A. V. Klimchuk[1], A. A. Zayaeva[1], S. Kulanthaivel[2], S. A. Khamidova[3], M. G. Nikolashin[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India, [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Purpose of the study is evaluation of the trabecular bone score (TBS) in postmenopausal patients with type 2 diabetes mellitus (T2DM) with normal bone mineral density (BMD) taking glucocorticoids for more than 3 months.
Methods: The study involved 60 patients – postmenopausal women with type 2 diabetes mellitus (T2DM) aged 55±6 years who took glucocorticoids for more than 3 months. The HBA1 level was 7.0±0.3%. In all patients, BMD and TBS were assessed using dual-energy X-ray absorptiometry (DXA). Exclusion criteria: other risk factors for secondary osteoporosis, decreased BMD according to the T-score.
Results: Of the 60 patients participating in the study, 43 patients (71.6%) had a decrease in TBS (≤ 1.31) against the background of normal BMD values.
Conclusion: TBS is a parameter that can complement DXA data to predict the risk of fractures in patients receiving glucocorticoids, regardless of BMD values.

P271

EVALUATION OF ADHERENCE TO TREATMENT WITH MODIFIED ANTI-INFLAMMATORY DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ISCHEMIC HEART DISEASE

E. M. Dolya[1], N. A. Revenko[1], A. V. Petrov[1], E. R. Zagidullina[1], S. Kulanthaivel[2], M. G. Nikolashin[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: To present the results of the analysis and assessment of the state of adherence of patients with rheumatoid arthritis (RA) depending on the presence of coronary heart disease (CHD) to treatment with Disease-modifying anti-rheumatic drugs (DMARDs) and to identify possible determinants of patient non-adherence.
Methods: An analysis and assessment of adherence to DMARD therapy was performed in 76 patients with confirmed RA without (n=42) and in combination with CHD (n=34), who had previously (before the start of this study) been prescribed a long-term course of treatment with DMARDs.
Results: In the examined patients with advanced RA, the number of patients adherent to basic therapy was 19.9%, the remaining patients (80.1%) were classified as partially adherent to treatment. It was revealed that the leading factors of non-adherence in patients suffering from RA to the treatment received were mostly due to the presence of side effects of drugs, as well as the existing concomitant disease of coronary heart disease drugs and the presence of coronary heart disease.
Conclusion: The results of the study indicate a very low adherence of patients suffering from RA, especially patients simultaneously suffering from coronary heart disease, to DMARD therapy, which shows the need to find modern approaches to improve the adherence of patients of this combination of patients to treatment, it is extremely necessary to conduct national educational programs.

P272

THE DYNAMICS OF THE INCIDENCE OF GERIATRIC PATIENTS IN WESTERN SIBERIA

A. Y. Moshkina[1], M. V. Tcikovskaya[1], D. G. Gubin[1], Z. V. Kuimova[1], D. A. Elfimov[1], I. I. Tchikovskaya[2]

[1]Federal State Budgetary Educational Institution of Higher Education "Tyumen State Medical University" of the Ministry of Healthcare of the Russian Federation, Tyumen, Russia, [2]State Budgetary Healthcare Institution of the Tyumen Region "Regional Clinical Psychiatric Hospital", Tyumen, Russia

Introduction. The main goal of public health according to the WHO concept of healthy aging was active functioning throughout life. Medical professionals in practical conditions could identify a decrease in physical and mental abilities (clinically expressed as health disorders) and took effective measures to prevent or slow down the development of these disorders.
The purpose of the study. To analyze the dynamics of the incidence of geriatric patients in the south of the Tyumen region based on the study of the "report on the health status of the population and the organization of healthcare in the Tyumen region based on the results of activities for 2022."
Materials and methods. We conducted an analysis of the "report on the health status of the population and healthcare organizations in the Tyumen region based on the results of activities for 2022."
Results. The general morbidity rate among people over working age increased by 14.8% (from 227,546.5 per 100,000 population of the corresponding age in 2020 to 261,112.1 in 2022). At the same time, the largest increase was observed in the class of respiratory diseases (15.2%), diseases of the endocrine system (14.7%), diseases of the circulatory system (12.9%), mental disorders (7.4%), certain infectious and parasitic diseases (6.2%). In the structure of registered diseases, the first place was occupied by diseases of the circulatory system (29.7%). This is followed by respiratory diseases (12.1%), diseases of the endocrine system (9.5%), diseases of the musculoskeletal system (8.6%), diseases of the eye and its appendage (7.2%), diseases of the digestive system (5.8%), neoplasms (5.4%) and diseases of the genitourinary system (5.1%). In 2022, there was an increase in the primary morbidity rate of people over working age by 45.8%. The greatest increase was observed in the following classes: diseases of the circulatory system (44.7%), diseases of the nervous system (24.7%), respiratory diseases (18.6%), diseases of the musculoskeletal system (10.1%), diseases of the genitourinary system (8.8%), diseases of the ear and mastoid process (8.0%), etc. A decrease in primary morbidity was noted in the class of diseases of the digestive system by 21.3%. In the structure of newly identified diseases, the first place was occupied by respiratory diseases (31.4%), followed by diseases of the circulatory system (10.8%), diseases of the eye and its appendage (3.7%), neoplasms (2.7%), diseases of the digestive system (2.5%), diseases of the ear and mastoid process (2.4%), diseases of the skin and subcutaneous tissue (2.3%).
Conclusions. By the age of 60, the main causes of disability and death were age-related hearing, vision, and mobility loss, as well as diseases such as dementia, heart disease, stroke, chronic respiratory diseases, diabetes mellitus, and diseases of the musculoskeletal system, in particular osteoarthritis and back pain.

P273

RARE LYSOSOMAL DISEASES IN NEUROLOGICAL PRACTICE

A. Zagorskaya[1], A. Filipovich[2]

[1]Minsk Regional Children's Clinical Hospital, Minsk, Belarus, [2]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

In the neurological department of the Minsk Regional Children's Clinical Hospital, we recently observed 2 cases of lysosomal diseases - glycolipidosis with a predominant lesion of the nervous system: GM2 gangliosis - Tay-Sachs disease, and cerebrosidosis - Krabbe's disease.
At the heart of Tay-Sachs disease is a genetically determined disorder of the metabolism of gangliosides, accompanied by their increase in the gray matter of the brain, liver, spleen. The type of inheritance is autosomal recessive, the deficiency of the enzyme hexosaminidase A is determined. The frequency of infantile gangliosidosis is 1: 250,000. Vision decreases and is rapidly lost, a special feature is the "cherry spot", which is translucent vessels at the site of destruction of several layers of the retina. Here is a brief description of the case. Girl KD, 1 year 5 months, complaints of developmental delay - does not hold her head, does not turn over, does not sit, does not walk, does not talk. From 1 year 4 months, seizures appeared in the form of short-term tremors of the limbs. Twice, up to 1 year 5 months, she was treated in the neurological department due to delayed psychomotor development, was examined by geneticists in order to clarify the diagnosis. Objectively: the head is macrocephalic in shape, does not hold the head, the large fontanelle is closed, does not turn over, does not sit, does not walk. Exotropia. Muscle tone is sharply reduced in the limbs, there is no support. Tendon-periosteal reflexes are reduced. R-CT of the brain: The cortex and white matter of the brain are well developed. No foci of pathological density were found in the brain matter. The ventricular system is moderately dilated. The lateral ventricles are symmetrical. The subarachnoid space of the cerebral hemispheres and cerebellum is uniformly expanded to 7 mm. Conclusion: CT - signs of mixed hydrocephalus. O. ophthalmologist: does not fix the toy, the direct reaction of the pupils is sluggish. The fundus of the eye: the optic nerve disks are pale, the contour is clear, the vessels are 1: 2 (3), the course is normal. In the macular zone, there is a bright red rounded dystrophic focus, rounded with a whitish corolla. Visible periphery without pathology. Diagnosis: Tay-Sachs disease. Partial atrophy of the optic nerves in both eyes. Results of genetic testing:
1. At the Institute of Genetics and Cytology of the National Academy of Sciences of Belarus (laboratory of nonchromosomal pathology), mitochondrial DNA

was analyzed for the presence of T8993 G mutations (maternal inherited Lee syndrome) and A3343 G (MELAS syndrome), as well as for the presence of large deletions of MT DNA. PCR analysis of DNA samples isolated from leukocytes was carried out. According to the results of DNA analysis, these violations of the mitochondrial genome were not revealed.
2. Activity of lysosomal enzymes in leukocytes: decreased activity of β-hexosaminidase A: 10.7; 7.2 mmol / g per mg of protein (norm 180-470).
Diagnosis: GM2 - gangliosidosis. Tay-Sachs disease. The risk of having a child with such diseases in the family is 25% - high. Material from a sick girl and her parents was sent for DNA research to the Medical Genetic Research Center of the Russian Academy of Medical Sciences, Moscow - a partial analysis of the HEXA gene (Tay-Sachs disease, H1H 272800). Treatment is symptomatic, specific enzyme replacement therapy has not been developed. The girl received anticonvulsants: depakin, carbamazepine, topamax, as well as diacarb, asparkam, emoxipin. 5 years ago, another girl with a diagnosis of globoid cell leukodystrophy - Krabbe's disease underwent inpatient treatment twice in the neurological department of the ultrasound department of the Moscow Regional Children's Clinical Hospital.
The child was admitted at the age of three months with complaints of delayed psychomotor development, constant unmotivated cry, malnutrition, then myoclonic convulsions appeared. The objective status was spastic tetraparesis, increased tendon-periosteal reflexes, pseudobulbar disorders, muscle hypertension, which was later replaced by hypotension. The disease progressed, due to a violation of swallowing, the child suffered aspiration pneumonia.
According to a decrease in the activity of the enzyme galactosylceramide-β-galactosidase in the medical genetic center of Minsk, the diagnosis was made - Krabbe's disease. At the age of 1, the girl died.
The type of inheritance of Krabbe's disease is autosomal recessive. To date, there are enzyme replacement drugs for the treatment of a number of extremely rare diseases: mucopolysaccharidosis - types 1,2,6, Gaucher disease, Fabry disease, Pompe syndrome, but in case of brain damage, there is no enzyme therapy, since the drugs do not penetrate the blood-brain barrier. Intensive clinical research is underway around the world to develop effective enzyme replacement therapy.

P274

X-LINKED OSTEOGENESIS IMPERFECTA DUE TO A NOVEL PLS3 PATHOGENIC VARIANT IN TWO BROTHERS

E. Mamedova[1], A. Zhdanova[1], E. Senyushkina[1], K. Smirnov[1], R. Salahov[1], R. Khusainova[1], Z. Belaya[1]

[1]Endocrinology Research Center, Moscow, Russia

Objective
Plastin-3 (PLS3) functions as an actin-binding protein which is involved in cytoskeleton remodeling. In bone, plastin-3 is part of the mechanosensitive mechanism of osteocytes and is involved in the mineralization process. We present clinical cases of two brothers with novel *PLS3* variants.
Methods
Whole-exome sequencing was performed on G400 (BGI, China) to identify the cause of bone fragility.
Results
Two brothers were referred due to bone fragility.
Patient 1, 20 y.o. suffered from multiple fractures starting from age 6 when bilateral forearm fractures occured. At age 15 multiple vertebral fractures (VFs) and a patellar fracture were diagnosed. DXA showed low BMD: L1-L4 -4.8SD, femoral neck -3.9SD, hip -4.2SD Z-score. Secondary causes of osteoporosis were excluded. This patient received levothyroxine 100mkg due to congenital hypothyroidism. At age 19 multiple Th2-8, 11-12, L1-5 VFs were diagnosed, along with elevated osteocalcin 94.89 ng/mL (24-70), CTx 1.56 ng/mL (0.1-0.85), alkaline phosphatase 204 IU/L (40-150). Treatment with zoledronic acid 5 mg was initiated. A year later DXA showed BMD improvement: L1-L4 -4.2SD, femoral neck -2.6SD, total hip -2.6SD Z-score, no new VFs or non-vertebral fractures were detected. One more infusion of zoledronic acid 5 mg was given.
Patient 2, 38 y.o. suffered multiple fractures (forearm bones, proximal humerus, ribs, metacarpal and metatarsal bones, multiple VFs, greater trochanteric fracture) from age 10. Secondary causes of osteoporosis were excluded. At age 35, this patient received zoledronic acid 5 mg. At age 37, DXA results were: L1-L4 -2.4SD, neck -2.3SD, hip -2.6SD Z-score. CT showed new VFs Th4-12, L1-L5. Teriparatide 20 µg daily was prescribed. A year later DXA did not show improvement, however no new fractures were recorded.
Both brothers had normal height, no visual bone deformities or blue sclera. Exome sequencing revealed a novel most likely pathogenic variant in *PLS3* (NM_005032/7) c.836_837dup (p.His280Phefs*43) which has not been previously described in the literature.
Conclusion: A novel *PLS3* variant in two brothers with multiple VFs and non-vertebral fractures adds to the description of this rare osteogenesis imperfecta with multiple fractures starting in a late childhood which may be successfully treated by zoledronic acid or teriparatide.

P275

SERUM OSTEOCALCIN AS A PREDICTOR OF TREATMENT EFFICACY IN PRIMARY OSTEOPOROSIS

A. Zoto[1], V. Salko[1], T. Backa[1], E. Rapushi[1], F. Spaho[1]

[1]UHC"Mother Teresa", Tirana, Albania

Objective: Osteocalcin levels vary widely among healthy individuals. The diagnosis of osteoporosis should be based on bone density or a clinical history that includes low-trauma fracture. Osteocalcin levels should not be used to diagnose osteoporosis. Serum osteocalcin has become known as a bone formation biomarker for the evaluation of treatment response in postmenopausal osteoporosis. The present study aim to evaluate if we can rely on baseline osteocalcin level as a predictor of treatment efficacy in

postmenopausal women.
Material and Method: Forty-one women with postmenopausal osteoporosis diagnosed by DEXA(Tscore≤-2.5) were included in this study. Mean age of the patients was 61±9.02 years. Serum osteocalcin, calcium and alkaline phosphatase (ALP) were measured at baseline and after 180 days. All the patients were put into treatment with ibandronic acid 150 mg/monthly. Mean serum osteocalcin at baseline was 16.33±4.1 ng/ml, which decreased significantly after 180 days of treatment with ibandronate, reaching 10.51±3.9 ng/ml.The reference range in adult female is 3.1-14.4 ng/ml.Mean value of DEXA at baseline was Tscore-3.5± 0.9 and after 6 month of treatment Tscore -3.2±1.1 .

Results: The group of patients with the lowest level of osteocalcin at baseline didn't show any difference at the outcomes after 180 days of treatment with ibandronate in comparison with the group of the patients with highest level of serum osteocalcin .

Conclusion: As the measurement of serum osteocalcin is considered a tool for monitoring the results of treatment in osteoporotic patient as the osteocalcin levels decreased after treatment of osteoporosis on the other hand it didn't show any correlation between serum osteocalcin levels before treatment and treatment outcomes

P276

BONE TISSUE STRUCTURE DISORDERS IN SPINAL MUSCULAR ATROPHY: THE ROLE OF ORTHOPEDIC DIAGNOSTICS

A. Zyma[1], T. Kincha-Polishchuk[1], A. Smaha[2], O. Skuratov[1], A. Cheverda[1], N. Samonenko[3], Y. Demyan[4]

[1]SI "The Institute of Traumatology and Orthopedics" by NAMS of Ukraine, Kyiv, Ukraine, [2]Municipal Non-Commercial Enterprise City Children's Clinical Hospital Chernivtsi, Ukraine, Chernivtsi, Ukraine, [3]Center of orphan disease and Gene disease NCSL OHMATDYT, Kyiv, Ukraine, [4]Regional Children`s Hospital, Mukachevo, Ukraine, Mukachevo, Ukraine

Objective: To evaluate orthopedic pathology and structural changes of bone in patients with spinal muscular atrophy (SMA).
Materials and methods. Five patients with SMA were examined: 3 patients - type I, 2 patients - type II. Patients' age: 1 adult - 35 years, 4 children - 8±2 years: female - 4, male - 1; did not move independently, are in a wheelchair. Orthopedic pathology: osteoporosis, pathological fractures were revealed in 2 patients: femur - 1, tibia - 1. Patients were examined clinically, radiologically, X-ray densitometrically; two patients received spinraza, risdiplam and zolgensma. In order to improve the structural condition of bone tissue and prevent pathological fractures of long bones, three patients were administered bisphosphonates (zoledronic acid - 0.025 mg / kg of weight) once every six months (2 injections).
Results and discussion. All patients had muscle strength of 2-3 points on the MRC scale. Orthopedic pathology was diagnosed: S-shaped scoliosis – 5, bilateral hip dislocation – 3; coxa valga bilateralis – 1, flexion contractures in the hip and knee joints – 5, foot deformities – 4. In all patients, a violation of the structural state of bone tissue was established: in an adult patient, T-criterion – lumbar spine - 4.7 SD, proximal femur - 3.6 SD, in pediatric patients, Z-criterion fluctuations in the lumbar spine range from – 1.1 SD to 1.4 SD, in the proximal part of the femur from - 3.6 SD to 3.8 SD. The absence of a decrease in bone mineral density in the lumbar spine in children, and its decrease in the proximal femur in all patients and the lumbar spine only in an adult, can be explained by the loading of the spine when sitting in children and age-related changes and the duration of the disease in adults.
Conclusion. In patients with SMA, there is a disruption of the neuromuscular connection, which, leads to the development of osteoporosis and pathological fractures. In order to prevent this, we believe it is necessary to undergo X-ray densitometric examination to determine the disruption of the bone tissue condition with its subsequent correction.

MUSCLE BODY COMPOSITION ANALYSIS IN PATIENTS WITH METABOLIC SYNDROME UNDERGOING MEDICAL REHABILITATION TREATMENT WITH INTERMITTENT HYPOXIA-HYPEROXIA THERAPY

A.-B. Uzun[1], A.-D. Nedelcu[1], L.-E. Stanciu[2], M.-G. Iliescu[2], L.-C. Petcu[3], A. Petcu[4], D.-E. Tofolean[5]

[1]Doctoral School, Faculty of Medicine, "Ovidius" University of Constanta, Constanta, Romania, [2]Department of Physical Medicine and Rehabilitation, Faculty of Medicine, "Ovidius" University of Constanta, Constanta, Romania, [3]Department of Biophysics and Biostatistics, Faculty of Dental Medicine, „Ovidius" University of Constanta, Constanta, Romania, [4]Department of Pharmaceutical Sciences, Faculty of Pharmacy, "Ovidius" University of Constanta, Constanta, Romania, [5]Department of Pulmonology, Faculty of Medicine, „Ovidius" University of Constanta, Constanta, Romania

Objective: Body composition analysis is essential for a detailed evaluation of body structure, providing valuable information about the proportions of muscle mass, fat, water, metabolic age and bone mass. This data allows a more precise assessment of health status, monitors progress following therapeutic interventions and helps personalize strategies for health promotion. Intermittent hypoxia-hyperoxia therapy (IHHT) involves alternating periods of exposure to hypoxia and hyperoxia, with significant results on various pathologies according to studies in the specialized literature [1,2]. This study aimed to analyze whether IHHT affects the assessment of muscle body composition in individuals with metabolic syndrome (MS).
Material and Methods: A study was carried out involving 40 individuals diagnosed with MS admitted to the Balneal and Rehabilitation Sanatorium of Techirghiol. Patients were randomized into two groups: a control group (20 patients) who received placebo therapy and an intervention group (20 patients) who received IHHT. At the same time, all patients also received complex medical rehabilitation treatment. The muscle body composition of

these patients was analyzed using a body composition analyzer scale.
Results: The study revealed no notable differences in muscle mass and muscle score between the two groups. Both groups, however, showed improvements in muscle quality (p=0.001 for the control group, p=0.040 for the intervention group), highlighting the importance of medical rehabilitation even without a significant effect of IHHT.
Conclusions: These findings emphasize the importance of medical rehabilitation as an essential approach to improving muscle quality in patients, regardless of the absence of IHHT as an additional intervention.

P278

DYNAMIC EVALUATION OF MUSCLE FUNCTION IN PATIENTS WITH SARCOPENIA USING ADVANCED METHODS WITHIN THE REHABILITATION UNITS

A.-D. Nedelcu[1], A.-B. Uzun[1], M. Minea[1], L.-E. Stanciu[2], M.-G. Iliescu[2]

[1]Doctoral School, Faculty of Medicine, "Ovidius" University of Constanta, Constanta, Romania, [2]Department of Physical Medicine and Rehabilitation, Faculty of Medicine, "Ovidius" University of Constanta, Constanta, Romania

Objective: Sarcopenia is an underdiagnosed pathology in medical practice worldwide. The dynamic assessment of muscle function through advanced methods in patients with sarcopenia involved in a complex medical rehabilitation program provides valuable insights for further research on this medical condition.
Material and Methods: This study, conducted over six months, between January and June 2024, included 100 patients hospitalized at the Balneal and Rehabilitation Sanatorium of Techirghiol, Romania. The patients included in the study were evaluated using specific tests. In confirmed cases, handgrip strength was assessed using a dynamometer, muscle mass and muscle quality were measured with a specialized electronic scale and muscle tone was evaluated through surface electromyography (sEMG). Assessments were performed at admission and discharge, following a complex medical rehabilitation program, designed to optimize the recovery of patients with sarcopenia.
Results: Sarcopenia was confirmed in 66% of the patients, of whom 82% were women and 18% were men, with a distribution of 36% in the 60-69 age group and 64% in the 70-79 age group. In confirmed cases, the rehabilitation treatment led to significant improvements in handgrip strength (88%), muscle mass (79%), muscle quality (86%) and muscle tone (86%). Statistically significant differences were observed over time, between admission and discharge, for muscle tone assessed through sEMG ($p<0.01$), handgrip strength ($p<0.01$), muscle quality ($p<0.01$) and muscle mass ($p<0.05$). Relevant correlations were identified between the assessment of muscle quality and handgrip strength at discharge, between muscle mass values and handgrip strength at both admission and discharge and between muscle tone values at admission and discharge.
Conclusions: Identifying sarcopenia, implementing a complex medical rehabilitation program and monitoring the dynamic improvement of body composition using anthropometric measurements and muscle tone through sEMG in the examined patients highlights the importance of increasing patients' access to rehabilitation units as they age, the need to routinely perform investigations for sarcopenia and opens new horizons for the development of a standardized protocol for patients with sarcopenia.

P279

HEMATOLOGICAL CHANGES IN SYSTEMIC SCLEROSIS (SS) PATIENTS AND CORRELATIONS WITH DISEASE SEVERITY: A SYSTEMATIC REVIEW

A.-E. Minea[1], M. Minea[2], M.-L. Groșeanu[3]

[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [2]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol. Ovidius University Faculty of Medicine Doctoral School, Constanța, Romania, [3]Saint Mary Clinical Hospital. Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Objectives: This review analyses how simple biomarkers – platelet to lymphocyte ratio (PLR), mean platelet volume (MPV) and red blood cell distribution weight (RDW), modify in SS and complications as interstitial lung disease (ILD).
Method: PubMed, Web of Science and ScienceDirect, Elsevier databases were researched by: ((rdw) OR (red blood cell distribution weight) OR (mean platelet value) OR (mpv) OR (platelet to lymphocyte ratio) OR (plr)) AND ((ssc) OR (systemic sclerosis)). PRISMA methodology was applied. 7 studies from the past ten years have been included. PLR, MPV and RDW were compared in SS patients and healthy controls and between patients with and without ILD.
Results: The meta-analysis showed a higher PLR in SS patients compared to controls - SMD=0.24, CI95%: [0.09, 0.39]. MPV and RDW in SS groups versus controls were not statistically significant (SMD MPV= 0.05, CI95% MPV: [-0.08, 0.19], SMD RDW= 0.01, CI95%: [-0.13, 0.16]). Regarding the changes in ILD patients compared to non-ILD patients, PLR was higher in the ILD group SMD=0.46 and 95%CI: [0.21, 0.72], as well as RDW, with a SMD= 0.36 and a 95%CI: [0.09, 0.62]. Nonetheless, MPV was not statistically significant different in the two cohorts.
Discussion: The results show that PLR is expected to be higher in SS patients, however the difference was modest. PLR and RDW were greater in those with lung involvement. MPV differences between the patients and controls and between ILD and non-ILD subjects were not significant. Nevertheless, the number of stud-

ies found to evaluate the connections presented was limited and not all of them assessed all 3 indicators.
Conclusions: Simple bloodwork parameters might modify in SS. PLR and RDW could increase in lung disease associated in SS patients, and introduced in severity predicting scores, as the changes observed individually were small. Regarding this subject, more research has to be done.

DIABETES DECOMPENSATION, OBESITY, HIGH ABDOMINAL FAT, LOW MUSCLE AND BONE MASS, VITAMIN D DEFICIENCY, AGE - CHARACTERISTIC OF HIP OSTEOPOROSIS IN POSTMENOPAUSAL DIABETICS

A.-M. Borissova[1], R. Mekova[1], K. Stoyanova[1]

[1]University Hospital Sofiamed, University of Sofia, Sofia, Bulgaria

In the country, there is a lack of systematic research in postmenopausal women with type 2 diabetes (T2DM) regarding the state of their bone system. **Aim**: To investigate a group of postmenopausal women with T2DM regarding factors that are associated with the development of osteoporosis/osteopenia in them. **Material**: 47 postmenopausal women with T2DM (59.19±6.53 years old) divided into two age groups: young – 49–59 years (n-22) and adults – 59–69 years (n-25); on oral treatment were 93.6% and significant percent of them were with HbA1c >7% (p<0.001) - 63.8% (30/47). **Methods**: Standard biochemical and hormonal tests, measurement of standard BMD (DXA), abdominal fat tissue (%), muscle and bone mass (Bio Impedance) were performed. **Results**: 80.9% (38/47) were with BMI ≥30 kg/m2 (p<0.001). The relative share of abdominal fat (%) in the entire group of subjects was significantly higher - 83.7% (36/43) (p<0.001). Muscle mass over 45 kg was present in the group of young people (49-59 y) in 81.8% (18/22), and in adults (59-69 y) only in 52% (13/25), p<0.02. Bone mass <2.5 kg was present in 64% (16/25) of 59-69 year old diabetics, while bone mass >2.5 kg is present only in 36% (9/25) - p<0.001. In the younger age group (49-59 years) there was no significant difference (<2.5 kg in 45.5% vs. >2.5 kg in 54.5%, NS). A significant difference was found when comparing groups with sufficient level of vitamin D (>30 ng/ml) and those with deficiency and insufficiency (<30 ng/ml): 19.15% (9/47) vs. 80.85% (38/47) - p<0.001. Osteoporosis and osteopenia in the spine were present in 29.8% (14/47) of the examined, with no significant difference between the two age groups. Osteoporosis and osteopenia of the hip in the group of older people (59-69 y) diabetics were present in in 91.66% (22/24), and in 8.34% normal BMD (2/24), p<0.02. In the younger group (49-59 years), no significant difference was found - 68.4% (13/19) vs. 31.6% (6/19), NS. **Conclusion**: Diabetics with hip osteoporosis and osteopenia have significantly more often HbA1c >7%, BMI >30 kg/m2, higher percentage of abdominal fat, low muscle and bone mass, vitamin D <30 ng/ml.

P281

PREVALENCE AND RISK FACTORS FOR VERTEBRAL COMPRESSION FRACTURES IN ANKYLOSING SPONDYLITIS PATIENTS UNDER 50: A CROSS-SECTIONAL STUDY

B. A. Boukabous[1], B. B. Bengana[1], L. S. Lefkir[1], D. R. Djidjik[1], N. A. Nebab[1], B. S. Bennedjema[1]

[1]University of medical sciences of Algiers/ Rheumatology department / Hospital of Beni Messous, Algiers, Algeria

Introduction
Vertebral compression fractures (VCFs) are a significant complication of ankylosing spondylitis (AS), particularly in younger patients. Unlike primary osteoporosis, which predominantly affects postmenopausal women and elderly individuals, VCFs in AS occur in patients under 50 years old due to systemic inflammation and disease-related bone fragility. The primary objective of this study was to determine the prevalence of VCFs in AS patients under 50 and identify associated risk factors.
Patients and Methods
This prospective, monocentric, observational cross-sectional study was conducted from October 2020 to October 2022. We included AS patients aged 18–49 without associated inflammatory rheumatic diseases or other clinical conditions predisposing to bone fragility, such as endocrine or gastrointestinal disorders, except those on corticosteroid therapy. VCFs were assessed using lateral spine radiographs and graded according to the Genant classification. BMD was measured using DXA at the lumbar spine (L1-L4) AP, femoral neck, and total hip.
Results
A total of 102 AS patients (70 men, 32 women) were included, with a mean age of 35.6 years. Chronic smoking was noted in 32.4% of the patients, exclusively in men. The mean age at symptom onset was 25 years, with a mean disease duration of 11 years. The average BMI was 26.56 kg/m². Peripheral joint involvement was present in 31.37%, and coxitis was reported in 23.57%. Most patients exhibited elevated inflammatory markers, with a mean CRP of 17.3 mg/L, and 59.8% were HLA-B27 positive. The mean ASDAS-CRP was 2.63, and 48% had at least one syndesmophyte. VCFs were observed in 34.31% (n=35) of patients, with 14 patients classified as grade 2 or 3. Trabecular bone loss (lumbar spine L1-L4) was present in 17.65% (n=18), and cortical bone loss (femoral neck or total hip) in 5.88% (n=6). In total, 21.57% (n=22) had low BMD at one or more sites. Risk factors for VCFs included male sex (p=0.005), elevated inflammatory markers (CRP ≥ 6 mg/L, p=0.002), thrombocytosis (p=0.027), and high disease activity scores (ASDAS-ESR, p=0.019; ASDAS-CRP, p<0.001).

Conclusion
VCFs are a common complication in AS patients under 50, affecting over one-third of the studied population. This fracture risk is strongly associated with systemic inflammation, disease activity, and trabecular bone loss. These findings emphasize the importance of early screening and targeted management of bone health in young AS patients to prevent debilitating complications. Further randomized controlled trials are needed to confirm these observations and develop optimal prevention strategies.

P282
THE SARC-F SCORE AND ASSOCIATED FACTORS IN COMMUNİTY-DWELLİNG OLDER ADULTS

O. Yilmaz[1], B. Aykent[2]

[1]Istanbul Training and Research Hospital, Istanbul, Turkiye, [2]Sisli Etfal Training and Research Hospital, Istanbul, Turkiye

Introduction: Sarcopenia, characterized by reduced muscle mass and strength, leads to functional decline, increased fall risk, and decreased quality of life in older adults. The SARC-F questionnaire is a widely used screening tool for sarcopenia. This study aims to evaluate the demographic, clinical, and biochemical factors influencing SARC-F scores in community-dwelling older adults.
Methods: We conducted the study retrospectively and cross-sectionally. We included 366 people aged ≥60 years who applied to the geriatric outpatient clinic.. Participants were categorized as SARC-F positive (≥4 points) or negative (<4 points). Data on demographic characteristics, chronic conditions, functional measures (ADL, IADL), cognitive performance (MMSE), nutritional status (MNA-SF), frailty (FRAIL), and biochemical parameters (e.g., CRP, ESR) were analyzed.
Results: SARC-F positivity was identified in 35.1% of participants. SARC-F positive individuals were older (77.1 ± 7.6 vs. 71.1 ± 7.0 years, p<0.001), predominantly male (83.1% vs. 34.4%, p=0.001), and had poorer functional (ADL, IADL, p<0.001), cognitive (MMSE, p=0.003), and nutritional (MNA-SF, p<0.001) status. Inflammatory markers (CRP, ESR) were significantly elevated (p=0.010, p=0.001). Regression analysis identified age, depressive symptoms (GDS-SF), functional independence (IADL), and cognitive performance (MMSE) as significant predictors of SARC-F positivity.

Conclusions: SARC-F scores are strongly associated with age, functional independence, cognitive impairment, and inflammation, reflecting the multifactorial nature of sarcopenia. Comprehensive assessment and multidisciplinary approaches targeting these factors are essential for early detection and management of sarcopenia in older adults.

P283
MANAGING ASYMPTOMATIC HYPERURICEMIA: INSIGHTS AND PRACTICES FROM A RHEUMATOLOGIST SURVEY

B. B. Bengana[1], B. A. Boukabous[1], O. I. Ouafi[1], C. F. Cheriat[1], G. H. Guerboukha[1]

[1]University of medical sciences of Algiers/ Rheumatology department / Hospital of Beni Messous, Algiers, Algeria

Introduction
Asymptomatic hyperuricemia (AHU) is a common condition in rheumatology practice, yet its management remains a subject of debate. Musculoskeletal ultrasound has recently emerged as a valuable tool for detecting urate deposits in patients with hyperuricemia or gout. Our survey aimed to explore rheumatologists' perceptions and practices regarding AHU, as well as their approach to using musculoskeletal ultrasound in this context.
Materials and Methods
We conducted a knowledge, attitudes, and practices (KAP) survey among Algerian rheumatologists. The survey, distributed as an anonymous online questionnaire, consisted of 16 questions across four themes: professional experience and practice settings (4 questions), the definition of asymptomatic hyperuricemia (3 questions), the use of musculoskeletal ultrasound (5 questions), and strategies for managing hyperuricemia (3 questions). A total of 246 responses were collected via professional networks and email invitations, with 89 responses validated for analysis.
Results
Among the 89 validated respondents, 39 had over 15 years of rheumatology experience, 25 had 5–15 years of experience, and 25% had less than 5 years of experience. A quarter of participants reported no experience with musculoskeletal ultrasound, while half had 1–10 years of experience or more.
Regarding the definition of AHU, one-third of rheumatologists defined it as serum urate levels exceeding 6 mg/dL in men and 5 mg/dL in women, while approximately half adhered to thresholds of 7 mg/dL in men and 6 mg/dL in women. Over half of the respondents reported measuring serum urate levels in the presence of comorbidities, whereas a quarter did so only when clinical signs of gout were apparent.
In terms of treatment, over 80% of rheumatologists did not treat AHU systematically, with only 10% doing so as a standard practice. Concerning the use of musculoskeletal ultrasound, more than one-third of respondents considered it unnecessary for managing AHU, while half employed it to detect "hidden" gout through urate deposits. One-fifth of participants did not use ultrasound to diagnose gout, and over 30% did not consider ultrasound-detected urate deposits or gout signs in their practice. Furthermore, more than 10% were unaware of current guidelines for managing AHU.
Conclusion
This survey highlights significant variability in rheumatologists' approaches to asymptomatic hyperuricemia and the use of musculoskeletal ultrasound. The findings underscore the need for continuous education and the standardization of guidelines to

optimize the management of AHU patients.

P284

SAFETY OF 23-VALENT PNEUMOCOCCAL POLYSACCHARIDE VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS (PRELIMINARY DATA)

B. B. S. Belov[1], B. M. M. Baranova[1], M. N. V. Muravyova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective(s)
To study the safety of 23-valent pneumococcal polysaccharide vaccine (PPV-23) in patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA).
Material and Methods
The open prospective study included 96 patients with RA, 52 with AS and 27 patients with PsA; 98 female; men age was from 20 to 79 years; disease duration was from 5 months to 42 years. At the time of vaccination, the disease activity in patients with RA according to the DAS28 index was 4,14±1,3, disease activity in patients with AS and PsA according to the BASDAI index was 4,3±2,2. The majority of patients (84.1%) at the time of inclusion in the study received immunosuppressive therapy: 73 – methotrexate (MT), 1– MT+sulfasalazine, 14 – leflunomide, 41 – TNF-α inhibitors±disease-modifiying anti-rheumatic drugs (DMARDs), 2 – abatacept (ABC)±DMARDs, 6 – rituximab (RTX)±DMARDs, 11 – IL-17 inhibitors±DMARDs, 1 – tofacitinib. PPV-23 was injected in an amount of 1 dose (0.5 ml) into the deltoid muscle of the shoulder against the background of anti-rheumatic therapy.
Results
Post-vaccination reactions (PVRs) were noted in 41.2% of patients with RA, 24.1% of patients with AS and PsA. 80.9% of PVRs were local. Of the local PVRs, the most frequently recorded were pain, redness and swelling (≤2.5 cm) at the injection site, of the systemic ones - subfebrile temperature. Three patients with PsA and one patient with AS developed a pronounced local reaction in the form of pain in the arm, infiltrate and hyperemia of the skin from 8 to 15 cm in diameter, accompanied in two patients by subfebrile temperature for 2 days, in two others - febrile fever for 3 days. The indicated PVRs were completely stopped by symptomatic therapy. In general, no significant negative effect of vaccination on the disease activity. One month after vaccination with PPV-23, DAS 28 was 3,7±1,2, BASDAI was 3,7±2,1. Within a month after the introduction of PPV-23, an exacerbation of the disease was observed in two patients with AS, aged 28 and 25.
Conclusion(s)
The data obtained indicate sufficient safety of PPV-23 in patients with RA, AS and PsA. Further studies are needed to assess the effect of the PPV-23 on the on the course of rheumatic diseases.

P285

IMMUNOGENICITY OF 23-VALENT PNEUMOCOCCAL POLYSACCHARIDE VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS (PRELIMINARY DATA)

B. B. S. Belov[1], B. M. M. Baranova[1], M. N. V. Muravyova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective(s)
To study the immunogenicity of 23-valent pneumococcal polysaccharide vaccine (PPV-23) in patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA).

Material and Methods
The open prospective study included 96 patients with RA, 52 with AS and 27 patients with PsA; 98 female; men age was from 20 to 79 years; disease duration was from 5 months to 42 years. At the time of vaccination, the disease activity in patients with RA according to the DAS28 index was 4,14±1,3, disease activity in patients with AS and PsA according to the BASDAI index was 4,3±2,2. The majority of patients (84.1%) at the time of inclusion in the study received immunosuppressive therapy: 73 – methotrexate (MT), 1– MT+sulfasalazine, 14 – leflunomide, 41 – TNF-α inhibitors±disease-modifiying anti-rheumatic drugs (DMARDs), 2 – abatacept (ABC)±DMARDs, 6 – rituximab (RTX)±DMARDs, 11 – IL-17 inhibitors±DMARDs, 1 – tofacitinib. PPV-23 was injected in an amount of 1 dose (0.5 ml) into the deltoid muscle of the shoulder against the background of anti-rheumatic therapy. Initially, 1, 3 and 12 months after vaccination, the level of antibodies to pneumococcal capsular polysaccharide was assessed using the EIA PCP IgG kit (TestLine Clinical Diagnostics s.r.o., Czech Republic).
Results
The dynamics of antibody concentration to pneumococcal capsule polysaccharide is presented in the table.

Table 1. Pneumococcal antibody levels in patients with RA, AS and PsA, U/ml, Me [25th, 75th percentiles].

Visit I	Visit II	Visit III	Visit IV
67.3 [31.5; 135.3]	197.95 [72.0; 266.4]	212.9 [61.95; 305.5]	134.2 [53.0; 250.62]

$p_{I\text{-}II, I\text{-}III, I\text{-}IV} \leq 0{,}001$

After 1, 3 and 12 months after vaccination, a significant increase in the concentration of antibodies to pneumococcal capsular polysaccharide was observed compared with the initial indications. A positive antibody response (≥ twofold increase pre- to postvaccination) was seen in 58.3% of RA patients, 16.7% of AS patients, 25% of PsA patients. Respondents had, on average, lower baseline levels of antibodies to pneumococcal capsular polysaccharide. Both groups (responders and non-responders) were

comparable in age and disease duration. Disease activity score and therapy, including TNF-α inhibitors and MT, did not significantly affect immunogenicity.
Conclusion(s)
The data obtained indicate sufficient immunogenicity of PPV-23 in patients with RA, AS and PsA. Further studies are needed to assess the effect of the therapy on the immunogenicity of PPV-23, as well as the clinical efficacy of this vaccine.

POST-CANCER PATIENTS HAVE A HIGH PREVALENCE OF OSTEOPOROSIS

B. Agbokponto[1], J. Bérardet[2], M. Gaudé[2], M. Seauve[2], M. Auréal[2], M. Meunier[1], E. Taravel[2], N. Tréhet-Mendel[3], E. Massy[1], J.-P. Larbre[2], S. Jacquin-Courtois[1], B. Confavreux[1]

[1]Hospices Civils de Lyon - Université Claude Bernard Lyon 1, Lyon, France, [2]Hospices Civils de Lyon, Lyon, France, [3]Prévention des Maladies Osseuses, Hospices Civils de Lyon, Lyon, France

Introduction. With the advancement of oncological strategies, more and more patients are in remission and entering a post-cancer state. Bone health becomes a crucial issue to recover physical activity and autonomy. Our aim is to describe the bone health of the post-cancer cohort in our institution.
Patients. Post-cancer patients at our institution undergo a one-day global health assessment (JUMP programme) within the 12 months of remission to identify sequelae and propose personalised care. Bone assessment includes risk factor questionnaire, biology and osteodensitometry (Horizon Wi/W, Hologic®).
Results. Between February 2022 and May 2024, 212 patients underwent the JUMP programme. The population was (mean ± SD) 53.2 ±13.3 years old, predominantly female (66%) and Caucasian (86%). BMI was 27.0 ±6.4 kg/m². The most common cancer etiologies were lymphoma (34%), breast (26%), testicular (11%), ovarian (6%), digestive (6%) and myeloma (5%).
Only 17 (8%) had a family history of hip fracture and 24 (11%) had a personal history of fragility fracture. 52 (25%) had a history of falls. Active smoking and alcohol consumption (>3 units per day) were more common in men (21% vs. 10%; p=0.03 and 11% vs. 4%; p=0.03 respectively). However the use of selective serotonin reuptake inhibitors was less frequent (8% vs 26% ; p=0.002). The use of proton pump inhibitors was common in both sexes (23%).
The prevalence of osteoporosis (T-score <-2.5) was higher in men (25% vs. 13%; p<0.05). Men had a higher prevalence of hip involvement (21% vs 7% at the neck and 15% vs 5% at the total hip). The highest prevalence of osteoporosis was observed in myeloma (46%), ovarian (23%) and lymphoma (18%). The youngest subjects in the cohort already had a significant prevalence of osteoporosis (15% under 40 years vs 13% [40-50[and 11% [50-60]).
Conclusions. The JUMP post-cancer cohort shows a high prevalence of osteoporosis, particularly in young men with a cumulative number of bone fragility risk factors. This bone fragility comes on top of the high risk of falling and should be recognised in post-cancer patients. The ultimate goal is to improve quality of life and autonomy during cancer remission.

P287
CHRONIC LOW BACK PAIN – APPROACH TO CONSERVATIVE THERAPEUTIC ATTITUDES IN GENERAL AND FAMILY MEDICINE

B. Duarte Ferreira[1], C. Pais Neto[1], M. Valente Mendes[1], C. Almeida[1]

[1]ULS de Entre Douro e Vouga - USF Novo Norte, Santa Maria da Feira, Portugal

SUMMARY:
Low back pain is the most common musculoskeletal disease, being considered the main cause of disability and absenteeism from work. It is recognized as the pathology that is expected to obtain the most benefit from rehabilitation treatments. Conservative treatments include different types of intervention, which aim at the functionality, independence and active participation of the patients. The aim of this literature review is to evaluate the role of conservative attitudes in the management of chronic low back pain, with regard to symptomatic control, functionality and the quality of life of these patients. A bibliographical research was therefore carried out in PubMed/ME-DLINE, Database of Abstracts of Reviews of Effects and The Cochrane Library, using the MeSH terms: “Chronic Back Pain” AND “Conservative Therapies”. It is concluded that the therapeutic exercise is considered the basis of the treatment of chronic low back pain. Of the articles that were analyzed, it is worth mentioning favourable data regarding pilates exercises in the pain control of chronic low back pain, resistance and spinal stabilization exercises in functionality, strength and muscular endurance, and aerobic exercises in mental health related to this pathology. Hydrotherapy has shown promising but meager results on pain intensity, associated disability, quality of life and sleep, and mental state. The results of acupuncture and electroacupuncture modalities, biofeedback therapy and laser therapy are still scarce.

Keywords: Chronic Low Back Pain; Conservative Treatment; General and Family Medicine.

VITAMIN D LEVELS AMONG HEALTHCARE WORKERS

B. Erhan[1], Y. Yumusakhuylu[1], B. Ozkan[1], M. Yasal[1]

[1]İstanbul Medeniyet University, School of Medicine; PMR Department, Istanbul, Turkiye

Vitamin D deficiency is widespread in our country and around the world. Vitamin D is essential for human health and is synthesised in the body largely through exposure of the skin to sunlight. Working in environments with insufficient sunlight exposure may increase the risk of vitamin D deficiency. In this study, we hypothesised that vitamin D levels may be quite low in healthcare workers who work in buildings with insufficient sunlight and who work night shifts, and aimed to investigate the effects of working

environment and working hours on vitamin D levels in healthcare workers.
Methods: In this retrospective cross-sectional case-control study, 25OHD$_3$ levels of healthcare workers working in our hospital were collected from the hospital data system. According to the National Endocrine Society values, a serum 25OHD$_3$ level of <20 ng/mL was considered deficient, levels between 20-30 ng/mL as insufficiency and >30 ng/mL as normal. Healthcare workers were divided into occupational subgroups and serum 25OHD3 levels were compared.
Results: 25OHD$_3$ levels were measured in 1934 [male: 510 (26%), female: 1424 (74%)] healthcare workers. The mean age of the participants was F/M: 33/36 years.
The staff subgroups were distributed as follows 525 doctors [residents (265), specialists (218)]. 460 nurses, 321 allied health professionals, 198 clerical staff, 430 other staff. The mean 25OHD$_3$ index of all participants was 16.49ng/ml. There was no statistically significant difference between the 25OHD$_3$ levels of women (16.36 ng/mL and men (16.86 ng/mL according to gender (p>0.05). In the physician group, the overall mean 25OHD$_3$ level was 20.38 ng/mL(17.72ng/mL for residents and 23.37 for specialists). In the nurse group the mean 25OHD$_3$ level was 15.41ng/mL in the allied health personnel group was14.67ng/mL in the clerical personnel group was 17.39ng/mL and in the other hospital personnel group was 13.76 ng/mL
Conclusion: In our study, we found that 25OHD$_3$ levels of health care workers were very low. Since vitamin D deficiency is an easily preventable and treatable condition, the detection of this deficiency is of great importance.

P289

GLOBAL, REGIONAL AND NATIONAL BURDEN OF KNEE OSTEOARTHRITIS 1990-2021: A SYSTEMATIC ANALYSIS OF THE GLOBAL BURDEN OF DISEASE STUDY 2021

B. F. Zhang[1], Z. Yang[1]

[1]Department of Joint Surgery, Honghui Hospital, Xi'an Jiaotong University, Beilin District, Xi'an, Shaanxi Province, China, Xi'an, China

Objective: The systematic analysis aimed to assess the levels and trends of knee osteoarthritis (KOA) in 204 countries and territories from 1990 to 2021.
Methods: We analyzed the data on the Global Burden of Diseases 2021 and reported the KOA burden and the trends from 1990-2021 by age-standardized incidence rate (ASIR), age-standardized prevalence rate (ASPR) and disability-adjusted life years (DALYs). All estimates were presented as counts and age-standardized rates per 100,000 people, calculating the estimating average annual percent change (EAPCs) with 95% uncertainty intervals (UIs).
Results: From 1990 to 2021, the KOA burden still showed an increasing trend globally, faster in females than males; the 35-39 years population has faster KOA symptoms, and 45-49 years have faster prevalence and DALYs. The high-middle SDI regions are experiencing the fastest increase. East Asia has the fastest growth, and North America has shown a stable trend with no change. The top 9 fastest growing countries and territories were Oman, Equatorial Guinea, Thailand, Saudi Arabia, Sudan, China, Taiwan (Province of China), Maldives, and Pakistan. By 2050 of prediction, there may be an obvious decreasing trend in KOA burden. Frontier analysis indicates the presence of unrealized opportunities to close the KOA burden gap in most countries and territories. Decomposition analyses indicate that population growth accounted for more than 70% of the global KOA burden. SDI level was positively associated with KOA burden increasing, and ASIR or HDI was not associated with the burden EPAC.
Conclusion: KOA is still a major global health challenge. Although there is variation between countries and regions, most countries' KOA burden is increasing, especially among females and young adults.

P290

THE ASSOCIATION BETWEEN ADMISSION TO OPERATION (ATO) TIME AND PREOPERATIVE DEEP VEIN THROMBOSIS (DVT) IN GERIATRIC HIP FRACTURE UNDER THE ANTICOAGULATION AND MECHANICAL THROMBOPROPHYLAXIS: A RETROSPECTIVE COHORT STUDY

B. F. Zhang[1]

[1]Department of Joint Surgery, Honghui Hospital, Xi'an Jiaotong University, Beilin District, Xi'an, Shaanxi Province, China, Xi'an, China

Objective: This study aimed to evaluate association between admission to operation (ATO) time and preoperative deep vein thrombosis (DVT) in geriatric hip fracture under the anticoagulation and mechanical thromboprophylaxis.
Methods: Geriatric patients with hip fractures were screened between January 2015 and September 2019. We collected the demographic information and DVT screening result in medical system. Multivariate binary logistic regression and generalized additive models were used to identify the linear and nonlinear associations between ATO and preoperative DVT. Also, we performed Propensity Score Matching (PSM) to test the robustness of our results in a real-world study.
Results: One thousand seven hundred and thirty-five patients were included in this study. There were 443, 726, and 566 patients in ATO≤2d, 2d<ATO≤4d, and ATO>4d groups, respectively. Preoperative DVT occurred in 543 (31.29%) patients. There was a "J" type in curve fitting, and the result shown that there was curvilinear relationship between ATO and preoperative DVT. ATO of 3 d was the inflection point. ATO increasing was not associated with increasing of preoperative DVT when ATO< 3d (OR=0.82; 95% CI: 0.66-1.02; *P*=0.0753), whereas ATO increasing was associated with DVT (OR=1.06; 95% CI: 1.00-1.13; *P*=0.0338) at ATO >3 d. In a real-world population of 1:1 under PSM, we found that the results were stable and the inflection point was same to total population.
Conclusions: ATO is nonlinearly associated with preoperative DVT in geriatric patients with hip fractures under the anticoagula-

tion and mechanical thromboprophylaxis. The 3 d was the important point in DVT formation, every one day increasing in ATO was associated with the rising 6% in incidence of preoperative DVT.

P291

OSTEOPOROSIS ASSOCIATED WITH A PLS3 GENE MUTATION: A CASE REPORT

B. Fernandes Esteves[1], M. Correia Natal[1], L. Costa[1], R. M. Ferreira[1]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal

Osteoporosis (OP) is the most common metabolic bone disease, mainly affecting postmenopausal women but also occurring in younger individuals and men. Secondary OP may arise due to chronic conditions, medications, or alcohol use. In young adults with severe OP, multiple fractures, a family history of OP, and no clear secondary cause, monogenic bone diseases should be investigated. The prevalence of OP in young patients is underestimated, and management strategies remain unclear.

We report the case of a 42-year-old man with multiple fragility fractures since age 30. After a femoral neck and olecranon low-energy fracture, he initiated alendronate 70mg/week in 2013, for six years. Despite treatment, he sustained several additional fragility fractures: the right 5th metacarpal (2014), bilateral wrists (2015), and vertebral bodies T3 and T4 (2018). He was referred to rheumatology. He showed no stigma of osteogenesis imperfecta, and possible secondary OP causes were ruled out. A detailed family history uncovered a maternal uncle with multiple fragility fractures from a young age. Therapeutic failure was assumed, and therapy was switched to teriparatide 20mcg/day (2019–2021). Despite no significant improvement in bone density, the patient did not suffer further fractures. Zoledronate was used as sequential therapy. He was also referred to a clinical geneticist. A hemizygous c.342C>G (p.Ser114Arg) variant in the PLS3 gene was identified by genomic test.

The X-linked *PLS3* gene, primarily affecting hemizygous males, encodes Plastin-3, a protein with bone-regulatory properties. The exact mechanism by which *PLS3* mutations cause OP and fractures is unknown. Patients with *PLS3* mutations typically develop early-onset OP, making sequential treatment essential. However, current therapies are based on postmenopausal OP studies, highlighting the urgent need for research into the efficacy and safety of therapies in this population.

P292

DENOSUMAB AS A NEW THERAPEUTIC OPTION IN PAGET'S DISEASE OF BONE: A CASE REPORT

B. Fernandes Esteves[1], M. Correia Natal[1], L. Costa[1], R. M. Ferreira[1]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal

Paget's disease of bone (PDB) is the second most prevalent metabolic bone disease. The clinical spectrum varies from asymptomatic to bone pain, deformities, or fractures. The principal marker for diagnosis and monitoring is alkaline phosphatase (ALP). First-line therapy is bisphosphonates (BPs), particularly zoledronate. BPs are contraindicated in glomerular filtration rate below 30mL/min. Even though few cases are described in the literature, denosumab appears to be an option for these patients.

We present a case of a 70-year-old man with a polyostotic PDB diagnosed in 2000, with involvement of the sacrum, iliacs, T11 and L1. He was treated with pamidronate (2000, 2003) and zoledronate (2009, 2011, 2015). He also had Crohn's disease, microcrystalline arthropathy, dyslipidemia, hypertension, chronic alcoholic liver disease, and chronic kidney disease, progressing to stage 4 by 2021. In March 2022, he developed a disabling low back pain, without response to analgesic treatment. A lumbar spine CT showed changes suggestive of PDB in L1 and L5. Nuclear bone scan showed heterogeneous radiopharmaceutical uptake consistent with reactivation of PDB. Analytically, he presented an increase in bone-specific ALP, serum ALP, beta-crosslaps and osteocalcin. Due to low renal clearance, he started treatment with denosumab 60mg every 6 months with complete resolution of pain after 2 weeks. The patient showed rapid analytic response, however, the ALP tended to increase when the next administration approached. This may suggest a rebound effect similar to the one observed in osteoporosis.

Zoledronate is the first-line treatment of PDB. Indications are less clear when there is intolerance or contraindication to BPs. Denosumab is a safe alternative for patients with renal impairment. To the authors' knowledge, there are no comparative studies between zoledronate and denosumab in PDB. In the literature, there are no studies indicating the frequency or duration of denosumab in PDB.

P293

PYROGENICITY ASSESSMENT OF CROSSLINKED HYDROGEL MICROPARTICLES (HMPS) UTILIZING THE RABBIT PYROGEN TEST IN ACCORDANCE WITH EUROPEAN PHARMACOPOEIA GUIDELINES

J. Schelfhout[1], B. Gür[1]

[1]Allegro NV, Liège, Belgium

Objective(s): To evaluate the safety profile of a biopolymer-based medical device designed for intra-articular administration in the treatment of joint pain and dysfunction. The primary objective

was to determine its non-pyrogenicity under controlled test conditions.
Material and Methods: The medical device, composed of highly purified biopolymers and intended for single-use intra-articular injection, was supplied in pre-filled, luer-lock syringes and sterilized via gamma irradiation. Three healthy New Zealand White rabbits (males, 2.3–3.1 kg) sourced from Charles River Laboratories, France, were housed under standardized conditions (temperature: 17–21°C; relative humidity >30%) as per EU Directive 2010/63.
Following acclimatization, a pyrogen test was performed. The test article was extracted at 37°C ± 1°C for 72 hours, homogenized, and administered intravenously via the marginal ear vein at 10 mL/kg body weight. Rectal temperatures were recorded every 30 minutes for 3 hours post-injection. Results were assessed against European Pharmacopoeia thresholds for pyrogenicity.
Results: The maximum cumulative temperature rise across the three rabbits was 0.64°C, significantly below the 1.15°C threshold indicative of pyrogenic activity. The extract's pH was 6.0, and the supernatant, following centrifugation, was cloudy but free of visible particulates. No adverse clinical observations or deviations were recorded during the study period.
Conclusion(s): Under the conditions of this study, the medical device was determined to be non-pyrogenic, meeting the requirements of the European Pharmacopoeia. These findings support its safety profile for intended therapeutic applications.
Acknowledgments: The study was conducted at NAMSA, an AAALAC International-accredited facility, with oversight by the NAMSA Ethical Committee and the French Ministry of Education, Higher Education, and Research. The contributions of trained personnel and strict adherence to standardized protocols ensured reliable data.
Disclosures: No sedation, anesthesia, or analgesia was used during the study. Results apply solely to the specific test article under the stated conditions.

P294

EVALUATION OF THE RELATIONSHIP BETWEEN VITAMIN D LEVELS AND BONE MINERAL DENSITY, FRACTURE RISK, AND MUSCLE STRENGTH IN THE GERIATRIC AGE GROUP

O. Nurlu[1], B. Haktanıyan[1], M. Varlı[1]

[1]Ankara University Faculty of Medicine, Ankara, Turkiye

Introduction and Aim: Vitamin D has a direct effect on bone health and muscle functions. Vitamin D deficiency may result in decreased bone mineral density and decreased muscle strength. The goal of our study is to investigate the correlation between vitamin D levels, bone mineral density, muscle strength, and fracture risk within the geriatric population.
Materials and Methods: Data of patients applying to the Ankara University Faculty of Medicine Geriatrics Department between January 2021 and December 2023 will be retrospectively analyzed. The vitamin D levels, grip strength, and FRAX scores of the included patients will be examined in the study.
Results: 192 participants were included in the study. Of these, 61.5% were female, with an average age of 78.1 years. Significant differences were observed in muscle strength between the sufficient and low vitamin D groups (p<0.001). In the sufficient vitamin D group, higher MNA total scores (p=0.037) and lower GDS scores (p=0.007) were noted. Femoral neck BMD values and T scores were also significantly higher in the sufficient vitamin D group (p=0.022, p=0.020). While no significant difference was found in FRAX fracture risk between the two groups, a significant negative correlation was observed between vitamin D and 10-year major osteoporotic (p=0.003) and hip fracture (p=0.014) risks. Positive correlations were also observed between vitamin D and femoral neck (p=0.004) and lumbar (p=0.019) T scores. Positive correlations were found between vitamin D levels and Katz (p=0.008), Lawton (p=0.006), MNA (p=0.03) scores, while negative correlations were observed with GDS (p=0.004) and FRAIL (p=0.028) scores.

	Vitamin D ≥ 20 n=85	Vitamin D < 20 n=107	p value
Femoral neck BMD, *g/cm²*	0.79±0.15*	0.74±0.15*	**0.022**
Femoral neck T score	-0.8±1.1*	-1.2±1.2*	**0.020**
FRAX, 10 year probability of fracture (%)			
Major osteoporotic	7.1±4.9*	8.5±5.9*	0.061
Hip fracture	2.1±1.8*	2.8±2.8*	0.088

**mean ± SD*

Conclusion: Adequate vitamin D levels were associated with increased muscle strength, higher BMD values, and decreased fracture risk. Maintaining adequate vitamin D levels is important for bone health and adequate muscle strength. Additionally, vitamin D may have an impact on increased daily life activities and decreased depression scores outside the musculoskeletal system.

P296

REAL-WORLD EFFECTIVENESS OF ROMOSOZUMAB: A SYSTEMATIC LITERATURE REVIEW

B. L. Langdahl[1], G. Adami[2], M. McClung[3], K. Ebina[4], J. Smith[5], S. Colgan[6], J. Timoshanko[7]

[1]Aarhus University Hospital and Aarhus University, Aarhus, Denmark, [2]University of Verona, Verona, Italy, [3]Oregon Osteoporosis Center, Portland, United States, [4]Osaka University, Osaka , Japan, [5]Costello Medical, Cambridge, United Kingdom, [6]Amgen, Thousand Oaks, United States, [7]UCB, Slough, United Kingdom

Objectives: To summarize observational, real-world evidence for use of romosozumab.
Material and Methods: A systematic literature review was conducted according to PRISMA guidelines. MEDLINE, Embase and relevant conference proceedings were searched to 2nd December 2024 for observational studies of patients receiving romosozumab reporting effectiveness outcomes.
Results: The SLR identified 362 records, of which 67 unique studies across 10 countries were included. The majority were retrospective cohort studies (n=39) and 29/67 were comparative. Numbers of patients ranged from six to 29,512 for romosozumab

and 21 to 537,927 for comparators, with denosumab most commonly reported. Mean patient age ranged from 52.3 to 84.4 years. Across both romosozumab and comparator arms, mean bone mineral density (BMD; T-score) at baseline ranged from −3.80 to −1.79 at the lumbar spine, −3.00 to −2.15 at the total hip, and −3.30 to −2.20 at the femoral neck. Mean percentage change in lumbar spine BMD at 12 months ranged from 0.97% to 20.0% and 1.07% to 8.10% for patients treated with romosozumab and comparators, respectively. Mean percentage change in total hip BMD ranged from −0.40% to 9.10% (romosozumab) and −2.80% to 3.60% (comparators) with similar changes in femoral neck BMD. Romosozumab was associated with significant improvements in BMD at 12 months versus baseline in 25/25 (lumbar spine), 18/22 (total hip) and 16/18 (femoral neck) studies. BMD gains in treatment-naïve patients were significantly larger compared with previously treated patients, in 11/12 (lumbar spine), 7/10 (total hip) and 5/8 (femoral neck) studies.

Conclusions: Across real-world data romosozumab improved BMD and demonstrated larger BMD gains versus comparators at 12 months. However, effectiveness was reduced in those previously treated with osteoporosis medications, highlighting the importance of treatment sequencing.

ASSESSING THE EFFICACY AND SAFETY OF ROMOSOZUMAB IN POSTMENOPAUSAL OSTEOPOROSIS: AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS

B. Lladó Ferrer[1], M. S. Moreno Garcia[2], S. Rojas Herrera[3], C. A. Egües Dubuc[4], G. Mariscal[5], J. Buades Reines[1]

[1]Hospital Son Llatzer, Palma de Mallorca , Spain, [2]Hospital Universitario Miguel Servet, Zaragoza, Spain, [3]Hospital de Merida, Merida, Spain, [4]Hospital de Donostia, San Sebastian, Spain, [5]Institute for Research on Musculoskeletal Disorders, School of Medicine, Valencia Catholic University, Valencia, Spain

Objective: This meta-analysis aimed to study the effects of romosozumab in postmenopausal women compared with other interventions, evaluating changes in bone mineral density (BMD), incidence of new vertebral fractures, bone biomarkers, and safety.

Material and Methods: A systematic search was conducted using three databases. Randomized controlled trials (RCTs) evaluating romosozumab in postmenopausal patients with osteoporosis were included. The main variables were BMD, incidence of new vertebral fractures, bone formation, and removal of markers and adverse events. Sensitivity analyses and GRADE assessments were conducted to ensure the robustness and certainty of the finding.

Results: Ten RCTs with 15,476 patients were included. Romosozumab demonstrated significantly greater improvements in lumbar spine BMD than placebo (MD 13.18, 95% CI 11.91 to 14.45; P < 0.00001), denosumab (MD 5.29, 95% CI 4.20 to 6.37; P < 0.00001), teriparatide (MD 4.35, 95% CI 4.09 to 4.61; P < 0.00001), and alendronate (MD 9.95, 95% CI 7.51 to 12.40; P < 0.00001). Romosozumab also showed higher levels of the bone formation marker P1NP than denosumab (MD -1.10, 95% CI -1.38 to -0.81; P < 0.00001) and alendronate. The safety profile of romosozumab was comparable to the comparator interventions.

Conclusions: This comprehensive meta-analysis provides robust evidence that romosozumab is an effective and safe treatment option for postmenopausal osteoporosis, with superior effects on BMD and bone formation biomarkers compared with other interventions. These findings support the use of romosozumab to improve clinical outcomes in this patient population.

P298

SAFETY AND OUTCOMES OF ROMOSOZUMAB IN ONCO-HEMATOLOGIC PATIENTS: A MULTICENTER STUDY FROM TWO SPANISH HOSPITALS

S. Vela -Bernal[1], L. Bernácer García[1], D. Ruiz-Raga[1], J. S. Buades Mateu[2], B. Lladó Ferrer[2]

[1]University Clinic Hospital of Valencia, Valencia , Spain, [2]Hospital Son Llátzer, Palma de Mallorca , Spain

INTRODUCTION AND OBJECTIVES:

The use of Romosozumab, with dual osteogenic and antiresorptive effect, has demonstrated in clinical trials its efficacy and safety for the treatment of osteoporosis (OP). Strict inclusion criteria may limit study populations, such as onco- haematological patients The aim of the study was to describe the demographic, clinical and densitometric characteristics of two cohorts of patients with a diagnosis of solid organ or haematological neoplasia in clinical remission

MATERIAL AND METHODS:

This is a retrospective cohort study which included patients with onco-haematological neoplasia assessed in the bone metabolism consultation of the Hospital Clínico Universitario de Valencia and the Hospital Universitario Son Llàtzer, treated with romosozumab from October 2022 to December 2024. Clinical and analytical data, fracture types, treatments and densitometric data were collected before and after the end of treatment. Safety has been assessed by assessing the need and cause for treatment discontinuation.

RESULTS:

35 patients were included being 26 women (74.29%) with a me-

dian age 78 ICR (71-83). The distribution of comorbility was :Diabetes mellitus 25,71% Hypertension 37,14% Dislipidemia 34,29% Chronic kidney disease 20% . The type of onco-haematological malignancies is described in graph 1.
Romosozumab was prescribed as secondary prevention in 88.57% (n: 31), the distribution of fracture types present in both cohorts is shown in graph 2. The prior treatment received by patients : Zaledronate (4) Teriparatide (4) Alendronate (3) Denosumab (3) Risedronate (2)
15 patients have control densitometry after finish of romosozumab. The mean densitometric T-score values are shown in graphs 3 and 4, where statistically significant differences are observed after romosozumab use.
No patients discontinued treatment due to adverse effects or drug interactions.No cardiovascular events occurred.

CONCLUSIONS:

In conclusion, we can state that romosozumab in routine clinical practice is a good therapeutic option in onco-haematological patients with very high-risk of fracture with a high degree of adherence, as well as a good safety and tolerability profile.
Disclaimer : Romosozumab is not approved on technical data sheet in men nor in oncohematological patients . The use in these patients , both male and female , was medically decided in the absence of other options.

CAUSES OF BIOTHERAPY DISCONTINUATION IN RHEUMATOID ARTHRITIS

B. Marwa[1], G. Rim[1], E. Nejla[1], B. Khadija[1], B. Elyes[1]

[1]Farhat Hached University Hospital, Sousse, Tunisia

Introduction: The advent of biotherapies has revolutionized the management of chronic inflammatory rheumatic diseases; however, in some situations, their temporary or definitive discontinuation is necessary.
Aim:
The aim of our study is to analyze the reasons for discontinuation of biotherapies in rheumatoid arthritis.
Materials and methods :
We retrospectively analyzed the files of patients with rheumatoid arthritis (RA) treated with biotherapies between 2000 and 2021. We have recorded the epidemiological characteristics, the indications for biological treatment, the duration of treatment and the reasons of discontinuation.
Results :
One hundred and eighteen patient records were analyzed (99

women and 19 men). The mean age of our population was 56.86 ± [28-81 years].Anti TNF ά was prescribed in 67 cases: Infliximab in 27 cases, etanercept in 16 cases, certolizumab in 13 cases, adalimumab in 9 cases and golimumab in 2 cases. As for anti Il6 and anti CD20, they were prescribed in 24 and 27 cases respectively. Discontinuation of biotherapy was indicated in 54 cases. Anti TNF was suspended in 37 cases (68.51%), anti CD20 in 15 cases (27.7%) and anti IL6 in 2 cases (3.7%). As for the anti TNF, infliximab was suspended in 19 cases, etanercept in 10 cases, adalimumab in 4 cases, certolizumab in 3 cases and golimumab in 1 case.The causes of discontinuation were dominated by the occurrence of adverse effects in 56% of cases, such as infection in 57 cases (48.3%), skin reaction in 4 cases (3.4%), and systemic allergic reaction in 2 cases (1.7%), two cases of neutropenia(1.7%) and one case of hepatic cytolysis(0.8%).Drug discontinuation rates due to lack of effectiveness were observed in 54 cases.
Conclusion :
Biotherapies have transformed the prognosis of refractory forms of RA. The frequency and severity of adverse effects of these molecules can be reduced by respecting the pre-therapeutic assessment, rigorous patient education and careful follow-up.

P301

MODALITIES OF METHOTREXATE USE IN RHEUMATOID ARTHRITIS BEFORE THE INITIATION OF BIOTHERAPY

B. Marwa[1], G. Rim[1], E. Nejla[1], B. Khadija[1], B. Elyes[1]

[1]Farhat Hached University Hospital, Sousse, Tunisia

Objective :
Methotrexate (MTX) remains the cornerstone of rheumatoid arthritis (RA) treatment, as evidenced by guidelines that indicate MTX as first-line therapy for most newly diagnosed patients. Optimization of MTX prior to initiation of biologic therapy is necessary in the management of RA. The aim of this study was to evaluate the use of MTX prior to biologic therapy in RA.
Material and methods :
This is a retrospective study that included patients followed for RA, treated with MTX for at least 3 months and requiring the use of biological treatments.
Results :
One hundred seven patients were included, 13 men and 94 women. The mean age was 55.71 years [28-81 years].MTX was prescribed as first-line oral therapy for all patients. The initial dose prescribed was 10mg/week for 24 patients (22.4%), 12.5mg/week for 4 patients (3.7%), 15mg/week for 54 patients (50.5%) and 17.5mg/week for one patient (0.9%).The highest prescribed dose of MTX was 25mg/week in one patient. 24 patients (22.4%) were prescribed a dose greater than or equal to 20mg/week. This maximum dose was prescribed after an average of 32 months. A switch to the parenteral form was made in 18 patients (16.82%) whose main indication was digestive intolerance (41.12%). A second synthetic treatment (csDMARDs) in combination with MTX was used in 75 patients (70.1%): Salazopyrine in 74 patients and leflunomide in one patient (0.9%). The mean duration of MTX therapy before initiation of the first biologic was 56 months. MTX was discontinued before one year in 20 patients (18.7%). The reasons for discontinuation of MTX were: digestive and neurosensory intolerance in 10 patients (9.3%), hepatic cytolysis in 2 patients (1.9%), leukopenia in one patient (0.93%), and toxidermia in one patient (0.93%).
Conclusion :
Our study shows that there are some deficiencies in optimizing of MTX prior to the use of biotherapy in the management of RA, including a delay in the instauration of an effective dose.

P302

EPIDEMIOLOGICAL ,CLINICAL AND EVOLUTIONARY ASPECTS OF GAMMAPATHIES OF UNDETERMINED SIGNIFICANCE IN THE ELDERLY

B. Marwa[1], G. Rim[1], B. Narimane[1], G. Marwa[1], Z. Saoussen[1], J. Mahbouba[1], B. Ismail[1]

[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia

Objective :
Monoclonal gammopathies are a group of disorders caused by abnormal plasma cell proliferation. Monoclonal gammopathies of undetermined significance (MGUS) represent the most frequent etiology. They are characterized by the presence of a plasma cell clone in the bone marrow, secreting a monoclonal immunoglobulin in the blood or urine, with no clinical or laboratory signs of malignant lymphoproliferation. MGUS is characterized by its asymptomatic nature and its incidental discovery in the majority of cases. It is a biological abnormality frequently found in the general population, particularly in the elderly, and its incidence is estimated at 3.5% in patients over 70.
Our aim is to describe the epidemiological, clinical and evolutionary aspects of MGUS in elderly subjects.
Material and methods :
This is a retrospective study conducted in the Clinical Hematology and Rheumatology Department of the Fattouma Bourguiba University Hospital (CHU) in Monastir over an 8-year period (from 2012 to 2020).
Results :
We identified 32 patients with MGUS, with a predominance of female and a sex ratio of 0.68. The age of our patients ranged from 65 to 88 years, with an average of 74 ±5 years. Twenty patients (62%) had more than two comorbidities, including 40% with diabetes and hypertension. MGUS was associated with rheumatological and autoimmune diseases in 25% and 6.25% of cases respectively. Six patients had an autoimmune disease: four had rheumatoid arthritis, one had autoimmune hepatitis and one had primary Gougerot Sjögren's syndrome. The two most frequent circumstances of discovery were: incidental finding in 30.7% and bone pain in 40.6% . Isolated anemia was observed in 12 cases (37.5%). No patient had thrombocytopenia or leukoneutropenia. The erythrocyte sedimentation rate (ESR) was accelerated in 6 cases (18.8%). CRP was negative in 29

patients (90%), and blood calcium and LDH levels were normal in all. Four patients (12.5%) had renal failure of the following etiology: Diabetic nephropathy and Nephro-angiosclerosis. The proteinuria was positive in 4 patients (12.5%). Six patients (18.8%) had hypoalbuminemia. Hypogammaglobulinemia was observed in 7 patients (21.9%), and the monoclonal peak was found in the Gamma and Beta zones respectively in 81% and 16% of EPPs requested. Monoclonal peak values ranged from 3g/l to 16g/l, with an average of 7g/dl ±3g/l. Non-IgM MGUSs represented the highest proportion of the total. Non-IgM MGUS accounted for 84.4% of cases. IgM MGUS was found in 5 patients (15.6% of cases). None of the patients included had Ig E, Ig D or light chain MGUS. All patients (100%) underwent a myelogram, and the rate of bone marrow plasmacytosis ranged from 0 to 8%, with an average of 3 ±1%. 1 patient (3.1%) underwent FISH karyotyping, which revealed no chromosomal abnormalities. Patient follow-up ranged from 0 to 9 years, with an average of 2 years. One case transformed into Indolent Multiple Myeloma with the following characteristics: Age at diagnosis:87 years, Duration of surveillance: 2 years, Initial peak size: 16g/l ,Ig Isotype: IgG, Percentage of Initial Plasmocytosis 7%.
Conclusion :
These results highlight the importance of performing a complete workup in the event of detection of a monoclonal peak on plasma protein electrophoresis (PPE), to ensure the absence of multiple myeloma or another lymphoproliferative pathology, and to anticipate possible clinical evolutions. A prognostic score can be calculated to better stratify the risk of transformation and adapt the rhythm and modalities of monitoring.

P303

FIRST LINE PHYSICIANS KNOWLEDGE AND PRACTICES REGARDING CHRONIC INFLAMMATORY RHEUMATIC DISEASES (CIRD)

B. Marwa[1], G. Rim[1], G. Marwa[1], B. Narimane[1], J. Mahbouba[1], Z. Saoussen[1], B. Ismail[1]

[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia

Objective:
Chronic inflammatory rheumatic diseases (CIRD) represent a major challenge in the management of patients by primary care physicians. The aim of this study is to assess the knowledge and practices of Tunisian general practitioners in terms of CIRD, as well as their training needs in relation to these diseases.
Material and methods :
A self-administered survey developed via Google-Forms was conducted among Tunisian primary care physicians in 2024.
Results :
Sixty-two physicians were included in our study: 35% men and 65% women. The mean age of the participants was 31 years [28-40 years]. Eighty percent of them worked in public health and 20% were self-employed, with an average number of years of practice of 2.9 years [1-13 years]. All the doctors questioned declared that they received patients with CIRD in consultation, with a frequency of less than five patients per month for 60% of them, between five and ten patients per month for 20%, and a frequency of more than 10 patients for the remainder (20%). The most common CIRD were rheumatoid arthritis (RA) in 92.5% of cases, spondyloarthropathy (SPA) in 27.5% and psoriatic arthritis (PsA) in 10%. RA was suspected in the presence of joint deformities (82.5%), polyarthralgia (77.5%) and polyarthritis (65%). SPA was suspected in the presence of rachialgia (72.5%) and association with chronic inflammatory bowel disease (45%). Ninety seven percent of doctors asked for a biological work-up in the case of suspected CIRD, and all doctors asked for standard X-rays, such as hand X-rays (87.5%) and forefoot X-rays (60%) in the case of RA, along with lumbar and cervical spine X-rays (80%) and pelvic X-rays (67.5%) in the case of SPA . When it came to screening for extra-articular manifestations, 60% thought it should be done systematically, and 40% did so only in the presence of warning signs on examination. Sixty-five per cent said they had difficulty diagnosing CIRD , and 35% did not. The sources of information in this case were calls to specialists (70%), continuing medical education (37.5%), medical websites (32.5%) and literature reviews (10%). Training in the management of CIRD was judged sufficient by 22.5%, superficial by 60% and very inadequate by 17.5%. 95% of them would like more training in inflammatory joint pathology. They referred patients to rheumatology immediately (22.5%), in the absence of improvement with symptomatic treatment (60%) and in extreme age groups (15%).
Conclusion :
The survey reveals a good awareness of the clinical signs of CIRD among primary care physicians, but highlights shortcomings in diagnosis and follow-up, as well as a significant need for further training to improve the management of patients suffering from these conditions.

P304

BIOTHERAPY IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS : EFFICIENCY AND TOLERANCE

B. Marwa[1], G. Rim[1], B. Narimane[1], G. Marwa[1], J. Mahbouba[1], Z. Saoussen[1], B. Ismail[1], B. Khadija[2], B. Raghda[2]

[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia,
[2]Farhat Hached University Hospital, Sousse, Tunisia

Objective:
Due to the exponential increase of biotherapies and their indications, several studies have been carried out to evaluate their impact on elderly patients suffering from autoimmune disease.The treatment of rheumatoid arthritis (RA) in the elderly, particularly by biotherapy, is made more difficult by the presence of associated pathologies and by the increase in side effects.
The aim of our work is to determine the frequency of biological treatment in elderly patients in a rheumatology department, and to reveal the clinic-biological profile of these patients, as well as the efficacy and tolerance of the prescribed treatments.
Material and methods :
This is a retrospective study including the records of patients over 65 years old followed up for RA according to the ACR/EU-

LAR 2010 criteria for RA in a rheumatology department and who were treated with biotherapy during the period between 2000 and 2021.
Results :
Among the 118 patients included, 33 patients were older than 65 years, a frequency of 23.9%. The mean age was 70.21 ±3.64 years [65-81 years old]. The sex ratio (M/F) was 0.27. The mean duration of evolution was 13 years [6-22 years]. The associated comorbidities were dominated by hypertension 42.4 in % of cases and diabetes in 57.6 %.Prior to the initiation of biologic therapy, almost all RA patients had received methotrexate (MTX) (81.8%), dual therapy with MTX and salazopyrin in 48.4 %, and triple therapy with MTX, salazopyrin, and plaquenil in 16.1%. Switching to biotherapy was indicated following failure of csDMARDS in 60.6 % of cases, for intolerance to csDMARDS in 51.5 % of cases, or for contraindication to csDMARDS in 10 % of cases. The mean initial DAS28 was 5.66 ± 1.06 [3.43-7.4] and the mean DAS28 at 12 months was 3.53 ± 1.56 [0.4-7]. 78.8 % of patients had a therapeutic response at 12 months, among them 36.4% had a moderate response and 42.4% had a good response. The first-line biotherapies used were anti TNFά in 18 cases (54.5%) (Infliximab in 12 cases(36.4%), Etanercept in 4 cases (12.1%), Adalimumab and Certolizumab in 1 case each (3%)), rituximab in 11 cases (33.3%%)and anti IL6 in 4 cases(12.1%). Drug retention rates were as follow: anti TNF with a rate of retention of 44.11± 28.13 months; anti IL6: 33.55±10.34 months and anti CD20:23±13.65 months. The bivariate analysis did not reveal any statistically significant factor associated with therapeutic response. Among our patients, 30.3% had a good tolerance to the biotherapies, but 69.7% presented adverse events dominated by infections in 63.6%, in particular respiratory infections (10 cases), urinary tract infections (9 cases) and cutaneous infections (6 cases).
Conclusion :
The efficiency and tolerance of biologic background treatments seem to be adequate and comparable to those of young patients. However, rigorous monitoring of elderly patients is still necessary due to the fragility of the terrain and the frequency of comorbidities that can condition the appearance of adverse effects under biotherapy.

P305
OSTEOARTICULAR MANIFESTATIONS OF SARCOIDOSIS

B. Marwa[1], F. Rym[1], K. H. Dhouha[1], E. Nejla[1], B. Khadija[1], B. Elyes[1]

[1]Farhat Hached University Hospital, Sousse, Tunisia

Objective :
Sarcoidosis is a multisystem granulomatosis that can affect all organs, with thoracic involvement being the most common and suggestive. Osteoarticular manifestations are rarely the initial presentation and are often misleading. Our objective was to describe the clinical, paraclinical, therapeutic, and evolutionary aspects of sarcoidosis in a rheumatological setting.
Material and methods :
This is a retrospective study of 15 cases of sarcoidosis collected in the Rheumatology Department of Farhat Hached Hospital in Sousse between 1997 and 2022. The diagnosis of sarcoidosis was established either based on a positive biopsy or the presence of Löfgren's syndrome.
Results :
The mean age was 47 years [32–70 years], with a sex ratio of 0.16 (13 women and 2 men). The average diagnostic delay was 13 months.The osteoarticular manifestations were : arthritis in 9 patients (polyarthritis in 7 patients, mono- and oligoarthritis in 2 patients), primarily affecting the ankles (n=8),inflammatory arthralgia in 3 patients,back pain in 2 patients and dactylitis in 1 patient. The extra-articular manifestations were observed in 9 patients: Löfgren's syndrome (n=6), dyspnea with cough (n=3), and hepatomegaly with splenomegaly (n=1). A biological inflammatory syndrome was noted in 11 patients, with an average ESR of 63 mm/h. Hypercalcemia at 2.84 mmol/L was observed in 1 patient. The angiotensin-converting enzyme (ACE) level was elevated in 3 patients.On imaging: the X-rays were normal in 13 patients,destructive involvement with multiple geodes in the hands was observed in 1 patient,destructive involvement of the tarsus was identified on MRI in another patient and standard chest X-rays and CT scans (n=13) revealed mediastino-pulmonary lesions: stage I in 10 patients and stage II in 3 patients .A biopsy of the accessory salivary glands (n=10) confirmed sarcoidosis in 9 patients.On the therapeutic level:corticosteroids at an average dose of 15 mg/day [10–40 mg/day] was administered to 9 patients.The progression was characterized by improvement in osteoarticular symptoms in 9 patients, while 6 patients experienced relapses of joint flare-ups.
Conclusion:
The osteoarticular manifestations of sarcoidosis are polymorphic and non-specific, highlighting the need to consider it in any joint involvement associated with suggestive extra-articular features such as erythema nodosum or the presence of lymphadenopathy.

P306
MORPHO-FUNCTIONAL EVALUATION OF FOOT INVOLVEMENT IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES: COMPARATIVE STUDY BETWEEN RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS

Z. S. Zanned[1], B. N. D. Ben Nessib[1], K. L. Kharrat[1], M. F. Majdoub[1], F. H. Ferjani[1], K. D. Kaffel[1], M. K. Maatallah[1], H. W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Mannouba, Tunisia

Introduction: Foot involvement is a key feature in chronic inflammatory rheumatic diseases (CIRD), including rheumatoid arthritis (RA) and spondyloarthritis (SpA), due to its frequent and often early occurrence, observed in approximately 75% of cases.
Objectives: To compare the morphological and functional foot alterations in patients with RA and SpA.
Methods: This was a cross-sectional study including patients fol-

lowed in a rheumatology department with RA according to ACR/EULAR 2010 criteria or SpA according to ASAS 2009 criteria over a two-month period. Patients were divided into two groups: RA and SpA. Sociodemographic and clinical data were collected. Each patient underwent a podoscopic examination using a podoscanner (DiasuPodoscan). Plantar footprints were analyzed using software for plantar morphometric assessment. The parameters studied included foot arch, maximum detected height, foot type, Arch Index, and global biomechanical postural index.

Results: Fifty-two patients were included: 32 in the RA group (mean age: 59.7±16 years) and 20 in the SpA group (mean age: 50±9.6 years). The SpA phenotype was axial in one patient, axial and peripheral in 27.1%, and peripheral in 8.3%. Among functional complaints, heel pain was more frequent in the SpA group, while metatarsalgia was more common in the RA group, with statistically significant differences between groups (p=0.01 and p=0.047, respectively). Regarding plantar footprint analysis, the foot arch was physiological in 57.1% of RA patients and 73.7% of SpA patients, with no significant difference. A square foot shape was observed in 57.1% of RA patients and 42.1% of SpA patients. Plantar morphometric analysis revealed a mean maximum foot height of 1±0.53 in the RA group and 1.24±0.6 in the SpA group. The total foot perimeter was 33.1±4 in the RA group versus 35.8±5.8 in the SpA group. The total foot volume had a median of 1.04 [0.4–1.7] in the RA group and 1 [0.4–2.1] in the SpA group. The global biomechanical postural index was 15.2±7 in the RA group and 14.3±8 in the SpA group, with pathological values observed in 48.3% of RA patients and 42.1% of SpA patients. No statistically significant differences were found between the two groups for these parameters. However, a pathological foot arch was significantly associated with the presence of metatarsalgia (p=0.021).

Conclusion: A detailed evaluation of plantar involvement could be useful in clinical practice to optimize management strategies for static disorders in patients with chronic rheumatic inflammatory diseases.

P307

SLEEPLESS WITH SPONDYLOARTHRITIS: UNVEILING THE PREVALENCE AND KEY DRIVERS OF SLEEP DISORDERS

Z. S. Zanned[1], B. N. D. Ben Nessib[1], K. L. Kharrat[1], M. F. Majdoub[1], F. H. Ferjani[1], K. D. Kaffel[1], M. K. Maatallah[1], H. W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Mannouba, Tunisia

Introduction: Spondyloarthritis (SpA) is a chronic inflammatory rheumatic disease that can lead to significant functional impairment and reduced quality of life, including poor sleep quality.

Objectives: The aim of this study was to evaluate the prevalence of sleep disorders in patients with SpA and identify associated factors.

Methods: A cross-sectional study was conducted in a rheumatology department. Patients diagnosed with SpA according to the ASAS 2009 criteria were included. Sociodemographic, clinical, and paraclinical data were collected. Each patient completed the ASQoL questionnaire to assess quality of life (QoL) (score ranging from 0 [good QoL] to 18 [poor QoL]). Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI).

Results: Thirty-six patients with SpA were included. The mean age was 42.6±12.5 years, with a male predominance (64.4%). The mean disease duration was 12.4±3.5 years, and 40% of patients had coxitis. The mean BASDAI was 4.5±2.3, and the mean BASFI was 4.6±2.2. The mean pain VAS was 24.12±10.4.

Regarding sleep quality assessment using the PSQI, the mean global score was 12.5±2.5 [7–25]. The mean scores for specific components were as follows: "subjective sleep quality" 1.9±0.6, "sleep latency" 2±0.7, "sleep duration" 2.3±0.6, "habitual sleep efficiency" 1.9±0.7, "sleep disturbances" 1.7±0.7, "use of sleeping medication" 0.4±0.5, and "daytime dysfunction" 2.1±0.6. The mean ASQoL score was 7.8±3.6.

Sleep disorders were significantly associated with the presence of coxitis (p=0.001) and nocturnal awakenings (p=0.007). Moreover, the PSQI score was correlated with BASDAI (p=0.01), ASQoL (p<0.01), and pain VAS (p=0.04).

Conclusion: Sleep disorders appear to be frequent and contribute to reduced quality of life in SpA, particularly in cases of active disease and the presence of coxitis.

P308

SLEEP DISORDERS IN RHEUMATOID ARTHRITIS: PREVALENCE AND ASSOCIATED FACTORS

Z. S. Zanned[1], K. L. Kharrat[1], B. N. D. Ben Nessib[1], M. F. Majdoub[1], F. H. Ferjani[1], K. D. Kaffel[1], M. K. Maatallah[1], H. W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Mannouba, Tunisia

Introduction: Sleep disturbances are frequently reported by patients with chronic conditions and are associated with a decrease in quality of life, psychological disorders, and increased morbidity and mortality. In rheumatoid arthritis (RA), chronic pain, functional disability, and joint stiffness can significantly affect sleep quality.

Objectives: The aim of this study was to determine the prevalence of sleep disorders in patients with RA and identify the associated factors.

Methods: This is a descriptive and analytical cross-sectional study. Patients diagnosed with RA according to the ACR/EULAR 2010 criteria were included. Data on patient characteristics and disease-related factors were collected. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI), while daytime sleepiness was evaluated with the Epworth Sleepiness Scale. The analysis was performed using SPSS software.

Results: Forty-two patients with RA were included, with a female predominance in 69% of cases. The mean age was 54.2 ± 9.8 years. The mean disease duration was 8.2 years [1–40]. The mean DAS28-CRP score was 4.1 ± 1.4 [1.75–8.2] and the mean HAQ score was 0.8 ± 0.6 [0–2.9].

Regarding sleep quality, the mean global PSQI score was 12.2 ± 2.9 [7–23]. The mean scores for the components were: subjective sleep quality (1.9), sleep latency (1.7), sleep duration (2.2), habitual sleep efficiency (1.2), sleep disturbances (1.7), use of sleep medication (0.6), and daytime dysfunction (2.0). The mean Epworth score was 6.6 ± 3.5 (range 3–20), with 26.1% of patients reporting sufficient sleep, 21.4% reporting improveable sleep quality, 11.9% having excessive daytime sleepiness, and 7.14% having very severe daytime sleepiness.
When evaluating sleep disorders based on disease activity, 42% of patients with active disease (DAS28 > 3.2) had sleep disturbances compared to 24.5% in those with low disease activity or remission, with a statistically significant difference ($p = 0.02$). Furthermore, the PSQI score was significantly correlated with the DAS28 ($p < 0.001$) and VAS pain ($p = 0.013$). The Epworth score was significantly correlated with the HAQ ($p = 0.025$) and nocturnal awakenings ($p < 0.001$).
Conclusion: Proper evaluation and management of sleep disorders in RA patients should be integrated into routine follow-up care to improve their quality of life.

P309

NON-FUNCTIONING PITUITARY ADENOMA AND OSTEOPOROSIS: A CASE REPORT

B. Presciuttini[1], U. Terenzi[2], V. Franzese[2], L. Di Filippo[3], M. Pagani[4]

[1]Endocrinology Unit, Department of Medicine, ASST Mantova, Carlo Poma Hospital, 46100 Mantua, Italy, Mantova, Italy, [2]Institute of Endocrine and Metabolic Sciences, San Raffaele Vita-Salute University, Milan 20132, Italy, Milano, Italy, [3]Institute of Endocrine and Metabolic Sciences, San Raffaele Vita-Salute University and IRCCS Hospital, Milan 20132, Italy, Milano, Italy, [4]Department of Medicina, ASST Mantova, 46100 Mantua, Italy, Mantova, Italy

Mrs. Maria (75 years old, menopause at 47, BMI 24 kg/m^2) was admitted to the internal medicine department because of hyponatremia (Na 125 mmol/L), nausea, dizziness and falls at home. Her medical history included arterial hypertension, gastroesophageal reflux, chronic treatment with antihypertensives and benzodiazepine. A brain CT scan revealed a sellar lesion. MRI showed a 14 mm pituitary adenoma with deviation of the anterosuperior stalk. The patient had been complaining of asthenia, loss of appetite and weight loss for a year. She did not have clinically detectable visual disturbances and defects in her visual field. Blood chemistry analysis showed anterior hypopituitarism: fT3 1.67 pg/ml [2-4.4], fT4 0.8 ng/dl [0.93-1.7], TSH 0.91 IU/L [0.27-4.0], FSH 2.8 IU/L, LH 2.3 IU/L, cortisol a.m. 7 µg/dl [6.0-18.4], ACTH 20 ng/l [4.7-48.8], IGF-1 39 mcg/L [60-190] and modest hyperprolactinemia (PRL 129 mcg/L [4.8-23.3]). Replacement therapy with levothyroxine 25 mcg o.d. and cortone acetate 12.5 mg o.d. was introduced and a low-dose of cabergoline (0.25 mg weekly) was started. DXA showed lumbar osteoporosis (T-score -3.0 SD) and femoral osteopenia (T-score femur neck -2.1 SD); x-rays showed a moderate D12 fracture on vertebral morphometry. Phosphocalcium metabolism tests showed normocalcemia, hypovitaminosis D (18 ng/ml), normal B-ALP and CTX (0.40 ng/ml). Anti-osteoporotic therapy was started with denosumab 60mg every 6 months and cholecalciferol 25.000 IU every 15 days. Three months later, PRL was very low (2 µg/l) and cabergoline was first reduced, then stopped. But 6 months after the first MRI, a new examination showed an increase in the size of the lesion to 16 mm with initial compression of the optic chiasm. Subsequently in Neurosurgery the adenoma was completely removed transnasally without complications (immunohistochemical examination was negative for PRL). Three months later, the improvement in plasma fT4, IGF-1 and cortisoluria allowed the replacement therapy (L-T4 and cortone) to be gradually stopped. After 12 months a new DXA showed bone densitometric improvement both at lumbar (BMD +5%) and femoral (+3%) level; no new fractures were reported at vertebral morphometry.

P310

OSTEOPOROSIS IN A 37-YEAR-OLD WOMAN DUE TO HIGH PARATHYROID HORMONE LEVELS

B. Rexhepi-Kelmendi[1], M. Rexhepi[1]

[1]Rheumatology Clinic, Univeristy Clinical Centre of Kosova, Prishtina, Kosovo, Albania

Osteoporosis is a metabolic bone disease characterized by low bone mass and increased risk of fractures, which occurs more frequently in postmenopausal women. The presence of fragility fractures with high mortality and morbidity characterizes severe osteoporosis. We will present the case of a 37-year-old woman who, one month after experiencing back pain, presented to her family doctor, was referred to a rheumatologist, and after performing an MRI of the thoracolumbar region, was found to have a Th12 fracture. Laboratory tests and a DEXA scan were requested. Despite her young age, she had osteoporosis in the lumbar region with a T score of -2.9 and a femur T score of -1.7. Laboratory tests revealed a high PTH of 107 pg/mL and a total Ca of 3.30 mmol/l; other tests were normal. In the thyroid ultrasound, a parathyroid adenoma is observed. In consultation with the endocrinologist, the diagnosis of primary hyperparathyroidism is established. The patient undergoes surgery, the parathyroid adenoma is successfully removed, and the PTH and calcium levels normalize (PTH: 39 pg/mL and Ca tot: 2.3 mmol/l). No other risk factors were found except for a positive maternal history of osteoporosis at the age of 45. Because the patient plans further births, initiation of bisphosphonate therapy or other osteoporosis drugs has not been recommended. She is currently taking vitamin D supplements. Osteoporosis is not common in premenopausal patients.
Risk factors that may increase the risk of fractures in patients with primary hyperparathyroidism should be carefully considered. Patients with risk factors for osteoporosis should be evaluated before a fracture occurs, even at a young age.

P311

THE IMPACT OF PHYSICAL THERAPY ON OSTEOPOROSIS IN PATIENTS WITH PARKINSON'S DISEASE

B. Sd[1]

[1]Faculty of Medicine Oradea, Oradea, Romania

Parkinson's disease is a progressive chronic disease with an insidious onset that can lead to the loss of autonomy. Balance disorders predispose to a risk of falling, therefore maintaining an optimal bone mineral density prevents this.
Material and methods:
The purpose of the study was to evaluate the effectiveness of the application of a medical recovery program focused on physical therapy in patients with Parkinson's disease who also had osteoporosis. 20 male and female patients aged between 51 and 65 were evaluated. Bone mineral density (BMD) was determined by dualenergy X-ray absorptiometry.
10 patients received combined therapy for osteoporosis, and 10 patients were included in the physical therapy group.
Results:
The studies found that in the patients in the physiotherapy group, the bone loss was 0.8 ± 0.4% of the total body, 1.5 ± 0.3% of the femoral neck, 1.2 ± 0.1% from the proximal femur and 1.1 ± 0.2% from the lower extremities. Those with combined therapy lumbar spine BMD increased by 3.0 ± 1.1%, upper extremities - by 2.3 ± 1.2%, femoral neck and proximal femur - by 1.3 ± 0.4 % and 1.7 ± 0.3 %, respectively.
Conclusion:
The use of physical therapy in patients with Parkinson's disease brings benefits, but it would be preferable to be associated with drug therapy.

P312

THE EFFECT OF MEDICAL RECOVERY IN THE TREATMENT OF MYOGELOSIS

B. Simona[1]

[1]Faculty of Medicine Oradea, Oradea, Romania

Myogeloses are frequently found in patients with vicious or sedentary positions. These can lead to a decrease in the quality of life leading to depression and insomnia.
Patients show an increase in muscle tone due to biomechanical changes in the spine.
The goal is to reduce clinical functional disorders and decrease muscle hypertonia.
Material and methods:
26 female patients between the ages of 25 and 40 with painful spine pathology were evaluated. Painful nodules were identified during the objective clinical examination on palpation. Pain was assessed using the VAS scale. The patients entered a 10-day medical recovery program consisting of physical therapy focused on spine recovery for 13 patients and relaxation methods - Jacobson exercises for 26 patients.
Results:
The pain relief was completely in the patients who performed relaxation exercises in the program, and those who did not benefit from this program declared only a partial decrease in pain. In total, an improvement in muscle strength was obtained.
Conclusion:
In order to maintain the long-term therapeutic effect, it is necessary to continue physical therapy and use a correct position.

P313

ASSOCIATION OF OSTEOPOROSIS AND CARDIOVASCULAR DISEASE IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

B. Stamenkovic[1], S. Stojanovic[2], V. Zivkovic[1], N. Dimic[3], I. Aleksic Milenkovic[3], J. Jocic[3], M. Sarac[3], J. Cvetkovic[1]

[1]Rheumatology Clinic, Institute for treatment and rehabilitation Niska Banja; Medical School, University of Nis, Nis, Serbia, [2]Rheumatology Clinic, Institute for treatment and rehabilitation Niska Banja;Medical School, University of Nis, Nis, Serbia, [3]Rheumatology Clinic, Institute for treatment and rehabilitation Niska Banja, Nis, Serbia

Background: While some research have found a link between osteoporosis (OP) and cardiovascular disease (CVD), just a handful have examined this relationship in postmenopausal women with rheumatoid arthritis (RA).
Objective The purpose of our study was to determine if postmenopausal women with OP in RA had a higher frequency of CVD and risk factors for it.
Material and method: The study included 200 postmenopausal RA women treated at the Niška Banja Institute's Rheumatology Clinic from 2018-2021. Clinical, laboratory and DEXA densitometric examination of the spine and hip was performed on all of them. Disease activity was assessed by the DAS 28 score. Risk factors for CVD (smoking, cholesterol level, diabetes, family burden), as well as the presence of CVD (hypertension, coronary disease, heart failure, sudden cardiac death) were analyzed in 49 postmenopausal patients with OP.
Results: Bone mineral density (BMD) was measured in all RA pts and in 49/200 (24.5%) osteoporosis was defined (Tscore < 2.5). 30 (61.2%) patients exhibited high RA activity, 16 (32%) had moderate activity, and only 3 (6.1%) had low disease activity.
Our findings revealed no link between CVD risk factors and osteoporosis, nor a higher frequency and association of heart failure and sudden cardiac death with OP in RA women as compared to the RA women without OP. A statistically significant association of OP with hypertensive heart disease and coronary disease was found in postmenopausal patients with rheumatoid arthritis as compared to the pts with RA, without OP ($p<0,01$ for hypertensive pts, $p<0,05$ for the pts with coronary disease). This association is more common in RA patients with high disease activity vs low or moderate disease activity.
Conclusion: To date, it has not been fully clarified whether there is

an association between osteoporosis and cardiovascular disease in rheumatoid arthritis women. Our findings unequivocally show that women with RA, particularly those with high disease activity and OP, are more likely to develop coronary heart disease and hypertension, which is why screening and early detection, as well as prevention of cardiovascular complications, are of the greatest importance in these patients.

Keywords: osteoporosis, rheumatoid arthritis, cardiovascular disease, risk factors for cardiovascular disease

P314

THE VARIABILITY OF MIR-146 AND FGF2 MICRORNA BINDING SITES DISRUPTS THEIR INTERACTION AND IS ASSOCIATED WITH A HIGH RISK OF OSTEOPOROSIS

B. Yalaev[1], A. Tyurin[2], Y. Karpova[1], R. Khusainova[1]

[1]Endocrinology Research Centre, Moscow, Russia, [2]Bashkir State Medical University, Ufa, Russia

Objective: analysis of the frequency of distribution of alleles and genotypes rs2910164 of the *miR-146* gene and rs6854081 of the *FGF2* gene in a case-control study in individuals with osteoporosis (OP), as well as bioinformatic prediction of the effectiveness of the interaction of miR-146 and mRNA of the *FGF2* gene in silico depending on polymorphic variants of microRNA binding sites.

Material and methods

A case-control study included 601 women (62.85±6.93) and 401 men (61±14.8), which included patients with OP underwent X-ray densitometry, as well as a sex- and age-matched control group with no fractures and normal BMD levels. Genotyping was performed using KASP™ technology. We used miRBase and IntaRNA 2.0 resources to evaluate the functional significance of variants associated with the OP, in silico prediction miR-146 with mRNAs of FGF2.

Results

We found that rs2910164 (χ^2=14.9, OR=4.81, CI=1.724-2.507, p=0.0001) and rs6854081 (χ^2=9.0019, OR=2.18, CI=1.296-3.678, p=0.004) are associated with a high level of significance with the OP. It has been established that miR-146 targets the mRNA of the *FGF2* gene. The presence of risky alleles changes the efficiency of their interaction and the energy of free binding. SNPs of binding sites can affect the secondary structure of mRNA, potentially limiting the accessibility of the mRNA-microRNA interactions (fig. 1).

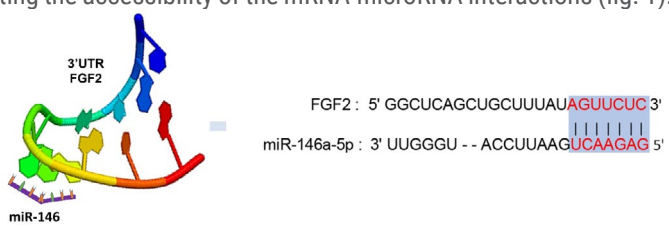

Fig. 1. miR146a5p directly targets FGF2.

Conclusion

Our results indicate previously unknown molecular mechanisms that increase the risk of osteoporosis based on microRNA epigenetic regulation. The research will continue.

Funding Statement

The research was funded by the Russian Science Foundation grant No. 24-75-00054.

P315

SYSTEMIC INFLAMMATORY MARKERS RELATED TO RISK OF FRACTURES AND HIP FRACTURE AMONG OLDER ADUTLS

B.-A. Cedeno-Veloz[1], A.-M. Rodriguez-Garcia[1], S. Dominguez-Mendoza[1], M. Fernandez-Gonzalez[1], V. Ruiz-Izquieta[1], N. Martinez-Velilla[1]

[1]Navarre University Hospital (HUN), Navarrabiomed - Institute for Health Research of Navarra (IDISNA), Pamplona, Spain

Objective: Systemic inflammatory markers, such as red cell distribution width (RDW), C-reactive protein (CRP), neutrophil-to-lymphocyte ratio (NLR), systemic immune-inflammatory index (SII), and others, have been increasingly recognized as key players in the field of inflammaging among older adults[1]. Their role in osteoimmunology (explores the interplay between the immune and skeletal systems) remains unclear but highlighting how inflammatory pathways affect bone metabolism and fracture risk[2]. Elevated inflammatory markers are associated with increased osteoclastogenesis and reduced bone formation, contributing to weakened bone structure and higher fracture susceptibility[3]. This study aims to investigate the relationship between inflammatory markers, bone mineral density (BMD), and fracture risk in older adults, while also exploring the stratified effects of these markers in fractured and non-fractured patients.

Material and Methods:

A retrospective analysis was performed on patients categorized as fractured (n=20) or non-fractured (n=20). Differences between groups in systemic inflammatory markers (RDW, PCR, NLR, SII, CALLY) were assessed using Student's t-test. Correlations between inflammatory markers, BMD parameters (HIP-BMD, LUM-BMD, WRIST-BMD) and fracture risk indices (FRAX-Total, FRAX-Hip) were analyzed using Pearson's correlation coefficient with significant differences between groups. A p-value <0.05 was considered statistically significant. Correlation matrix by www.bioinformatics.com.cn/en

Results: Fractured patients exhibited significantly higher levels of PCR (66.2±70.3 vs. 3.8±4.0, p=0.0008) and SII (1399.7±1143.4 vs. 751.4±400.8, p=0.025) compared to non-fractured patients. No significant differences were observed for RDW, NLR, or CALLY. Correlation analysis revealed a positive association between PCR and all BMD sites (HIP-BMD -0.63 p 0.002; LUM-BMD -0.6 p 0.005; WRIST-BMD -0.6 p 0.005). No significant correlation were observed for SII or FRAX values (figure 1)

Conclusion: The findings suggest that systemic inflammatory markers, particularly PCR and SII, are associated with increased hip fracture and PCR with BMD. The differences observed between fractured and non-fractured patients highlight the importance of

stratifying analyses by fracture status. These results support the potential use of inflammatory markers as complementary tools in fracture risk assessment and underscore the complex interplay between inflammation and bone health.

ROMOSOZUMAB PROFILE AMONG FRAIL OLD WOMEN: EXPERIENCE FROM A SPANISH FLS

B.-A. Cedeno-Veloz[1], A.-M. Rodriguez-Garcia[1], S. Dominguez-Mendoza[1], M. Fernandez-Gonzalez[1], A. Casajus-Ortega[1], I. Zazpe-Cenoz[1], N. Martinez-Velilla[1]

[1]Navarre University Hospital (HUN), Navarrabiomed - Institute for Health Research of Navarra (IDISNA), Pamplona, Spain

Introduction Frail patients, particularly those of advanced age and with multiple comorbidities, pose a unique challenge in the management of osteoporosis due to the combination of fracture risk, comorbities, and polypharmacy. Romosozumab emerges as a novel therapeutic option but with limited studies in frail very old adults. The objective of this study is to evaluate the clinical profile and outcomes of treatment with romosozumab in fragile patients.

Material and Method An observational analysis was conducted on patients treated with romosozumab in our FLS during 2023. The sample included patients with a comprehensive evaluation of clinical and laboratory parameters, including the Cumulative Illness Rating Scale-Geriatrics (CIRS-G), fracture risk using FRAX, levels of calcium, vitamin D, and parathyroid hormone (PTH). Additionally, prior treatments, cardiovascular risk factors, clinical frailty scale, functional impairment (SPPB), and prescription approval issues were recorded.

Results Fourteen patients with a mean age of 86.14 years (SD 6.02), predominantly female, and an average body mass index (BMI) of 23.11 (SD 4.15) were included. Patients had an average CIRS-G score of 11.64 (SD 3.01) and a high fracture risk (FRAX major: 26.14% (SD 11.97); hip: 14.6% (SD 9.39)). Baseline fractures were 50% hip and 50% vertebral, with an average of 2.7 fractures per patient. Laboratory levels showed mean calcium of 9.17 mg/dL (SD 0.45), vitamin D of 26.14 ng/mL (SD 6.87), and PTH of 91.92 pg/mL (SD 51.54). Previous bone mineral density (BMD) values were CAD-TS: -3.51 (SD 0.96), LUM-TS: -3.25 (SD 1.71), and WRIST-TS: -4.45 (SD 0.67). Previous treatments included teriparatide (40%) and antiresorptives (5%). Ninety-two percent had hypertension, 10% had diabetes, and 20% had renal disease (eGFR <35). The clinical frailty scale averaged 4.92 (SD 0.91), and functional impairment (SPPB) was 4.78 (SD 2.88). No fractures were reported during the intermediate follow-up, with two deaths unrelated to cardiovascular events. No adverse effects were observed post-administration, and the treatment's ease of use was highlighted.

Conclusions The profile of patients treated with romosozumab corresponds to frail individuals at very high risk with multiple comorbidities, albeit without ischemic disease. Preliminary results suggest that romosozumab is well-tolerated and may be an effective therapeutic option for this population, standing out for its ease of use and the absence of fractures during the intermediate follow-up. These findings underscore the importance of considering romosozumab for this patient profile (figure 1).

COMPARATIVE STUDY ON THE TREATMENT EFFECT OF STRETCHING AND HIGH-FREQUENCY DIATHERMY IN SUBJECTS WITH GASTROCNEMIUS TIGHTNESS

B.-S. Kim[1], Y. X. Wang[1], Y. J. Kim[1], M. Y. Kim[1], H. S. Jeon[1]

[1]Yonsei University, Wonju-si, South Korea

Objective(s)
Ankle flexibility is important for maintaining proper biomechanical function because the ankle is susceptible to injury during athletic activities. Static stretching (ST) is a widely used intervention for improving flexibility with minimal risk. Transfer Energy Capacitive and Resistive (TECAR) therapy has recently gained attention for enhancing flexibility and circulation. However, there is a lack of comparative studies evaluating the effectiveness of TECAR therapy versus ST. This study aims to compare the effects of static stretching alone and TECAR combined with static stretching (T-ST) on tightness of the gastrocnemius muscle (GCM) in healthy individuals.
Material and Methods
27 participants with bilateral GCM tightness were recruited. To administer ST, participants stood for 15 minutes on a wedge with a 0-15° incline with both feet. Concurrently, TECAR therapy in RET mode was applied to only one side GCM. The assignment of which side GCM received TECAR therapy was determined randomly. Muscle stiffness (MyotonPRO), dorsiflexion ROM (DROM), Peak torque, pennation angle (PA) of GCM measured before and after the intervention. PA was assessed using ultrasound, and it refers to the structural angle at which muscle fibers align relative to the direction of force transmission. Normality was confirmed with Shapiro–Wilk tests. Group differences and pre- and post-intervention changes within legs were analyzed with paired t-tests.
Results
There were no significant differences between the legs in any measured variables before the intervention. Both the ST and T-ST legs showed significant improvements in all measured variables after the intervention ($p < 0.05$). Especially, the T-ST leg demonstrated significantly greater increase in dorsi flexion and greater decrease in PA compared to the ST leg ($p < 0.05$).
Conclusion(s)
T-ST outperforms ST in reducing PA and increase DROM by promoting deep tissue relaxation and stimulating metabolic activity. This may leads to reduced pain and greater flexibility compared to ST. Maintaining an optimal PA ensures efficient force transmission during exercise, as evidenced by the observed increase in peak torque.

P318

PREVALENCE OF FALLS AMONG OLDER ADULTS IN THE MUNICIPALITY OF XOCHITEPEC, MORELOS, MEXICO

C. A. Martínez[1], H. Rangel[1], A. Rivera[1], M. Romero[1], Y. Hernández[2], A. Delgadillo[3], K. Abarca[3], C. Flores[3], E. Dominguez[3], R. Robledo[2]

[1]National Institute of Public Health of Mexico, Cuernavaca, Mexico, [2]Health Directorate of the Municipality of Xochitepec, Xochitepec, Mexico, [3]Latin American University, Morelos, Mexico

Keywords: Falls, older adults, municipal comprehensive care program

Introduction: As the population ages, the incidence of falls has risen, becoming one of the leading contributors to the disease burden among older adults (OA).
Objective: To determine the prevalence of older adults who experienced a fall in the past 12 months.
Methodology: This was a descriptive cross-sectional study conducted among older adults in Xochitepec, Morelos, from August to December 2022. A non-probabilistic sample of 278 participants enrolled in the Municipal Comprehensive Care Program was used. Data collection was carried out using validated and standardized survey instruments focused on geriatric syndromes, following informed consent. Statistical analyses were performed using R software (version 4.4.2; R Core Team, 2025).
Results: A total of 278 older adults participated, with a mean age and standard deviation of 67.3 and 7.35 years, respectively. Three participants did not respond. The prevalence of falls was 41.1% (113/275), of whom 78.8% were women. A significant association was found between falls and sex (p-value = 0.007626 < 0.05) using Fisher's exact test. The most frequent age among participants was 62 years. However, no significant association was observed between falls and age (p-value = 0.4121 > 0.05) based on the Wilcoxon test. Similarly, Fisher's exact test revealed no significant association between falls, diabetes (p-value = 1), or involuntary urinary incontinence (p-value = 0.4202), both exceeding 0.05. Among those who experienced falls, 71.7% reported falling 1 to 3 times during the year.
Conclusion: The results of this study provide sufficient evidence to support the implementation of prevention and control strategies in the municipality of Xochitepec, Morelos.

P319

BISPHOSPHONATES IN RHEUMATOLOGY: INDICATIONS AND TOLERANCE PROFILE

C. Abid[1], Z. Gassara[1], A. Feki[1], S. Ben Jemaa[1], M. H. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]CHU hedi chaker sfax, Sfax, Tunisia

Introduction Bisphosphonates have demonstrated their effectiveness in various rheumatological conditions such as primary and secondary osteoporosis, Paget's bone disease, multiple myeloma, and hypercalcemia. Despite their proven efficacy in strengthening bones, these medications can lead to various adverse effects. The objective of our study was to examine the indications and prevalence of adverse effects of bisphosphonates in a Rheumatology department and to assess the tolerance profile of these treatments.

Patients and Methods We conducted a descriptive and retrospective study involving patients who received bisphosphonates, either orally or via injection, for various conditions in a Rheumatology department.

Results A total of 43 patients were included, with a mean age of 66.95 years [52.93]. A clear female predominance was observed (90% of cases). The indications of bisphosphonate use were osteoporosis (67.5% of cases), Paget's bone disease (22.5% of cases), multiple myeloma (15% of cases), and hypercalcemia (2.5% of cases). Among osteoporosis patients, bisphosphonate use was indicated due to fractures in 33.5% of cases. For Paget's disease, bisphosphonate indications included the presence of high-risk localizations (70% of cases), symptomatic disease with bone pain (20% of cases), or biological signs of progression (elevated alkaline phosphatase levels, 10% of cases). Regarding the bisphosphonate molecules administered, 55.8% of patients received zoledronic acid intravenously, while 44.2% received oral bisphosphonates: risedronate (18.6%), alendronate (16.3%), and pamidronate (9.3%).

Adverse effects were observed in 18.6% of patients (n=8). These included : A flu-like syndrome in 3 patients (7%),esophagitis in 2 patients (4.7%),hypocalcemia in 1 patient with multiple myeloma,acute functional renal failure in 1 patient, and jaw osteonecrosis in 1 patient.

Risedronate was implicated in the 2 cases of esophagitis. Pamidronate caused 1 case of flu-like syndrome, while zoledronic acid was responsible for all other adverse effects observed (62.5% of adverse effects). Adverse effects led to contraindications for bisphosphonate administration in 9.3% of cases (n=4) (for esophagitis, hypocalcemia, and jaw osteonecrosis). For other adverse effects, outcomes were favorable, with the flu-like syndrome resolving within hours under symptomatic treatment and normalization of creatinine levels after hydration in the case of renal failure.

Conclusion The indications for bisphosphonates in our department were diverse, with osteoporosis and Paget's bone disease being the most common. These treatments are generally well-tolerated, but adverse effects can sometimes occur. They can be severe and necessitate the interruption of these treatments.

P320

SCHEUERMANN DISEASE: A VERTEBRAL FRACTURE MIMICKER

C. Abreu[1], T. Stein Novais[1], S. Matias[1], A. Morais Castro[1], M. J. Santos[1], R. Freitas[1]

[1]Unidade Local de Saúde Almada-Seixal, Hospital Garcia de Orta, Almada, Portugal

Introduction: Scheuermann disease is more commonly seen in adolescent males, presenting with thoracic spine kyphosis. Later in life, vertebral wedging and kyphosis can resemble osteoporotic fractures, although the radiographic findings of Scheuermann disease are distinctive.

Clinical Case: A 70-year-old male patient was referred to our Fracture Liaison Service following a recent thoracic spine computed tomography (CT) scan report, requested due to chronic low back pain, with decreased bone mineral density and wedge-shape collapse of multiple vertebrae suggesting osteoporotic fractures. As a result, the patient had started monthly ibandronate.

He had a personal history of hypertension and dyslipidemia, no family history of femoral neck fractures, no smoking habits or alcohol use and he was physically active. He had no prior fragility fractures and had no history of trauma or acute back pain. Physical examination was relevant for kyphosis, present since his adolescence, and spinous process palpation was painless.

Bone densitometry revealed a T-score of 0.8 at the femoral neck and -0.5 at the lumbar vertebra. FRAX assessment indicated a 3.3% risk of major osteoporotic fracture and 1% for hip fracture according to our population.

Given the lack of symptoms, normal bone densitometry and absence of secondary osteoporosis causes, a magnetic resonance imaging (MRI) was performed. MRI documented kyphosis (Cobb angle 46°) with anterior vertebral body wedging and irregularity of the endplates suggesting Scheuerman disease (Figure 1).

Following this diagnosis, anti-osteoporotic treatment was stopped.

Conclusion: This case underscores the importance of an accurate diagnosis and investigation of osteoporosis, to avoid exposure to unnecessary treatments. We intend to highlight the role of Scheuermann disease as a differential diagnosis of vertebral fractures.

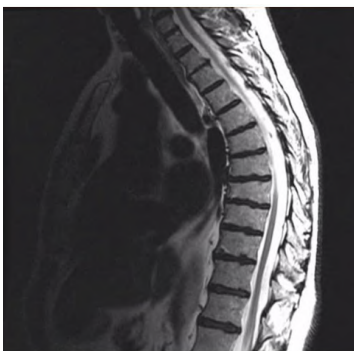

Figure 1 - Sagittal T2-weighted thoracic MRI scan: Thoracic spine kyphosis, wedging of four adjacent vertebrae (T6 to T9) and endplate irregularity (T5 to T10).

OSTEOARTHRITIS HAS A STRONG ASSOCIATION WITH OSTEOPOROSIS IN OLDER CHILEANS

C. Albala[1], R. Saguez[1], G. Fasce[2], F. Salech[2], C. Marquez[3], M. Sandoval[1]

[1]Inta, Universidad de Chile, Santiago de Chile, Chile, [2]Clinical Hospital, Universidad de Chile, Santiago de Chile, Chile, [3]Faculty of Nedicine, Universidad La Frontera, Santiago de Chile, Chile

Objective
The addition of the adverse consequences on health and quality of life of osteoarthritis and the high risk of falls and fractures of osteoporosis, make the association of both an important risk factor for disability. In that context, our objective was to study the association of osteoarthritis with osteoporosis in older Chileans
Methods
Cross-sectional study of 325 subjects ≥60y, mean age 64y, (30.8% men), from the ALEXANDROS cohort study, with DEXA scan, anthropometry and mobility measurements. WHO standards for Bone Mineral Density (BMD) classified them as normal, osteopenia and osteoporosis. WHO standards of BMI determine nutritional state except for undernutrition, measured with a cut point under 20 kg/m2. Short Physical Performance Battery (SPPB) was evaluated with a cut point under 10 for poor performance. Weak handgrip dynamometry was defined with cut points validated for Chileans as < 15 kg for women and < 27 kg for men.
Results
SPPB was < 10 points in 11% of both men and women. Nutritional state according to BMI categories showed 22.8% of normal BMI, undernutrition 1,5%, overweight 43.7% and obesity 32%, similar in men and women p=0.122. Weak handgrip dynamometry was observed in 16% of the sample, similar for both sexes. Osteoarthritis was reported in 42.8% of women and 19%of men (p<0.001) and Osteoporosis in 30.8% of women and 10.6% of men (p<0.001). The crude association of osteoarthritis with osteoporosis was OR=2.14; 95% CI:1.09-4.20, p<0.015. After multiple logistic regression model adjusted by age, sex, SPPB and hand grip strength, the association of osteoarthritis with osteoporosis was OR=2.6; 95%CI:1.07-4.77, p=0.032 with an area under the ROC curve for the model = 0.8052.
Conclusion.
Considering the severe consequences of osteoarthritis over health and quality of life, the high frequency of Osteoporosis with its associated risks, especially in women, and the strength of the association between both conditions, the screening of osteoporosis is highly recommended In older people with Osteoarthritis.

P322

COMPARING SILICONE-COATED SELF-ADHESIVE ABSORBENT POLYURETHANE FILMS WITH TRANSPARENT ABSORBENT FILMS FOR BILATERAL HIP DRESSING: A PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

C. Anusitviwat[1], V. Yuenyongviwat[1]

[1]Prince of Songkla University, Songkhla, Thailand

Objective: Silicone-coated self-adhesive absorbent (SSA) and transparent films with absorbent (TFA) dressings are reportedly effective postoperative knee surgery dressings; however, there have been no direct comparative studies on these two innovative dressings over the hip areas. In this study, we aimed to compare user satisfaction and potential complications between TFA and SSA dressings for the hip area.
Material and Methods: This prospective randomized controlled trial was conducted at a tertiary hospital. The hip side to receive the polyurethane film with SSA dressing (Mepilex® Border Post-Op) was randomly allocated. The other side of the hip was covered with TFA (OPSITE Post-Op). Participants were scheduled for follow-ups 7 and 14 days after the initial application. Between-group outcomes were compared using a two-sample t-test or Wilcoxon signed-rank test for continuous variables and McNemar's chi-square test for categorical variables
Results: Thirty-two participants (30–60 years) without a history of hip surgery were included in the study. The participants were predominantly female, with a mean age of 42.8 years. Pain, difficulties in daily activities, and satisfaction scores were similar between the groups. However, moisture accumulation was significantly higher with the TFA dressing (37.9% vs. 13.8%, p<0.01), with more dressing failures (34.5% vs. 20.7%, p=0.016) and complications (37.9% vs. 17.2%, p=0.012) at the 14-day follow-up than with the SSA dressing.
Conclusions: SSA dressings are preferable for hip wound care because of better moisture management, fewer dressing changes required, and fewer complications if applied for >7 days. Both dressings offered high user satisfaction, minimal pain, and minor difficulties in daily activities.

P323

POSTOPERATIVE OUTCOMES OF COLLARED VERSUS COLLARLESS STEM IN HIP FRACTURE PATIENTS UNDERGOING HIP ARTHROPLASTY: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Anusitviwat[1], V. Yuenyongviwat[1], K. Iamthanaporn[1]

[1]Prince of Songkla University, Songkhla, Thailand

Objective(s): This meta-analysis aims to assess and compare the postoperative outcomes, including periprosthetic fractures (PPF) and complications between collared and collarless femoral stems in hip fracture patients undergoing arthroplasty.

Material and Methods: We conducted a systematic review and meta-analysis following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The studies indexed in Medline, Scopus, and Web of Science from 2014 to 2024 were included if they reported outcomes comparing collar and collarless femoral stems. The data were extracted and analyzed using a random-effects model for periprosthetic fractures and complications, with results presented as pooled risk ratios (RR) and 95% confidence intervals (95% CI). All analyses were performed using the R program. Results: Five studies involving 29,681 patients were included. Cemented collarless stems were associated with a significantly higher risk of periprosthetic fractures (RR: 6.18, 95% CI: 2.90–13.18, $p < 0.01$) compared to cemented collar designs, with moderate heterogeneity. When both cemented and cementless stems were considered, a similar increased risk of periprosthetic fractures was observed (RR: 4.37, 95% CI: 1.68–11.34, $p < 0.01$), though the heterogeneity was high. No significant differences were found in the overall complication rates between collar and collarless femoral stem designs. Conclusion(s): While collarless femoral stems had a higher risk of periprosthetic fractures, overall complications and outcomes appear similar to those with collar designs. The observed heterogeneity suggests the need for further high-quality studies with standardized protocols to reduce variability and refine treatment strategies in hip arthroplasty.

P324

THE PRESENCE OF THE ENDOCANNABINOID SYSTEM IN AN IN VITRO MODEL OF GORHAM-STOUT DISEASE AND ITS POSSIBLE ROLE IN THE PATHOGENESIS

C. Aurilia[1], G. Palmini[2], S. Donati[1], I. Falsetti[3], G. Galli[1], L. Margheriti[4], T. Iantomasi[1], A. Moro[4], M. L. Brandi[2]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy, Florence, Italy, [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso, F.I.R.M.O Onlus, Florence, Italy, Florence , Italy, [3]1 Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy, Florence, Italy, [4]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy, Florence, Italy

Objective: Gorham-Stout Syndrome (GSD) is a rare bone disease, characterized by a massive bone resorption process, a lack of tissue regeneration and an excessive proliferation of blood and lymph vessels. The GSD etiogenesis still remains unknown and the available therapies are not resolutives. Over the last years, the Endocannabinoid System (ES) resulted to be capable of regulating several physiological mechanisms, including bone remodeling. Therefore, in this study we investigated if ES could be involved in the pathogenesis of GSD.
Materials and methods: First, we established and characterized as mesenchymal stem cell lines two primaries lines, signed as hBMMSCs and hBMMSC-GS-1, obtained from a healthy and pathological bone marrow biopsy samples from a healthy donor and a GSD patient respectively. After we have evaluated the osteoblastogenesis in both these cell lines, assessing the alkaline phosphatase (ALP) activity and hydroxyapatite deposition, through fluorimetric assay. Finally, we analyzed the presence of ES components in the two cell lines, by using TaqMan technology.
Results: Both the cell lines display the mesenchymal stem phenotype. After, we reported a reduced capacity to differentiate in osteogenic sense in hBMMSCs-GS-1 compared to hBMMSCs line. Moreover, our analyses revealed that hBMMSC-GS-1 line exhibits lower ALP activity and hydroxyapatite deposition than the hBMMSCs line. The molecular analyses showed not only the presence of the ES components in the hBMMSC-GS-1 line, but also their altered expression in these cells compared to hBMMSCs.
Conclusions: Our results showed for the first time that ES is expressed in an *in vitro* cellular model of GSD and that this molecular network may be involved in the GSD progression. Nowadays we are evaluating the possible modulation of ES components expression in hBMMSCs and hBMMSC-GS-1 cells during osteogenic differentiation, and how cannabinoids could influence this process. These data will provide a better understanding of the molecular mechanisms that may underlie the progression of GSD, paving the way to the development of innovative therapeutic strategies against GSD based on the use of phytocannabinoids contained in *Cannabis sativa*
Acknowledgments: Supported by Fondazione Ente Cassa di Risparmio di Firenze and by F.I.R.M.O. Onlus.

P327

IS DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS ASSOCIATED WITH A HIGHER RISK OF CARDIOVASCULAR DISEASE?

O. Saidane[1], C. Ben Ammar[1], N. El Amri[2], L. Rouached[1], R. Fakhfakh[2], S. Bouden[1], D. Khalifa[2], A. Ben Tekaya[1], K. Baccouche[2], L. Abdelmoula[1], I. Bouajina[2]

[1]Charles Nicolle Hospital, Tunis, Tunisia, [2]Farhat Hached Hospital, Sousse, Tunisia

Objective Cardiovascular risk is elevated in rheumatoid arthritis (RA). This is primarily due to chronic systemic inflammation and higher prevalence of traditional cardiovascular risk factors. The risk is even greater in patients with difficult-to-treat rheumatoid arthritis (DTRA), a more severe form of RA that is resistant to conventional treatments. This study aimed to assess cardiovascular risk factors in an RA population, and particularly in the difficult-to-treat subgroup.
Methods This bicentric cross-sectional study included 92 patients with RA diagnosed based on the 2010 ACR/EULAR criteria. Difficult-to-treat RA was defined according to the 2021 EULAR criteria. Sociodemographic, and cardiovascular risk as age, body mass index, smoking, hypertension, diabetes, cholesterol and triglyceride levels were collected, and a comparative study was performed between difficult to treat and non-difficult to treat subgroups.
Results We included 92 patients, 10 men and 82 women, with a mean age of 54 years [26–81]. Mean disease duration was 15 ±

11 years. Seventy percent had at least one cardiovascular risk factor. Mean BMI was 26.35 ± 6.18 kg/m². We noted active smoking in 15, 2%, passive smoking in 7.6%, wood smoke exposure in 15,2%, hypertension in 23,9%, dyslipidemia in 12%, and diabetes in 18.5%. Of these, 21.7% (n=20; 16 women and 4 men) were classified as having difficult-to-treat RA. We compared cardiovascular factor risks between the difficult to treat and the non-difficult to treat subgroups in table1.

	Difficult to treat RA	Non-difficult to treat RA	
Age	55±12years	54±12years	P=0,758
At least one cardiovascular risk	80%	70,59%	P=0,406
BMI	27,59±8,23 kg/m²	25,60±5,02 kg/m²	P=0,06
Active Smoking Passive Smoking Wood smoke exposure	15% 5% 10%	12,12% 8,3% 16,67%	P=0,28 P=0,492 P=0,332
Hypertension	45%	18,05%	P=0,012
Uncontrolled Diabetes	35%	13,88%	P=0,031
Dyslipidemia Mean triglycerides Level Mean total Cholesterol Level	15% 1,73±0,98mmol/l 4,92±0,99mmol/l	11,1% 1,75±2,73mmol/l 4,9±0,97mmol/l	P=0,635 P=0.976 P=0,930

Conclusion Frequency of cardio vascular risk factors among all the population was 70%. Patients with difficult-to-treat RA had a higher prevalence of hypertension and uncontrolled diabetes. Close monitoring and management of cardiovascular factors are critical to improving prognosis and quality of life for these patients.

P328

RHEUMATOID ARTHRITIS: DIFFICULT TO TREAT, EASY TO FRACTURE?

O. Saidane[1], C. Ben Ammar[1], N. El Amri[2], L. Rouached[1], R. Fakhfakh[2], S. Bouden[1], D. Khalifa[2], A. Ben Tekaya[1], K. Baccouche[2], L. Abdelmoula[1], I. Bouajina[2]

[1]Charles Nicolle Hospital, Tunis, Tunisia, [2]Farhat Hached Hospital, Sousse, Tunisia

Objective Bone involvement in rheumatoid arthritis (RA) is a significant comorbidity requiring regular monitoring. It worsens disease prognosis, particularly in the difficult-to-treat population, being a considerable challenge for rheumatologists.
The aim of this study was to evaluate the prevalence and the risk factors of bone involvement in a difficult-to-treat population of RA.
Methods A cross-sectional, bicentric study including RA patients fulfilling the 2010 ACR-EULAR criteria, was conducted over one year (May 2023–May 2024).
Difficult-to-treat RA was defined according to the 2021 EULAR criteria Sociodemographic, comorbidities, bone involvement, DEXA scanresults, activity score DAS28CRP, HAQ and current corticosteroid intake were collected, and a statistical analysis was performed.

Results
We included 92 patients (10 men and 82 women) with a mean age of 54 years [26–81] and a mean disease duration of 15 years±11, 51. Bone involvement was identified in 64.1% of cases: 38.98% had osteopenia and 61.01% osteoporosis. The mean T-score was -1.5 ± 1.63 at the vertebral site and -1.1 ± 1.69 at the femoral site. Pathological fractures were observed in 9.78% of this population. We compared bone involvement, risk factors for osteoporosis falls and fractures between the difficult to treat (D2T) and the non-difficult to treat subgroups in Table1.

	D2T subgroup	Non D2T subgroup	
Bone involvement **Osteoporosis** **Osteopenia** **Fractures**	75% 35% 40% 25%	61,11% 40,27% 20,83% 5,55%	p=0.252 p=0,669 p=0.08 p=0,01
Disease activity score DAS28CRP	4,44±1,70	3,36±1,39	p=0,007
Uncontrolled diabetes **Thyroid Dysfunction** **Functional Impairment (HAQ)**	35% 20% 1,62±1,77	13,88% 2,77% 0,86±0,64	p=0.031 p=0,033 p<0,01
corticosteroids	100%	77,7%	p=0.034

Table 1: Comparison between difficult to treat and non-difficult to treat RA regarding bone involvement risk factors for osteoporosis and falls

Conclusion
Bone involvement was observed in up to 75% of D2T patients. This subgroup had significantly higher prevalence of fractures. This could be explained by uncontrolled disease, higher use of corticosteroids, impaired dysfunction and poorly controlled diabetes and thyroid function.

P329

FIBROMYALGIA AND RHEUMATOID ARTHRITIS ASSOCIATION: A VICIOUS CYCLE

O. Saidane[1], C. Ben Ammar[1], N. El Amri[2], L. Rouached[1], R. Fakhfakh[2], D. Khalifa[2], S. Bouden[1], A. Ben Tekaya[1], K. Baccouche[2], L. Abdelmoula[1], I. Bouajina[2]

[1]Charles Nicolle Hospital, Tunis, Tunisia, [2]Farhat Hached Hospital, Sousse, Tunisia

Objective The association between fibromyalgia (FM) and rheumatoid arthritis (RA) is common, complicating disease assessment and management. FM often leads to overestimation of disease activity by both patients and physicians and increases the risk of iatrogenesis due to treatment overuse. This study purpose was to assess the impact of fibromyalgia on RA, focusing on clinical overlap, disease activity, and treatment challenges.
Methods This cross-sectional bicentric study included patients diagnosed with RA based on the 2010 ACR-EULAR criteria, conducted over one year (May 2023 – May 2024). Sociodemographic, clinical, and biological data were collected, along with therapeutic

aspects. Quality of life was assessed using the SF-36, and FM was screened using the FIRST score. Patients were divided into two groups for a comparative study: G1 (RA with FM) and G2 (RA without FM).

Results we included 80 patients (8 men and 72 women). The mean age was 55 ± 12 years, and the mean disease duration was 16±11 years. FM was noted in 38.8% (31 patients). Comparative study was resumed in table 1.

	G1	G2	
Age	55±12years	53±12years	p=0,417
Mean disease duration	18,81±11,03years	14,87±13,08 years	p=0,176
DAS28CRP	4.51±1.42	2.77±1.17	p<0.001
CRP level	12.92±16.64mg/l	8.25±9,59mg/l	p=0,117
Global assessment score	5.65±2.24	3.88±2.15	p<0.001
SF-36 physical functioning SF-36 mental health SF36-Fatigue HAQ	35.42±31.66 52.93±21.57 41.61±20.05 1.48±0.75	68.84±26.5 77.22±18.3 71.63±19.61 0.69±0.73	p<0.001 p=0.002 p<0.001 p<0.001
cumulative corticosteroid doses	47,102.39 mg	32,765.32mg	p=0,48
Fulfilling difficult to treat EULAR-2021criteria	35.54%	16.32%	p=0.049

Table 1: Comparison of the characteristics of RA patients with and without fibromyalgia

Conclusion Fibromyalgia was diagnosed in 38.8% in RA patients. It significantly affected disease assessment and management in RA patients. Overestimation of disease activity and increased risk of iatrogenic complications emphasize the need for systematic screening and individualized treatment strategies to improve patient outcomes.

P330

SELF-CARE BEHAVIORS AND HEALTH LITERACY CAN SERVE AS PREVENTIVE FACTORS IN OSTEOPOROSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS

A. Fezaa[1], C. Ben Ammar[1], S. Miladi[1], H. Boussaa[1], Y. Makhlouf[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Mongi Slim Hospital, La Marsa, Tunisia

Objective Osteoporosis is a frequent complication of rheumatoid arthritis (RA), and factors such as self-care and health literacy play a crucial role in influencing health outcomes.

This study aimed to explore the preventive impact of self-care behaviors and health literacy in older women with osteoporosis.

Methods This cross-sectional study including patients with RA diagnosed based on the 2010 ACR/EULAR criteria. Sociodemographic, bone involvement, DEXA scan results, Hls-eu-q16 health literacy questionnaire and menopause rating scale were collected. The **HLS-EU-16** questionnaire measures health literacy **and** the **Menopause Rating Scale (MRS)** is a tool used to assess the severity of menopause symptoms

Results Our study included 30 female patients, 15 of whom were osteoporotic and 15 with normal bone density. The average age of these patients was 59.43±8.83 years. The mean T-score at the vertebral site was -1.06±1.85, while the T-score at the femoral site was -1.48±1.58. Pathological fractures were observed in 6.7% of cases, predominantly in the osteoporotic group.From a therapeutic perspective, 66.7% of patients were on calcium supplementation, 73% on vitamin D supplementation, and 3.3% were receiving bisphosphonates. The average HLS-EU 16 score was 51.46±10.11, and the average Menopause Rating Scale (MRS) score was 13.13±8.57.

A comparative analysis between the osteoporotic group and the group with normal bone density is summarized in Table 1.

Parameter	Osteoporotic Group	Normal Bone Density Group	P-value
Age	62.87±8.70 years	56±7.78 years	p=0.031
Body Mass Index	24.97±3.59 kg/m²	27.44±4.47 kg/m²	p=0.116
Age at Menopause	44.67±6.30 years	43.13±17.19 years	p=0.748
Mean HLS-EU 16 Score	10.23±2.64	6.04±1.55	p=0.001
Mean MRS Score	8.76±2.26	4.51±1.16	p=0.001

Table1: Comparative of patient's characteristics, self-care behaviors and health literacy scores between osteoporotic and non-osteoporotic patients with RA

Conclusion:

The self-care behaviors and health literacy can play important preventive roles in older female osteoporosis with RA and it is recommended to take into account health literacy as one of the most important tools to improve self-care in patients with RA.

P331

SOS: THE SEA HOSPITAL SHEET TOOL FOR IDENTIFICATION AND TREATMENT OF PATIENTS WITH FRAGILITY FRACTURES

C. C. Coppola[1], D. A. Agnusdei[2], S. B. Balzano[3]

[1]Dept of Orthopedics & Traumatology, Trauma Center – Ospedale del Mare (Sea Hospital), General Hospital, ASL NA1 Centro, Italian NHS, Napoli, Italy, Napoli, Italy, [2]Indipendent Scientific Consultant, Siena, Italy, Siena, Italy, [3]Dept. of Economics & Law, University of Cassino (FR), Italy, Cassino (FR), Italy

Objectives As shown in the IOF-SCOPE study (2021), in Italy, out of a total of 2,889,000 women with osteoporosis, only 834,000 receve treatment, with a treatment gap of 71%.
In the Fracture Liaison Service (FLS) team the orthopedic surgeon has a crucial role, after surgery, in the implementation of therapeutic protocols, following updated guidelines, aimed to prevent the risk of a new fracture. To facilitate this action we propose a dedicated tool, developed at our institution, called the **SOS** (**S**ea h**O**spital **S**heet). Therefore, the major objective of our study is to provide an easy and effective tool for the orthopaedic surgeons to better identify and treat patients with fragility fractures.
Methods The SOS includes several domains: personal data, identification of the fracture site, family and personal history of fractures, comorbidities and previous osteoporosis treatments, detection of pain and pre-operative functional skills, DXA T-score values, ASA risk, time to and duration of the surgery, surgical technique and need for blood transfusion, a domain on discharge and post-operative functional capacity, proper anti-refracture drug treatment, and a battery of tests for the follow-up.
Results This retrospective analysis includes a cohort of 1263 patients (880 women, 383 men) with proximal femur fractures, admitted between January 2014 and December 2016, when an operative FLS was not available, and a cohort of 1110 patients (765 women, 335 men) admitted between January 2017 and December 2019, identified using SOS. Here to follow the data: before the use of SOS, at discharge, only 13% received drug therapy, after the use of SOS 83% received appropriate drug therapy (TPTD 36%, DNB 33%, BP 31%).
The clinical data, in the latter cohort were as follows: mean time to surgery was 16.5 h (min. 6 h – max 36 h); 28.5% of patients required blood transfusions; 64% of the patients presented lateral fractures, and hemiarthroplasty was performed in the 66% of patients with medial femoral fractures; at the admission, only 17.5% of patients were on therapy for osteoporosis (mean duration 16 months).
Conclusions In our clinical experience, the use of a dedicated and quick-to-fill identification tool, such as the SOS, can be a valuable support for the orthopaedic surgeon to better manage patients with fragility fractures. The use of SOS allowed a significant improvement of the occurence of a new fragility fracture through a proper drug therapy and follow up.

P332

ASSESSMENT OF BONE MINERAL DENSITY USING RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) TECHNOLOGY IN SUBJECTS WITH BONE MARROW EDEMA

C. Mondillo[1], A. Al Refaie[2], A. Versienti[2], G. Cavati[2], M. D. Tomai Pitinca[2], L. Gennari[2], S. Gonnelli[1], C. Caffarelli[2]

[1]University of Siena, Siena, Italy, [2]Department of Medicine, Surgery and Neuroscience, University of Siena, Italy, Siena, Italy

Objective
Bone Marrow Edema (BME) syndromes are diseases of unknown etiology characterized by the presence of bone marrow edema on magnetic resonance imaging (MRI). It is known that patients with BME exhibit reduced bone mineral density (BMD) values compared to healthy controls. The aim of our study was to evaluate whether the use of Radiofrequency Echographic Multi Spectrometry (REMS) allows for BMD assessment comparable to DXA in subjects affected by BME.
Material and Methods
In a cohort of 69 subjects (57.44 ± 12.99 years) with BME and in 50 healthy patients, we measured lumbar (BMD-LS) and femoral (femoral neck: BMD-FN, total femur: BMD-FT) BMD using the DXA method; furthermore, an evaluation of the same anatomical sites was performed using the REMS technique. Among the patients with BME, 23 patients had a presentation compatible with Complex Regional Pain Syndrome type 1 (CRPS-1), 20 patients had BME at the hip level, and 26 patients at the knee level.
Results
BMD values were reduced in subjects with BME compared to controls at all skeletal sites examined with both DXA and REMS methods. All three subgroups of BME patients showed a higher prevalence of osteoporosis compared to controls, and this prevalence was more evident in patients with CRPS-1 and hip BME compared to those with knee BME. Also in this case, the REMS method, like DXA, was able to discriminate T-score values in the three BME subgroups.
Conclusion
Our data confirm the validity of the REMS method in assessing bone mineral density in patients with BME; therefore, the REMS method can be proposed as a valid alternative to DXA measurement in a category of patients where the underlying condition of bone fragility is commonly not evaluated.

P333

USE OF RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) FOR MONITORING BONE MINERAL DENSITY IN A YOUNG WOMAN AFFECTED BY VITAMIN D-DEPENDENT RICKETS DURING PREGNANCY AND LACTATION

C. Mondillo[1], A. Al Refaie[2], A. Versienti[2], G. Cavati[2], S. Gonnelli[1], C. Caffarelli[2]

[1]University of Siena, Siena, Italy, [2]Department of Medicine, Sur-

gery and Neuroscience, University of Siena, Italy, Siena, Italy

Vitamin D-Dependent Rickets Type I (VDDR-I) is an early-onset, inherited disorder of vitamin D metabolism, characterized by severe hypocalcemia leading to osteomalacia and rachitic skeletal deformities, and moderate hypophosphatemia. In patients with conditions affecting the skeleton, it is important to have a method for monitoring bone status during pregnancy, but especially during lactation. For some years, a new ultrasound approach, defined as Radiofrequency Echographic Multi Spectrometry (REMS), has been available. This method does not use ionizing radiation and can be applied to women during pregnancy and lactation.
Case Report: C-P, a 27-year-old woman with VDDR-I carrying a CYP27B mutation, has been followed for many years at the Skeletal Bone Diseases Clinic of the University of Siena, Italy. Periodic blood tests show calcium and phosphorus levels at the lower limits of normal with a slight increase in PTH. The patient is treated with calcitriol combined with cholecalciferol and calcium carbonate but has poor treatment adherence. Over the years, the patient has reported fractures at the distal levels of the lower and upper limbs (left tibia and fibula, right elbow, and left elbow). In March 2023, she announced her pregnancy; therefore, it was decided to monitor her bone status by performing serial densitometric measurements using the REMS method throughout pregnancy, during lactation, and one year postpartum. Figure 1 shows the longitudinal assessment of bone mineral density (BMD) at the femoral neck in the first and third trimesters and a further check-up after delivery. The ability to assess bone status using the REMS method in young women is revolutionary, as it offers a safe option for evaluating bone health d

P334

ANALYSIS OF BONE TURNOVER MARKERS IN PATIENTS TREATED WITH ROMOSOZUMAB IN ROUTINE CLINICAL PRACTICE

C. Calomarde-Gomez[1], A. Prior-Español[1], F. Salabert[1], R. Ugena[1], C. Rocamora[1], A. Riveros[1], S. Holgado[1], R. Serrano[1], L. Mateo[1], L. Gifre[1]

[1]Hospital Universitary Germans Trias i Pujol, Rheumatology department, Badalona, Spain

Introduction: Romosozumab (Rmab) is an anti-sclerostin medication indicated for patients at high risk of fracture. This study aims to describe the prior therapeutic sequences (and their effects on bone turnover markers [BTMs]) in patients treated with Rmab in real-world clinical settings, as well as their densitometric response, adverse events, and post-Rmab treatment sequences.
Materials and Methods: Descriptive observational study including patients treated with Rmab for at least 3 months. Clinical data, laboratory analyses, BTMs, spine X-rays, and bone densitometry were collected.
Results: Seventeen postmenopausal women, mean age 70.5±8 years, were included. Of these, 8 completed 12 months (12M) of treatment and 6 completed 6 months (6M). All patients had a history of fragility fractures (median of 2 fractures per patient): 11 vertebral, 6 distal radius, 4 proximal humerus, 3 pelvis, and 2 femur fractures. Regarding prior treatment, 8 patients had received bisphosphonates (BF) (4 zoledronate, 4 alendronate), 4 teriparatide, 3 denosumab (Dmab), and 2 raloxifene.
Overall, bone mineral density (BMD) increased: lumbar spine +7.1% and +8.9% at 6M and 12M, respectively; femoral neck +2.2% at both 6M and 12M; and total hip +2.9% and +4.4% at 6M and 12M. Patients previously treated with BF showed greater BMD gains compared to those treated with teriparatide or Dmab, although the differences did not reach statistical significance.
The evolution of BTMs varied depending on the prior treatment. Patients previously on BF showed a rise in PINP (+46%) and a decline in CTX by 1 month. Those transitioning from Dmab had marked increases in both markers at 3 months (+1204% and +273%, respectively). In contrast, patients transitioning from teriparatide exhibited a decline in BTMs.
During Rmab treatment, 3 patients experienced skin reactions, 1 had an injection site reaction, and 2 developed rhinosinusitis (one case led to Rmab discontinuation). One patient sustained a femoral fracture at 3 months. No new vertebral fractures were reported.
After completing 12 months of Rmab, 7 patients initiated Dmab and 1 began intravenous BF therapy.
Conclusions: In real-world clinical practice, the prior therapeutic sequence influences both BTM and BMD responses to Rmab. Patients previously treated with BF achieved superior BMD increases compared to those transitioning from teriparatide or Dmab. The BTM behavior suggests a potential "rebound" effect in patients transitioning from Dmab to Rmab. After completing 12 months of Rmab, all patients started antiresorptive therapy. Notably, 35% of patients experienced adverse events, although only one required Rmab discontinuation.

P335

COMBINED DENOSUMAB AND CORE DECOMPRESSION IN PATIENTS WITH OSTEONECROSIS: A PILOT STUDY

C. Chen[1], S. Lin[1], J. Li[1], C. Ho[1]

[1]Kaohsiung Medical University, Kaohsiung City, Taiwan

Osteonecrosis of the femoral head (ONFH) is a debilitating condition that often leads to femoral head collapse and ultimately requires total hip arthroplasty (THA) in advanced stages. While core decompression is a widely used joint-preserving surgery, its outcomes remain inconsistent. Denosumab, a potent antiresorptive agent, has shown promise in reducing bone resorption and potentially delaying femoral head collapse, though its efficacy in ONFH remains uncertain. This study explores the potential synergy of combining denosumab with core decompression to improve femoral head survival and reduce the need for THA in patients with extensive necrosis. Over five years, 53 patients (67 hips) with Steinberg stage IIC or IIIC ONFH were retrospectively analyzed. The denosumab group (n=32) received two postoperative 60 mg doses, while the control group (n=35) underwent core decompression alone. The denosumab group achieved a higher THA-free sur-

vival rate (87.5% vs. 64.71%), though the difference was not statistically significant (p=0.0821). Radiographic progression rates were comparable between groups (56.25% vs. 58.82%; p=0.85). Notably, subgroup analysis revealed a potential benefit for patients with Steinberg stage IIC. These findings suggest that combining denosumab with core decompression could be a promising strategy to delay THA in ONFH, especially in early-stage patients with large necrotic areas. Further studies are warranted to validate these results and refine treatment protocols.

P336

ASSESSMENT OF BONE HEALTH PARAMETERS AND FRAGILITY FRACTURE PREVALENCE IN A POPULATION OF MEN OVER 50 IN ARGENTINA

S. B. Bostico[1], C. F. Firpo[1], F. S. Subies[1], M. S. E. Escudero[1], C. H. Habib[1], F. G. Geraci[1]

[1]Sanatorio Las Lomas, SAN ISIDRO, Argentina

Objective To describe the characteristics of the studied population and analyze clinical and bone health parameters associated with fragility fractures.

Materials and Methods This retrospective study reviewed 504 electronic records of Caucasian men >50 years referred for bone health evaluation between January 2022 and December 2024. Bone assessments included DXA (Lunar iDXA, GE Healthcare) with Trabecular Bone Score (TBS), Lumbar Vertebral Assessment (LVA), and FRAX®. Data included age, BMI, risk factors, and fracture history. Variables were described as proportions or mean ± standard deviation. Associations with fractures were analyzed using chi-square or t-tests ($p < 0.05$). Institutional review board approval was obtained.

Results The mean age was 67.7 ± 9.2 years, and mean BMI was 29.2 ± 4.4 kg/m², with 83.9% overweight/obese. Osteoporosis (BMD-based) was found in 11.2%. TBS (n=358) averaged 1376.7 ± 117.4, with pathological values (<1300) in 26.3%. Vertebral fractures were detected in 25 patients via LVA. FRAX® (n=262) estimated a mean 10-year fracture risk of 5.1% for major osteoporotic fractures (MOF) and 2.1% for hip fractures (HF) in patients without prior fractures. These risks were significantly higher in patients with prior fractures, reaching 9.4% for MOF and 5.1% for HF ($p < 0.001$ for both comparisons).

A total of 69 fractures occurred in 62 patients: 36 vertebral (11 clinical, 25 morphometric), 15 hip, 7 radius, 6 tibia-fibula, 4 shoulder, and 1 pelvic. Fractures were more frequent in patients with low femoral neck BMD ($p<0.001$). TBS was significantly lower in patients with fractures ($p=0.005$), particularly clinical vertebral fractures ($p<0.001$). Morphometric fractures showed no differences in TBS or BMD compared to non-fractured individuals. The most significant risk factor was prior fracture (12.3%). Diabetes prevalence was 15.7%.

Among overweight/obese and diabetic men, pathological TBS or higher fracture prevalence was not observed. However, other risk factors were associated with lower TBS ($p<0.001$) and increased fracture risk ($p<0.001$).

Conclusions This study highlights the combined utility of BMD, TBS, and FRAX in fracture risk assessment. Comprehensive evaluations using these markers and risk factors are essential to guide prevention and treatment strategies for fracture risk.

P337

SHORT SLEEP DURATION IS ASSOCIATED WITH A HIGHER RATIO OF OSTEOPOROSIS IN OLDER ADULTS: A LONG-TERM CARE FACILITY-BASED STUDY IN TAIWAN

C. H. J. Hong Jhe[1], C. T. Y. Tien-Yu[2]

[1]Pingtung Veterans General Hospital, Pingtung City, Taiwan, [2]Department of Psychiatry, Tri-Service General Hospital, School of Medicine, National Defense Medical Center, Taipei, Taiwan, Taipei, Taiwan

Objectives: This study primarily aims to analyze the relationship between osteoporosis and sleep quality. Sleep quality is assessed using the the snoring, tiredness, observed apnea, high BP, BMI, age, neck circumference, and sex questionnaire(STOP-Bang) and Pittsburgh Sleep Quality Index (PSQI) questionnaires, with a particular focus on individuals over the age of 65.

Methods: In this cross-sectional study, osteoporosis screening was conducted among older adults in long-term care facilities operated by Kaohsiung Veterans General Hospital in Taiwan in 2019. osteoporosis was diagnosed using dual-energy X-ray absorptiometry. STOP-Bang and PSQI questionnaires explored the relationship between sleep quality and bone mineral density. Initially, data from 357 participants were collected, with missing data and participants under 65 years of age excluded, resulting in 326 participants for the final analysis.

Results: This study involved 326 participants with a mean age > 80 years. Sleep duration < 4 h was significantly associated with osteoporosis (odds ratio: 2.30, 95% confidence interval: 1.15–4.57) regardless of sex. Additionally, HRV was not significantly associated with sleep quality or osteoporosis.

Conclusions: Among older adults aged >80 years, sleep duration < 4 h revealed a notably higher ratio of osteoporosis. Sex may not significantly contribute to osteoporosis in older adults, and HRV may not be an optimal indicator of sleep quality in this demographic.

GAPS IN OP GUIDELINE-ADHERENT TREATMENT: A CLAIMS DATA ANALYSIS ON WOMEN AGED 55+ IN GERMANY

S. Melnik[1], H. D. Pannen[2], C. Hermsen[2], R. Bley[2], J. Puschmann[1], L. Möckel[2]

[1]Gesundheitsforen Leipzig, Leipzig, Germany, [2]UCB Pharma, Monheim am Rhein, Germany

Objectives According to German osteoporosis guidelines, women with femoral or vertebral fractures face a very high risk of subsequent fractures and are advised to receive specific treatment[1,2]. We evaluated treatment initiation rates, subsequent fracture risks, and nursing home discharge in women aged 55+.

Material and Methods This retrospective analysis of a German claims database (4.1 million insured) included statutorily health insured (SHI) women aged 55+ years with proximal femoral or vertebral fractures in 2017–2021, before 2023 guideline update[2]. For 2021 cases, we assessed treatment status and nursing home referrals within one year. Subsequent fracture risk within one year was analyzed for all years.

Results In 2021, extrapolated to SHI, 145,188 women with new vertebral (0.96%; mean age 71.8 [SD 10.5] years) and 58,851 with femoral (0.39%; 76.4 [SD 10.9] years) fracture were identified.

Of those patients with vertebral fracture and known osteoporosis (OP), 24.7% were treated before index fracture, 15.8% initiated treatment and 59.5% remained untreated within 6 months after index; those numbers were 1.5%, 14.0% and 84.6% for unknown OP, respectively. Following femoral index fracture with known OP, 17.1% were already treated, 4.7% started treatment and 78.1% remained untreated; for unknown OP respective numbers were 0.7%, 4.6% and 94.7%. The mean time to treatment initiation was 75.1 (SD 46.1) days after femoral and 62.0 (SD 46.9) days after vertebral fracture. Of untreated patients, at least 16.7% (femoral) and 6.4% (vertebral) were discharged from hospital to nursing home within one year.

In untreated femoral fracture patients (n=282,026; period 2017–2021), 28.1% had another femoral fracture and 5.0% a vertebral fracture within one year. Untreated patients with vertebral fracture (n=630,102) had a risk of 27.8% for a second vertebral and 2.0% for a femoral fracture within one year after index.

Conclusion Although guidelines included an option to initiate OP therapy without a prior BMD measurement in patients with a femur or higher-grade vertebral fracture the majority remain untreated. This suboptimal care of osteoporosis patients in Germany substantially increased rates of secondary fractures. Urgent adherence to osteoporosis treatment guidelines is needed for high-risk patients. DVO 2023 guideline update included a 3-year fracture risk threshold to ensure that patients receive an adequate treatment[2].

THE ROLE OF NON-MASS BONE PROPERTIES IN FRACTURES OF OSTEOPENIC PATIENTS

C. Horvath[1], T. Leel-Össy[1], E. Hosszu[2], E. Csupor[3], A. Tabak[1], S. Meszaros[1]

[1]Department of Internal Medicine and Oncology, Semmelweis University, Budapest, Hungary, [2]Department of Pediatrics, Semmelweis University, Budapest, Hungary, [3]Endocrin Unit, Budavar Health Centre, Budapest, Budapest, Hungary

Osteopenia (T-score from -1.0 to -2.5) is common in people older than 65 ys, and more than half of fractures occur in osteopenia. It is not clear whether this fragility is caused simply by the decreased bone mass or non-mass bone properties also contribute? Our aim was to examine some non-mass bone properties in osteopenic patients with or without previous fracture, using trabecular bone score (TBS) and quantitative ultrasonosography (QUS). In a 2 years period 4,758 patients were sent to our Densitometry Lab with suspected osteoporosis (1,544 (32%) with previous fractures). We analyzed data of 4170 women (fracture in 1387 = 33%). BMD measurements were done at the lumbar spine, hip and forearm. QUS was performed on 397 patients (83 fractures), and TBS on 689 patients (149 fractures). Patients were grouped as normals (T-score >-1 on all bones), osteopenics (T<-1 on at least one bone, but not below -2.5 on any bone) and osteoporotics (T-score <-2.5 on at least one bone).

BMD was measured by DEXA (Lunar Prodigy, WI, US) and TBS was calculated from spine densitometry. QUS was performed on the heel bone (Lunar Achilles Plus, WI, US). Fracture probability was calculated by FRAX. In case of previous fracture the FRAX was also calculated without taking the fracture into account.

We found 480 normals (49 fracture), 2506 (818) osteopenics and 1299 (520) osteoporotics (OP). The fractured patients were 4-9 years older in the groups ($p<0.001$), and their height was 1-3 cm less ($p<0.01$). In normals, the BMD and T-score in the fractured and non-fractured subjects were the same, while fractured subjects showed lower BMD and T-score on all bones ($p<0.002$) in osteopenia and OP groups. QUS and TBS showed the same pattern: no difference in normals, and lower values ($p<0.02$) in osteopenia and OP in fractured than in non-fractured patients. Excluding the younger ones from the non-fracture osteopenic patients, we formed an osteopenic non-fracture group with equal age to osteopenic fractured patients (69.1 and 69.2 years, $p>0.61$): comparing these two groups, the axial (spine and hip) BMD differences remained, but the differences in QUS and TBS values disappeared between fractured and non-fractured patients. In the meantime, however, the FRAX differences between the fractured and non-fractured patients remained even if the previous fractures were not taken into account in FRAX recalculation.

Our data did not prove the role of non-mass characteristics in the

fragility of osteopenia. However, the age-adjusted FRAX calculated without fracture indicates that in osteopenia, in addition to the decreasing BMD, other factors may be involved in the occurrence of bone fracture.

P340

EFFECTS OF AMORPHOUS CALCIUM CARBONATE (ACC) SUPPLEMENTATION ON BONE HEALTH IN POSTMENOPAUSAL WOMEN WITH OSTEOPENIA: A RANDOMIZED CONTROLLED TRIAL

C. K. Chun Kai[1], Y. K. Yih Kuang[2], H. S. Hou Tsung[3], Y. W. Yi Wen[4]

[1]National Taiwan Ocean University, Keelung City, Taiwan, [2]UNIVERSAL INTEGRATED CORP., Taipei, Taiwan, [3]Chang Gung Memorial Hospital, Kaohsiung, Gaoshiung, Taiwan, [4]Taipei Medical University, Taipei, Taiwan

Osteopenia, characterized by reduced bone mineral density (BMD), poses a significant risk for osteoporosis and fractures, particularly in postmenopausal women. This randomized, double-blind clinical trial aimed to investigate the effects of amorphous calcium carbonate (ACC) supplementation on BMD and bone turnover markers (BTMs) in postmenopausal women with osteopenia. Forty-four participants were initially recruited, with 35 completing the 6-month intervention. The ACC group (n = 18) received 400 mg/day of ACC, while the control group (n = 17) received a placebo. Dual-energy X-ray absorptiometry (DXA) was used to assess BMD, and BTMs including bone-specific alkaline phosphatase (BAP), C-terminal telopeptide of type I collagen (CTX), and procollagen type 1 N-terminal propeptide (P1NP) were measured. Results showed significant improvements in BMD, particularly at critical skeletal sites, and favorable changes in BTMs with ACC supplementation, suggesting a potential role in osteopenia management.

P342

IMPACT OF DENOSUMAB DISCONTINUATION ON BONE HEALTH IN WOMEN WITH EARLY-STAGE BREAST CANCER: INSIGHTS FROM THE SWISS PROLIA STUDY

C. L. Campisi[1], F. M. Faouzi[2], G. E. Gonzalez Rodriguez[1], B. P. Burckhardt[3], T. B. Buclin[3], O. L. Lamy[4]

[1]Interdisciplinary Center of Bone Diseases/ Service of Rheumatology/Lausanne University Hospital, Lausanne, Switzerland, [2]University Center for Primary Care and Public Health Biostatistics/ Lausanne University Hospital, Lausanne, Switzerland, [3]Faculty of Biology and Medicine, University of Lausanne, Lausanne, Switzerland, [4]Service of Internal Medicine, CHUV, Lausanne University Hospital, Lausanne, Switzerland

Objective(s): To evaluate the effects of denosumab (Dmab) discontinuation (DD) on vertebral fracture (VF) risk in postmenopausal women with early-stage breast cancer (ESBC) undergoing adjuvant aromatase inhibitor therapy, and to identify associated risk and protective factors.

Material and Methods: Data derived from the Swiss Prolia Study cohort[1] included 797 postmenopausal women (134 ESBC) treated with Dmab. All received ≥ 2 injections and were followed for ≥30 months post-discontinuation. Key outcomes included VF prevalence, multiple VF (MVF) and total VF count. Bone turnover markers (BTM), bone mineral density (BMD) and fracture occurrence were analyzed across three periods: before, during and after discontinuation. Statistical analyses utilized Cox proportional hazard models and logistic regression.

Results: At baseline, ESBC patients were younger (mean age 62 vs 66 yo, p<0.001), had higher baseline BMD (at all sites p<0.001), less VF and non-VF, and were less pretreated with bisphosphonates (BP) (22% vs 53%, p<0.001) than women without breast cancer (WBC). ESBC patients received more Dmab doses (6.7 vs 5.7, P=0.002). After DD, 62.7% of ESBC patients received BP (vs 67.1% in WBC); BMD decreased significantly at all sites, more pronounced in ESBC. 17 ESBC patients (12.7%) had 46 VFs of whom 13 (10%) had MVF (3.2VF/patient). In WBC, 65 (9.8%) had 169 VF, 47 (7.1%) had MVF. Prior VFs and elevated BTMs after DD were strongly associated with the risk of VF after DD. No protective factor was identified. Non-VF were rare, with no cases after DD in ESBC.

Conclusion(s): DD in ESBC patients is associated with a high risk of VF, particularly MVF, despite higher BMD and younger age. Our findings highlight the importance of cautious decision-making regarding Dmab initiation, particularly in younger women or with higher BMD. Incorporating BP into the therapeutic regimen before or during the rebound period may reduce fracture risk[1-2], especially in those at low fracture risk.

SURVIVAL, DISABILITY, PAIN AND HEALTH-RELATED QUALITY OF LIFE FOLLOWING HIP FRACTURE IN ZIMBABWE: A PROSPECTIVE COHORT STUDY

C. L. Gregson[1], M. I. Nasser[1], A. Burton[1], H. Wilson[1], T. Manyanga[2], P. Mushayavanhu[3], M. Ndekwere[4], J. Chipanga[2], S. Hawley[1], S. Graham[5], J. Masters[5], K. A. Ward[6], M. Costa[5], R. A. Ferrand[7]

Objective

In Africa fragility fracture risk is increasing as longevity increases. We assessed health outcomes in the year after hip fracture in older adults in Zimbabwe.

Methods

A cohort of adults ≥40 years with hip fracture, presenting to hospitals in Harare (2 public; 5 private) (2021-22) were followed-up for one-year. Operative management, survival, health-related quality

of life (HRQoL) utilities from EQ-5D-5L, disability (WHODAS), and pain were measured. Associations between patient characteristics and odds of operative management were assessed.

Results

Of 196 hip fracture patients (49% female and median age 74·0 years [IQR 63·0-83·0]), 86·2% were fragility fractures, 173 (88·3%) were managed in public hospitals, where just 96 (55·5%) received operative hip fixation; all 23 (11·7%) managed in private facilities received an operation. After 365-days, 55 (29·4%) had died (41·9% of those age ≥70 years, and 8·6% of those <70 years). In public hospitals, 42.5% of non-operated patients died, vs. 19·4% of those operated.

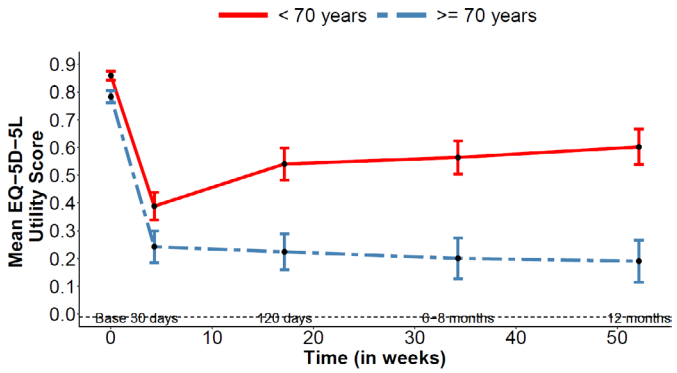
By 30-days the mean HRQoL utility score had fallen by 64·1% from 0·81[95%CI 0·79,0·82] pre-fracture to 0·29[95%CI 0·25,0·33]. After 120-days, minimal recovery was seen, especially in those age ≥70 years (Fig-1). Post-fracture disability was near universal, with only 2% disability-free by 365-days, when 97% still reported hip injury-related pain, with 94% having pain interfering with walking, and 80% with sleep. Higher household income was associated with higher odds (OR=3.02[95%CI 1.55,6.16]), and malnutrition with lower odds (OR=0·31[95%CI 0·14,0·65]), of being operated.

Conclusions

Substantial health inequities in hip fracture care provision have been identified by these unique data. Following hip fracture in Zimbabwe, quality-of-life and survival fall substantially, more so than seen after stroke in other regions, demanding implementation of guidelines to standardise care and improve operative capacity to manage the predicted rise in fractures.

Fig-1

HRQoL prior to hip fracture and over 12-months



P345

WHOLE-ORGAN MAGNETIC RESONANCE IMAGING SCORE (WORMS) DOES NOT CORRELATE WITH CLINICAL IMPROVEMENT FOLLOWING PRP INJECTIONS IN KNEE OSTEOARTHRITIS

C. Lertmahandpueti[1], A. Tanavalee[1]

[1]King Chulalongkorn Memorial Hospital, Bangkok, Thailand

Objective

This observational prospective cohort study investigates the effectiveness of three doses of platelet-rich plasma (PRP) injections in patients with knee osteoarthritis (OA). The semi-quantitative whole-organ scoring system (WORMS) was employed to assess structural changes in the knee post-PRP injection over a 6-month period.

Materials and Methods

Twenty patients diagnosed with knee OA received PRP injections as an alternative treatment. They were evaluated pre- and post-injection using the WORMS scoring system to assess structural changes. Clinical outcomes were measured through:

- Visual Analog Scale (VAS) for pain
- Patient-reported outcome measures (PROMs), specifically the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) Index
- Performance-based measures (PBMs), including:
  - Timed Up and Go Test (TUGT)
  - 5-Time Sit to Stand Test (5 × SST)
  - 3-Minute Walk Test (3-min WT)

Results

- The overall WORMS score increased from 38.15 ± 17.48 (pre-treatment) to 40.30 ± 18.87 (post-treatment), indicating a mean change of 2.15 (95% CI: 0.82, 3.48).
- Notably, the WORMS score for articular cartilage demonstrated the most substantial increase, with a mean change of 1.45 (95% CI: 0.5, 2.4).
- Significant improvements in VAS were recorded at 3 weeks post-treatment, achieving both clinical and statistical significance by 6 weeks and sustained at the 6-month follow-up.
- Delayed improvements in PBMs were also observed at the 6-month mark.

Conclusion

Despite clinical improvements following three PRP injections for knee OA, there was no correlation with the changes in the whole-organ magnetic resonance imaging score (WORMS) after 6 months. While WORMS scores indicated potential structural deterioration or minimal change, notable improvements in VAS, PROMs, and PBMs were documented. A novel technique is proposed to elucidate these contrasting findings.

P346

IMAGE-BASED ROBOTIC TOTAL HIP ARTHROPLASTY RESTORES THE HIP JOINT ANATOMY AND LEADS TO FAVORABLE OUTCOMES AT A MINIMUM OF 2 YEARS FOLLOW-UP

C. Koutserimpas[1], C. Matzaroglou[2], S. Naoum[3], K. Raptis[4], E. Veizi[5], M. Piagkou[6], E. Chronopoulos[7], K. Dretakis[8]

[1]Orthopaedic Surgery and Sports Medicine Department, Croix Rousse University Hospital of Lyon, Lyon, France, [2]Department of Physiotherapy, School of Rehabilitation Health Sciences, University of Patras, Patras, Greece, [3]Department of Trauma and Orthopaedics, Royal Berkshire Hospital, Reading, Reading, United Kingdom, [4]Department of Orthopaedics and Traumatology, "251" Hellenic Air Force General Hospital of Athens, Athens, Greece, [5]Department of Orthopedics and Traumatology, Yıldırım Beyazıt University, Ankara City Hospital, Ankara, Ankara, Turkiye, [6]Department of Anatomy, School of Medicine, Faculty of Health Sciences, National and Kapodistrian University of Athens, Athens, Greece, [7]Laboratory for Research of the Musculoskeletal System "Theodoros Garofalidis", School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [8]2nd Department of Orthopaedic Surgery, "Hygeia" General Hospital of Athens, Athens, Greece

Objectives:
Total hip arthroplasty (THA) is a commonly performed procedure aimed at alleviating pain and restoring joint function in patients with hip arthritis [1, 2]. Accurate restoration of hip joint anatomy is critical for achieving optimal outcomes and longevity of the implant. Recent advancements in image-based robotic systems have enabled precise preoperative planning and execution of the procedure [3, 4]. This study evaluates the clinical and radiographic outcomes of image-based robotic THA in restoring hip joint anatomy and achieving favorable functional outcomes with a minimum follow-up of 2 years.

Material and Methods:
This retrospective analysis included 80 consecutive patients (58 females, 72.5%) who underwent image-based robotic THA between 2019 and 2021. The mean age of the cohort was 77.5 years (SD=6.2), and the mean follow-up duration was 3.6 years (SD=0.3). Preoperative and postoperative Harris Hip Scores (HHS) were recorded to assess functional outcomes. Accuracy in component placement was evaluated by comparing the planned and actual inclination and anteversion angles of the acetabular cup. Statistical analysis was performed to assess the significance of clinical improvements and radiographic accuracy.

Results:
The mean preoperative HHS was 49.8 (SD=7.8), which significantly improved postoperatively to 92.4 (SD=4.6), reflecting a mean increase of 85.6%. The mean difference between planned and final cup inclination was 1.8° (SD=0.4), and the mean difference in anteversion was 1.3° (SD=0.2), indicating high accuracy in component placement. Only one case (1.3%) of traumatic dislocation was recorded, requiring open reduction. No other complications were noted in this cohort.

Conclusions:
Image-based robotic THA demonstrates high accuracy in restoring hip joint anatomy, with a minimal deviation from planned acetabular component positioning. This precision is associated with significant improvements in functional outcomes, as evidenced by a substantial increase in HHS. At a minimum of 2 years follow-up, image-based robotic THA provides reliable, favorable results, suggesting its potential as a valuable tool in hip arthroplasty, particularly in elderly patients. Further studies with longer follow-up are warranted to assess the durability of these outcomes.

Objectives:
There is limited information on the long-term success of threaded

cups in patients aged over 65 [1, 2]. Threaded, coated cups provide immediate mechanical stability, which may be advantageous for this demographic [3,4]. This study aims to evaluate clinical outcomes and complications associated with the use of the porous-coated EcoFit® SC threaded cup (ImplantCast) in elderly patients with osteopenia.

Material and Methods:

The study included 100 consecutive patients over the age of 65 who underwent total hip arthroplasty (THA) with the modified anterolateral minimally invasive (ALMIS) approach between 2014 and 2016 [5, 6]. All patients had a DEXA score between -1.5 and -2.5. We assessed implant survivorship, functional outcomes (Harris Hip Score), patient-reported satisfaction, and recorded complications.

Results:

Patients were followed for an average of 7.6 years (±1.2). The average age at surgery was 77.4 years (±5.5), with 78% of patients being female. The mean postoperative Harris Hip Score was 89.1, and the average satisfaction rating (scale 1–10) was 8.7 (SD 0.8). Two revisions were performed: one for prosthetic joint infection and another for aseptic loosening. Additionally, one patient experienced a traumatic dislocation, which was managed by closed reduction without further surgical intervention.

Conclusions:

Threaded, coated cups demonstrate favorable mid-term outcomes in elderly patients with osteopenia, potentially benefiting from their immediate mechanical stability [2, 3]. However, further studies are required to comprehensively understand the long-term performance of these implants in this patient population.

Objectives:

Image-based robotic arm-assisted total knee arthroplasty (RATKA) using the Stryker Mako system (Mako Surgical Corp., Fort Lauderdale, FL, USA) has shown promising mid-term outcomes with minimal system-related complications [1-3]. This study aims to assess prosthesis survivorship, report complications, and document patient satisfaction and functional outcomes associated with this technique.

Material and Methods:

A retrospective analysis was conducted on 100 consecutive patients who underwent RATKA. Patient demographics, including age and gender, were recorded. The Oxford Knee Score (OKS) was collected preoperatively and at least two years postoperatively. Subjective satisfaction rates, complications, and any revisions were also documented.

Results:

The cohort consisted of 72 females and 28 males with a mean age of 72.6 years (SD = 5.8). The mean follow-up period was 41.2 months (SD = 3.6). One revision (1%) was performed due to prosthetic joint infection. Statistically significant improvements were observed in the Oxford Knee Score. Additionally, 97% of patients reported being "very satisfied" or "satisfied" with their outcomes. One case of a superficial pin-site infection in the tibia was noted and managed conservatively. No further system-related complications were observed.

Conclusions:

RATKA appears to be a safe and effective procedure with minimal complications, low revision rates, and favorable mid-term results [2, 4]. This study demonstrated high patient satisfaction,

improved clinical outcomes, and robust implant survivorship. While similar studies have confirmed the safety and efficacy of this technique, further research is required to investigate long-term implant survivorship [1, 3, 5].

Objectives:

This report details a case of polymicrobial prosthetic joint infection (PJI) in a 72-year-old woman, occurring three years after initial knee arthroplasty revision surgery. Periprosthetic polymicrobial infections with a fungus are extremely challenging in revised arthroplasties that require multidisciplinary approach [1-3].

Material and Methods:

We describe the patient's clinical and laboratory findings, along with her clinical progression.

Results:

The patient, a 72-year-old female with a history of diabetes mellitus, and obesity, underwent a two-stage exchange knee arthroplasty to address PJI. Initial cultures from the first stage identified methicillin-resistant *Staphylococcus aureus* (MRSA). After the second stage, the surgical wound appeared purulent. Surgical debridement was performed, with intraoperative cultures revealing both *Candida albicans, E. coli* and MRSA; blood cultures confirmed the presence of *Candida albicans*. The patient received intravenous fluconazole and vancomycin for four weeks. Due to comorbidities the patient was commenced on lifelong suppression treatment. At her four-year follow-up, she remained symptom-free with no signs of active infection.

Conclusions:

Fungal PJIs, though uncommon, present a complex treatment challenge necessitating a multidisciplinary approach [3, 4]. This case was polymicrobial with two bacteria and a fungus. The combination of two-stage revision surgery and extended antifungal therapy has been reported to be an effective management strategy [5, 6]. This case raises the question of whether life-long antifungal suppression could be a viable option in instances where additional surgery might result in poor outcomes due to technical constraints (e.g., severe bone loss, limited reconstructive options) or significant patient comorbidities. While complete infection eradication may not be achievable, the patient remains mobile and free of infection symptoms.

Objectives:
New-generation threaded acetabular components, such as the EcoFit® SC cup (Implantcast, Buxtehude, Germany), have shown positive outcomes in total hip arthroplasty (THA). These threaded cups offer immediate mechanical stability, which may be beneficial in achieving secure fixation, particularly in certain patient populations [1-4]. However, complications specific to this implant type have been observed, often related to surgical technique and patient anatomy. This report aims to present notable complications associated with the EcoFit® SC cup.

Material and Methods:
We reviewed a series of complication cases involving the EcoFit® SC cup in THA. Surgical techniques were assessed, with a focus on acetabular preparation and implant insertion. Specific attention was given to cases of acetabular roof and posterior wall fractures, as well as instances of incomplete component placement. We also considered patient anatomical factors and intraoperative findings to outline contraindications for the use of threaded cups.

Results:
Several complications were identified, including fractures of the acetabular roof and posterior wall, as well as incomplete placement of the threaded component. These complications were often associated with inadequate preparation of the acetabular rim, as the threaded cup diameter exceeds that of standard reamers used in acetabular preparation. In cases where the anterior or posterior acetabular walls were notably thin, torque forces exerted during implant insertion increased the risk of intraoperative fractures.

Conclusions:
While threaded acetabular components like the EcoFit® SC cup provide immediate stability and favorable outcomes in THA, careful consideration of surgical technique and patient anatomy is essential to avoid complications. Ensuring thorough preparation of the acetabular rim is critical to achieving proper component placement [2, 5]. Additionally, avoiding the use of threaded cups in cases with thin acetabular walls may reduce the risk of intraoperative fractures. Further studies are recommended to better define patient selection criteria and refine techniques to optimize outcomes with threaded cups in THA.

P351

MORPHOMETRIC STUDY OF SCIATIC NERVE AND ITS RELATION WITH SARCOPENIA IN PATIENTS WITH DISCOPATHY

C. Matzaroglou[1], M. Tsekoura[1], C. Koutserimpas[1], E. Trachani[1], J. Gliatis[2], E. Chroni[1], E. Athanaselis[3]

[1]Unit of Neuromuscular Disorders of University Hospital of Patras and Department of Physiotherapy, University of Patras, Patras, Greece, [2]Department of Orthopedic Surgery, University Hospital of Patras, Patras, Greece, [3]Departmnet of Orthopedic Surgery, University Hospital of Larissa, University of Thessaly, Larissa, Greece

Objective: Patients suffering from chronic low back pain with associated sciatica, experience neurological symptoms in the lower back and leg. Ultrasonography (US) has been used recently to characterize sciatic nerves. And because of less daily activities and exercise in these patients are likely to experience sarcopenia. We examine the sciatic nerve with ultrasound in patients with LBP and unilateral radiculopathy (sciatica). We

evaluate the possible changes of nerve structure in patients with low back pain with unilateral sciatica due to lumbar disc herniation by ultrasound imaging and possible relation with sarcopenia. **Methods:** Forty - two (42) volunteers patients with 84 sciatic nerves, aged 22-81 years old, which complained for sciatica and they identified with lumbar disc prolapse in MRI, were studied with US (sciatic nerve). Age, sex, height, weight were recorded and the size and morphology of sciatic nerve were obtained. Sarcopenia was identified by muscle strength, muscle mass and gait speed assessment using the European Working Group on Sarcopenia in Older People (EWGSOP2) criteria. **Results:** The mean size of sciatic nerves were 0.578 ± 0.034 cm2 in males and 0.488 ± 0.03 cm2 females respectively. Pearson's correlation analysis showed that the mean size were correlated with height and weight. There was no difference in mean size among the different age. Women had smaller size of the sciatic nerves than men. Also the "pathologic sciatic nerves they have morphology of "edema" and the size were smaller in patients with recently diagnosed for disc prolapse in MRI, and in contrast enlargement sciatic nerves in patients with chronic sciatica, radiculopathy and positive MRI for disc prolapse more than 3 years ago (difference = 0.052 cm2). In addition, 23.3.% were diagnosed with probable sarcopenia and 4.8% with severe sarcopenia. Using regression analyses, sarcopenia was positively associated with sciatica (OR=0.12; CI 0.08-0.15); and age (OR=0.008; CI 0.004-0.01). **Conclusion:** Peripheral nerve ultrasonography is a reliable andreproducible diagnostic method in the hands of experienced examiners. The reliability aspect of measuring sciatic nerves and echointensity of the sciatic nerve with ultrasound in patients with LBP and unilateral radiculopathy has received little attention in the literature. Also the relative magnitude of fat/fibrosis infiltration were observed in all our cases of chronic sciatica and radiculopathy.The results of this study show that there is a positive correlation between sarcopenia and sciatica in patients with radiculopathy; this association had not been previously confirmed in Greece. Further research with larger sample is indicated in order clarify the precise association of specific characteristics of patients with sarcopenia and discopathy.

Objectives/Introduction: Osteoarthritis (OA) of the knee is one of the most frequent degenerative cartilage pathologies. Scientific research has, in recent years, advanced new therapies that target adenosine A2 receptors, which play a significant role in human health against many disease states by activating different protective effects against cell damage. Among these, it has been observed that intra-articular injections of polydeoxyribonucleotides (PDRN) and Pulsed Electromagnetic Fields (PEMF) [1,2,3,4], can stimulate the adenosine signal, with significant regenerative and healing effects. The present paper highlights how intra-articular

injections of PDRN create beneficial effects by reducing pain and improving functional clinical scores.

Patients and Methods: A total of 63 patients, aged between 72 and 87 years old, affected by bilateral knee osteoarthritis, were enrolled in this study. They received PEMF therapy and PDRN injections on the right leg [PEMF therapy: Two- 30-minute sessions per week for a period of 6 weeks, while the left leg did not receive any treatment and served as control. An intra- articular amp containing PDRN (5,625 mgr./3ml) was administered during PEMF therapy. At baseline and 3 months post-PEMF/PDRN therapy, Visual Analog Scale (VAS) was used to assess knee pain and Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) was used to measure knee pain, stiffness and physical function.

Results: Changes in VAS and WOMAC scores were calculated for both knees as baseline minus post-treatment. A two sample Student's t-test, comparing change in knee-related VAS pain for PEMF-PDRN treated leg (46.2 ± 1.34) vs control leg (10 ± 1.2), showed a significant difference in favor of PEMF - PDRN therapy ($P < 0.001$). A two sample Student's t-test comparing change in knee-related WOMAC pain, stiffness, and physical function for PEMF-PDRN treated leg (9.5 ± 0.3, 3.7 ± 0.2, 39.4 ± 2.11, respectively) vs control leg (2.2 ± 0.1; 1.6 ± 0.2; 4.3 ± 0.5 respectively), also showed a significant difference in favor of PEMF – PDRN therapy ($P < 0.001$). No adverse reactions to therapy were observed.

Conclusions: As has been shown, polynucleotides are polymeric molecules with a viscoelastic property because they bind large quantities of water molecules [1,3,5]. This allows them, as part of the treatment of osteoarthrosis (OA), to have the capacity to reorganize the articular cartilaginous structure through the regulation of the coordination and orientation of water molecules, thus increasing the moisture of the articular surfaces when the PDRN is injected into the joints [3,4]. As mentioned above, PDRN can inhibit metalloproteases of the extracellular matrix, thus reducing the degradation of extracellular matrix proteoglycans. Polynucleotides are also correlated to stimulating cell growth, collagen production, migration of anti-inflammatory cell types, and decreasing inflammation. The intra-articular use of PDRN yielded similar functional outcomes to HA, and the pain relief effect was superior for up to 2 months post-injection. Therefore, PDRN could be a favorable alternative to HA for treating knee OA with persistent pain, while also avoiding common HA side effects. Additionally, the pain-relief benefits of PDRN in clinical practice could offer a complementary role for other injection treatments. Adenosine replacement in the joint may be a new therapeutic approach to diseases involving cartilage damage, such as OA.

PERCEPTION OF HEALTHY LIFESTYLE AMONG MEDICAL STUDENTS AND NON-MEDICAL UNIVERSITY STUDENTS

C. Matzaroglou[1], M. Kremmyda[2], M. Matzaroglou-Chairistanidou[3], M. Kouzeli[3], E. Matzaroglou-Heristanidu[4]

[1]Unit of Neuromuscular Disorders of University Hospital of Patras and Department of Physiotherapy, University of Patras, Patras, Greece, [2]School of Medicine, Faculty of Health Sciences of Aristotle University of Thessaloniki, Greece, Thessaloniki, Greece, [3]School of Medicine, European University of Cyprus, Nicosia, Cyprus, [4]School of Medicine, School of Health Sciences, University of Patras, Patras, Greece

Introduction / Objectives: Doctors have a special role in helping patients make lifestyle changes, and they are more effective if they are role models. The aim of the present study was to evaluate ideas and motivational attitudes of medical school students towards a healthy lifestyle and its components. The study aims also to assess behavioral lifestyle, to compare these behaviors between two groups of students (medical and non-medical) and found out the relationship between healthy lifestyle with their socio-demographic data.

Methods: The study was conducted from March until November 2024. We ran a medical and sociological survey of 386 randomly selected students from three universities. A comparative study was carried out. The data was analyzed using a descriptive and inferential statistical approach. A total of 340 students completed the Healthy Lifestyle and Personal Control Questionnaire (HLPCQ), which aims to assess the concept of empowerment through a constellation of daily activities. The article presents the results of the medical and non-medical students and sociological study aimed at assessing the ideas and motivational attitudes of medical students towards a healthy lifestyle and its elements.

Results: The findings reveal that healthy lifestyle behaviors toward all the students were moderate level within 79.3%, 74% (M±SD=105.22 ± 9.545), (M±SD=106.00 ± 9. 539) for medical and non-medical colleges students respectively. Our research showed that students at medical schools, while recognizing the importance of preserving their own health, are still largely committed to an unhealthy lifestyle, secondly, they refuse sports activities even more often than non-medical students, and, thirdly, they prove not to be active enough when it comes to disease prevention and health preservation.

Conclusion: Although lifestyle medicine knowledge is valued by medical students, appears to be ineffective in preventing worsening lifestyle behaviors. This is especially concerning as physicians are unlikely to provide effective guidance if they cannot sustain healthy behaviors themselves. Taking into consideration the obtained results, healthy lifestyle among students at medical schools is an exception rather than common practice.

Introduction/Objectives: CrossFit has gained immense popularity over the last two decades[1,2,3], leading to an increased number of injuries, particularly to the upper extremities. Due to its competitive nature and high-repetition workouts, shoulder injuries are prevalent among CrossFit athletes, more so than traditional weightlifting. This multicenter study aims to familiarize clinicians

with CrossFit and review shoulder pathologies in young CrossFit athletes using MRI and clinical examination.
Patients/Methods: A survey was conducted among 47 CrossFit student-athletes from 5 different Universities. Forty-one participants (mean age: 23.5 years; 25 males, 16 females) with chronic shoulder pain underwent clinical and MRI examinations.
Results: The most common injuries included partial lesions of the supraspinatus tendon (48.78%), labral lesions (24.39%), subscapularis tendon lesions (17.07%), pulley lesions (12.19%), and infraspinatus muscle lesions (4.8%).
Conclusions: This study highlights the need for awareness and prevention of shoulder injuries in CrossFit [3,4]. Understanding injury patterns allows for targeted training adaptations and therapy. It is the first study to present structural shoulder changes in young CrossFit athletes.
Discussion: Current CrossFit research is limited, with most studies being case reports or series [3,4]. Although shoulder injuries are well-documented, high-level studies identifying modifiable risk factors and improving safety in training are needed.
Keywords: CrossFit; Exercise; Injury; Shoulder Injuries; Rotator cuff injuries
Limitations: Further research is needed to investigate whether the current findings hold for student population

ANXIETY AND DEPRESSION AMONGST MEDICAL STUDENTS VERSUS NON-MEDICAL STUDENTS IN EUROPEAN UNIVERSITIES

E. Matzaroglou-Heristanidu[1], C. Matzaroglou[2], M. Kremmyda[3], M. Kouzeli[4], M. Matzaroglou-Chairistanidou[4], A. Kouzelis[5], M. Diamantakis[1], C. Koutserimpas[2], M. Tsekoura[2], E. Billis[2], E. Athanaselis[6], P. Antzoulas[5], J. Gliatis[5], P. A. Alexopoulos[7]

Objectives/ Introduction: Professional concern about perceived increases in student - mental health problems raises questions about whether questionnaire assessments can provide valid estimations of such disorders. The aim of this study was to validate the Hospital Anxiety and Depression Scale (HADS) against DSM-IV diagnoses in university students [1,2]. The target of the study is to assess the prevalence of anxiety and depressive symptoms in medical students compared to students of other faculties, and the possible impact those symptoms have on academic and educational achievements of the students.
Material and Methods: One hundred and fifty – eight students were administered with the HADS followed by the Structured Interview for DSM-IV. A cross-sectional study was conducted in this sample of 158 students: 45 medical students, 44 Physiotherapy students, 17 Nursing students and 52 non- health related students. All students anonymously completed a socio-demographic survey and the Hospital Anxiety and Depression Scale (HADS). Statistical analysis was performed using the Mann-Whitney test, Spearman correlation coefficient or Kruskal Wallis test. Results: We found a total prevalence of 20.8% (n = 33) for anxiety symptoms and 4.4% (n = 7) for depressive symptoms. Being a medical student was more significantly associated with symptoms of anxiety ($p = 0.032$) compared with other "categories" of students. Being a physiotherapy and nursing faculty student, was more significantly associated with NO symptoms of anxiety ($p = 0.022$) compared with others. Depressive symptoms were NOT associated with poor academic performance ($p < 0.01$) in all «categories»: of students. A percentage of 75.7% (n = 25) of students with anxiety symptoms and 71.4% (n = 5) of students with depressive symptoms did not "search" for medical or psychological care at that time. High HADS anxiety scores were not significantly associated with other measured indicators of serious mental health problems.
Discussion: Medical students in this sample seem to have more symptoms of anxiety than Physiotherapy and Nursing students. possibly explained by heavier and harder curriculum program in "Medical Faculties" and a higher number of female students in that sample. Depressive symptoms could not have an evident correlation with poor academic performance [1,3,4].
Conclusion: Considering the high levels of anxiety symptoms [1,4,5,], the possible impact of depressive symptoms in academic performance and the lack of psychiatric or psychological follow-up reported in this study, it is urgent to develop adequate means of support to improve students' well-being and mental health.
Limitations: Further research is needed to investigate whether the current findings hold for student populations with higher social diversity.

INTELLIGENT SYSTEM PREDICTING RECOVERY OF SPINAL CORD INJURY PATIENTS BASED ON CLINICAL & ELECTROPHYSIOLOGICAL ASSESSMENT

D. Chrysanthakopoulou[1], C. Koutsojannis[2], E. Trachani[1], C. Koutserimpas[1], S. Koffas[3], C. Matzaroglou[1]

[1]Unit of Neuromuscular Disorders of University Hospital of Patras and Department of Physiotherapy, University of Patras, Patras, Greece, [2]Health Physics & Computational Intelligence Laboratory, Physiotherapy Department, School of Health Rehabilitation Sciences, University of Patras, Patras, Greece, Patras, Greece, [3]Department of Orthopedic surgery, Inselspital, University Hospital , Bern, Switzerland, Bern, Switzerland

Objective: The pronounced association between Evoked Potentials (EPs) and American Spinal Injury Association (ASIA) scores in individuals with Spinal Cord Injury (SCI) indicates that EPs may serve as dependable predictive markers for the progression of rehabilitation. Numerous studies have confirmed that variations in somatosensory evoked potentials (SEPs) demonstrate a relationship with ASIA scores, particularly during the early stages of the disease. Additionally, Machine Learning (ML) has witnessed a notable increase in significance within the medical field, primarily due to the increasing availability of health-related data and progressive enhancements in machine learning algorithms. The present study aims to apply ML techniques to identify predictors linked to the progression of SCI as assessed by the disability index, ASIA Impairment Scale (AIS), and final motor recovery. Aiming to quantify the role of Electrophysiological testing including Sensory evoked potentials (SEPs), Motor Evoked Potentials (MEPs), and Nerve Conduction Studies (NCSs) additively used with clinical assessment in the prognostication of SCI, the present approach aided to formulate predictive models for disease progression, tailoring treatments adapted to each patient rehabilitation needs. The strategic utilization of data driven models could considerably elevate the quality of patient care, reduce healthcare costs, and promote the formulation of personalized and effective medical interventions.
Methods: We analyzed empirical data obtained from a free medical database consisting of 125 records resulted from a retrospective analysis of 748 individuals from the European Multicenter Study about Spinal Cord Injury (NCT01571531), showing associations between corticospinal tract (CST) sparing and upper extremity recovery in SCI, which improves the prediction of hand muscle strength recover as presented form Balbinot et al. (2023).Clinical assessment, as well as electrophysiological including Sensory evoked potentials (SEPs), Motor Evoked Potentials (MEPs), and Nerve Conduction Studies (NCSs) were taken as inputs for the prognostication of SCI based on upper limb Motor recovery and ASIA score. Different ML algorithms (Neural Networks, Decision Trees, Naïve Bayes and Ensemble algorithms as Voting) were tested to identify the best predictors (Figure 1).
Results: Most approaches revealed EPs as the best predictors compared with other Electrophysiological studies. Throughout our experimental evaluation, SEPs achieved an accuracy of 80%, which is close to the full electrophysiology evaluation that obtained an accuracy of 89% and are mostly better than MEPs and NCSs results for AIS scale determination. Additionally, SEPs achieved accuracies of 90%, which are comparable to full electrophysiology evaluation that obtained accuracies of 93%, and mostly better than MEPs and NCSs results for motor recovery prediction. SEPs could be established as the best predictors comparable to global electrophysiology assessment of SCI, resulting in more accurate efficacy than other diagnostic findings. Finally, an intelligent system was developed to predict the motor recovery of SCI incorporating the algorithm with the best accuracy performance (Table 1).
Conclusion: According to our results as well as other recent clinical studies, electrophysiology assessment should always be included, when available, as it elevates the total accuracy from only clinical investigation up to 93% (from at most 75%) for final motor recovery prediction, ASIA score determination, and consequently disease follow-up, up to 89% (from at most 66%). More data is needed to certify the above results. Finally, the Decision Support system that was developed as the objective alternative to ASIA scale, with the use of only sensory electrophysiology assessment data, resulted in up to 86% accuracy. Further investigation is necessary to quantify the importance of sensory electrophysiology assessment, which is significantly less expensive, portable, and simpler to administer than other prognostic tests, and more effective than clinical assessment methods, independently functioning as biomarker for SCI scaling and prediction of recovery possibility.

DOES THE INTERFACING ANGLE BETWEEN PEDICLE SCREWS AND SUPPORT RODS AFFECT CLINICAL OUTCOMES AFTER POSTERIOR THORACOLUMBAR FUSION?

C. Matzaroglou[1], D. Noriega[2], R. Eastlack[3], S. Spitz[4], V. Papathanidis[5], J. Gliatis[5], T. Stavropoulos[5], K. Kafchitsas[6]

[1]Unit of Neuromuscular Disorders of University Hospital of Patras and Department of Physiotherapy, University of Patras, Patras, Greece, [2]Department of Orthopaedics, University Hospital of Valladolid, Calle Ramon y Cajal, Valladolid, Spain., Valladolid, Spain, [3]Department of Orthopaedics, Scripps Clinic, N Torrey Pines Rd, La Jolla, CA, USA., La Jolla, United States, [4]Department of Neurosurgery, Northside Hospital, Northside Cherokee Blvd, Canton, GA, USA., Canton, United States, [5]Department of Orthopedic Surgery, University Hospital of Patras, Patras, Greece, [6]Asklepios Orthopaedic Clinic Lindenlohe, Lindenlohe, Schwandorf, Germany, Lindenlohe, Germany

Introduction/Purpose: Proper alignment and tightening of the pedicle screw/rod assembly after instrumented posterior fusion of the lower spine is known to be crucial in order to achieve satisfactory clinical results [1,2,3]. Such interfacing angle mismatches indicate stress overloading of the implant system. The objective of this study is to investigate the incidence of postoperative screw/rod interfacing angle mismatch and to analyze the impact of mismatches on clinical outcome in terms of (1) revision surgery, (2) adjacent segment degeneration (ASD), and (3) pain. This is a monocentric retrospective observational study.

Methods: Revision refers to subsequent procedures in which all or part of the original implant configuration is changed or removed. Radiographic parameters are evaluated using a/p and lateral radiographs at final follow-up. The interfacing angle mismatch between pedicle screw and rod is measured as the angle between two parallel lines on either side of each pedicle screw head and a line laterally along the associated rod. Multiple comparisons are counteracted by Bonferroni correction, adjusted significance level is at *p<.01.

Patient sample: Patients underwent fusion surgery with pedicle screw/rod systems for predominantly degenerative pathologies.

Outcome measures: Pedicle screw/rod interfacing angle mismatch (mismatch is the angular deviation from 90° formed by the rod axis and the pedicle screw head axis as an indicator for missing form-fit) revision rate, ASD at the immediately adjacent cranial segment and VAS pain.

Results: Pedicle screw and rod interfacing angle mismatch was found in 171/406 (42.1%) of patients undergoing fusion surgery, affecting 613/3016 (20.3%) screws. The overall revision incidence was 11.8% (48/406), and a new ASD occurred in 12.1% of all patients (49/406) with an average follow-up of 5 years. Mean VAS pain score at final follow-up was 2.0. Comparison of the two groups with and without mismatches revealed statistically significantly higher (1) numbers of revision procedures performed (26.9% vs 0.9%), (2) numbers of new ASD developed (27.5% vs 3.8%), and (3) higher VAS pain scores (2.8/10 vs 1.4/10) for cas-

es with mismatch. When comparing patients who underwent intraoperative correction and/or reduction with those who did not, statistically significant more screw mismatches (63.4% vs 39.7%) and revision surgeries (29.3% vs 9.9%) were noted in patients who had these forceful maneuvers.
Conclusions: Pedicle screw/rod interfacing angle mismatch is a frequent occurrence [4,5] after fusion surgery. Mismatches indicate that the construct was assembled under mechanical stress. All preventable mechanical stresses, for example, unintentional uncontrolled forces on the instrumentation, should be avoided as much as possible, as they can negatively influence the clinical outcome.

PSEUDOARTHROSIS OF THE OS - ACROMIALE IN BOXER-ATHLETES: THE IMPORTANCE OF DIAGNOSIS FOR SUCCESSFUL CONSERVATIVE TREATMENT WITH THERAPEUTIC EXERCISE

G. Petropoulou[1], S. Chatzivasilis[1], C. Koutsojannis[2], E. Trachani[1], K. Fousekis[1], S. Koffas[3], J. Gliatis[4], C. Matzaroglou[1]

[1]Unit of Neuromuscular Disorders of University Hospital of Patras and Department of Physiotherapy, University of Patras, Patras, Greece, [2]Health Physics & Computational Intelligence Laboratory, Physiotherapy Department, School of Health Rehabilitation Sciences, University of Patras, Patras, Greece, Patras, Greece, [3]Department of Orthopedic surgery, Inselspital, University Hospital , Bern, Switzerland, Bern, Switzerland, [4]Department of Orthopedic Surgery, University Hospital of Patras, Patras, Greece

Objectives/Introduction: Normally, the acromion of the scapula is formed by the synostosis of secondary ossification nuclei, but failure in this process leads to the formation of a fibrocartilaginous connection of the os acromiale (You et al., 2019, Macalister 1893). The incidence of os acromiale varies from 0.7% to 8.5%, depending on the population studied (Kumar et al., 2013, Aibinder et al., 2017, Sammarco 2000, Boehm et al., 2005, Rovesta et al., 2017), while the global prevalence appears to be around 7% (Yammine 2014). Hypotheses for the etiology of the pathology include mechanical stress and genetic causes, although there does not seem to be a bilateral expression of os acromiale. The diagnosis of os acromiale is difficult because patients often describe chronic pain symptoms similar to those of subacromial impingement, rotator cuff tear, such as painful and limited range of motion above head height, as well as pain when sleeping in a supine position on the affected side (Neer 1983, lebus et al., 2017, Guo et al., 2019). The os acromiale is usually evident on conventional radiographs, especially on ax-

illary radiographs (Ulrich et al., 2018, Burbank et al., 2007).The purpose of thiw study was to document the history and physiotherapy interventions for the treatment of a painful shoulder in four boxer-athletes, who was initiallyattributed to tendonitis, edema and a possible acromial stress fracture, before the diagnosis of os acromiale. Also the presentation of a successful post-diagnosis exercise program for the treatment of symptomatic os acromiale with follow-up 3 years after the intervention. **Patients and Methods**: Three right-handed boxer – athletes (17 -21 years old) with severe pain in the left acromion area, especially during abduction movements, but also during palpation, and positive clinical tests Neer, Hawkins, Whipple and Yocum tests examined. The athlete followed a series of physiotherapeutic interventions lasting 2 years without success until the diagnosis of os acromiale was made with MRI - CTs. After the diagnosis, the athletes followed a strengthening program of 11 exercises for a total duration of 8 months, (5X10 repetitions, 4 times a week). **Results**: After the implementation of the 8-month exercise program, full range of motion in abduction was achieved, painless abduction with resistance, painless palpation of the acromion in all patients. Also, the clinical tests Neer, Hawkins, Whipple, Yocum were negative. After the 8-month period of implementation of the exercises to treat the os acromiale, the athletes returned to systematic exercise and sports and continue with maintenance exercises3 times a week. Three years later, following the maintenance program 3 times a week, he has no pain, nor any limitation in shoulder movements. **Conclusions:** The treatment of the acromion in athletes involved many challenges. Initially, in the first therapeutic approaches, the acromion (os acromiale) was not diagnosed as the cause of the imaging findings. Thus, the exercise regimen that was applied was to strengthen the rotator cuff muscles, due to the symptoms that referred to subacromial friction syndrome. Then, due to the nature of the sport of boxing, which requires strong tachydynamic muscle contractions in abduction, internal and external rotation of the shoulder. Also, movements above shoulder height when appropriate, as well as responding to rapid reaction movements of the opponent during boxing. Finally, the patient's age and the type of acromion (convex type II according to Bigliani), which did not allow for a surgical approach, as the possibility of permanent motor dysfunction, as well as rejection of the bone graft, could not be ruled out. The holistic approach through exercise used here focused on the global strengthening of the shoulder joint (focused strengthening of the rotator cuff and stabilization of the scapula of the affected side), with a greater number of exercises. In conclusion, shoulder pain can be due to a multitude of pathologies, with similar symptoms, so the need for a clear diagnosis of an os acromiale as a source of pain and dysfunction and the exclusion of other pathologies becomes important, while it is a necessary condition for a successful conservative treatment, focused on the pathology. Equally important is the maintenance program that must be followed systematically, in order to maintain the strength of the muscles in the area, especially in the affected shoulder.

Key words: os acromiale, shoulder pain, conservative treatment, boxing

CROSS-CULTURAL ADAPTATION FOR FREEZING OF GAIT'S QUESTIONNAIRE ON PARKINSON'S PATIENTS IN GREEK LANGUAGE

A. Ignjatovic[1], A. Giannouli[2], C. Matzaroglou[1], S. Lampropoulou[2]

[1]University of Patras, Physiotherapy Department, Rio, Greece,
[2]University of Patras, Physiotherapy Deprtment, Rio, Greece

Introduction: Patients with Parkinson's, which is one of the most common degenerative neurological diseases, have frequent gait disturbances, difficulty in taking the first step and "freezing" during their gait. The Freezing of Gait Questionnaire (FoGQ) is perhaps the only self-reported means of assessing this symptom, but it is not available in English.

Purpose: The present study conducted as part of a pre-graduate thesis aims at the cross-cultural adaptation of the Freezing of Gait Questionnaire in Greek and the pilot application of the final translated version in a group of Parkinson's patients in order to test comprehension and reliability.

Materials and Methods: With the authors' approval, the questionnaire was adapted into Greek through forward translation, re-translation and necessary modifications. It was distributing to 10 Parkinson's patients (5 male, 5 female), following written consent to ensure content understanding. Inter-rater reliability was tested by comparing responses from two independent raters, while test-retest reliability was evaluated by redistribution the questionnaire, after 14 days. Statistical analysis was performed using the intraclass correlation index (ICC), with the SPSS version 28.1.

Results: The translations were implemented without any particular difficulty and the pilot implementation demonstrated full understanding of the content of the translated questionnaire. Both inter-rater reliability (ICC=0.901, p>0.001) and inter-rater reliability (ICC=0.901, p>0.001) were found to be extremely high. The internal consistency index came out very high (cronbach's α = 0.835).

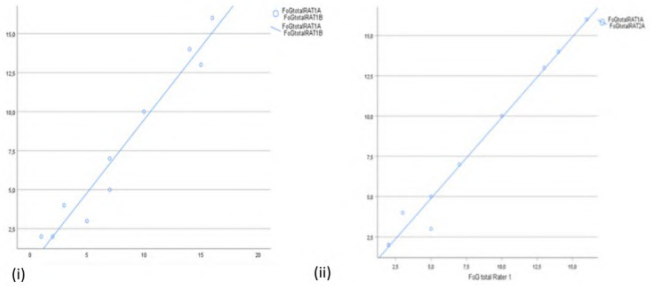

Figure 1: Reliability assessment i) between first (A) and second (B) assessment *(test-retest reliability)* and ii) between first (RAT1) and second (RAT2) raters *(inter-rater reliability)* on FoG questionnaire total score (n=10)

Conclusions: This study suggests a reliable, user-friendly tool with high consistency across assessors and repeated measures. Further testing on a larger sample is needed to assess validity, responsiveness, and sensitivity before widespread use in Greek clinical settings.

Keywords: Parkinson, freezing of gait questionnaire, reliability

BILATERAL ARM TRAINING VERSUS CONSTRAINT INDUCED MOVEMENT THERAPY FOR IMPROVING UPPER LIMB MOTOR FUNCTION AND DEXTERITY AFTER STROKE, A SYSTEMATIC REVIEW

E. Papadimitriou[1], T. Bania[2], V. Sakellari[3], C. Matzaroglou[1], S. Lampropoulou[2]

[1]University of Patras, Physiotherapy Department, Rio, Greece,
[2]University of Patras, Physiotherapy Deprtment, Rio, Greece,
[3]University of West Attica, Department of Physiotherapy., Athens, Greece

Objective Among many treatments to improve motor function and dexterity of the hemiplegic upper limb (UL) post stroke (1) are bilateral exercise (BAT) and restrictive motor therapy (CIMT)(2), (3). The present study aims to compare the effectiveness of the two methods on the motor function and skill of AA after stroke.
Materials and Methods Systematic review of randomized control trials in the electronic databases Pubmed, PEDro and Science Direct from 01/01/2000 to 31/12/2022 in English, with keywords defined by PICO (Population, Intervention, Comparison, Outcome) and MeSH terms. Quality assessment was performed using the Cochrane risk of bias 2 (RoB2) tool for RCTs. Data were extracted in terms of outcome measures for motor function, activities of daily living and dexterity.
Results After searching the databases, in total 20827 articles were collected. By removing duplicates and checking the inclusion and exclusion criteria, 134 studies were included for full text screening and from these finally 5 studies were included in the systematic review. Total sample consisted of 198 participants, of which 138 patients (3 studies) were in the chronic stage, 30 patients (1 study) in the subacute stage and 30 patients (1 study) in the acute stage. The duration of the therapeutic intervention ranged from 3 to 4 weeks. When controlling for bias, two studies were classified as "low risk" and three as "high risk" (Fig 2). Significant improvement was seen in motor function with both the application of CIMT and BAT. Moderate evidence was found for the superiority of BAT over CIMT in improving proximal UL movement disorders. Also with moderate evidence, CIMT was revealed as more effective than BAT in activities of daily living. Finally, regarding the dexterity, the results were contradictory as far as the superiority of BAT compared to CIMT was concerned.

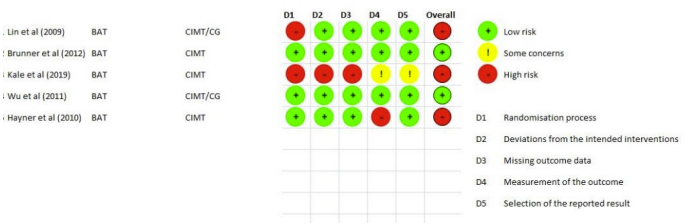

Figure 1. Risk of Bias assessment of the 5 Randomized Controlled Trials finally included in the Systematic Review, as it was conducted with the RoB tool of Cochranes´ Library

Conclusions The lack of evidence regarding the superiority of either intervention, alongside the positive effects of both on UL motor function and dexterity highlights both equally for UL retraining after stroke. Future systematic investigations may include motor assessment and meta-analysis.
Key words: stroke, hemiplegia, bimanual exercise, constraint induced movement therapy, motor function

«THE EFFECTIVENESS OF A PILATES PROGRAMME IN THE IMPROVEMENT OF STATIC AND DYNAMIC BALANCE IN PATIENTS WITH MULTIPLE SCLEROSIS

A. Tatsi[1], I. Papakosta[1], D. N. Provata[1], S. Xergia[2], C. Matzaroglou[2], S. Lampropoulou[1]

[1]University of Patras, Physiotherapy Deprtment, Rio, Greece,
[2]University of Patras, Physiotherapy Department, Rio, Greece

Objective The aim of this study is to assess the effectiveness of Pilates method in the enhancement of static and dynamic balance (1,2), in comparison to conventional physiotherapy program in patients with Multiple Sclerosis (3).
Materials and Methods A total of eighteen patients, participated in the study (8 males, 10 females, of 58±8 years of age), and they were divided equally into two intervention groups (Pilates, conventional therapy) and one control group. Intervention programs were undertaken 2 times per week, in 45 minutes-sessions, for a total of 8 weeks. Assessments were conducted before the initiation of the intervention (baseline), in the middle of the intervention (4 weeks), at the end of the intervention (8 weeks) and one month later (follow up). The primary outcome measures were the static and dynamic balance. The assessment tools consisted of a stable force platform «Bertec Acquire 4», the scale «Mini Balance Evaluation System Test», the «Functional Gait Assessment» scale and the «Short Physical Performance Battery» scale. The secondary outcome measures included the lower limb motor function through the «Fugl – Meyer Sensorimotor Assessment».
Results The duration of the single-leg support on the left lower limb increased in the intervention groups for both the Pilates method (3.9±1.85 sec) and the conventional physiotherapy (1.2±0.55 sec) compared to the control group, in which the duration decreased by 1.87±0.42 sec. The CoP displacement area in all static balance tests on the force platform («eyes open, legs together», «eyes closed, legs together», «single standing on left-leg», «single standing on right-leg», «tandem left», «tandem right»), did not show

statistically significant differences, both within groups due to the intervention and between the groups. Furthermore, the overall performance on the mini-BESTest improved in both the Pilates (by 3.29±1.7 in the total score), and in the conventional physiotherapy group (by 4.6±2 in the total score), compared to the control group in which it decreased by 1.6±6.7. These results did not lead to statistically significant differences (p>0.05) (Fig. 1). Dynamic balance, as assessed through walking, recorded a statistically significant improvement after the intervention (F(1.81, 25.36)=6.59, p=0.006, np2=0.32), but without a statistical difference between the groups (p>0.05).

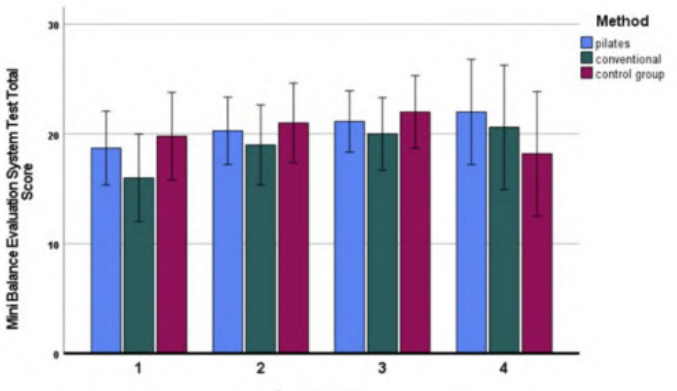

Figure 1: Changes in balance, as assessed by the Mini Balance Evaluation Systems Test (mini-BESTest) scale (total scores), between baseline (1st measurement), mid- intervention (2nd measurement), at the end of the intervention (3rd measurement) and during the repeated measurement (follow up) one month after the end of the intervention (4th measurement). Data from (n=17 patients).

Conclusion Results suggest that Pilates method improved the static and dynamic balance and lower limb mobility, however it does not surpass conventional therapy. In conclusion, further research is required in the future.

THE EFFECT OF RESISTANCE - EXERCISE ON ALKALINE PHOSPHATASE LEVELS IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS AND SARCOPENIA

C. Matzaroglou[1], J. Gliatis[2], G. Petropoulou[1], S. Chatzivasilis[1], K. Fousekis[1], S. Xergia[1], P. Antzoulas[2], A. Kouzelis[2], C. Koutserimpas[1], M. Tsekoura[1]

[1]Unit of Neuromuscular Disorders of University Hospital of Patras and Department of Physiotherapy, University of Patras, Patras, Greece, [2]Department of Orthopedic Surgery, University Hospital of Patras, Patras, Greece

Introduction/Objectives: Alkaline phosphatase (ALP) is an enzyme that plays an important role in the calcification of osteoid (the non-calcified part of bone) and mineralization. The cell membrane of osteoblasts is rich in alkaline phosphatase, the concentrations of which increase in the blood when there is intense activity by osteoblasts. Alkaline phosphates are widely used as a marker of bone formation, but is not specific for bone turnover (Marini et al., 2020). Total ALP is examined by measurements of the alkaline phosphatase enzyme in the bloodstream (Kuo et al., 2017). The aim of the study was to examine the effect of a 6-month resistance exercise program on blood alkaline phosphatase levels in postmenopausal women with osteoporosis and sarcopenia who were not previously exercising.

Patients and Methods: A total of 46 women aged 59.06±7.56 years, body weight 74.78±6.79 kg, height 156.93±7.23 cm participated in the study and established the typical inclusion criteria [postmenopausal women with sarcopenia and osteoporosis]. Of these, 35 individuals aged 54.2±7.81 years, body weight 79±8,69 kg, height 159.8±6.32 cm, completed the initial and final blood sampling before the start and at the end of the 6-month exercise program for the measurement of alkaline phosphatase. The exercise program was performed 3 times a week for 60 minutes each time. It included resistance exercises of the large muscle groups of the upper and lower extremities in 4 sets of 10 repetitions with dumbbells, bars and elastic straps as well as the use of body weight. In six women which had the economic "capacity" biomarkers (IL-6, TNF, CRP, P1NP, sCTX) were measured also.

Results: Blood alkaline phosphatase levels increased by an average of 11% in the second blood draw (104.8±39.1) compared to the first blood draw (93.8±38.1), approaching 42% in some cases, however with a large variation. Also looked at the levels of inflammatory biomarkers (IL-6, TNF, CRP) in a group of 6 postmenopausal women before and after the six-month exercise intervention - training dramatically decreased IL-6, TNF-, CRP. Procollagen type 1 N-terminal peptide (P1NP) also increased significantly after six months of training, while collagen type 1 cross-linked C-telopeptide (sCTX) did not rise significantly (K. Zemanidis 2023).

Conclusion/Discussion: Systematic 6-month resistance exercise in postmenopausal women had a positive effect on increasing osteoblastic activity, as assessed by blood alkaline phosphatase concentrations. The present study outlines the beneficial effect of resistance training in postmenopausal women, preventative and therapeutically. The optimal program has not yet been determined. Heterogeneity of studies creates ambiguity in the production of guidelines. Higher-quality studies provide evidence that axial loading at moderate to high intensities combined with progressive resistance training is the most efficient stimulus (K. Zemanidis 2023). Our study outlines, that, even for women with low to extremely low BMD, and sarcopenia, high-intensity exercise seems to be a safe treatment strategy when done under the right supervision.

SHORT- AND LONG-TERM EFFECTS OF SOFT TISSUE MOBILIZATION AND EXERCISE ON SWAY BACK POSTURE AND CERVICALGIA PATIENTS

K. Mylonas[1], G. Chatzis[1], P. Angelopoulos[1], E. Tsepis[1], C. Matzaroglou[1], K. Fousekis[1]

[1]University of Patras, Physiotherapy Department, Patras, Greece

Objectives: The study was conducted to compare the short- and long-term effect of combined soft tissue mobilization techniques (massage and Ergon IASTM Technique) along with a comprehensive strengthening and stretching exercise program for correction of sway back posture and reduction of neck pain in cervicalgia and postural abnormalities.
Material and Methods
Thirty participants (12 males, 18 females) aged 20–34 years suffering from neck pain for at least three months and exhibiting sway back posture were randomized into two Group A was given soft tissue mobilization techniques and strengthening and stretching exercises for cervical and thoracic areas. Group B did all the same, with the addition of trunk exercises. Both groups received 4 weeks of therapy (3 times/week) and performed exercises at home until the 8th week. Assessments performed at the baseline, after the 6th and 12th sessions, and at the 8th and 16th weeks included forward head projection, trunk sway, lumbar lordosis, cervical range of motion (ROM), neck muscle strength, and pain (VAS).
Results Both groups experienced significant improvements in forward head projection, trunk sway-back posture, and pelvic tilt following treatment. The differences in forward head and sway-back posture were significantly improved for group B (intervention + trunk exercises) at 8th week. Group A and Group B both demonstrated improvements in ROM, but Group B was superior in flexion, right lateral flexion and rotation, while Group A demonstrated superiority in extension and left lateral flexion. The strength of cervical flexion and extension was superior in Group B until the 8th week. Pain relief was significant for groups until the 12th session, with Group B reporting greater relief. No group maintained benefits at the 16th-week follow-up.
Conclusions A combined intervention of soft tissue mobilization, strengthening, and stretching exercises for the trunk and cervical region can improve postural alignment, ROM, and pain in individuals with sway back posture and cervicalgia. Long-term benefits require ongoing intervention to sustain improvements.

P364

THE EFFECTS OF ERGON IASTM TECHNIQUE AND CORE STABILITY TRAINING ON THE SWAY BACK POSTURE AND PAIN IN PATIENTS WITH KNEE OSTEOARTHRITIS

K. Mylonas[1], P. Angelopoulos[1], E. Billis[1], C. Matzaroglou[1], K. Fousekis[1], E. Tsepis[1]

[1]Univesity of Patras, Physiotherapy Department, Patras, Greece

Objectives: To investigate the effect of the Ergon IASTM Technique, along with local knee strengthening exercises and core stability exercises, to improve sway back posture and decrease pain in patients with knee osteoarthritis. Material and Methods: A total of 18 participants (9 women, 9 men) with sway back posture and knee osteoarthritis were randomly assigned to either a control group (n= 7) and experimental group (n= 5). Group A received 10 minutes of massage, 20 minutes of Ergon Technique, knee strengthening and knee stretching. Group B performed the same protocol with core stability exercises and trunk stretching. The intervention was delivered over 6 weeks, consisting of 12 sessions (2 per week). Participants continued with a home-based exercise program during the study. Also, images on the sagittal plane were taken for postural evaluation by observing (1) forward head posture, (2) the angle of trunk sway, (3) pelvic tilt, and (4) knee hyperextension. Pain was assessed with the Visual Analog Scale (VAS). Results: There was a significant improvement ($p < 0.05$) in forward head posture and trunk sway angle after the first session in both groups. However, these gains were not sustained over the following sessions. No difference in change in pelvic tilt occurred in either group. Pain scores in both groups improved significantly during the first seven sessions ($p < 0.05$), with Group B showing a significantly higher reduction in pain in comparison to Group A ($p = 0.022$). Conclusions: Combining the Ergon Technique, knee strengthening and core stability exercises decreased pain levels more than group A. Incorporation of the core stability exercises likely enhances the outcomes of soft tissue mobilization in patients with knee osteoarthritis and sway back posture.

NEUROMUSCULAR PREDICTORS OF PERFORMANCE IN THE MODIFIED ATHLETIC SHOULDER TEST IN SWIMMERS

C. Tsarbou[1], N. Liveris[1], Z. Kokkinakis[1], A. Bakaraki[1], A. Skoura[1], E. Billis[1], C. Matzaroglou[1], E. Tsepis[1], S. Xergia[1]

[1]Department of Physiotherapy, School of Health Rehabilitation Sciences, University of Patras, Patras, Achaia, Greece

Objectives

The modified Athletic Shoulder Test (mASH) (2) is an innovative upper extremity assessment tool suitable for replicating shoulder muscle contraction in sports involving repetitive overhead movements such as swimming (1). However, the neuromuscular factors associated with mASH test performance have not yet been elucidated.The present study aimed to identify neuromuscular predictors of mASH performance in swimming athletes.

Materials and Methods

Eighteen (18) healthy swimmers (13-17 years old) underwent a holistic musculoskeletal assessment during the pre-season period, which included: the mASH test, the assessment of isometric strength of the internal rotators (IR) and external rotators (ER) of the shoulder with a handheld dynamometer, the Closed Kinetic Chain Upper Extremity Stability (CKCUES) test to assess shoulder stability, the Biering-Sorensen test to assess back muscle endurance, the Shoulder Endurance Test (SET) to assess the endurance of shoulder external rotators, the Posterior Endurance Shoulder Test (PSET) to assess the endurance of the trapezius muscles, as well as the range of motion of shoulder external rotation. The stepwise multiple regression models included the variables with a significant correlation ($p<0.05$).

Results

In the full abduction position (180 degrees) in the mASH test, the regression model included only the strength of the IR (Adjusted R-Square (Adj.R^2) 0,532, p=0,000) on the left and the strength of the IR along with CKCUES (Adj.R^2 0,55 $p<0.05$) on the right. At 135 degrees in mASH test, the model involved only ER strength (Adj. R^2 0,406 p=0,003) on the left and IR strength along with trapezius endurance on the right (Adj.R^2 0,63, $p<0,05$). In the 90-degree position in the mASH test, the model included the strength of the IR on the left (Adj.R^2 0,336, p=0.007) and on the right hand respectively (Adj.R^2 0,519, p=0,000).

Conclusions

IR and ER strength, shoulder stability, and trapezius muscle endurance contribute to mASH test performance, with IR strength being the most dominant factor. Exercises that strengthen these muscle groups may positively contribute to mASH test performance.

TACROLIMUS REDUCED CELL VIABILITY OF RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES THROUGH INHIBITION OF AUTOPHAGIC FLUX

C. N. Son[1], K. M. Kim[2], J. W. Hur[3], H. J. Jung[4], J. K. Kim[4], S. H. Kim[5], W. K. Baek[4]

[1]Department of Rheumatology, Uijeongbu Eulji Medical Center, Eulji University School of Medicine, Uijeongbu, South Korea, [2]Eulji Rheumatology Research Institute, Eulji University, Uijeongbu, South Korea, [3]Department of Rheumatology, Nowon Eulji Medical Center, Eulji University School of Medicine, Seoul, South Korea, [4]Department of Microbiology, Keimyung University School of Medicine, Daegu, South Korea, [5]Division of Rheumatology, Department of Internal Medicine, Keimyung University School of Medicine, Daegu, South Korea

Objectives: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that causes inflammation and pain, and is characterized by hyperplasia of the synovial membrane and cartilage destruction. Tacrolimus is calcineurin inhibitor that inhibits inflammatory, and regulates cell death through the autophagy pathway during kidney and liver damage. But the mechanism underlying the effect of tacrolimus in RA remains unclear. We aimed to investigate the effect of tacrolimus on human fibroblast-like synoviocyte-rheumatoid arthritis (HFLS-RA), and determine whether it induces apoptosis.

Material and Methods: Cell viability and cell cycle progression were analyzed using hemocytometry and flow cytometry, respectively, after treating HFLS-RA with tacrolimus. Western blot analysis was performed by pretreating the cells with the autophagy inhibitors 3-Methyladenine(3-MA) and Bafilomycin A1(BafA1) to determine the effect on expression of proteins LC-3 and p62. To analyze the effect of tacrolimus on lysosomal function of tacrolimus, flow cytometry analysis was performed using LysoTracker, and Confocal was confirmed via double-staining for LAMP-1 and LC-3.

Results: When HFLS-RA was treated with tacrolimus at 0-80 μM, the cell viability decreased in a concentration-dependent manner to 20%, 60%, and 93%, respectively, and in a time-dependent manner to 23%, 53% and 65%, respectively at 8-24h. Regarding the cell cycle progression, the number of cells in the sub-G1 stage increased in a concentration-dependent manner (control: 6.05%, 40 μM: 11.5%, 60 μM: 33.45%, and 80 μM: 61.5%). Increased LC-3 II protein expression and decreased p62 protein expression were offset when cells were treated with the autophagy inhibitor 3-MA, but not when they were pretreated with BafA1. Confocal confirmed an increase in the formation of LAMP-1 puncta in HFLS-RA treated with tacrolimus, however, LC-3 was within the nucleus, and puncta were barely formed.

Conclusions: Our findings revealed that tacrolimus does not induce apoptosis in RA but induces autophagy. During autophagy, lysosomes accumulate in cells owing to lysosomal dysfunction, suggesting that apoptosis may occurs. Further research is needed to elucidate the precise mechanism by which tacrolimus induc-

es cell death by lysosome dysfunction in autophagy, and understanding these interactions will aid in the development of future targeted therapies.

P367

LOW-DOSE FEBUXOSTAT EFFECTIVELY REDUCES URIC ACID LEVELS IN GOUT PATIENTS WITH CHRONIC KIDNEY DISEASE: RESULTS FROM THE TWO-YEAR FOLLOW-UP STUDY OF THE URATE LOWERING THERAPY (ULTARA) REGISTRY

C. N. Son[1], Y. J. Oh[1], J. W. Hur[2]

[1]Department of Rheumatology, Uijeongbu Eulji Medical Center, Eulji University School of Medicine, Uijeongbu, South Korea, [2]Department of Rheumatology, Nowon Eulji Medical Center, Eulji University School of Medicine, Seoul, South Korea

Objectives: Gout is an inflammatory arthritis caused by hyperuricemia and is highly prevalent in patients with chronic kidney disease (CKD). Reduced renal function in CKD patients impairs uric acid excretion, contributing to the development and progression of gout. This study aimed to analyze longitudinal changes in uric acid levels according to stages of CKD in patients with gout. In addition, febuxostat dosage was compared in the normal and CKD groups over a 2-year period.

Material and Methods: A total of 516 patients enrolled in the Urate Lowering TheRApy (ULTARA) registry over a 2-year period were compared to the uric acid levels at baseline, 6 months, 1 year, and 2 years among the normal, CKD stage 3 and CKD stage 4-5 groups. The febuxostat dosage at each time point was compared in 182 patients who were exclusively using febuxostat in this registry.

Results: The baseline uric acid levels were significantly higher in CKD 3 and 4-5 groups (9.0 ± 1.9 mg/dL and 10.2 ± 2.0 mg/dL) compared to normal group (8.4 ± 1.7 mg/dL, P<0.001). After urate-lowering therapy, the uric acid levels were lower in CKD groups compared to those in normal group over a 2-year period. Meanwhile, among the patients using febuxostat, the mean dosages of febuxostat were lower in CKD groups (40.5 ± 17.6, 39.2 ± 13.8, 40.0 ± 12.6 in CKD stage 3, and 40.0 ± 20.0, 37.5 ± 22.5, 20.0 ± 0.0 in CKD stage 4-5) compared to those in normal group (47.7 ± 19.1, 48.1 ± 20.2, 60.0 ± 20.0) at 6-month, 1year and 2years, respectively.

Conclusion: In gout patients with CKD, uric acid levels were well-controlled with urate-lowering therapy, even though the lower febuxostat dosage compared to that in patients with normal renal function. Therefore, uric acid levels can be effectively reduced in CKD patients using lower doses of febuxostat.

P368

FRACTURE RISK IS ASSOCIATED WITH INTRINSIC CAPACITY IN OUTPATIENTS ASSESSED FOR OSTEOPOROSIS

C. Oliveri[1], P. Furfaro[1], E. Giovinazzo[1], C. Parisi[1], C. Guidara[1], N. Morabito[1], G. Basile[1], M. Cesari[2], A. Catalano[1]

[1]University of Messina, Messina, Italy, [2]University of Milan, Milan, Italy

The incidence of fragility fractures has become an urgent health issue as the global population ages. Intrinsic capacity (IC) is defined by the World Health Organization (WHO) as the combined physical and mental capabilities an individual can draw on.

Objective: This study investigates the association of IC with fracture risk in postmenopausal women.

Material and Methods: The five domains of IC model were assessed in accordance with the Integrated Care for Older People (ICOPE) guidelines. Patients' characteristics including comorbidities evaluated by the Charlson Comorbidity Index (CCI), the FRAX derived 10-yr clinical risk for fragility fracture, BMD detected by DXA and muscle strength measured by Jamar dynamometer, were also taken into consideration.

Results: 202 postmenopausal women (mean age 68.1 ± 8.6 yr) were consecutively recruited. All but 5 (2.5%) presented impairment in at least one IC domains. By classifying the participants into groups according to FRAX- i.e. low, intermediate, and high fracture risk - a significantly different distribution of patients with IC impairment was observed (p<0.05). The number of compromised domains was positively associated with the 10-yr probability of major osteoporotic fracture (r=0.392, p<0.001) and the CCI (r=0.335, p<0.001); and it was negatively associated with handgrip strength (r=-0.471, p<0.001). At multiple regression analysis, the preserved visual function was associated with reduced prevalence of fragility fracture (OR=0.2545, CI 0.0693 to 0.9349). The very high fracture risk (FRAX score >20%) was independently associated with hearing loss (OR=2.3908, CI 1.2689 to 4.5046), malnutrition (OR=4.0114, CI 1.5091 to 10.6630) and limited mobility (OR=2.7898, CI 1.4650 to 5.3127); the latter (OR=0.4370, CI 0.2416 to 0.7904) was also associated with osteoporosis at the lumbar spine.

Conclusions: Our data suggest that IC evaluation could help physicians to identify patients at high fracture risk and may be promoted as routinary assessment in older persons.

P369

ROLE OF PLATELETS AND SYSTEMIC INFLAMMATION INDEX AS A MARKER OF FRACTURE RISK IN POST MENOPAUSE

C. Oliveri[1], A. Di Giovanni[1], F. Malacarne[1], S. Crescimone[1], M. C. Furci[1], A. Midili[1], N. Morabito[1], G. Basile[1], A. Catalano[1]

[1]University of Messina, Messina, Italy

Emerging experimental evidence highlights the potential involvement of platelets in the regulatory mechanisms underlying bone remodeling and the repair process following a fragility fracture.
Objective: The aim of our study was to investigate the role of platelets and the systemic inflammation index in postmenopausal women with osteoporosis.
Material and Methods: The following variables were evaluated from a complete blood count: platelet count, mean platelet volume (MPV), platelet distribution width (PDW), plateletcrit (PCT), percentage of large platelets (P-LCR), platelet-lymphocyte ratio (PLR), and the Systemic immune-inflammation index (SII, calculated as (NxP)/L, where N, P, and L are the counts of neutrophils, platelets, and lymphocytes, respectively). Bone mineral density (BMD) was measured using gold-standard dual-energy X-ray absorptiometry (DXA).
Results: Participants (n=124) were stratified into two groups according to the median platelet count; the "lower platelet count group" had a count of 200,000 (174,000 to 226,000), while the "higher platelet count group" had a count of 281,500 (256,500 to 308,500). A borderline significant difference (p=0.08) was noted for hip fracture risk, with a higher risk in the "higher platelet count group". A statistically significant difference was found in lumbar spine BMD between the two groups, with lower BMD in the "higher platelet count group" (p=0.03). Dividing the participants based on SII into two groups (higher and lower SII, respectively 950848.6±746097.9 vs 355751.2±88662.6; p <0.0001) a different estimated 10-year probability of femoral fracture was observed between the group with a higher SII value compared to the group with a lower value (10.5±10 vs 5.2±4.8%; p=0.01). Univariate regression analysis revealed a correlation between chronological age and PDW (r=0.188, p=0.047), and P-LCR (r=0.208, p=0.03), and an association between vitamin D status and P-LCR (r=-0.301, p=0.034).
Conclusion: The SII and total platelet count are markers of fracture risk and, due to their reproducibility and cost-effectiveness, their role could be further investigated in future prospective studies to enhance screening models for postmenopausal osteoporosis and fragility fractures.

P370

EXPANDING THE SCOPE OF THE FUNCTIONAL REACH TEST INDEX: COULD IT DETECT SARCOPENIA IN OLDER ADULTS?

C. Kilic[1], S. Ozkok[2], Z. Sahin Tirnova[2], C. Ozer Aydin[3], H. Ozalp[2], T. Erdogan[2], G. Bahat Ozturk[2], M. A. Karan[2]

[1]Istanbul University Istanbul Medical School Department of Internal Medicine Division of Geriatrics, Istanbul, Turkiye, [2]Istanbul University Istanbul Medical Faculty Department of Internal Medicine Division of Geriatrics, Istanbul, Turkiye, [3]Istanbul Goztepe City Hospital Department of Internal Medicine Division of Geriatrics, Istanbul, Turkiye

Amaç
Çalışmanın temel amacı, denge ve düşme riskini değerlendirmek amacıyla kullanılan fonksiyonel erişim test indeksinin (FRTI) yaşlı bireylerde sarkopeni ile ilişkili bağımsız bir parametre olup olmadığını değerlendirmek ve farklı sarkopeni tanımlarını öngören eşik değerini belirlemektir.
Malzemeler ve yöntemler
Bu kesitsel çalışmaya, ayakta tedavi gören 60 yaş ve üzeri hastalar dahil edildi. FRT, katılımcıların sabit bir pozisyonda ayakta dururken dengelerini kaybetmeden öne doğru uzanabildikleri maksimum mesafenin ölçülmesiyle gerçekleştirildi. FRT sonuçları boydan etkilendiği için, FRTI elde etmek için FRT ölçümü boy için ayarlandı. Muhtemel ve doğrulanmış sarkopeni tanımları kullanıldı: El kavrama gücünü değerlendirmek için bir Jamar hidrolik el dinamometresi kullanıldı ve kas kütlesi değerlendirmesi için bioelektrik empedans analizi kullanıldı. Temel demografik ve klinik veriler kaydedildi ve tüm katılımcılar için kapsamlı geriatrik değerlendirme yapıldı. Düşük FRTI ile sarkopeni tanımları arasındaki ilişki, tek ve çok değişkenli analizler kullanılarak değerlendirildi. Sarkopeniyi öngören optimum FRTI değerlerini belirlemek için ROC analizi yapıldı.
Sonuçlar
411 katılımcının %70,3'ü (n=289) kadındı (ortalama yaş 74,1±6,7 yıl). Ortalama FRTI 0,182 ± 0,03 cm/cm idi ve cinsiyetler arasında anlamlı bir fark yoktu. FRTI<20. persentil (<0,152 cm/cm) düşük FRTI olarak kabul edildi. Yaş, cinsiyet, BMI, eşlik eden hastalık sayısı ve geriatrik sendromların listesi ayarlandıktan sonra, düşük FRTI hem olası hem de doğrulanmış sarkopeni ile bağımsız olarak ilişkilendirildi (OR = 2,32 (95% CI = 1,05-5,12)] ve OR = 3,11 (1,35-7,15), sırasıyla). Muhtemel sarkopeniyi öngörmek için optimum FRTI eşiği ≤0,180 cm/cm (AUC = 0,789; duyarlılık = %87, özgüllük = %56,7) olarak belirlenirken, doğrulanmış sarkopeniyi öngörmek için eşik ≤0,173 cm/cm (AUC = 0,795; duyarlılık = %78,9, özgüllük = %66,5) olarak belirlendi.
Çözüm
Denge ve düşme riski değerlendirmesi için kullanılan FRTI, yaşlı yetişkinlerde sarkopeni riskini aynı anda değerlendirebilir. Bu nedenle, sarkopeni değerlendirmesi için zaman veya ekipman kısıtlamaları olan ortamlarda, düşme riski olan bireyler daha etkili bir şekilde belirlenebilir.

P371

ROMOSOZUMAB IMPROVES BONE MICROARCHITECTURE MEASURED BY TISSUE THICKNESS-ADJUSTED TRABECULAR BONE SCORE AT SIX MONTHS: A REAL-WORLD STUDY FROM OSWESTRY, UK

C. Rakieh[1], C. Mennan[1], S. Ho[2], T. Robert[1], J. Cole[1], B. Tins[3], D. Powell[1]

[1]Metabolic Bone Department, Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, United Kingdom, [2]Care of the Elderly, Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, United Kingdom, [3]Radiology Department, Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, United Kingdom

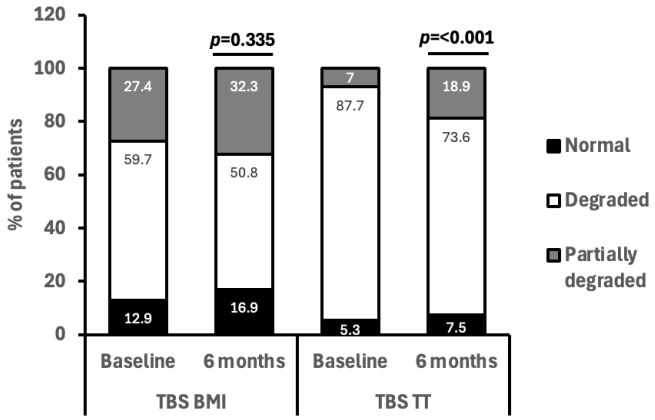
Objectives:
An updated trabecular bone score (TBS) algorithm accounting for regional soft tissue thickness (v4 TBS_{TT}) at lumbar spine (LS) has been developed to address some limitations associated with the body mass index (BMI)-corrected TBS (v3 TBS_{BMI}). This study evaluated early changes in bone microarchitecture measured by both TBS versions and bone mineral density (BMD) in response to romosozumab at six months in a real-world setting.

Materials and Methods:
This prospective observational study included postmenopausal women with osteoporosis and prior fractures initiated on romosozumab in a UK metabolic bone service. Percentage changes in TBS_{TT}, TBS_{BMI}, and BMD (Hologic Horizon®) at LS, total hip (TH), and femoral neck (FN) were assessed at six months using paired t-tests. TBS scores from both algorithms were categorised as normal (TBS > 1.31), partially degraded (1.23 < TBS ≤ 1.31), and degraded (TBS ≤ 1.23), with distributions at baseline and 6 months compared using Pearson chi-square tests. Response at six months was also assessed using least significant change (LSC).

Results:
Data from 69 patients (mean age 75.5 ± 7.2 years; 65% with vertebral fractures, 18% with hip fractures) were analysed. Baseline mean LS T-score was -2.65 (±1.3), FN T-score -2.8 (±0.7), and TBS_{TT} 1.160 (±0.06). Significant improvements in the group mean TBS_{TT} were observed (2.12%, p =0.003), while TBS_{BMI} increased numerically (1%, p = 0.290). BMD improved significantly at the LS (9.6%), FN (3.3%), and TH (3.5%), all p<0.001. Using LSC, a favourable response was observed for 83.8% of patients for LS BMD compared to 28.4% at TH, 34.3% at FN, p<0.05. Increases in TBS_{TT} and TBS_{BMI} exceeded LSC for 38% and 35% of patients, respectively. By 6 months, the proportion of patients with degraded TBS_{TT} decreased from 87.7% to 73.6%, while normal TBS_{TT} increased from 5.3% to 7.5% (p < 0.001). TBS_{BMI} distributions showed no significant changes (Figure 1).

Conclusions:
Romosozumab significantly improved bone microarchitecture as assessed by the tissue thickness-adjusted TBS (v4 TBS_{TT}) within 6 months. This version was more sensitive to change than TBS_{BMI} and should be considered in clinical trials and routine practice to evaluate treatment response.

Figure 1. Percentage of patients by TBS_{BMI} and TBS_{TT} risk category: Baseline vs. 6 months



P372

VALIDATION OF 30-DAY MORTALITY PREDICTION MODELS FOR HIP FRACTURES USING THE NSQIP DATABASE

Z. A. Issa[1], R. Yammine[1], C. Rhayem[1], A. Ghosn[2], J. S. Alwan[3], G. El-Hajj Fuleihan[1]

[1]American University of Beirut, Beirut, Lebanon, [2]Memorial Sloan Kettering, New York, United States, [3]Children's Hospital of Michigan, Detroit, United States

Objective: This study aims to validate our previously developed calculators to predict 30-day mortality, preoperatively and on-discharge, following hip fractures, using the National Surgical Quality Improvement Program (NSQIP) 2018–2020 database.
Material and Methods: We identified 58,840 hip fracture patients from the NSQIP 2018–2020 database and applied the originally derived equations and beta estimates from the same calculators we developed based on a prior database (2011-2017). The baseline characteristics of the populations in both databases were comparable. The only exception were some changes in the procedure used. Open reduction and internal fixation were less common, and intramedullary fixation became more prevalent, in the 2018-2020 database. We assessed performance using area under the curve (AUC) values for discrimination and Hosmer-Lemeshow goodness-of-fit test for calibration.
Results: The calculators maintained strong predictive performance in the updated cohort. The preoperative parsimonious model (10 variables: male gender, age, lower BMI, white race, poorer functional health status, higher creatinine, lower hematocrit, >10% weight loss in the prior 6 months, congestive heart failure within 30 days before surgery, and chronic obstructive pulmonary disease) achieved an AUC of 0.750 (R^2 = 0.9855), compared to 0.739 in the original cohort. The preoperative full model (16 variables) achieved an AUC of 0.755 (R^2 = 0.9836) compared to 0.742 in the original cohort. On-discharge parsimonious model (11 variables: all preoperative predictors except white race, hematocrit and > 10% weight loss in the prior 6 months, with the addi-

tion of unplanned intubation, cerebrovascular accident, myocardial infarction, and pneumonia) demonstrated an AUCs of 0.814 (R^2 = 0.999), and the full (27 variables) model an AUC of 0.826 (R^2 = 0.998), compared to 0.800 and 0.813, respectively, in the original cohort.

Conclusion: The validation of our mortality calculators using the NSQIP 2018–2020 cohort demonstrates sustained robust performance. This study highlights the continued relevance and utility of the parsimonious calculators for real-world clinical applications.

Disclosures: All authors declare having no conflict of interest with regards to the submitted work.

Figure. Area Under the Curve (AUC) for the Various 30-Day Mortality Prediction Models.

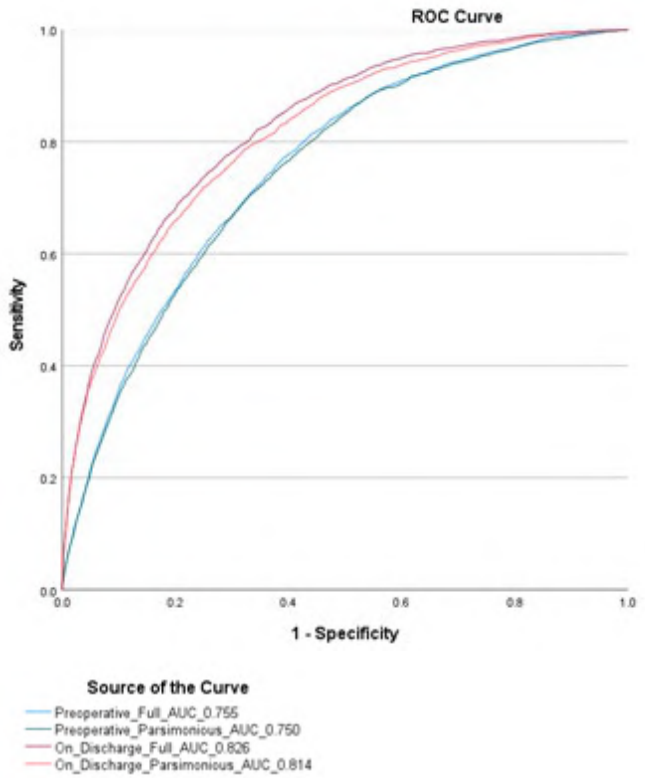


Figure legend. The preoperative full model consists of 16 variables, the preoperative parsimonious model of 10 variables; the on-discharge full model consists of 27 variables, and the on-discharge parsimonious model of 11 variables. Variables detailed under Results.

IMPACT OF THE SECONDARY PREVENTION PROGRAM FOR FRAGILITY FRACTURES AT THE ORTHOGERIATRIC PROGRAMA AT FUNDACIÓN SANTA FE DE BOGOTÁ (FSFB) BETWEEN 2014-2024

A. M. López[1], C. Rojas-Osorio[1], C. M. Olarte[1], V. Canedo-Pelaez[2], R. Pesantez[1], A. Patiño[1], V. Sanint[1], J. Salavarrieta[1], D. C. Morales[1], M. X. Meneses[1]

[1]Hospital Universitario Fundación Santa Fe de Bogotá, Bogotá, Colombia, [2]Universidad de Los Andes, Bogotá, Colombia

Objective(s): Assess the impact of the Secondary Prevention Program for Fragility Fractures at the Orthogeriatric Program of FSFB from 2014 to 2024, focusing on osteoporosis management outcomes and fragility fracture reduction

Materials and Methods: We analyzed a retrospective cohort study of 701 patients with hip fracture who underwent surgical management.

We used multivariate logistic regressions controlled for age, sex, BMI, screening for osteoporosis, pharmacological management for osteoporosis, preoperative levels of calcium, vitamin D and PTH and indication for osteoporosis treatment and bone densitometry at discharge.

Results: The mean age of patients was 83 years (SD: 8), with 77.5% being women and 22.5% men. The mean body mass index (BMI) was 19 (SD: 3). The program cares for a mean of 64 patients annually.

At the beginning of the program, it was not common to perform osteoporosis screening or provide treatment after discharge. Given the high-quality evidence supporting the importance of secondary prevention programs, we have implemented our secondary prevention program and these are the results: In 2014, 0% of patients were prescribe for osteoporosis however, over time, this improved: in 2022, 2023, and 2024, treatment was prescribed for 88.7%, 87%, and 66% of patients, respectively. Refracture rates for the hip or other bones were 11.6%, 5.6%, and 9.1% in 2022, 2023, and 2024, respectively. 51% of the patients who experienced a refracture had been prescribed osteoporosis treatment at discharge. However, we do not have data from previous years to compare the impact of osteoporosis treatment on fracture prevention. Vitamin D levels at admission were significantly associated with refracture rates: patients who refractured had a mean level of 24 ng/mL (SD: 11), compared to 28 ng/mL (SD: 13) in those without refractures ($p < 0.05$). Other variables were not significantly associated with refracture rates.

Conclusion (s): Our study highlights the significant progress in osteoporosis management within our orthogeriatric program, demonstrating a substantial increase in treatment prescription rates over the years. Vitamin D deficiency remains a major factor associated with refractures.

Disclosure: The author (s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this study.

PREDICTORS OF 1-YEAR MORTALITY IN OLDER ADULTS WITH HIP FRACTURES TREATED IN A JCI-CERTIFIED ORTHOGERIATRIC CLINICAL CARE PROGRAM

A. M. López[1], C. Rojas-Osorio[1], C. M. Olarte[1], J. L. Rojas[1], R. Pesantez[1], A. Patiño[1], V. Sanint[1], J. Salavarrieta[1], D. C. Morales[1], J. Tihanyi[1], J. D. Bernate[1], A. Libos[1]

[1]Hospital Universitario Fundación Santa Fe de Bogotá, Bogotá, Colombia

Objective(s): To assess one-year mortality and its predictive factors in older adults with hip fractures managed within a Joint Commission International (JCI)-certified Orthogeriatric Clinical Care Program (CCP) over a ten-year period.
Materials and Methods: This retrospective analysis of prospectively collected data included patients aged ≥65 years with hip fractures treated at Fundación Santa Fe de Bogotá between 2014 and 2024. Of 638 patients initially assessed, 411 were included in the final logistic regression model. Variables evaluated included age, sex, preoperative hemoglobin and vitamin D levels, nutritional status (Mini-Nutritional Assessment), functional status (Parker and Barthel indices), comorbidities (Charlson index), preoperative delirium, EQ-5D health state scores and intensive care unit (ICU) requirement. Logistic regression identified independent predictors of one-year mortality, and model performance was assessed using the area under the curve (AUC).
Results: Among 638 patients, 79 (12.3%) died within one year postoperatively. Severe preoperative immobility was strongly associated with mortality, with a 5.26-fold increased risk compared to good mobility (OR = 5.26; 95% CI: 1.57–17.17; p = 0.007). Patients with preoperative malnutrition exhibited 3.25 times higher odds of mortality compared to those with normal nutrition (OR = 3.25; 95% CI: 1.30–7.04; p = 0.010). High comorbidity was associated with 3.02 times higher mortality compared to low comorbidity (OR = 3.02; 95% CI: 1.30–7.04; p = 0.010). Higher preoperative hemoglobin levels were protective, reducing mortality risk by 22% per 1 g/dL increase (OR 0.78; 95% CI: 0.66–0.92; p = 0.003). ICU requirement during hospitalization was associated with 2.48-fold higher odds of mortality (OR = 2.48; 95% CI: 1.17–5.25; p = 0.017), while males were at increased risk compared to females (OR = 2.41; 95% CI: 1.05–5.57; p = 0.039). The logistic regression model demonstrated good predictive capacity (AUC = 0.822).
Conclusion(s): The one-year mortality rate of 12.3% in this cohort was notably lower than rates reported in the literature, underscoring the effectiveness of a comprehensive orthogeriatric care program. Identifying high-risk patients based on functional mobility, nutritional status, and comorbidities is critical to implementing tailored interventions and optimizing survival outcomes for older adults with hip fractures.
Disclosure: The author(s) declare no potential conflicts of interest with respect to the research, authorship, and/or publication of this study.

P375

A COST-CONSEQUENCE ANALYSIS FOR GERIATRIC PATIENTS WITH FRAGILITY HIP FRACTURES TREATED AT HOSPITAL UNIVERSITARIO FUNDACIÓN SANTA FE DE BOGOTÁ (FSFB) BETWEEN 2018 AND 2022, BOGOTÁ, COLOMBIA

C. M. Olarte[1], C. Rojas-Osorio[1], A. M. López[1], A. J. Solano[1], R. Pesantez[1], A. Patiño[1], V. Sanint[1], J. Salavarrieta[1], D. C. Morales[1], J. D. Bernate[1], A. Libos[1], K. K. Rojas[1], D. Londoño[1]

[1]Hospital Universitario Fundación Santa Fe de Bogotá, Bogotá, Colombia

Objectives: To determine the potential saving of the managing fragility hip fractures in the Orthogeriatrics Clinical Care Center (OCCC) at FSFB, compared to national and international benchmarks, using a cost-consequence analysis.
Materials and Methods: A cost-consequence study was conducted on patients aged ≥65 with fragility hip fractures who were candidates for surgical treatment, treated between 2018 and 2022 through the clinical care program at the OCCC of FSFB. This was compared to the 2022 National Annual Hip Fracture Registry of Spain and data obtained from a search of scientific publications in Colombia and worldwide. Outcomes at the time of surgery (in-hospital delirium, percentage of patients operated on within 48 hours, length of stay, and surgery time) and postoperative outcomes (surgical site infection and readmission within the first 30 days related to surgery) were considered. The analysis was performed from the perspective of the health system.
Results: The average cost of the procedure in Spain ranged from 9,231.9 to 10,723.9 dollars, in Mexico from 5,895.9 to 10,723.9 dollars, and in Colombia from 1,717.8 to 2,742.0 dollars. The outcomes at FSFB were better than the benchmark: delirium (-3.4%), patients operated on in less than 48 hours (39.2% more), length of stay (-3.92 days), and surgical site infection (-6%), while readmission rates were slightly higher by 1.06%. Due to the significant differences in costs, it was decided to keep the initial intervention and complication costs the same for both the benchmark and FSFB. This results in lower costs for short- and medium-term outcomes due to their frequency, leading to a savings of 3,235.23 dollars per individual per month of intervention. If 40% of the procedures in the city were performed by our OCCC, an annual savings of 21,399,105.31 dollars could be achieved.
Conclusions: The results demonstrate the efficiency and cost-consequence of the OCCC at FSFB in Colombia, where treatment costs are significantly lower than in Spain and Mexico. This demonstrates that higher-efficiency care model can lead to significant savings without compromising patient outcomes.
Disclosure: The authors declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this study.

P376

MEDICATION RELATED OSTEONECROSIS OF JAW; EXPERIENCE IN A TERTIARY CARE CENTRE IN UK

C. Rosa[1], S. Banerjee[1], G. Kasavkar[1], T. Blake[1], K. Chaudhuri[1]

[1]University Hospitals Coventry and Warwickshire NHS Trust, Coventry, United Kingdom

Background:
Medication related osteonecrosis of the jaw (ONJ) is a rare complication of anti resorptive therapy. It is often associated with pain, swelling, infection, exposed bone and pathological fracture of the jaw. It is known to occur after bisphosphonate therapy and denosumab which are used in osteoporosis (OP) as well as in multiple myeloma and metastatic cancers. While the risk of osteonecrosis of the jaw is much higher in patients with cancers, it is still reported in patients in whom these agents are used to treat osteoporosis.
There are additional risk factors such as IV/parenteral drug use, cancer and chemotherapy, long duration, higher dose, dental extractions, concomitant steroid use, poorly fitting dentures, smoking, diabetes and pre-existing dental issues.
Objectives:
To describe clinical characteristics of a case series of patients with osteonecrosis of the jaw
Methods:
Cohort of patients under the care of rheumatology and documented evidence of osteonecrosis of the jaw by an Orofacial maxillary surgeon were selected. Demographic characteristics, anti-resorptives used, additional risk factors and subsequent management of osteoporosis were described.
Results:
Of the 5 cases, all the patients were female. All of them were on anti-resorptive therapy when they developed ONJ. Four patients were on treatment for osteoporosis while one developed ONJ while on treatment for multiple myeloma. Of the 4 osteoporosis patients, 3 were on denosumab and another was on Alendronic acid. The other patient developed ONJ while on 3 weekly IV zoledronic acid infusions for multiple myeloma. Four cases developed ONJ after dental extractions while another occurred spontaneously on a background of poor dental hygiene. Of the 5 cases, 3 were on steroids. One was on low-dose prednisolone for rheumatoid arthritis, another was on budesonide for lymphocytic colitis and the other was on steroids as part of a chemotherapy regime.
Key message:
While fracture risk reduction following anti resorptive therapy is much higher than the chance of developing ONJ, it is important to assess the risk of ONJ prior to and during anti resorptive therapy. Patient education and proper consenting prior to initiation is of paramount importance. Dental extractions appear to be a common precipitant. Generally, the literature does suggest an increased risk of ONJ associated with denosumab which is the case in our case series. Similarly, another well-known risk factor is the use of concomitant steroids which is also seen in a majority the cases which we have described.

	Case 1	Case 2	Case 3	Case 4	Case 5
Gender	Female	Female	Female	Female	Female
Age in years	56	74	88	51	64
Risk factors For osteoporosis	Crohn's disease, inflammatory arthritis, oophorectomy	Chronic axial spondyloarthorpathy	Rheumatoid arthritis	Low body weight Lymphocytic colitis	Multiple myeloma Steroids
Fractures	Vertebral	Vertebral	No fractures	Wrist and vertebral	Vertebral
Treatment	Ibandronic acid 4 years of Denosumab	Ibandronic acid for 5 years 5 years of Denosumab	10+ years of Alendronic acid	Risendronic acid for 7 years Denosumab – two doses	IV Zoledronic acid – 3 weekly for 18 months
Risk factors	Following dental extraction Not on steroids	Following dental extraction Not on steroids	Following dental extraction Prednisolone	Following dental extraction Budesonide	No documented dental extractions Steroids as part of oncology treatments

Table 1 – demographics and clinical characteristics of our ONJ patient cohort

Objectives: Hip fracture (HF) is a catastrophic event and it is associated with several biomedical, social and economic burdens. Identifying patients at high risk of 30-day mortality may help the decision-making for the optimal treatments.
The Nottingham Hip Fracture Score (NHFS) is one of the most reliable tools for assessing post-surgery mortality. This study aims to validate the NHFS in a cohort of Italian patients with HF and to identify variables enhancing the predictive model.
Methods: A multicenter prospective study was conducted in patients who underwent surgical treatment and received comprehensive assessment at admission, with data about 30-day survival status from regional death registries. Bivariate and multivariate logistic regression analyses were performed to assess the prediction of 30-day mortality. The predictive accuracy of the NHFS and adapted scores was measured using the ROC curves.
Results: 1189 patients were included, 72.5% women, aged 84.7±7.3 years. The 30-day mortality rate was 4.3% (n = 52). The NHFS distribution showed that most patients scored between 4 and 7, with the highest concentrations at scores of 5 (31.9%, n = 379) and 6 (28.1%, n = 334). The predictive capacity of NHFS versus ASA score for 30-day mortality was tested and the Area Under the Curve (AUC) for NHFS was 0.677, compared to 0.588

for ASA score, showing no significant difference (p=0.089). The revised NHFS with the addition of METs (Metabolic Equivalent of Task Score) showed the highest predictive power with significant differences in the ROC curves, and the modified NHFS was more accurate than the original.

Conclusion: The NHFS is a reliable tool for estimating 30-day mortality in Italian orthogeriatric patients undergoing HF surgery. The combination of revised NHFS and METs may improve the prediction power and accuracy of 30-day mortality.

P378

SYNERGISTIC MODULATION OF "IL6-TGFB" AXIS ENHANCES BONE LOSS IN T1R LEPROSY REACTION

C. Saini[1], L. Sapra[1], A. Bhardwaj[1], V. Ramesh[2], P. Puri[3], R. Srivastava[1]

[1]All India Institute of medical Sciences New Delhi India, New Delhi, India, [2]ESI college and hospital, Faridabad, India, [3]Safdarjung Hospital, New Delhi, India

Introduction: Th17 cells have been previously implicated in the immunopathogenesis of T1R, contributing to both inflammation and bone loss. Cytokines such as IL-6, TGF-β, and IL-23 are critical drivers of Th17 cell differentiation. Therefore, understanding their specific roles in leprosy-associated bone loss is essential for immunotherapy.

Objective: To assess the role of IL-6, TGF-β, and IL-23 in Th17 cell differentiation augmenting bone loss in patients with leprosy T1R reaction.

Methods: 15 patients each with T1R and 15 non-reaction (NR) patients attending the leprosy OPD. For recruitment of patients, BMD was measured in the spine, femur, neck, and forearm by DXA. 48 hours PBMCs cultures were established with different combinations of recombinant human IL-6, IL-23, and TGF-β with or without *Mycobacterium leprae sonicated antigen* (MLSA). Subsequently, PBMCs cultures were blocked with either antagonized *sIL6R* or *sIL23R* antibodies. Real Time PCR was further used for gene expression analysis of *IL-17A, IL23A, IL-6, TGF-β, IL-6R, IL-23R* and *RUNX2, P1NP* (Osteoblast markers) and culture supernatant was estimated for cytokine ELISA.

Results: In this study, leprosy reactions (T1R-S) showed a significantly ($p<0.001$) high percentage of IL-17A producing $CD4^+IL6R^+$ T cells as compared to non-reaction (NR) patients. Surprisingly, osteoblast markers (*RUNX2* and *P1NP*) showed a significant ($p<0.02$) positive correlation with $CD4^+IL6R^+$ T cells. Furthermore, recombinant IL-6, IL-23, and TGF-β significantly ($p<0.001$) promoted IL-17A in $CD4^+IL6R^+$ T cells. Subsequently, IL-6R and IL-23R blocking experiments showed significantly ($p<0.01$) downregulated IL-17A in T1R reaction as compared to NR leprosy patients. Although, gene and protein expression of Osteoblast markers (*RUNX2* and *P1NP*) in IL-6R and IL-23R blocking experiments showed a significantly ($p<0.01$) positive correlation ($r^2=0.74$) with IL-17 production.

Conclusion: This study for the first time establishes that pathogenic Th17 cells produce IL-17 via IL-6R pathway in leprosy T1R reactions. Secondly, leprosy reactions and steroid treatment have enhanced levels of pathogenic/inflammatory Th17 cells and thus could lead to leprosy reaction mediated bone loss. The study has clinical implicationsn with respect to the management of bone health in leprosy disease conditions.

P379

RADIOFREQUENCY ECHOGRAPHIC MULTY SPECTROMETRY (REMS) FOR THE ASSESSMENT OF BONE FRAGILITY IN MASTOCYTOSIS

C. Stomaci[1], E. Casciaro*[2], F. R. Contaldo*[1], F. Conversano*[2], M. Di Paola*[2], R. Franchini*[2], F. A. Lombardi*[2], G. Luceri*[3], G. Peluso*[4], P. Pisani*[2], A. C. Stetco*[1], S. Casciaro[2]

[1]University of Salento, Department of Biological and Environmental Sciences and Technologies, Lecce, Italy, [2]National Research Council, Institute of Clinical Physiology, Lecce, Italy, [3]R&D Department, Echolight S.p.a., Lecce, Italy, [4]University of Salento, Department of Innovation Engineering, Lecce, Italy

*Equal contributor in alphabetic order

Objective(s): Mastocytosis (MC) is a rare disease characterized by the abnormal accumulation of mastocyte, leading to a persistent allergic response and subsequent inflammation. One of the most commonly affected tissues is bone characterized by reduced bone mineral density (BMD), fragility fracture, and bone pain. Bone loss seems to primarily affect trabecular bone more than cortical one,[1] likely due to the direct colonization of mastocytes in the bone marrow. Therefore, the quality assessment of bone microarchitecture in patients affected by mastocytosis (MCp) is crucial.

This study aims to evaluate the impact of MC on the quality of bone microarchitecture by using the REMS-based Fragility Score (FS) parameter. The FS is an indicator of skeletal fragility independent of BMD, ranging from 0 to 100, where 100 indicates the maximum similarity to a fractured model, and 0 indicates the maximum similarity to a healthy model.

Material and Methods: A total of 35 MCp patients were enrolled and compared to a healthy control group (HC) matched for age and BMI. All patients underwent REMS scans of the proximal femur, and the difference in FS values between the 2 study groups was evaluated using a t-test.

Results: The mean REMS-FS was significantly higher in MCp patients (78.8 ± 6.7) than in the HC (38.1 ± 18.9) ($p<0.0001$). As shown in Figure 1, the FS accurately discriminates between the 2 groups.

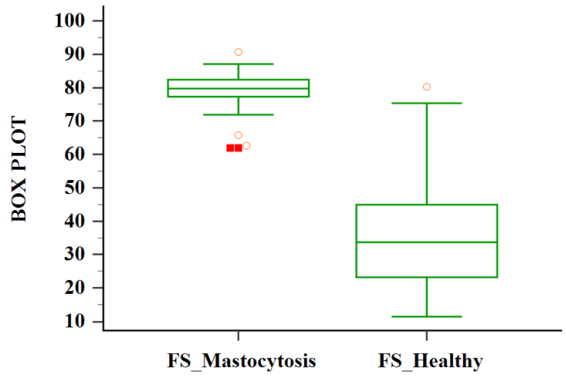

Figure 1

Conclusion(s): This study, as expected, shows a significant deterioration in bone quality in MCp patients. These findings highlight the importance of assessing bone microarchitecture quality in MCp through the REMS-based FS parameter.

THE ASSOCIATIONS OF 10-YEAR INCIDENT VERTEBRAL AND NON-VERTEBRAL FRACTURES WITH MUSCLE PARAMETERS: INSIGHTS FROM THE OSTEOLAUS COHORT

C. Vendrami[1], E. Gonzalez Rodriguez[1], G. Guillaume[1], P. Vollenweider[2], P. Marques-Vidal[2], O. Lamy[2], D. Hans[1], E. Shevroja[1]

[1]Interdisciplinary Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital and University of Lausanne, Switzerland, Lausanne, Switzerland, [2]Department of Medicine, Internal Medicine, Lausanne University Hospital and University of Lausanne, Switzerland, Lausanne, Switzerland

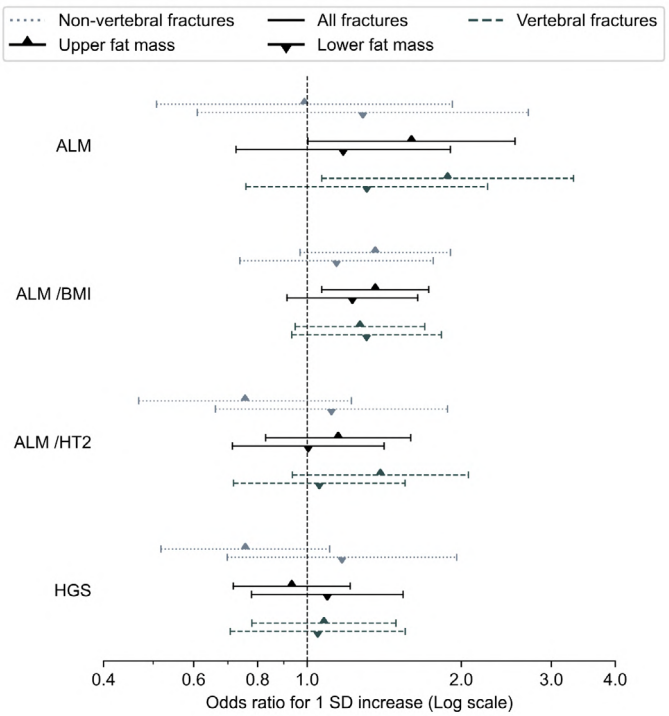
Objectives: Muscle parameters are associated with falls, fractures, and mortality, but the results vary across studies. We explored the associations of muscle strength and mass with 10 years incident vertebral and non-vertebral fractures.

Materials and methods: We followed 1475 postmenopausal women aged 50–80 years (OsteoLaus cohort, Lausanne, Switzerland) each 2.5 years for 10 years. Handgrip strength (HGS) was assessed with a Jamar dynamometer, and lean mass (LM) and appendicular LM (LMA) was assessed by DXA. Primary outcomes included hip, humerus and forearm low-trauma fractures identified via in-person interviews (non-vertebral fractures) and radiological vertebral fractures. For crossectional analysis baseline values were compared via two-sided t tests or Wilcoxon tests (Bonferroni adjustment: significative if $p<0.0028$). In the prospective study multivariate logistic regression models were used to retrieve the odds ratio (OR), 95% confidence interval (CI).

Results: After 10.2±0.4 years of follow-up, 944 women remained enrolled (age 73.0±6.9 years, BMI 25.7±4.8 kg/m^2, ALM 16.8±2.5 kg, HGS 21.2±5.5 kg), 260 of whom experienced fractures, including 174 vertebral and 107 non-vertebral fractures. Compared with nonfractured participants, participants with an incident fragility fracture had a 1.5 kg lower HGS at baseline but no significant difference in their ALM, ALM/height^2 or ALM/BMI. HGS was also not significant in the multivariate model. One SD increase in ALM (+2.58kg) or total body LM (+5.38kg) was associated with a 1.65 (CI:1.09–2.49) and 1.89 (CI:1.15–3.11) greater risk of vertebral fractures over 10 years, respectively, but not at shorter follow-up periods. There was no association with ALM/height^2 or ALM/BMI. No association was demonstrated for non-vertebral fractures. Further 2nd- and 3rd-order regressions did not provide a better visual fit. Baseline muscle parameters were not different for participant with or without incident fall or death.

Conclusions: Lean mass is an independent risk factor for incident vertebral fractures over 10 years but not for non-vertebral fractures. Mechanical and endocrine differences could explain this weight dependence in vertebral and non-vertebral fractures. Further studies are needed with greater sample sizes, other muscle assessment modalities, and considering the previous limitations.

Figure 1. Subgroup analysis by fracture type and fat mass median



P381

MACHINE LEARNING FOR THE PREDICTION OF FRAGILITY FRACTURES BY BONE AND BODY COMPOSITION PARAMETERS: FINDINGS FROM THE OSTEOLAUS 10 YEARS POPULATIONAL COHORT

C. Vendrami[1], G. Gatineau[1], E. Gonzalez Rodriguez[1], O. Lamy[2], D. Hans[1], E. Shevroja[1]

[1]Interdisciplinary Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital and University of Lausanne, Switzerland, Lausanne, Switzerland, [2]Department of Medicine, Internal Medicine, Lausanne University Hospital and University of Lausanne, Switzerland, Lausanne, Switzerland

Objectives: Recent reviews highlighted the potential value of artificial intelligence in improving fragility fracture prediction. However, no studies have comprehensively integrated bone and body composition metrics from Dual X-ray Absorptiometry (DXA) in fracture prediction models. We aim to analyse the prediction of fragility fractures using regional and total body DXA assessments using a machine learning pipeline.

Material and methods: 1475 Swiss post-menopausal women (age 64.5±7.6years, body mass index 25.9±4.5kg/m^2) from the Osteo-Laus cohort were followed for 10 years (2010-2022). Parameters of bone health (hip and spine DXA: 34 variables) and body composition (Whole body DXA: 65 variables) were assessed by DXA scans. Vertebral fractures were screened with lateral DXA. Other risk factors (15 variables) and fragility fractures were collected from questionnaires. These parameters were tested separately or combined (114 variables) in different datasets. All datasets were split for training (85%) and testing (15%) with a balanced fragility fractures proportion. Models were trained using logistic regression, multilayer perceptron, random forest, and XGBoost, with hyperparameters optimized through grid search and 5-fold internal cross-validation, to maximize the area under the curve (AUC).

Results: 590 to 957 participants were included in the final complete case analyses, with 237 fragility fractures. Across all models and datasets, the training AUC values ranged from 0.69 to 1.0, while the test AUC values ranged from 0.55 to 0.78. The combination of bone, body composition and fracture risks parameters in the same dataset achieved the best test AUC (0.65-0.78). Logistic regression demonstrated the best balance between performance (AUC 0.78) and generalizability (specificity 0.66, recall 0.69). Other models showed varying trade-offs between overfitting and reduced test performance (eg. XGBoost: AUC 0.72, specificity 0.82, recall 0.25).

Conclusions: These findings emphasize the value of combining DXA-derived bone and body composition parameters for fragility fracture prediction in postmenopausal women. While logistic regression produced the most promising results in this preliminary study, the other models remain at interest for further analysis in combination with image based analysis. Further studies including a comparison with FRAX®, larger sample size and external validation are needed.

P382

TERIPARATIDE-ASSOCIATED OSTEOSARCOMA: A 20-YEAR RETROSPECTIVE STUDY USING REAL-WORLD DATA FROM THE EUDRAVIGILANCE DATABASE

C. Vilafanha[1], S. F. Azevedo[1], A. Barcelos[1]

[1]Rheumatology Department, Unidade Local de Saúde da Região de Aveiro, Aveiro, Portugal

Objectives: Teriparatide is a recombinant human parathyroid hormone analog that stimulates osteoblastic activity, promoting new bone formation. It is used to treat osteoporosis and has demonstrated well-established clinical efficacy. However, concerns about a potential link between teriparatide and osteosarcoma, based on preclinical studies, have limited its broader application. We aim to evaluate osteosarcoma's occurrence as a suspected adverse event of teriparatide in a real-world pharmacovigilance database.

Material and Methods: This study employed the EudraVigilance public version database to collect suspected adverse reactions (SARs) of teriparatide, focusing on osteosarcoma cases, between January 2005 and December 2024. Only SARs reported by healthcare professionals were included. SARs possibly related to other drugs and duplicated cases were excluded. Data including age group, sex, therapeutic indication and outcome were retrieved from the public database. A descriptive analysis of the available data was performed.

Results: Over the study period, 16,614 reports of SARs related to teriparatide were submitted to the EudraVigilance database. Of these, 15 reports involved osteosarcoma, accounting for 0.09% of all teriparatide-associated SARs.

Most cases concerned patients from outside the European Economic Area (86.7%), and the majority were women (71.4%) aged between 65 and 85 years (60.0%). All patients with available treatment indication data were being treated for osteoporosis. Among patients experiencing these SARs, 5 (33.3%) are known to have had a fatal outcome. Every case was considered serious by the reporter. In four reports, osteosarcoma was reported alongside other neoplastic conditions, including one case each of lung cancer, urothelial carcinoma, ductal breast carcinoma, and chondrosarcoma.

Conclusions: Real-world data are valuable in identifying rare side effects, particularly in diverse patient populations. In our study, osteosarcoma is a rare adverse event associated with teriparatide, with a very low incidence in the EudraVigilance database. Given the small number of cases, it isn´t possible to establish a cause-effect relationship.

P383

PREVALENCE AND ASSOCIATED RISK FACTORS OF SARCO-OSTEOPOROSIS AMONG COMMUNITY-DWELLING OLDER ADULTS IN TAIWAN

C.-C. Chou[1], C.-F. Huang[1], W. P. Chan[2], C.-H. Wu[3]

[1]En Chu Kong Hospital, New Taipei City, Taiwan, [2]Wan Fang Hospital, Taipei, Taiwan, [3]National Cheng Kung University Hospital, Tainan, Taiwan

Objective:
Sarcopenia and osteoporosis are significant age-related conditions that share risk factors and pathophysiological mechanisms. Their co-occurrence, termed 'sarco-osteoporosis,' may lead to adverse health outcomes. This study aimed to determine the prevalence of sarco-osteoporosis and identify its associated risk factors among community-dwelling older adults in central Taiwan.

Materials and Methods:
We conducted a cross-sectional study of adults aged ≥65 years in Changhua County, Taiwan. Bone mineral density and whole-body appendicular muscle mass were measured using mobile dual-energy X-ray absorptiometry (DXA, Horizon, Hologic Inc). Muscle strength and physical performance were assessed via handgrip strength and 6-meter gait speed tests. Participants completed questionnaires covering medical history, the Study of Osteoporotic Fractures (SOF), and lifestyle habits including exercise. Osteoporosis was defined as a T-score ≤-2.5 in either lumbar spine or hip. Sarcopenia was defined according to the Asian Working Group for Sarcopenia (AWGS 2019) criteria. Age-standardized prevalence was calculated using the 2010 Taiwan population and housing census and 2001 WHO age standardization rates.

Results:
The study enrolled 163 community-dwelling older adults (80.4% female, mean age 75.5 years). Raw prevalence rates were 66.9% for osteoporosis, 22.1% for sarcopenia, and 16.6% for sarco-osteoporosis. Age-standardized prevalence rates per 100 persons weighted by Taiwan standard population were 63.8, 20.3, and 15.2 for osteoporosis, sarcopenia, and sarco-osteoporosis, respectively. When weighted by world standard population, the rates were 62.2, 19.0, and 14.3 per 100 persons. Multivariate logistic regression analysis identified four independent risk factors for sarco-osteoporosis: body mass index (OR 0.643, 95% CI 0.522-0.794), frailty (OR 5.083, 95% CI 1.177-21.948), hypertension (OR 3.932, 95% CI 1.312-11.788), and exercise habit (OR 0.306, 95% CI 0.106-0.882). The prediction model was defined as: Logit(p) = −0.847 + 0.009(Sex) + 0.031(Age) − 0.441(BMI) + 1.51(Frailty) + 1.31(Hypertension) − 1.213(Exercise).

Conclusions:
Sarco-osteoporosis is prevalent among older adults in Taiwan. Lower body mass index, frailty, and hypertension were associated with increased risk, while regular exercise was protective. These findings highlight the importance of risk factor modification and regular exercise in preventing sarco-osteoporosis.

P384

IS MULTILEVEL INTERVENTION MORE EFFECTIVE? AN ANALYSIS OF CALCIUM, VITAMIN D, EXERCISE, AND MEDICATION ON BONE MINERAL DENSITY

Y.-L. Huang[1], C.-H. Liang[1]

[1]Tungs' Taichung MetroHarbor Hospital, Taichung, Taiwan

Objective
Effective management of osteoporosis requires selecting appropriate intervention strategies based on the patient's condition. This study compared the changes in bone mineral density (BMD) of three patients under different intervention levels: no intervention, intervention with calcium, vitamin D, and exercise, and a multilevel intervention combining calcium, vitamin D, exercise, and medication. The results showed that the higher the level of intervention, the more significant the improvement in BMD, providing important reference for clinical treatment.

Methods

Research objects:
IPatient A: No intervention was performed and served as the control group.
IPatient B: Calcium, vitamin D supplementation and exercise intervention.
IPatient C: Calcium, vitamin D supplementation, exercise intervention and drug treatment.

Intervention content:

Patient A (control group)	INo specific intervention, no special adjustments to daily life.
Patient B (mid-level intervention)	IDaily calcium supplement (600mg) IDaily vitamin D supplement (800IU) IResistance or aerobic exercise three times a week
Patient C (Multilevel Intervention)	IThe same calcium and vitamin D intake and exercise regimen as patient B IAdd RANKL inhibitor drug (Denosumab, once every six months)

Assessment method:
IBone density measurement: using dual-energy X-ray absorptiometry (DXA).
IHealth status monitoring: including patient feedback, blood biochemical indicators and side effect records.
Observation period: 12 months after intervention.

Results

	2023 BMD T score	2024 BMD T score	Improvement
Patient A	-1.4	-1.7	-21.43%
Patient B	-2.1	-1.9	9.52%
Patient C	-2.6	-1.9	26.90%

Conclusion

This study found a close correlation between various interventions and the improvement in bone mineral density (BMD). The increase in intervention levels was positively correlated with improvements in BMD. Moderate-level interventions provide an efficient, low-side-effect treatment option. Multilevel interventions showed the best results and are suitable for patients at high fracture risk. Tailoring interventions based on patient characteristics is key to enhancing bone health.

P385

CALCIUM SUPPLEMENTATION AND THE RISK OF CARDIOVASCULAR EVENT RECURRENCE: A POPULATION-BASED STUDY

C.-L. Cheung[1], X. Zhang[2], K. Tan[2], G. Li[3]

[1]Laboratory of Data Discovery for Health Limited (D24H), Pak Shek Kok, Hong Kong SAR China, [2]The University of Hong Kong, Pokfulam, Hong Kong SAR China, [3]The Hong Kong Polytechnic University, Pokfulam, Hong Kong SAR China

Objectives: Calcium supplements are widely used, but their safety is questioned due to a potential link to cardiovascular risk. The impact of calcium supplements on individuals with major cardiovascular disease (CVD) remains unstudied. Objectives: To investigate the association between calcium supplementation and the risk of CVD recurrence and all-cause mortality in patients with prior CVD. Material and Methods: This retrospective population-based study used the territory-wide electronic health records in Hong Kong. Individuals ≥ 40 years old and newly diagnosed with CVD from 1 January 2006 to 31 December 2015. Those who died on the same day as the event or during the hospitalization of the event were excluded. The treatment group consisted of CVD patients prescribed calcium supplements, while the control group consisted of those who never prescribed calcium supplements from 1 January 2005 to 31 December 2020. CVD recurrence and all-cause mortality were the primary outcomes. Propensity score (PS) matching was adopted to balance the baseline characteristics of treatment and control groups, and the Cox proportional hazard model was used to estimate relative hazards. Results: The matched cohort included 17,720 CVD patients in each arm. Calcium supplementation is associated with an increased risk of recurrence of adverse CVD events (hazard ratio [HR], 1.10; 95% CI, 1.07-1.14) and a reduced risk of all-cause mortality (HR, 0.97; 95% CI, 0.94-1.00). However, heterogeneity exists in the associations. Calcium-only supplementation is associated with a greater risk of CVD recurrence (HR, 1.21; 95% CI, 1.17-1.25) compared to the combination of vitamin D (HR, 0.97; 95% CI, 0.93-1.01), and with a more pronounced association noted in males (HR, 1.15; 95% CI, 1.09-1.20) than females (HR, 1.07; 95% CI, 1.03-1.11). Conclusions: In patients with major CVD, calcium supplementation is linked to an increased risk of CVD recurrence. Caution should be exercised when prescribing or using calcium supplements among patients with CVD, especially for males. The combination of calcium and vitamin D supplementation may pose fewer concerns than calcium-only supplementation.

P386

ANALYSIS OF OSTEOPOROSIS AND MORTALITY RISK IN VETERANS ACROSS DIFFERENT MILITARY RANKS

C.-R. Li[1], H.-T. Lee[2], Y.-L. Deng[3]

[1]Department of Neurosurgery, Neurological Institute, Taichung Veterans General Hospital, Taichung, Taiwan, [2]Lee's Medical Corporation, Taichung, Taiwan, [3]Department of Nursing, Taichung Veterans General Hospital, Taichung, Taiwan

Objective

This study aimed to investigate the relationship between military ranks and osteoporosis, as well as the associated mortality risk among veterans. The study also explored whether osteoporosis acts as a mediating factor in mortality risk within this population.

Methods

A retrospective study was conducted on 1,423 veterans who underwent their first dual-energy X-ray absorptiometry (DXA) scan at Taichung Veterans General Hospital between January 2010 and December 2022. The participants were categorized into three military ranks: enlisted (n=154), non-commissioned officers (n=481), and commissioned officers (n=788). Statistical analyses, including Kruskal-Wallis tests and Chi-square tests, were performed to compare demographic characteristics, bone mineral density (BMD), and comorbidities among ranks. Cox regression models were applied to evaluate the association between military rank, osteoporosis, and mortality risk, with subgroup analyses by age, bone status, and comorbidities.

Results

Higher military ranks were associated with lower bone mineral density (BMD) and a greater prevalence of osteoporosis. Commissioned officers had the highest prevalence of osteoporosis (54.5%), compared to non-commissioned officers (27.4%) and enlisted personnel (13.8%) ($p<0.001$). Chronic kidney disease (CKD) and chronic heart failure (CHF), significant predictors of mortality,

were more prevalent in higher-ranking groups (p<0.01). Cox regression analysis indicated that osteoporosis independently increased the risk of mortality (HR=1.60, 95%CI: 1.21-2.11, p<0.01). Subgroup analysis showed that commissioned officers aged ≥81 years had a significantly higher mortality risk (HR=2.29, p<0.001). After adjusting for confounders, military rank itself was not an independent predictor of mortality.

Conclusion

Commissioned officers exhibited a higher burden of osteoporosis and comorbidities, which significantly contributed to increased mortality risk. The findings highlight the importance of early osteoporosis screening and integrated management of comorbidities, particularly for high-ranking veterans, to reduce mortality risk.

P387

REDUCING FALL AND FRACTURE RISK THROUGH TARGETED OSTEOPOROSIS CARE AMONG COMMUNITY-DWELLING OLDER ADULTS:- SECONDARY ANALYSES OF A RANDOMIZED CONTROLLED TRIAL

Y.-C. Lu[1], S.-H. Fu[2], N.-H. Sei[1], C.-Y. Wang[1]

[1]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei Township, Taiwan, [2]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Huwei Township, Taiwan

Objective

To evaluate the effectiveness of osteoporosis care in reducing the risk of falls and fractures among community-dwelling older adults.

Methods

This secondary analysis of a cluster randomized trial was conducted in rural communities in Taiwan. Participants aged 50 years or older were assigned by community level to either the osteoporosis care (OC) group or the usual care (UC) group. The OC intervention focused on osteoporosis screening and treatment. Participants in the OC group with a FRAX major osteoporotic risk >20% or FRAX hip fracture risk >3% were considered at high fracture risk and recommended for anti-osteoporotic medication (AOM). The study followed participants for two years, with primary outcomes being fall and fracture incidence. A multivariable Cox proportional hazards model assessed the risk of these outcomes between groups, adjusting for confounders.

Results

A total of 188 participants (aged 75.6 ± 8.7 years) in the UC group and 201 participants (aged 74.4 ± 8.6 years) in the OC group were included. Osteoporosis and sarcopenia prevalence did not differ between groups, but the OC group had significantly higher education levels and urbanization rates (p < 0.05). In the OC group, 73.6% (n=148) were at high fracture risk, and 50.7% (n=102) received AOM. After adjusting for urbanization and FRAX scores, the hazard ratio for falls was slightly lower in the OC group (1 vs. 0.8, 95% CI: 0.6–1.1, p = 0.198), while the adjusted hazard ratio (aHR) for fractures was significantly reduced (aHR: 0.3, 95% CI: 0.1–0.8, p = 0.011).

Conclusion

This study demonstrated that osteoporosis care may reduce the risk of fractures in community-dwelling older adults. Although the fall incidence was lower, the difference was not statistically significant. These findings suggest that targeted osteoporosis care could be an effective intervention for fracture prevention in community settings.

P388

A HOMOZYGOUS SP7/OSX MUTATION CAUSES OSTEOGENESIS AND DENTINOGENESIS IMPERFECTA WITH CRANIOFACIAL ANOMALIES

D. Almutairi[1]

[1]Kuwait University/ Faculty of Medicine/ Department of Pathology, Kuwait, Kuwait

Osteogenesis imperfecta (OI) is a heterogeneous spectrum of hereditary genetic disorders that cause bone fragility, through various quantitative and qualitative defects of type 1 collagen, a triple helix composed of two α1 and one α2 chains encoded by *COL1A1* and *COL1A2*, respectively. The main extra-skeletal manifestations of OI include blue sclerae, opalescent teeth, and hearing impairment. Moreover, multiple genes involved in osteoblast maturation and type 1 collagen biosynthesis are now known to cause recessive forms of OI. In this study a multiplex consanguineous family of two affected males with OI was recruited for genetic screening. To determine the causative, pathogenic variant(s), genomic DNA from two affected family members were analyzed using whole exome sequencing, autozygosity mapping, and then validated with Sanger sequencing. The analysis led to the mapping of a homozygous variant previously reported in SP7/OSX, a gene encoding for Osterix, a transcription factor that activates a repertoire of genes involved in osteoblast and osteocyte differentiation and function. The identified variant (c.946C > T; p.Arg316Cys) in exon 2 of *SP7/OSX* results in a pathogenic amino acid change in two affected male siblings and develops OI, dentinogenesis imperfecta, and craniofacial anomaly. On the basis of the findings of the present study, *SP7/OSX*:c.946C > T is a rare homozygous variant causing OI with extra-skeletal features in inbred Arab populations (Al-Mutairi *et al.*, 2024).

Maria" Clinical Hospital, Department of Internal Medicine and Rheumatology, Bucharest, Romania, [3]Department of Internal Medicine and Rheumatology, "Dr. Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania; Department of Internal Medicine and Rheumatology, "Dr. Ion Cantacuzino" Clinical Hospital, 011437, Bucharest, Romania, [4]Central Military Emergency University Hospital "Dr. Carol Davila", Department of Internal Medicine 2, Bucharest, Romania; "Dr. Carol Davila" University of Medicine and Pharmacy, Department of Internal Medicine and Rheumatology, Bucharest, Romania

Objectives: The aim of our study was to assess the risk factors for osteoporosis and osteoporotic fractures in patients with anti-Tumor Necrosis Factor (TNF) therapy and Conventional Synthetic Disease-Modifying Antirheumatic Drugs (csDMARDs).
Materials and Methods: We conducted a retrospective study at Central Military Emergency University Hospital "Dr. Carol Davila". Medical records spanning from March 2023 to November 2024 were reviewed, resulting in the inclusion of 92 patients. The study group included 52 patients with psoriatic arthritis - PsA (that met Classification Criteria for Psoriatic Arthritis – CASPAR) on anti-TNF therapy - 32 patients, Methotrexate - 12 patients and Leflunomide - 8 patients. The control group included 40 age and sex-matched patients. All patients underwent evaluation using hip and lumbar Dual-Energy X-Ray Absorptiometry (DXA) - Bone Mass Density - (BMD), T-score, Fracture Risk Assessment Tool (FRAX) score, Disease Activity in Psoriatic Arthritis (DAPSA) and evaluation for risk factors (25-OH Vitamin D, Homocysteine - Hcy, hemoglobin levels, smoking status, body mass index - BMI) at an interval of 12 months.
Results: In the control group, we observed that 15% of them had osteoporosis and 27.5% had osteopenia. In the PsA group, we observed that 19.2% had osteoporosis and 32.7% had osteopenia. Only 5.8% had osteoporotic fractures -3.8% vertebral fractures and 1.9% femoral neck fractures. T-score was significantly lower in menopausal females that had scalp psoriatic lesions. FRAX score was correlated with high level of Hcy (p=0.0002) as well as with low 25-OH Vitamin D levels (p=0.0001) and chronic anemia (p=0.001). Low T-scores were correlated with high Hcy levels (p=0.0002) and low 25-OH Vitamin D levels (p=0.0003). Low BMI and high levels of Hcy were correlated with a greater risk of osteoporosis. Active disease was correlated with low T-score (p=0.0001). After 12 months, patients treated with anti-TNF treatment had an increase in T-score compared to csDMARDs treated patients.
Conclusion: FRAX scores were higher in PsA patients than controls. Hyperhomocysteinemia, chronic anemia and 25-OH Vitamin D deficiency were associated with higher osteoporosis risk and FRAX scores in PsA patients. Anti-TNF therapies were associated with improved BMD and FRAX scores after 12 months.

P390

CLINICAL AND BIOCHEMICAL CHARACTERIZATION OF PAGET'S DISEASE OF BONE: INSIGHTS INTO PHENOTYPES AND TREATMENT OUTCOMES

D. Augusto[1], H. Gonçalves[2], P. Pereira[2], C. Campinho Ferreira[2], M. Correia[2], A. R. Ribeiro[2], J. Leite Silva[2]

[1]Serviço de Reumatologia da Unidade Local de Saúde da Guarda, Guarda, Portugal, [2]Serviço de Reumatologia da Unidade Local de Saúde de Braga, Braga, Portugal

Objectives: To characterize a cohort of Paget's disease of bone (PDB) patients and assess phenotypic differences and treatment effects.
Methods: Retrospective analysis of patients treated in the last 5 years in our Rheumatology department. Socio-demographic, disease and treatment related data were collected. Descriptive and comparative analysis used the means, T-tests and Mann-Whitney U Tests.
Results: 13 patients were included in this analysis, of whom 9 (69.20%) were male. Mean age at diagnosis was 76.38 ± 8.65 years. Nine (69.20%) patients had monostotic disease. Polyostotic disease involved between 2 and 6 bones. Three (23.10%) patients had a prior fragility fracture at first evaluation.
Sacrum was the most affected site, in 5 (38.46%) patients.
Six (46.20%) patients were referred to our clinic due to incidental findings on computed tomography scans.
Baseline alkaline phosphatase (AP) mean levels were 189.69±151,20 U/L, with no significant differences between genders (p=0.825), PDB type (p=0.825) or the presence of pain (p=0.769).
Twelve (92.30%) patients were treated with a single dose of zoledronate infusion. In this group, AP levels after treatment were significantly reduced compared to baseline (p=0,003). No patients reported adverse effects.
Conclusions: This work highlights the clinical profile of PDB patients, a rare osteometabolic disease. In our sample, patients were mostly male, with monostotic and sacral involvement, as described in the literature[1]. AP levels at baseline are similar across demographic and clinical characteristics, suggesting that these factors do not influence biochemical activity. Lastly, it reinforces zoledronate therapy as a safe and effective therapy, by significantly reducing AP levels while being safely tolerated in all patient subgroups.

SEVERE OSTEOPOROSIS WITH FRACTURES AS THE INITIAL MANIFESTATION OF AXIAL SPONDYLARTHRITIS: A DIAGNOSTIC CHALLENGE

D. Augusto[1], F. Magalhães[1], S. P. Dinis[1], F. Cunha-Santos[1], J. F. Ferreira[1], C. Vaz[1], N. Madeira[1]

[1]Serviço de Reumatologia da Unidade Local de Saúde da Guarda, Guarda, Portugal

Introduction: In spondylarthritis (axSpA), chronic inflammation disrupts bone metabolism, leading to both new bone formation and bone loss in the spine. In axSpA, osteoporosis (OP) and fractures are a common occurrence. We report a case where OP preceded the diagnosis of axSpA.

Case report: A 45-year-old male was referred to our Osteoporosis department after a compression fracture of the 10th thoracic vertebra, presenting as mechanical back pain. He denied significant trauma. He had a personal history of obesity and a left femoral neck insufficiency fracture from transient hip OP one year earlier. He described a 4-year history of inflammatory back pain and bilateral tibiotarsalgy. Aside from daily smoking and alcohol use, no other risk factors for OP were identified. Dual-energy X-ray absorptiometry showed femoral neck and lumbar T-scores of -2.6SD, -3.4SD, respectively, and Z-scores of -2.7SD, -4.0SD, respectively. Spinal X-rays revealed three vertebrae planae, with no other findings. Blood work including hormonal study was normal. During follow-up, he reported spontaneous fractures of costal arches and the 5th right metatarsus.

Suspecting axSpA, sacroiliac joints nuclear magnetic resonance showed bone marrow edema in the left sacral aspect of the joint. Having excluded other causes for 2nd OP, it was assumed a diagnosis of fracturary OP secondary to axSpA. Zoledronate was started, and lacking response to 2 NSAIDs, adalimumab therapy was proposed.

Conclusion: This case shows OP preceding axSpA diagnosis, contrary to the typical temporal sequence seen in clinical practice. More, the patient's notably low lumbar T-score contrasts with axSpA expected new bone formation. These atypical findings underscore the value of considering axSpA in patients presenting initially with OP, especially when features like inflammatory back pain are present. Early treatment is crucial to improve bone prognosis.

P392

PREDICTIVE FACTORS FOR THE DELAY BEFORE THE FIRST CONSULTATION IN PEDIATRIC RHEUMATOLOGY DEPARTMENT FOR CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

D. Ben Nssib[1], A. Zaatouri[1], L. Kharrat[1], F. Mejdoub[1], H. Ferjani[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]

[1]Mohamed Kassab ortopaedic hospital, Mannouba, Tunisia

Introduction Although it is the most common form of chronic arthritis in children, Juvenile idiopathic arthritis (JIA) remains poorly known by primary care physicians. This lack of awareness can lead to diagnostic delays, which may alter the appropriate management during the early stages.

Objective The study aimed to analyze the duration between the onset of symptoms and the first pediatric rheumatology (PR) consultation and to identify predictive factors influencing this delay.

Methodology This retrospective longitudinal study included patients diagnosed with JIA based on ILAR 2001 criteria and followed in a PR department. Data were collected on care pathways, symptom onset, and clinical, biological, and radiological findings from the first pediatric rheumatologist evaluation. The duration between symptom onset and the first PR consultation was recorded, and factors affecting this delay were analyzed.

Results The study included 56 children with a mean age of 15 +/- years. The mean age at symptom onset was 10 +/- 4.1 years, and the sex ratio was 1. The most common JIA subtype was enthesitis-related arthritis (ERA) (40%). The median delay before the first PR consultation was 10 +/- months. Pain was the most frequently reported initial symptom (70%). On average, three physicians were consulted before the first pediatric rheumatologist examination. General practitioners were the first consulted in 36% of cases, but pediatric orthopedists were the most frequent referrers to PR (51%).Significant associations were found between the delay before the first PR consultation and the number of physicians consulted ($p = 0.022$) , the number of swollen joints ($p = 0.042$) and limping as the initial symptom ($p = 0.023$).No significant association was noted with the number of painful joints ($p = 0.59$) , the age at symptom onset ($p = 0.335$) ,symptoms such as fever ($p = 0.465$), pain ($p = 0.693$), or enthesitis ($p = 0.496$).The longest delays were observed in cases of ERA ($p = 0.001$). There was no significant association between the delay and sex ($p = 0.83$). Neither the involvement of an orthopedist nor an emergency physician as the first consulted professional was associated with a longer delay. Despite pediatric orthopedists being the most frequent referrers to PR, their involvement as the initial point of care was not linked to shorter delays ($p = 0.219$).

Conclusion The delay to the first PR consultation in this series was longer compared to other countries. Improved awareness of JIA is essential for earlier diagnosis and to prevent subsequent Complications.

P393

CLINICAL EFFICACY AND PROGNOSTIC FACTORS IN SHOCKWAVE THERAPY FOR PAINFUL SOFT TISSUE CONDITIONS: A REAL LIFE EXPERIENCE

D. Borda[1], R. Sebio[1], R. S. Salinas[1], J. G. Moranta[1], P. Peret[1], J. D. Rivadeneira[1], S. Vázquez[1], C. Unyó[1], C. Rodríguez[1], C. Closa[1], S. Laxe[1]

[1]Hospital Clínic de Barcelona, Barcelona, Spain

Introduction: Extracorporeal Shockwave Therapy (ESWT) is a non-invasive treatment for chronic soft tissue injuries. Despite its growing use, the efficacy of focused shockwave therapy (FSWT) varies, necessitating further investigation into its clinical effectiveness and the factors influencing outcomes. The aim of this study was to determine the clinical efficacy and influencing factors in a real life situation.
Materials and MEthods: A retrospective cohort study analyzed medial records of 116 patients with chronic soft tissue pain treated with FSWT at a tertiary hospital between July 2021 and August 2023. Inclusion criteria included patients over 18 with pain lasting more than 3 months.
Data on demographics, clinical characteristics, and treatment outcomes were extracted and analysed using descriptive statistics, analysis of variance and multivariate regression.
Results: The average Visual Analog Scale (VAS) improvement was 38.5%. There was no significant difference in improvement between gender or different pathologies. Prior corticosteroid infiltrations showed less improvement (30%) compared to those without (48%) p<0.005 Multivariate analysis identified previous infiltration as a key factor negatively affecting VAS improvement.
Conclusion: FSWT is an effective alternative for reducing pain in chronic soft tissue conditions, though its effectiveness is lower in patients with prior corticosteroid infiltrations. Further studies are needed to refine treatment protocols and understand the varying responses among different patient groups.
Key words: Focal shockwave therapy, FSWT, tendinopathies, rehabilitation.

P394

ABALOPARATIDE IN OSTEOPOROSIS: A DESCRIPTIVE STUDY FROM A SPANISH MULTICENTER COHORT

D. Fernandez-Lozano[1], E. Flores-Fernández[2], P. Andújar-Brazal[3]

[1]Rheumatology department, Hospital Clínico Universitario de Valencia, Valencia, Spain, [2]Rheumatology department, Hospital General Universitario de Castellon, Castellon, Spain, [3]Rheumatology department, Hospital General Universitario Doctor Peset, Valencia, Spain

Background:
Abaloparatide (ABL) is a novel synthetic analog of human parathyroid hormone that recently has been approved in Spain for the treatment of osteoporosis in patients at high risk of fractures.
Objectives:
To describe the clinical features of a cohort of spanish patients with osteoporosis who initiate treatment with ABL.
Methods:
A retrospective multicentre descriptive study was conducted between May 2024 and January 2025 on patients treated with ABL in 3 hospitals in eastern Spain. Statistical analysis was performed with SPSS version 21.0.
Results:
A total of 58 patients were included in the study, with a median age of 67.5 years [IQR 61.25–74]. 79.3% had at least one previous fracture, with vertebral fractures being the most frequent (60.71%), followed by wrist (10.71%) and hip (8.93%). Among previous treatments, the most frequent were oral bisphosphonates (31%) and denosumab (19.34%). Some patients were treated with teriparatide with a median time of 11.5 months [IQR 5.25-17.75]. Densitometry showed a mean T-score in the lumbar spine of -2.90 ± 1.24 SD, in the femoral neck of -2.64 ± 1.01 SD, and in the total hip of -2.70 ± 1.21 SD. 32 patients (55.17%) received the treatment as a first-line therapy while 22 patients (37.93%) as a second line. During follow-up there were 5 discontinuations: 4 were due to non-severe adverse effects and 1 was due to the patient's own decision. No fractures were recorded during the follow-up period.
Conclusion:
This multicentre cohort study shows a predominance of abaloparatide use in spinal osteoporosis, used as first and second-line treatment. No fractures were recorded during follow-up, and discontinuations were mostly related to mild adverse effects. These results support the role of abaloparatide in the treatment of patients with high fracture risk and previous therapeutic difficulties.
Disclosure of interest: None declared

P395

ASSOCIATION BETWEEN BETA BLOCKER USE, BONE MINERAL DENSITY, AND BONE TURNOVER: INSIGHTS FROM A LARGE CROSS-SECTIONAL STUDY OF OLDER ADULTS

D. Fitzpatrick[1], R. Lannon[2], E. Laird[3], C. Cunningham[2], M. Ward[4], C. Hughes[4], L. Hoey[4], J. J. Strain[4], H. Mcnulty[4], K. Mc Carroll[2]

[1]Medicine for the Older Person, Mater Misericordiae University Hospital, Dublin , Ireland, [2]Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland, [3]Atlantic Technological University, Sligo, Ireland, [4]Ulster University, Coleraine, United Kingdom

Objective Beta blockers are widely prescribed in older adults and exert their effects by inhibiting the adrenergic system, which is known to stimulate bone resorption and suppress bone formation. There is some research to suggest that beta blockers may positively influence bone health by increasing bone mineral density (BMD) and reducing fracture risk. This study aims to expand on this evidence base.

Material and Methods Study participants were from the Trinity Ulster University Department of Agriculture (TUDA) study, a large cross-sectional cohort of adults aged >60 years. Participants on osteoporosis treatments were excluded. BMD, measured by densitometry at the femoral neck, total hip, and lumbar spine, was compared between beta blocker users and non-users. Least squares mean BMD values were adjusted for age, sex, body mass index, physical performance status, vitamin D level, parathyroid hormone, renal function, comorbidities, lifestyle factors, glucocorticoid exposure, and medications known to affect bone health. Bone turnover markers (BTMs), including bone alkaline phosphatase (BAP) and tartrate-resistant acid phosphatase 5b (TRAP5b), were analysed in a subsample.
Results The study included 2,218 participants with a mean age of 70.1±6.5 years; 58.3% were female, and 29.0% (n=644) were beta blocker users. Beta blocker users exhibited significantly higher BMD at the femoral neck (0.867 vs. 0.853 g/cm², p=0.017) and lumbar spine (1.119 vs. 1.096 g/cm², p=0.015) in fully adjusted models, with a trend toward significance at the total hip (p=0.073). In subsample analysis (n=1,639), beta blocker users demonstrated significantly lower levels of BTMs: BAP (16.4 vs. 17.4 µg/L, p=0.005) and TRAP5b (2.98 vs. 3.15 µg/L, p<0.001).
Conclusions This study supports the association between beta blocker use and improved bone health in older adults, as evidenced by higher BMD and lower BTMs. The observed reduction in BTMs provides new insights into potential mechanisms underpinning these effects. However, these findings are limited by the cross-sectional of this study, and robust longitudinal studies and randomized controlled trials are needed to confirm these observations and better understand this potential relationship.

P396

TERIPARATIDE USE IN A BONE HEALTH CLINIC – AN IRISH EXPERIENCE.

D. Gargan[1], D. Fitzpatrick[2], G. Steen[1], N. Maher[1], N. Fallon[1], C. O'Carroll[1], R. Lannon[1], K. Mccarroll[1]

[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Dublin, Ireland, [2]Mater Miscericordiae University Hospital, Dublin, Dublin, Ireland

Objective: Teriparatide is the first osteoanabolic used for the treatment of patients with osteoporosis at high risk of fracture and became available in 2002. Guidelines for use vary by country with key criteria including lumbar spine T-score and presence of vertebral fracture(s). We aimed to explore the characteristics of patients treated with teriparatide in adults attending an Irish bone health clinic between 2002 and 2020.
Material and methods: We explored our Bone Health Clinic database to identify patients started on treatment with teriparatide during the period (2002 – 2020). Patient characteristics including age, sex and presence of vertebral fracture(s) were recorded. Predictors of teriparatide treatment versus other therapies was explored in multinomial regression.
Results: We identified 992 patients who were treated with teriparatide, 90% female, median age 69.6 years (IQR 60.9 – 70.1). The median lumbar spine T-score was -3.5 (IQR -2.6 to -4.1). The oldest patient was aged 94.5 years, and the lowest lumbar spine T-score was -7.0. Approximately, half (49.5%) had vertebral fracture(s) and of those 20.3% had osteopenia in the lumbar spine. Compared to other patients (n=5450) those prescribed teriparatide were more likely to have a vertebral fracture(s) (OR 2.26, CI 2.18 – 3.13, p<0.001), have lower spine T-scores (p<0.001), be female (OR 2.13, CI 1.59 – 2.84, p<0.001) and be of a younger age (p<0.0010).
Discussion: Teriparatide use as expected was predicted by history of vertebral fracture(s) and and was also independent of lower lumbar spine T-scores. Indeed, a significant proportion of patients with vertebral fracture(s) on teriparatide had osteopenia in the spine. Overall, about half of patients had T-scores below -3.5 in the lumbar spine. Lower usage in older patients may be due to frailty and factors related to teriparatide administration. The greater proportion of female users may be accounted for by their higher diagnosis rate of osteoporosis compared to males.

P397

HIGH PREVALENCE OF LOW 24-HOUR URINARY CALCIUM IN PATIENTS AT A BONE HEALTH CLINIC: PREDICTIVE OF SECONDARY HYPERPARATHYROIDISM AND LOWER HIP BONE MINERAL DENSITY.

D. Gargan[1], D. Fitzpatrick[2], G. Steen[1], N. Maher[1], N. Fallon[1], C. O'Carroll[1], R. Lannon[1], K. Mccarroll[1]

[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Dublin, Ireland, [2]Mater Miscericordiae University Hospital, Dublin, Dublin, Ireland

Objective: Low urinary calcium (hypocalciuria) can indicate poor dietary calcium intake. We aimed to evaluate the prevalence of low 24-hour urinary calcium in patients attending our bone health clinic. Furthermore, we sought to explore the relationship between hypocalciuria and secondary hyperparathyroidism (SHPT) and bone mineral density (BMD).
Material and methods: We identified patients who had routine 24-hour urinary calcium levels measured as part of a normal screen at our bone health clinic. Exclusion criteria was hypercalcaemia (serum calcium > 2.50 mmol). The prevalence of hypocalciuria (urinary calcium < 2.5 mol) and its relationship with SHPT (serum PTH > 65pg/ml) and hip BMD was explored in multinomial regression adjusting for relevant covariates.
Results: There were 1778 patients, 70% female, mean age 69.9 years with 30.8% having hypocalciuria. In a subsample where all covariate data was available (n = 1200), predictors of hypocalciuria were lower serum vitamin D (p<0.001) and higher eGFR (p<0.001). Hypocalciuria versus normal urinary calcium predicted SHPT (OR 2.57, CI 1.50 – 4.43, p<0.001) and lower hip BMD (p=0.004) after adjusting for age, sex, eGFR, BMI and serum vitamin D.
Conclusion: A high proportion (one third) had hypocalciuria likely reflecting poor dietary calcium intake. Consistent with this, hypocalciuria more than doubled the risk of SHPT independent of

serum vitamin D, eGFR and BMI and was associated with lower hip BMD. A limitation is that we could not account for the use of thiazide or loop diuretics which impact urinary calcium. Findings suggest that calcium intake is inadequate in a high proportion of patients attending a specialist bone health clinic.

P398

CLINICAL FEATURES OF OSTEOPOROSIS IN TYPE 1 AND TYPE 2 DIABETIC PATIENTS IN TÜRKIYE: A LARGE SCALE, NATIONWIDE STUDY

D. Gogas Yavuz[1], C. Haymana[2], T. Akkan[3], M. M. Yalçın[4], Z. Hekimsoy[5], I. Taşçı[6], M. A. Eren[7], N. Ata[8], S. Birinci[9], A. Sönmez[10], F. Bayram[11]

[1]Marmara University School of Medicine, Department of Endocrinology and Metabolism, Istanbul Türkiye, İstanbul, Turkiye, [2]University of Health Sciences, Gulhane School of Medicine, Department of Endocrinology and Metabolism, Ankara Türkiye, Ankara, Turkiye, [3]University of Health Sciences, Eskişehir City Hospital, Department of Endocrinology and Metabolism, Ankara Türkiye, Eskisehir, Turkiye, [4]Gazi University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkiye, [5]Celal Bayar University, School of Medicine, Department of Endocrinology and Metabolism, Manisa, Turkiye, [6]University of Health Sciences, Gulhane School of Medicine, Department of Internal Medicine, Ankara, Turkiye, [7]7Lokman Hekim University, School of Medicine, Department of Endocrinology and Metabolism, Ankara Türkiye, Ankara, Turkiye, [8]Department of Strategy Development, Turkish Ministry of Health, Ankara, Turkiye, [9]Deputy Minister of Health, Turkish Ministry of Health, Ankara Turkiye, Ankara, Turkiye, [10]Ankara Guven Hospital, Department of Endocrinology and Metabolism, Ankara, Turkiye, [11]Erciyes University School of Medicine, Department of Endocrinology and Metabolism, Kayseri, Turkiye

Aim:Diabetes patients are at a significantly higher risk of fracture than the general population. The incidence of fragility fractures in diabetic people has significantly risen globally, along with increased life expectancy. Bone mineral density (BMD) decreases in type 1 diabetes. Type 2 diabetes raises the risk of fracture even in people with normal to high bone mineral density.Enhanced fracture risk in diabetes due to disease length, poor glucose control, vascular problems, and medications. This study examines osteoporosis frequency and causes in a large, nationwide population with type 1 and type 2 diabetes in Türkiye.
Methods: This retrospective population-based cohort study utilized the national electronic database of the Turkish Ministry of Health. Diabetic patients were enrolled from January 2015 to December 2021. Osteoporosis has been identified with ICD codes M80 and M81 within the diabetic population.
Results: The national diabetes cohort consisted of 82,050 patients (44.3±19.1 years, F/M: 45.5/54.5%) with type 1 diabetes and 7,050,118 patients with type 2 diabetes (59.1±13.4 yrs, F/M: 60.2/39.8%). Osteoporosis was observed in 10% (n: 8,575) of type 1 diabetics and 19.2% (n: 1,352,609) of type 2 diabetics.Osteoporosis was observed more frequently in type 1 (15.5%) and type 2 diabetic women (27.8%) compared to type 1 (6.2%) and type 2 diabetic men (6.1%). Osteoporosis frequency increases with age both type 1 and type 2 diabetes groups. The fracture rate is higher in type 1 diabetes (0.92%) than in type 2 diabetes (0.55%).
Type 1 diabetic patients with osteoporosis compared to type 2 diabetic patients have higher rates of coronary artery disease (63.4% vs. 54.5%), stroke (8.7% vs. 5.7%), peripheral artery disease (21.8% vs. 11.3%), heart failure (29.4% vs 15.3%), chronic renal disease (53.7% vs. 24.7%), retinopathy (14.1% vs. 3.6%), and neuropathy (45.7% vs. 34.3%).
The prevalence of osteoporosis rises in individuals with both type 1 and type 2 diabetes who have lower estimated glomerular filtration rates (eGFR). Bisphosphonate therapy is administered to 4.7% of individuals diagnosed with type 1 diabetes and osteoporosis and 6% of individuals diagnosed with type 2 diabetes and osteoporosis. 1.5% of patients with type 1 DM and 1.2% of individuals with type 2 DM were prescribed Denosumab. Cholecalciferol replacement therapy was administered to 32% of individuals diagnosed with type 1 diabetes and 40.1% of individuals diagnosed with type 2 diabetes with osteoporosis.
Conclusions: Osteoporosis was observed in 10% of type 1 diabetics and 19.2% of type 2 diabetic patients in a cohort from Turkiye. Osteoporosis frequency is more common in type 2 diabetes and increases with age. However, macrovascular and microvascular complications are more common in osteoporotic patients with type 1 diabetes than osteoporotic type 2 diabetic patients. There is a limited number of patients who are undergoing pharmacological intervention.

P399

BALANCE IMPROVEMENT AND FALL RISK REDUCTION IN GERIATRIC OSTEOARTHRITIS: A STUDY OF OTAGO AND SQUARE STEPPING EXERCISES

D. Gohil[1], G. Baxi[2], T. Palekar[1]

[1]Dr. D. Y. Patil College Of Physiotherapy, Pune, India, [2]Institute of Medical Education Technology and Teachers' Training, Maharashtra University of Health Sciences, Nashik, Pune, India

Body
Osteoarthritis (OA) is a chronic degenerative joint disease that leads to disability. The prevalence of symptomatic knee OA is approximately 22% to 39% in India, which causes significant morbidity and impairment in elderly individuals.
Objective:
To study the effects of Otago exercise versus squarestepping exercises (SSEs) on balance, fall, and functional activities in geriatric individuals with OA knee
Methods:
A study was carried out at Pune among 40 geriatric individuals with age over 65 years. The individuals were assigned at random to the Otago exercise group or SSE. Both groups performed exercises for 40–45 min for 10 days. The primary outcome was balance, which was measured by the Berg Balance Scale and Limits of Stability test. The secondary outcomes were risk of fall, mea-

sured by the Morse fall scale and functional activity, measured by the Western Ontario and McMaster Universities Arthritis Index (WOMAC) scale.
Results:
Both the groups showed significant differences post intervention within the groups ($P < 0.05$). Betweengroup analysis showed that the Otago exercise group showed a higher mean difference in the primary outcomes that is in the Berg Balance Scale (19.25 > 15.24) and limits of stability. The SSE group showed a higher mean difference in Morse fall scale (18.81 > 8.8) and WOMAC scale (18.81 > 8.8).
Conclusion(s):
The study concluded that, in older patients with OA knee, Otago exercise is more successful at enhancing balance but SSE is more effective at enhancing fall risk and functional activity.
Implications:
Between group analysis of Berg balance and balance master parameters was statistically significant. The result of the study provides evidence that Otago exercise is more effective than the SSE on balance and the SSE is also effective on the risk of fall and functional activity.

P400

"IMPROVING OUTCOMES IN KNEE OSTEOARTHRITIS THROUGH TASK-SPECIFIC TRAINING"

D. Gohil[1], G. Baxi[2], T. Palekar[1]

[1]Dr. D. Y. Patil College Of Physiotherapy, Pune, India, [2]Institute of Medical Education Technology and Teachers' Training, Maharashtra University of Health Sciences, Nashik, Pune, India

Body: Task-specific training improves functional performance in older adults requiring assistance with activities of daily living (ADLs) as well as community-dwelling older adult. While this approach seems appropriate for individuals with chronic knee pain, there is a lack of evidence regarding the effects of task-specific training to improve performance or general function in this population.
Objective: This study explores the role of task-specific training for individuals with knee osteoarthritis (KOA), with respect to pain and Physical functions to improve efficacy of performing ADLs and knee related Quality of Life (QOL).
Methods: A study was carried out at Pune among 40 geriatric individuals with age over 65 years. The individuals were assigned at random to the Otago exercise group or SSE. Both groups performed exercises for 40–45 min for 10 days. The primary outcome was balance, which was measured by the Berg Balance Scale and Limits of Stability test. The secondary outcomes were risk of fall, measured by the Morse fall scale and functional activity, measured by the Western Ontario and McMaster Universities Arthritis Index (WOMAC) scale.
Results: There was significant improvement ($p<0.001$) seen in all outcome measures. NPRS reduced from 5.9±1.7 to 3.4±1.8, 30-SCRT repetitions increased from 9.06±3.4 to 12.76±3.82, TSCT seconds reduced from 27.06±7.38 to 20.76±6.38, FTT seconds reduced from 12.03±4.23 to 9.43±3.73. In KOOS, ADL score improved from 30.13±9.86 to 14.50±7.92 and QOL score improved from 9.4±3.03 to 4.5±1.9 after 8 treatment sessions of functional training.
Conclusion(s): Task-specific training program is effective in reducing pain, improving performance and functional ability and quality of life in patients with KOA.
Clinical Implications: Many patients reported clinically improvement in stair climbing with increased speed and less assistance, floor transfer with reduced discomfort and minimal assistance. It is possible that the alternative techniques allow the patients to negotiate with less pain.

P401

SHORT-TERM FRACTURE RISK AND THE UTILITY OF FRAX®: INSIGHTS FROM THE DXA HIP COHORT

D. Gonzalez-Garza[1], M. Fitzgerald[1], A. Brennan[2], L. Yang[1], E. Erjiang[3], J. Carey[1], R. Egan[4], K. Gorham[4]

[1]School of Medicine, University of Galway, Galway, Ireland, [2]School of Computer Science, University of Galway, Galway, Ireland, [3]School of Management, Guangzi Minzu University, Nanning, China, [4]Department of Rheumatology, Galway University Hospitals, Galway, Ireland

Objective
FRAX® significantly underestimates fracture risk in high-risk populations, particularly those with prior fractures (Fx). Short-term risk may be more clinically meaningful for these people. We compared FRAX® Major Osteoporotic Fracture (MOF) risk with incident Fx among adults with and without prior Fx.
Material and Methods
Data from a previously published subgroup of the DXA HIP cohort who all had baseline DXA and VFA imaging and follow-up to end of 2024 were analysed. Subjects were stratified into four groups based on fracture history: No Fx, Prior Fx, Prior Vertebral Fracture (VFx), and Prior VFx + Other Fx. Baseline FRAX® MOF scores were recorded. Cohort details and ethical approval are previously published. Cumulative MOF incidence was calculated over 1, 2, and ≥3 years after baseline scans
Results
1,261 subjects had baseline scans and follow-up data available: 77% female, median age: 69 years (IQR: 62, 76), median follow-up duration: 2.8 years (IQR: 2.04, 3.32). 49% had prior Fx, including 12% with Vertebral Fx; 35% were taking osteoporosis medication (93% anti-resorptive). Baseline MOF risk was 9.3%, 15.6%, 17.6%, and 20.4% for the 'No Fx', 'Prior Fx', 'Prior VFx', and 'Prior VFx + Other Fx' groups, respectively. Cumulative Fx incidence rose incrementally during follow-up among all groups (see figure). Cumulative fracture incidence exceeded baseline MOF for all 4 groups by study end, in particular for those with Prior VFx and other Fx (figure).
Conclusion
Short-term fracture risk is particularly high among patients with multiple prior fractures. This highlights the need for tools which address short-term fracture risk for those at very high risk. While

FRAX® estimates 10-year fracture risk in patients at low risk or without fractures, FRAX® MOF score underestimated fracture risk in our very high-risk cohort.

Cumulative Fracture Incidence (%) by Group

Year 3+ includes cumulative incidence for Years 3, 4, and 5

IMPACT OF A FRACTURE LIAISON SERVICE ON MORTALITY AND SECOND FRACTURE RATES: FIVE-YEAR RESULTS IN ELDERLY HIP FRACTURE PATIENTS

D. González-Quevedo[1], M. Bravo-Bardají[1], C. Rubia-Ortega[1], J. M. Sánchez-Siles[1], D. García-de-Quevedo[1], I. Tamimi[1]

[1]Regional University Hospital of Málaga, Málaga, Spain

Objectives:
Hip fractures in the elderly are associated with high mortality and second fracture rates. We aimed to evaluate the impact of a Fracture Liaison Service (FLS) implementation on survival, complications, second fracture and mortality rates over five years.
Material and Methods:
We conducted a prospective cohort study including patients over 60 years old who sustained a hip fracture before and after the implementation of the FLS in our center (between January 2016 and December 2019). Patients were followed for five years after the index date and outcomes included mortality, second fracture rates, adherence to osteoporosis treatment (Proportion of Days Covered, PDC), and complications. A Multivariate Cox proportional hazard model was used to compare the two groups, adjusting for confounders such as age, ASA score, and fracture type.
Results:
A total of 1401 patients were included in this study (355 before FLS implementation and 1046 after FLS implementation). Anti-osteoporotic drugs were more frequently prescribed after FLS implementation (77.5% vs 12.1%; p<0.01). Adherence to anti-osteoporotic treatment significantly increased (48.9% vs 30.2%; p<0.01), and second fracture rates were significantly lower in adherent patients (10.8% vs 19.1%; p<0.01). A total of 618 (59.1%) patients after FLS implementation and 194 (54.6%) individuals before (p=0.17) died during the five-years follow-up period. Patients after the implementation of the FLS protocol had a lower all cause one-year mortality [adjusted Hazard Ratio (HR) 0.77 (0.60–0.99)]. In addition, in multivariate analysis, osteoporosis treatment adherence (PDC <0.50) was associated with lower mortality [adjusted HR 0.50 (0.40-0.57)].
Conclusions:
The implementation of a FLS protocol was associated with a significant reduction in one-year all-cause mortality and improved adherence to osteoporosis treatment, leading to fewer second fractures. However, five-year mortality remained unchanged, emphasizing the need for additional long-term interventions.

P403

PREDICTORS OF MOBILITY AND HAND GRIP STRENGTH RECOVERY IN HIP FRACTURE PATIENTS: THE ROLE OF OSTEOPOROSIS TREATMENT

D. González-Quevedo[1], D. Raya-Roldán[2], M. Bravo-Bardají[1], F. J. Sotelo-Sevillano[3], D. García-de-Quevedo[1], I. Tamimi[1]

[1]Regional University Hospital of Málaga, Málaga, Spain, [2]University Hospital of Poniente, Almería, Spain, [3]University Hospital of Jerez, Cádiz, Spain

Objectives:
Hand grip strength (HGS) has been associated with numerous signs of aging and is a major symptom of sarcopenia, fragility, and mortality. Mobility score, on the other hand, is used to monitor post-operative recovery, and return to pre-fracture mobility is considered a quality indicator. This study aims to identify predictive factors for both parameters. Additionally, we evaluated the impact of anabolic and antiresorptive treatment on HGS and mobility after hip fracture in elderly patients.
Material and Methods:
We conducted a multicenter prospective cohort study including 91 patients over 60 years old who sustained a hip fracture and were treated with either antiresorptive (bisphosphonates, denosumab) or osteoanabolic agents (abaloparatide, teriparatide). Mobility and HGS were assessed at baseline and at 30-, 60-, and 90-days post-treatment initiation. Linear regression models evaluated predictors of functional recovery, adjusting for age, ASA score, pre-fracture mobility, and treatment type.
Results:
In the HGS regression model, increasing age was associated with lower HGS at all follow-ups (β=-0.237 to -0.538, p<0.05). How-

ever, results suggest that patients receiving osteoanabolic treatment experienced a smaller decline in HGS over time compared to those on antiresorptive therapy, although differences were not statistically significant.
For mobility, age was also a key determinant (β=0.065 to 0.097, p<0.05), while pre-fracture mobility had the strongest association with post-fracture mobility at all time points (β=0.699 to 0.808, p<0.01). Osteoanabolic treatment did not significantly improve mobility in regression models (p>0.05), but there was a trend toward slightly greater mobility recovery in the osteoanabolic group compared to the antiresorptive group.
ASA Score did not show a statistically significant association with either mobility or HGS recovery (p>0.05).
Conclusions:
Pre-fracture mobility and age are key determinants of functional recovery in hip fracture patients, whereas osteoporosis treatment plays a secondary role in short-term outcomes. Despite the lack of statistical significance, osteoanabolic treatment was associated with a better preservation of HGS and a slight trend toward greater mobility recovery. Future studies should explore long-term effects of osteoanabolic agents on functional improvement beyond 90 days.

P404

SPONTANEOUS REMISSION OF PRIMARY HYPERPARATHYROIDISM AFTER ACUTE SEVERE HYPERCALCEMIC CRISIS IN 80 YRS OLD PATIENT

D. Grigorie[1], A. Badici[2], A. Sucaliuc[2]

[1]Carol Davila University of Medicine, Bucharest, Romania, [2]National Institute of Endocrinology, Bucharest, Romania

Objective: to describe an unusual case of primary hyperparathyroidism (PHPT) with acute hypercalcemic crisis which went into spontaneous remission after parathyroid auto-infarction.
Material and Methods: Neck images and laboratory tests including serial serum calcium and parathyroid hormone (PTH) were performed to evaluate parathyroid function and auto-infarction.
Case Report. A 80-year-old female patient presented during a heatwave in August 2023 with a 1-month history of lethargy, polyuria and general malaise with no neck discomfort. She was an old patient of the clinic monitored for a benign thyroid nodule. She is obese, with high blood pressure and chronically anticoagulated for atrial fibrillation. Four years before, a diagnosis of PHPT was made (Ca 10.7 mg/dl, PTH 94.7 pg/ml) and in the next 2 yrs both calcium and PTH increased (Ca 11.4 mg/dl, PTH 165 pg/ml). On admission her biochemistry showed Ca 14 mg/dL, PTH 716 pg/mL, 25-hydroxy vitamin D 17.4 ng/ml and normal renal function. After iv hydration she was given denosumab with unexpected halving of PTH 341 pg/mL in three days. Neck ultrasound showed a 1.4-cm hypoechoic nodular lesion with echogenic center, suggestive of a left superior parathyroid adenoma. 99Tc-sestamibi scan was negative. Computed tomography scan confirmed a 1.4-cm enlarged left superior parathyroid gland with inhomogeneous contrast uptake. The patient denied surgery. A cardiac MRI showed caseous necrosis of the mitral annulus, which could have explained the hypercalcemic crisis, but was excluded due to PTH dependence. 7 months after denosumab a recurrence of hypercalcemia (13.9 mg/dL), possibly due to a rebound effect[1], was managed with 4 mg zoledronic acid. Serum calcium fluctuated but normalized by July 2024, with a steady decline in PTH. At the last evaluation, after 18 mo., Ca 9.2 mg/dL, PTH 55 pg/mL. On ultrasound the adenoma was 8 mm, with a central cystic component.
Conclusion: This case highlights the very rare spontaneous resolution of severe primary hyperparathyroidism, with no neck discomfort and without recurrence for six months. In the absence of surgery, the mechanism of remission is a matter of speculation.

BISPHOSPHONATE THERAPY FOR REDUCED MINERAL BONE DENSITY AND PREVENTION OF VERTEBRAL FRACTURES IN PATIENTS WITH DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS (DISH) OF THE LUMBAR SPINE

D. Jovanovska-Jordanovski[1], V. Dimitrioski[2], I. Bozhinovska[3]

[1]PHI Healthcare Center Skopje - Polyclinic Jane Sandanski, Skopje, Republic of North Macedonia, [2]PHI Healthcare Center Skopje -Polyclinic Jane Sandanski, Skopje, Republic of North Macedonia, [3]Clinical Hospital Acibadem Sistina, Skopje, Republic of North Macedonia

Background: Diffuse idiopathic skeletal hyperostosis (DISH), which has also been known as ankylosing hyperostosis, Forestier disease, and Forestier-Rotes-Querol disease, is a common condition of unknown etiology characterised by calcification and ossifications of the entheses affecting mainly the spine and peripheral joints (elbow, shoulder etc.) In end-stage DISH subjects due to the inability of the stiff spine to absorb tearing forces, the vertebral column becomes more vulnerable to trauma which leads to fractures even after relatively low energy trauma. Bisphosphonates are medications used for treatment of reduced mineral bone density and prevention of vertebral fractures.
Methods : We present a clinical case of an 68 year old male patient with a past medical hystory of diabetes mellitus type 2 and complain of low back pain, stiffness and limited range of motion of the lumbar spine. Physical examination includes labs, X ray, CT scan and DEXA scan.
Treatment : Bisphosphonates, pain relievers, physical therapy and exercises, swimming, weight and blood sugar control, surgery etc.
Results: Use of bisphosphonates in patients with reduced bone mineral density and diffuse idiopathic skeletal hyperostosis (DISH) inhibits bone resorption, increases bone strength and reduces risk of osteoporotic fractures.
Conclusion: The spine of patient with diffuse idiopathic skeletal hyperostosis (DISH) generally becomes increasingly rigid and osteoporotic and fractures may occur after even a relatively minor

trauma. Thus bisphosphonates are necessary for treatment in patients with DISH.

Keywords : Bisphosphonates, diffuse idiopathic skeletal hyperostosis (DISH), lumbar spine, prevention,vertebral fractures

ANXIETY, DEPRESSION, AND PAIN INTERACTION IN FIBROMYALGIA: A PERSONALIZED MANAGEMENT PERSPECTIVE

D. Matei[1], M. Cealicu[2], M. A. Matei[3], R. Traistaru[1]

[1]University of Medicine and Pharmacy Craiova/Medical Rehailitation Department, CRAIOVA, Romania, [2]University of Medicine and Pharmacy Craiova/Faculty of Medicine, CRAIOVA, Romania, [3]University of Valencia/Faculty of Medicine, Valencia, Spain

Fibromyalgia (FM) is defined as a clinical entity characterized by a multisymptom disorder that cannot be attributed to other diseases or alterations (1,2). Similar to other immune rheumatological conditions (3-5), the etiology and pathogenesis of FM are not yet fully understood (6). Its manifestations remain consistent across environmental, cultural, or socio-economic factors.

Objective: This observational prospective study aims to analyze the possible relationships between emotional variables, such as anxiety and depression, and pain perception in FM patients.

Patients and Methods: A total of 120 women (mean age 57.45 ± 6.1 years) previously diagnosed with FM and comorbid anxiety and/or depression participated in this research. The patients were selected based on clear inclusion and exclusion criteria. All participants provided written informed consent after being thoroughly informed about the study's purpose, as well as its potential benefits and risks. A multidimensional approach was employed to assess FM pain, including the following measures: Self-reported pain, evaluated using an 11-point numerical pain scale (VAS), Pressure pain sensitivity, assessed via pressure pain thresholds (PPT), Anxiety and depression levels, measured using the Hospital Anxiety and Depression Scale (HADS). The study protocol was approved by the local Ethics Committee and adhered to the principles of the Helsinki Declaration.

Results: The results revealed no significant interaction effects for pressure pain sensitivity parameters, anxiety, or depression ($p > 0.05$). However, a significant interaction effect was identified between depression/anxiety and self-reported pain ($p < 0.001$).

Conclusion: Extrinsic factors, such as those associated with psychiatric conditions, can significantly influence pain perception in FM. These findings underscore the necessity of adopting a personalized, differentiated approach to the management of FM for each individual patient.

NON-TRAUMATIC MYOSITIS OSSIFICANS OF THE TIBIALIS ANTERIOR MUSCLE: FAVORABLE FUNCTIONAL RECOVERY FOLLOWING REHABILITATION THERAPY

D. Matei[1], M. A. Matei[2], M. Cealicu[3], R. Traistaru[1]

[1]University of Medicine and Pharmacy Craiova/Medical Rehailitation Department, CRAIOVA, Romania, [2]University of Valencia/Faculty of Medicine, Valencia, Spain, [3]University of Medicine and Pharmacy Craiova/Faculty of Medicine, CRAIOVA, Romania

Non-traumatic myositis ossificans (MO) is a rare variant of MO where no apparent causative factor, such as trauma, can be identified (1). Similar to other rheumatological or orthopedic diseases (2-4) the pathophysiology remains unclear but may involve genetic, metabolic, or vascular factors leading to abnormal tissue differentiation and ossification. Differential diagnoses include soft-tissue sarcomas and other malignant lesions, necessitating biopsy for definitive diagnosis. Here, we report a case of non-traumatic myositis ossificans affecting the left tibialis anterior muscle in a 68-year-old female- a housewife residing in a rural area, with no history of local trauma. The patient has provided informed consent specifically for the publication of her medical case and approval from an Hospital Ethics Committee was obtained. The patient presented with pain and weakness in left foot motion, an altered gait persisting for more than two months, and unexplained weight loss without accompanying symptoms of anorexia or fever. Clinical symptoms, combined with imaging results, initially raised suspicion of a malignant lesion. However, a biopsy confirmed the diagnosis of non-traumatic myositis ossificans. The lesion caused significant limitation in dorsiflexion strength and

range of motion in the left foot. Conservative management was chosen due to the lesion's size and the patient's functional impairment. The treatment protocol included: local Low Laser Therapy (applied to reduce inflammation and pain), Shockwave Therapy (to improve local tissue function and promote healing, Kinesitherapy (focused on regaining range of motion, strength, and gait improvement). The evolution of the patient's pain and functional status was favorable in the short term, with improvement in gait pattern and a reduction in local pain. To assess the lesion's stability, to evaluate for potential complications and ensure long-term functional recovery, periodic monitoring was recommended. Conclusion: This case highlights the need to consider non-traumatic myositis ossificans in the differential diagnosis of soft-tissue masses, particularly in patients without a history of trauma. Biopsy is essential for a definitive diagnosis, and the early initiation of individualized conservative non-pharmacological therapy can lead to improved functional outcomes, as demonstrated in other rheumatological (5), metabolic (6) or orthopedic diseases (7).

P408

COMPLETE MANAGEMENT IN PATIENTS WITH CERVICAL RADICULOPATHY AND FIBROMYALGIA

R. Traistaru[1], D. Kamal[2], A. M. Bumbea[1], D. Matei[1]

[1]University of Medicine and Pharmacy, Craiova, Romania, [2]Filantropia Hospital, Craiova, Romania

BACKGROUND:

Cervical radiculopathy (CR), a painful condition caused by nerve root compression in the cervical spine, is a leading cause of neck pain and disability worldwide, often resulting from intervertebral disc herniation, spinal canal narrowing, or positional cervical cord compression, all of which significantly impair quality of life. Fibromyalgia (FM), a chronic disorder marked by widespread pain, fatigue, sleep disturbances, and cognitive impairments, requires a combined approach of pharmacological and non-pharmacological therapies (1,2) to address its biopsychosocial complexities. Cervical spine compression can disrupt nerve signals and potentially intensify the central sensitization seen in fibromyalgia, where the central nervous system becomes hypersensitive to pain stimuli.

AIM:

In our study we investigated if complete management (ProHumano-SpineDinamic daily, 1 tablet, 2 months and rehabilitation program – educational measures, TENS, laser therapy, aerobic and proprioceptive exercises, daily, 12 sessions, followed by adapted home-trainig program) influence pain and functional status and improve quality of life in overlap condition – CR and fibromyalgia.

METHOD:

We performed a prospective randomized double-blind, controlled trial in outpatient medicine clinic. 58 LR patients (aged 35 – 48 years, 40 females, 18 males) were complete evaluated before rehabilitation program, to exclude the potential confounding comorbidities for cervical pain, and were randomly divided into the experimental group (EG - underwent complete program) and control group (CG - received only rehabilitation program, without SpineDinamic therapy). Improvement in pain (Visual Analog Scale – VAS, McGill questionnaire), and quality of life (Cervical Radiculopathy Impact Scale - CRIS) were compared. These outcomes were measured at baseline and post rehabilitation. We used SPSS Statistics 22.0 for the data analysis.

RESULTS:

Parameters in both groups had an improving trend. The VAS and McGill scores decreased significantly in the EG compared to the CG ($p < 0.001$ and $p = 0,004$, respectively). The CRIS score were significantly improved in EG. Between-group differences were statistically significant post rehabilitation ($p < 0.05$).

DISCUSSION AND CONCLUSION:

Our results sustained the well-known benefit of TENS, laser therapy and exercise program for clinical and functional status in fibromialgic patients diagnosed with CR. Combining SpineDinamic therapy with rehabilitation program might enhance both the altered pain perception and quality of life, due to the SpineDinamic effects on the normal functioning of the peripheral nervous system and on the musculoskeletal system health. Pain level and

quality of life in patients with the overlap between fibromyalgia and CR are deeply interconditioned and require both careful assessment and complete management. Understanding the potential interplay between cervical spine conditions and fibromyalgia can lead to better management strategies and improve the quality of life for those affected by these disorders.

P409

REHABILITATION IN PATIENTS WITH LOW-GRADE DEGENERATIVE SPONDYLOLISTHESIS AND OSTEOPOROSIS

R. Traistaru[1], M. Cealicu[1], M. Matei[2], D. Matei[1]

[1]University of Medicine and Pharmacy, Craiova, Romania, [2]University of Valencia, Faculty of Medicine, Valencia, Spain

Background. Degenerative spondylolisthesis (DS) and osteoporosis (Op) are two complex diseases that affect the spine in people over 50 (1, 2), with clinical-dysfunctional impact that accumulates and impacts quality of life. In the early stage, both DS patients and those with Op may be asymptomatic and the rehabilitation program is selected in accordance with clinical and functional individual status.

The aim of the present study is to investigate if the rehabilitation program (pharmacological and educational measures, dietary with optimal sources of calcium and hygienic, posture and bracing, physical procedures - magnetotherapy, transcutaneous electrical nerve stimulation, low laser therapy for paravertebral and hip girdle muscles, and kinetic exercises) relieves pain and restores physical function and quality of life in 55 females with postmenopausal Op and DS with degree of slip ranged from 5%–25%, Meyerding grade I, during six months.

Methods. All patients (over 55 years old) were randomized (Study group - 28 patients, Control group – 27 patients) and complete assessed (standard laboratory tests, radiological examination of the lumbar column, dual energy X-ray absorptiometry, using a Stratos densitometer). Functional parameters (the VAS - Visual Analogue Scale, the SRM - Roland-Morris Disability Questionnaire, and the SF-MOS - Medical Outcomes Study Questionnaire Short Form 36 Health Survey) were measured at admission to inpatient rehabilitation (T1), after 4 weeks (T2), and 6 months (T3) following the commencement of rehabilitation. We used Student's t test to compare study and control groups for each measured variable and each moment, and ANOVA to compare the three sets of result obtained for each measured variable over time.

Results. There is a highly significant difference between the values of the studied parameters (VAS, SRM and SF-MOS) of the subjects in the study group and those in the control group, those in the study group having higher average values than the others for VAS ($p = 0.00000079 < 0.001$) and SRM ($p = 0.000016 < 0.001$), but lower than the others ($p = 0.000000014 < 0.001$) for SF-MOS. The results confirmed the complex dimension of the level of functionality and the results had not statistical significance in the T2 and T3 assessment.

Conclusions. Careful assessment in osteoporotic patients with DS is necessary to establish the level of all clinical and functional parameters (range of motion, muscle grading and strengthen, activities of daily living impairment, gait) for vertebral column and lower limbs. Non-surgical care and rehabilitation program is one of the optimal choices in osteoporotic patients with minimal DS, especially after 60 years old. Bracing and exercises are essential in the correction of fall risk, vertebral slippage and preventing the vertebral fractures and other neurological complication.

ANALYSIS OF BONE TISSUE STATUS IN ADOLESCENTS TAKING INTO ACCOUNT BSML AND FOKL POLYMORPHISMS OF THE VDR GENE

T. Frolova[1], D. Mcgowan[2], N. Osman[1], O. Savvo[3], I. Tereshchenkova[1], I. Siniaieva[1], A. Amash[1], Y. Karpushenko[1]

[1]Kharkiv National Medical University, Kharkiv, Ukraine, [2]Spine & Orthopedic Surgery Associates, Nebraska, United States, [3]V. N. Karazin Kharkiv National University, Kharkiv, Ukraine

Objectives: To determine the features of the state of bone tissue in children of different sexes in puberty based on the study of densitometry indicators and BSML and FokI polymorphisms of the VDR gene.

Materials and methods: 157 children aged 10-17 years were examined. They were divided into two groups depending on gender: 83 males and 74 females. Inclusion criteria: absence of chronic somatic and endocrine pathologies, hereditary and genetic diseases. Children presented to University Pediatric Clinic for routine examination, ultrasound densitometry (QUS) (Sonost-2000, Korea) and dual-energy X-ray absorptiometry (DXA) (HOLOGIC QDR W Explorer, USA) were performed according to indications, molecular diagnostics: BSML and FokI polymorphisms of the VDR gene. According to the recommendations of The International Society For Clinical Densitometry, 2019, the criterion for reducing of

bone mineral density was considered the BMDZ-score ≤ -2.
Results: 89 children, according to QUS, showed normal bone mineral density indicators with a Z-score value of -1.2 ± 0.56 in males; -1.4 ± 0.44 in females. Pathological mutations (heterozygous and homozygous) of the BSML polymorphism of the VDR gene were detected in 47 % of males and 57.2 % of females, and pathological mutations of the FokI polymorphism of the VDR gene were founded in 66.7 % of males and in 85.7 % of females.
Low bone mineral density was diagnosed in 68 adolescents, namely in 40.9% of males (Z-score -2.3 ± 0.32) and 45.9 % of females, in whom the Z-score was -2.4 ± 0.31. 44 % of males had pathological mutations of the BSML polymorphism of the VDR gene and 71.4 % of males had the FokI polymorphism of the VDR gene. 56.2 % of females who had low bone mineral density had pathological mutations of the BSML polymorphism of the VDR gene and 62.5 % had the FokI polymorphism of the VDR gene. Adolescents who had a decrease in bone mineral density according to the results of QUS underwent DXA, which confirmed the results.
Conclusions: Decreased of bone mineral density was shown in 40.9 % of males and 45.9 % of females, while low bone mineral density was detected more often in females than in males.
Also, pathological mutations of the BSML and FokI polymorphisms of the VDR gene dominate in the examined children, which indicates a predisposition to impaired mineral metabolism and the need to carry out preventive measures to maintain the health of bone tissue.

P411

UNVEILING THE TREATMENT GAP IN THE VERY ELDERLY WITH FRAGILITY FRACTURES: A TETRIARY CENTRE'S EXPERIENCE IN PORTUGAL

D. Melim[1], A. Moniz[1], S. Rodrigues[1], J. Tremoceiro[1], M. Santos[1], L. Gago[1], J. Branco[1], M. Costa[1]

[1]Rheumatology Department, Hospital de Egas Moniz, Unidade Local de Saúde Lisboa Ocidental, Lisbon, Portugal

Objectives: This study aims to assess the delay in osteoporosis (OP) treatment among elderly patients referred to rheumatology due to fragility fractures. The secondary objective is to assess adherence to Portuguese recommendations for screening, diagnosis and management of OP in elderly patients.
Methods: This single-centre retrospective observational study included patients aged over 80 years old, who were referred between 2023 and 2024 to a Portuguese tertiary rheumatology department, in Lisbon, as part of a secondary fracture prevention program. Demographic, clinical and analytical data were collected through a review of electronic medical records.
Results: A total of 53 patients were included (84,9% female and 15,1% male) with a mean age of 84 (±3 SD) years. The mean time of delayed treatment after a fragility fracture was 3,7 (±5,3 SD) years. The most common initial fractures were vertebral (64,2%) followed by hip fractures (15,1%). The mean number of fragility fractures before the first rheumatology evaluation was 2,9 (±1,6 SD). Seventeen patients (32,1%) had a dual-energy X-ray absorptiometry compatible with OP before the sentinel fracture and only three (17,6%) of them were treated with anti-osteoporotic drugs before the first fracture. Thirty-six patients (67,9%) were never screened for OP before their first fracture.
Conclusion: This study highlights the lack of adherence to the Portuguese OP guidelines in very elderly individuals, not only concerning its screening but also the beginning of anti-osteoporotic treatment after OP diagnosis and/or after a fragility fracture. Despite the challenges of managing osteoporosis in this age group, it is important to address the increased risk of fractures after a sentinel fracture to reduce morbidity and mortality. We consider that adhering to national guidelines and implementing secondary fracture prevention programs are essential steps in improving outcomes for this population.

P412

SKELETAL COMPLICATIONS IN ADULT PATIENTS TREATED FOR TYPE 1 GAUCHER'S DISEASE (GD1): SINGLE CENTER EXPERIENCE

D. Miljic[1], N. Suvajdzic Vukovic[1], Z. Jemuovic[1], Z. Pravdic[1], I. Cekic[1], I. Jevtic[1], B. Kurcubic[1], M. Nikolic-Djurovic[1]

[1]University Clinical Center of Serbia, Belgrade, Belgrade, Serbia

Introduction: Skeletal complications in adult patients with GD1 are common and represent significant comorbidity burden contributing to chronic pain, decreased quality of life, mobility and physical performance.

Study design: We conducted an observational cross-sectional study in adult patients with GD1 treated at the University Clinical Center of Serbia over the last 2 decades.
Aim: To investigate prevalence of skeletal complications and associated risk factors in GB1 and compare bone mineral density (BMD) parameters with matched controls.
Patients and methods: Study included 26 patients diagnosed with GB1 (14 females (53,8%), 7 postmenopausal) median age 49 (range 27-70) years. Age and sex matched control group of 20 healthy subjects (11 female (55%), 7 postmenopausal) median age 52.5 (range 24-79) years, was used for comparisson. Median age at diagnosis was 21.5 (range: 2-49) years, median duration of specific treatment for GD1 was 14.6 (range: 1-25) years. Two thirds of GB1 patients received enzyme replacement (ER) 16/25 (65%), one third 10/25 (36%) substrate reduction treatment (SRT). Clinical, genetic and osteodensitometric data were collected and analysed statistically.
Results: Skeletal complications were reported in majority of patients with GD1: bone pain (76.9%), deformities (58.8%), bone crises 38.5%, fractures (23%). Decreased bone mineral density (BMD) at lumbar spine or hip was more prevalent i GD1 group (18/26) compared to controls (9/20, p=0.05). Mean T score values at lumbar spine, but not hip (femoral neck), were significantly lower in patients compared to controls (-1.6±1.5 vs 0.01±1.3, p<0.01).
The most prevalent genotype in our cohort, N370S/RecNcil (23%) was associated with 1) significantly lower spine and hip T score

values compared to other GB1 genotypes (p=0.023), and higher prevalence of bone crises (83.33% vs 20%, p=0.05).
Eight out of 26 (30.7%) GB1 patients underwent splenectomy. T score values (hip or spine using the worst value) were significantly lower in these patients (-2.8±1.5 splenectomzed vs GB1 alone -1.4±1.1, p=0.014), and bone crises more prevalent (6/8 (75%) vs GB1 alone 4/18 (22.2%), p=0.026).
SRT induced statistically significant improvement in hip T score values compared to ER (mean delta T score difference 0.22±0.62 for SRT vs -0,2±0.4, p=0.048 for ER), finding related to duration of follow-up/treatment period (P=0.039).
Conclusion: Lumbar spine T scores in GB1 are significantly lower compared to matched healthy controls. N370S/RecNcil genotype and splenectomy were associated with lower T score values at spine/hip and higher prevalence of bone crises in our GB1 cohort. SRT induced more significant improvement in hip T scores compared to ER.

P413

THE ROLE OF LASER THERAPY IN MANAGING OSTEOPOROSIS AND PSORIATIC ARTHROPATHY

D. Munteanu-Covila[1], E. Russu[1], L. Groppa[1]

[1]Discipline of rheumatology and nephrology, Nicolae Testemițanu State University of Medicine and Pharmacy, Chisinau, Moldova

Background
Psoriatic arthropathy (PsA) is a chronic inflammatory disease affecting joints, skin, and entheses, frequently associated with systemic complications such as osteoporosis (OP). Chronic inflammation, corticosteroid use, and altered bone remodeling significantly contribute to the prevalence of OP in PsA patients. Laser therapy has emerged as a potential adjunctive treatment to systemic therapies, offering benefits for both skin lesions and entheses, and potentially improving bone health.
Objectives
This study aimed to evaluate the prevalence and progression of osteoporosis in PsA patients, its impact on disease activity and quality of life, and the potential benefits of laser therapy as an adjunct to standard PsA management.
Methods
A prospective study of 78 PsA patients diagnosed using CASPAR criteria was conducted. Patients were divided into two groups: one receiving standard systemic therapy (methotrexate and biologics) and the other combining systemic therapy with laser treatment targeting skin lesions and entheses. Bone mineral density (BMD) was measured using DXA at baseline and six months. Disease activity was assessed using the Disease Activity in Psoriatic Arthritis (DAPSA) score, while skin severity was measured with the Psoriasis Area and Severity Index (PASI). Quality of life and functional impairment were evaluated using PsAQoL and HAQ-DI.
Results
Osteoporosis was identified in 34.6% of patients, predominantly in postmenopausal women and those aged >60 years. Patients with osteoporosis exhibited higher DAPSA scores (p<0.05), reduced physical function, and worse quality of life (PsAQoLscores 23% lower, p<0.01). The laser therapy group showed significant reductions in PASI (-65% vs. -42%, p<0.01) and DAPSA scores (-35% vs. -22%, p<0.05) compared to the control group. Notably, 15% of patients in the laser group demonstrated improved BMD, compared to 8% in the control group.
Conclusions
Osteoporosis significantly exacerbates the burden of PsA, highlighting the need for integrated management. Laser therapy, as an adjunct to systemic treatments, not only improves skin and joint outcomes but also shows potential benefits for bone health. These findings advocate for the inclusion of laser therapy in comprehensive PsA treatment strategies to enhance patient outcomes and address comorbidities like osteoporosis.

P414

ONE-YEAR MORTALITY RATES OF FRAGILITY FRACTURES OF THE PELVIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

D. N. A. Tran[1], C. Y. Hsu[2], P. M. Rommens[3], T. T. Nguyen[4], Y. J. Kuo[5], S. J. Cheng[5], Y. P. Chen[5]

[1]The International PhD Program in Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan, [2]Department of General Medicine, Taipei Medical University Hospital, Taipei, Taiwan, [3]Department of Orthopaedics and Traumatology, University Medical Centre Mainz, Johannes Gutenberg University, Mainz, Germany, [4]Department of Orthopedics, Faculty of Medicine, Can Tho University of Medicine and Pharmacy, Can Tho, Vietnam, [5]Department of Orthopedics, Taipei Municipal Wan-Fang Hospital, Taipei Medical University, Taipei, Taiwan

Objective: This study investigates the one-year mortality of fragility fractures of the pelvis (FFP) patients categorized under this system and treated with surgery or conservative methods, aiming to assess the algorithm's effectiveness. **Material and Methods:** We systematically searched PubMed, Embase, Scopus, and Web of Science for English studies on the one-year mortality of FFP with no publication date restrictions. Study quality was assessed using the Newcastle-Ottawa Scale. Pooled one-year mortality rates were calculated using random-effects models. Additionally, if applicable, odds ratios (OR) with 95% confidence intervals (CI) were employed. PRISMA guidelines were followed for reporting, and the study was registered with PROSPERO. **Results:** Analysis of 22 studies encompassing 3265 patients with FFP revealed a concerning overall one-year mortality rate of 15.5%. Mortality varied by fracture type, with FFP IV having the lowest rate (7.5%) and FFP III having the highest (17.0%). All studies concurred on conservative treatment for FFP I. For other fracture types, mortality rates differed between conservative and surgical approaches. Conservative treatment resulted in rates of 14.9%, 21.8%, and 5.1% for FFP II, III, and IV, respectively. Conversely, surgical treatment yielded mortality rates of 16.8%, 19.5%, and 24.2% for FFP II, III, and IV, respectively. **Conclusion:** Fragility fractures of the pelvis have high mortality, especially in FFP III. Conservative treatment may be suitable for FFP I, while surgery might be better for FFP III. The rarity of FFP

IV fractures limits conclusions, and FFP II fractures lack a clear treatment consensus. Further research is needed to optimize management for these fracture types.

P415

ARE THERE DIFFERENCES IN THE CALCULATIONS OF THE LSC IN TBS IF WE EXCLUDE SOME REGIONS OF INTEREST?

R. Abdala[1], D. O. Messina[2], M. Sesta[1], M. B. Zanchetta[1]

[1]IDIM (Instituto de Diagnóstico e Investigaciones Metabólicas), Buenos Aires , Argentina, [2]IRO Medical Centre, Buenos Aires, Argentina

Introduction:
TBS is a gray-level texture measurement acquired from DXA images of the lumbar spine and is an indirect index of microarchitecture. It is currently considered a useful tool for decision-making in the approach to patients with osteoporosis. According to recommendations recently issued by the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis, and Musculoskeletal Diseases (ESCEO) and the International Osteoporosis Foundation (IOF), TBS may be useful for monitoring treatment with denosumab and anabolic drugs. According to ISCD recommendations, regions with severe structural or pathological artifacts (e.g., flat spine, laminectomy, hardware, metastatic lesions) should not be reported. For this reason, the aim of our study was to evaluate the precision error (PE) and least significant change (LSC) according to the inclusion of all regions of interest (L1-L4), 3 vertebrae (L1-L3, L2-L4), and 2 vertebrae (L1-L2, L2-L3, L3-L4).
Materials and methods
A prospective design study was carried out to evaluate the accuracy and LSC in a reference center in the city of Buenos Aires during 2024. Thirty representative women from the center were included to be scanned two times after repositioning, ensuring degrees of freedom for a 95% CI. The coefficient of variation, PE, and LSC were calculated according to the International Society for Clinical Densitometry guidelines. CL BMD (g/cm²) was measured using a GE Lunar Prodigy device (GE Lunar, Madison, WI, USA), and TBS version 3.0.2.0 was used for analysis.
Results
Mean age of the sample was 64.72±12.31, and weight was 65.18±13.22 (kg). EP according to the regions included were as follows: L1-L4 (1.5%), L1-L3 (1.75%), L2-L4 (1.61%), L1-L2 (2.05%), L2-L3 (1.97%), L3-L4 (1.68%). The LSC in % was for L1-L4 (4.15%), L1-L3 (4.45%), L2-L4 (4.45%), L1-L2 (5.69%), L2-L3 (5.45%), and L3-L4 (4.68%). L1-L4 showed less variability compared to L1-L2 (0.012 vs. 0.017; p = 0.0015) and L2-L3 (0.012 vs. 0.016; p = 0.0033).
Conclusions
In clinical practice there are situations where regions of interest should be ruled out. In accordance with recent recommendations by ESCEO on treatment monitoring and TBS, we believe it is appropriate for each center to be able to evaluate the LSC for different vertebral combinations.

P416

METABOLIC COMORBIDITIES AND OSTEOPOROSIS IN OSTEOARTHRITIS – A COMPLEX INTERACTION

D. Postovan[1], E. Russu[1], L. Groppa[1]

[1]Nicolae Testemițanu State University of Medicine and Pharmacy, Chișinău, Moldova

Background: Osteoarthritis (OA) is a degenerative joint disease marked by cartilage loss, subchondral bone remodeling, and chronic inflammation. In addition to its musculoskeletal impact, OA is closely associated with metabolic comorbidities such as obesity, type 2 diabetes mellitus (T2DM), and dyslipidemia. Osteoporosis (OP), a systemic skeletal disorder characterized by low bone mineral density (BMD), frequently coexists with OA and metabolic disorders, amplifying the disease burden and complicating management.
Objectives: To assess the prevalence of metabolic comorbidities and osteoporosis in patients with OA, explore the interplay between these conditions, and analyze their combined impact on disease severity, progression, and quality of life.
Methods: A cross-sectional study was conducted involving 180 patients with primary OA diagnosed per ACR criteria. Clinical assessments included demographic and metabolic profiling, radiographic grading (Kellgren-Lawrence scale), and BMD measurements using DXA. Metabolic comorbidities were identified through medical history, laboratory tests (lipid profile, fasting glucose), and anthropometric measurements. Statistical analyses were performed to examine associations between metabolic comorbidities, OP, and OA severity.
Results: The mean age of participants was 64.2 ± 7.1 years, with 68% being women. Osteoporosis was diagnosed in 36% of patients, primarily in postmenopausal women and individuals over 65 years. Metabolic comorbidities were highly prevalent, including obesity (45%), T2DM (30%), and dyslipidemia (32%). Patients with coexisting OP and metabolic disorders demonstrated significantly higher KL grades (III-IV) and worse WOMAC scores in pain, stiffness, and physical function domains ($p<0.001$). Reduced BMD was strongly associated with obesity and T2DM ($p=0.004$ and $p=0.01$, respectively). Elevated systemic inflammation (CRP >10 mg/L) and insulin resistance (HOMA-IR >2.5) were identified as independent predictors of OP and metabolic comorbidities in OA patients.
Conclusions: Osteoporosis and metabolic comorbidities are highly prevalent among OA patients, exacerbating disease severity and functional limitations. The interplay of systemic inflammation and metabolic dysregulation underscores the need for a multidisciplinary management approach targeting both OA and its comorbid conditions. Comprehensive strategies addressing bone health, metabolic control, and lifestyle interventions are critical to improving patient outcomes. Future research should focus on the pathophysiological connections between OA, OP, and metabolic disorders to develop targeted therapeutic approaches.

P417

OSTEOPOROSIS AND OSTEOARTHRITIS – INTERSECTING PATHOLOGIES IN A COMORBID LANDSCAPE

D. Postovan[1], E. Russu[1], L. Groppa[1]

[1]Nicolae Testemițanu State University of Medicine and Pharmacy, Chișinău, Moldova

Background: Primary osteoarthritis (OA) is a chronic degenerative disease primarily affecting cartilage, subchondral bone, and synovium. Alongside OA, osteoporosis (OP) emerges as a common comorbidity, both sharing risk factors such as aging, obesity, and systemic inflammation. The coexistence of OA and OP complicates disease progression and management, necessitating an integrated clinical approach to address overlapping pathophysiology and improve patient outcomes.
Objectives: This study investigates the prevalence of osteoporosis in patients with primary OA, explores the interrelationship between these conditions, and evaluates the influence of comorbidities on disease severity, functional impairment, and quality of life.
Methods: A cross-sectional study was conducted on 150 patients diagnosed with primary OA according to the ACR criteria. Comprehensive assessments included clinical examination, Kellgren-Lawrence (KL) radiographic grading for OA, and dual-energy X-ray absorptiometry (DXA) for bone mineral density (BMD). Disease severity and functional limitations were evaluated using the WOMAC index. Comorbidities, including osteoporosis, were identified through clinical history, laboratory testing, and imaging. Statistical analyses were performed to identify correlations between OA, OP, and other comorbid conditions.
Results: The study cohort had a mean age of 63.8 ± 7.2 years, with a female predominance (72%). Osteoporosis was diagnosed in 36% of patients, with higher prevalence in postmenopausal women and individuals aged >65 years. Comorbid conditions included obesity (46%), hypertension (58%), and type 2 diabetes mellitus (31%). Patients with coexisting OP and OA reported significantly worse WOMAC scores in pain ($p=0.02$) and physical function domains ($p<0.01$). Advanced KL grades (III-IV) were associated with reduced BMD at the femoral neck ($p=0.001$) and lumbar spine ($p=0.003$). Obesity and metabolic syndrome further exacerbated disease severity and functional decline.
Conclusions: Osteoporosis and osteoarthritis often coexist, creating a synergistic burden that worsens clinical outcomes. This study underscores the need for early diagnosis and integrated management of these conditions, addressing both joint and bone health. Targeted interventions, including weight management, bone-strengthening therapies, and multimodal pain management, are essential to improve patient quality of life and reduce disability. Further research should explore the shared inflammatory and metabolic pathways underlying OA and OP to develop more effective therapeutic strategies.

P418

THE ROLE OF IMMUNOMODULATORS IN OSTEOARTHRITIS (GONARTHRITIS)

D. Ruci[1], E. Kaçi[1], M. Jordhani[1], L. Dumbo[1], A. Kapiti[1], L. Zavalani[1], A. Ndrea[1]

[1]Mother Theresa Hospital, Tirana, Albania

Objective: This study evaluates hydroxychloroquine's potential as a disease-modifying therapy for knee osteoarthritis, focusing on its anti-inflammatory effects, symptom relief, and progression slowing in inflammatory cases.
Material and Methods: A double-blind, placebo-controlled trial was conducted at the University Hospital Center "Mother Teresa" in Tirana, involving patients with primary gonarthritis classified as Kellgren and Lawrence grade II or III. Participants were randomly assigned to receive either hydroxychloroquine tablets (200 mg twice daily) or placebo. Symptom progression was monitored using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at baseline and at 6, 12, 18, 24, 30, and 36 weeks.
Results: Thirty patients were included, with 14 in the hydroxychloroquine (HCQ) group and 16 in the placebo group. Mean ages were 62.8 ± 7.0 years and 62.4 ± 6.4 years, respectively, with no significant baseline differences. At 36 weeks, the HCQ group showed significant improvements in knee pain, stiffness, and function compared to placebo, as reflected in WOMAC total and subscale scores. The placebo group exhibited notable improvement at week 6, with no further significant progress, while the HCQ group experienced substantial improvement at week 12, continuing throughout the follow-up. Significant differences between groups were observed at all assessed intervals. Three patients in the HCQ group reported diarrhea and headache; no side effects were noted in the placebo group. Additionally, the HCQ group consumed fewer painkiller pills on average throughout the trial.
Conclusion: Hydroxychloroquine demonstrates potential as an immunomodulatory treatment for gonarthritis, providing significant symptom improvement in mild to moderate cases. These findings suggest that immunomodulators could serve as promising alternatives to traditional therapies.

P419

THE ROLE OF INTERFERONS IN THE DEVELOPMENT OF CLINICAL MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS

D. Rusanov[1], S. Spitsina[2]

[1]Volgograd State Medical University, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia

Objective: To study and summarize the data on the mechanisms of production and influence of type I INF on the course of SLE.
Methods: Data from PubMed Central were analyzed.

Results: The earliest disturbance in the immune system in SLE patients is an increase in type II INF (IFNγ) levels, detectable more than 4 years before disease onset and autoantibody detection. IFNγ is expressed by many cells of both the innate and adaptive immune system, including T and B cells, and, like other IFNs, transmits signals through the JAK-STAT pathway. The activity of IFNγ and related genes correlates with SLEDAI score and antibody levels to double-stranded DNA, further indicating its role in pathologic autoantibody production. Sirobhushanam S. et al. showed that levels of circulating type I IFN correlate with SLE activity. Large studies have identified specific effects of IFNs that contribute to specific organ damage. A direct effect of type I INF on bone marrow has been revealed: INFα suppresses bone marrow production, resulting in leukopenia, anemia and thrombocytopenia. The contribution of type I INF to lymphopenia in patients with SLE is further supported by data from clinical trials with anifrolumab, in which blockade of the type I IFN receptor was accompanied by normalization of lymphocyte counts. Also, IFN blockade with anifrolumab improved skin manifestations of SLE: the activity and severity index of cutaneous lupus erythematosus improved by more than 50%. In vitro studies in mice have long established the role of IFN in the pathophysiology of lupus nephritis: INF type I receptor deficiency reduces the risk of nephritis, while systemic administration of INFα and INFβ to mice increased tubular inflammation and proteinuria, decreased differentiation of renal progenitor cells into podocytes, promoting scar formation, and led to therapy resistance. The role of INFγ is less studied but may also contribute to lupus nephritis. Studies of synovial tissue from patients with arthritis in SLE have shown increased expression of type I INFγ, which is different from rheumatoid arthritis and osteoarthritis. A recent analysis showed that INFγ may correlate more strongly with lupus arthritis compared with other clinical manifestations. INFs affect endothelial cell function and thus are involved in increasing cardiovascular risk in SLE.
Conclusion: Thus, IFNs are one of the key links in the pathogenesis of SLE, they participate in the development of lesions of the main target organs, which explains the increased interest in the use of antibodies to type I interferon receptors.

"HOME REHABILITATION IN PATIENTS WITH FRACTURES: FUNCTIONAL IMPROVEMENT AND TREATMENT EFFICIENCY"

D. Sanchez Corretger[1], F. Orient Lopez[1], C. Agudo Fernandez[1], F. E. Fontg Manzano[1], B. Zeballos Buscaglia[1]

[1]Hospital Universitari Sagrat Cor Quironsalud Barcelona, Barcelona, Spain

OBJECTIVE: Our Rehabilitation Service (RHB) provides treatment both at outpatient and home level to public health patients in the Eixample Esquerra area of Barcelona, assisting a population of approximately 154,413 inhabitants, of which more than 12% are over 70 years of age. The aim of this study is to analyse the functional results of fractures that received rehabilitation treatment at home by our service during the year 2024.

MATERIAL AND METHODS: Patients treated at home for fractures in 2024.Design:Prospective descriptive study. January-December 2024. n=207. Variables: age, sex, diagnosis, Barthel index (previous, initial and discharge), functional improvement (increase in Barthel) and RHB sessions performed (number). A descriptive analysis of the data was performed. The qualitative variables are presented in absolute frequency and percentage (%) and the quantitative variables with mean and standard deviation (SD).
RESULTS: Of 1,041 patients treated at home, 207 had fractures. Population: 78.3% female, mean age: 81.12 years (SD:8.19) and 21.7% male, mean age: 74.3 years (SD:9.21). Aetiology: 66.3% femur fractures, 19.2% humerus fractures, 10.4% branch/pelvic fractures and 5.4% ankle fractures. In 24 patients (11.6%) there were multiple fractures (most frequent association femur and humerus (n=9)). Middle Barthel – pre-fracture 79.05, initial RHB 57.90 and discharge 73.06 points. Mean functional improvement: increase of 15.16 Barthel points (SD: 5.32), with a mean of home RHB sessions of 11.92 (SD: 4.01)
CONCLUSIONS: The RHB treatment of fractures at home achieves an efficient functional outcome (Barthel increase 15 points) with a tight number of sessions. The results obtained are comparable (Barthel increase and number of RHB sessions) to those observed in fractures treated on an outpatient basis in our department in patients of the same age range.

P421

FUNCTIONAL RESULTS OF THE FAST-TRACK HOME REHABILITATION PROGRAM IN TOTAL HIP AND KNEE ARTHROPLASTIES

F. Orient Lopez[1], D. Sanchez Corretger[2], C. Agudo Fernandez[1], B. Zeballos Buscaglia[1], F. E. Fontg Manzano[1]

[1]HU Sagrat Cor. Quironsalud, Barcelona, Spain, [2]HU Sagrat Cor Quironsalud, Barcelona , Spain

OBJECTIVES: Our physical medicine and rehabilitation department treats patients in the basic health areas of the Eixample Esquerre, Barcelona; assisting a population of approximately 154.413 inhabitants, in which more than 25% over 65 years of age. Our study aims to analyze the functional outcome of total hip arthroplasty(THA) and total knee arthroplasty(TKA) under a fast-track program, performed as a home-based rehabilitation treatment(HRT) during 2024.
MATERIAL AND METHODS: Prospective descriptive study. From January to December 2024. N = 141.Patients under home based rehabilitation for THA and TKA. Variables: age, sex, Barthel index-(previous, initial and discharge), functional improvement(Barthel increase) and rehabilitation sessions performed(number). Descriptive data analysis. Qualitative variables are showed as absolute frequency and percentage(%), and quantitative variables are showed as mean and standard deviation(SD).
RESULTS: Of the 975 patients assessed under HRT, 141 were THR and TKA. THR: n = 45, women 60,52%, mean age 72,90(SD 9,15) and 39,48% men, mean age 73,52 years(SD 8,02). Average Barthel: initial 67,40, at discharge 92,10, mean functional improvement 24,70 points, with a mean of rehabilitation sessions 12.21(SD

2.01). TKA: n = 96, women 69,80%, mean age 80,01(SD 9,18) and 30,20% men, mean age 73,9 years(SD 10,11). Average Barthel: initial 71,30, at discharge 95,97, average functional improvement 24,67 points, with an average of sessions of rehabilitation 12,01(SD 1,81).

CONCLUSIONS: HRT under a fast-track program for THA and TKA achieves an efficient functional outcome (Barthel increase> 24 points) with an adjusted number of sessions, similar to that accomplished at the outpatient level, avoiding the complications and costs derived from the patient's displacement to the rehabilitation center.

[1]Brugmann university hospital - Universite Libre de Bruxelles, Brussels, Belgium

Objective: We assessed the associations between osteoporosis, sarcopenia, osteosarcopenia with the presence of fragility fractures in the past two years in community-dwelling postmenopausal women from the *Fracture Risk Brussels Epidemiological Enquiry (FRISBEE2)* cohort.

Methods: Retrospective cohort design. The FRISBEE2 cohort study included 907 community-dwelling postmenopausal women in Belgium. Sarcopenia (according to eight definitions: EWGSOP2 "probable" and "confirmed"; IWGS; SCWD; SDOC; FNIH; Baumgartner; and Newman), osteoporosis (T-score BMD of lumbar spine, total hip, or femoral neck ≤-2.5 SD), and osteosarcopenia (8-combination-based approach) were assessed at baseline. We recorded and validated recent (i.e., within the 2 years *before* baseline) central or major osteoporotic -MOF- fractures (dichotomous variable). Multivariate regression models, adjusted for age, BMI, sedentary lifestyle, and comorbidities were used to evaluate the associations between osteoporosis, sarcopenia, and osteosarcopenia at baseline and the presence of recent fragility fractures.

Results: Forty-seven (5.2%) of the 907 included women aged 77 (75–81) years had experienced recent central or MOFs in the 2 years prior to study inclusion. The crude analysis showed significant associations between osteoporosis, sarcopenia, and osteosarcopenia, and the presence of a recent fracture. In a multivariate analysis, only EWGSOP2 "probable" sarcopenia, defined by a low handgrip strength, was associated with a history of recent fracture [OR= 2.14 (1.05-4.35); p= 0.035]. As expected, the prevalence of sarcopenia (ranging from 5.6% by SCWD to 35.9% by Baumgartner definition) and osteosarcopenia (2% by osteoporosis & SCWD to 11.4% by osteoporosis & Baumgartner definition) at baseline varied widely depending on the definitions used.

Conclusions: Postmenopausal women with a history of recent fragility fracture had a low handgrip strength (EWGSOP2 "probable" sarcopenia), highlighting the close crosstalk between bone and muscle strength. The presence of a recent central or MOF fracture in a post-menopausal woman should alert on probable sarcopenia. Further longitudinal, prospective studies are needed to explore the role of muscle strength as a potentially modifiable, treatable clinical risk factor for fragility fractures.

P424

SARCOPENIA AND ELECTROCARDIOGRAPHIC MARKERS OF ARRHYTHMIA RISK IN OLDER ADULTS

O. Erdogan[1], T. Erdogan[2], Z. Fetullahoglu[2], D. Erbas Sacar[3], D. Seyithanoglu[2], O. Kumet[4], S. Ozkok[2], M. A. Karan[2], G. Bahat[2]

[1]Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery, Training, and Research Hospital, Istanbul, Turkiye, [2]Istanbul University Faculty of Medicine, Department of Geriatric Medicine/Istanbul Musculoskeletal Health Consortium, Istanbul, Turkiye, [3]Kartal Dr. Lutfi Kirdar City Hospital, Istanbul, Turkiye, [4]University of Health Sciences Turkey, Van Training and Research Hospital, Van, Turkiye

Background: Cardiac arrhythmias are prevalent among older adults and significantly increase morbidity and mortality. Sarcopenia, a progressive skeletal muscle disorder, is associated with systemic inflammation, oxidative stress, and structural remodeling, potentially affecting cardiac function. This study investigates the relationship between sarcopenia and electrocardiographic (ECG) parameters indicative of arrhythmia risk.

Methods: A cross-sectional retrospective study was conducted with 283 community-dwelling older adults (≥60 years) who underwent comprehensive geriatric assessments. Sarcopenia was diagnosed based on the EWGSOP2 criteria, incorporating handgrip strength (35 kg for male and 20 kg for female) and skeletal muscle mass index (SMMI) (SMM/BMI). ECG parameters, including QTc interval, P-wave dispersion, Tp-Tend interval, and fragmented QRS, were measured. Multivariate logistic regression was performed to analyze the association between sarcopenia and ECG abnormalities.

Results: Sarcopenia was identified in 35.7% of participants, who were older (mean age 75.9 ± 6.3 years, p < 0.001) compared to

non-sarcopenic individuals. Fragmented QRS (17.0% vs. 8.2%, p = 0.032) and atrial fibrillation (6.9% vs. 1.6%, p = 0.038) were significantly more prevalent in sarcopenic patients. P-wave dispersion, which reflects atrial electrical heterogeneity and remodeling, a known predictor of atrial fibrillation, was higher in the sarcopenia group (51.95 ± 16.94 ms vs. 46.79 ± 16.66 ms, p = 0.042). Fragmented QRS, an indicator of heterogeneous ventricular depolarization often associated with myocardial fibrosis or scarring, was independently associated with sarcopenia (OR: 2.415, 95% CI: 1.051–5.547, p = 0.038) in multivariate analysis.
Conclusion: Sarcopenia is associated with significant alterations in ECG parameters indicative of arrhythmia risk, including fragmented QRS and P-wave dispersion. These findings suggest that sarcopenia may contribute to electrical remodeling and arrhythmogenesis. Further prospective studies are warranted to explore the causal pathways linking sarcopenia and arrhythmias.

P425

THE ROLE OF MEDICATION TYPE IN OSTEOPOROSIS TREATMENT: EFFECTS ON ADHERENCE, PERCEPTION, AND BELIEFS

D. Sindel[1], F. M. Akpınar[1], F. B. Kıvanç İnanöz[1], E. Temeloğlu Şen[2]

[1]İstanbul University, İstanbul Faculty of Medicine, Department of Physical Medicine and Rehabilitation, İstanbul, Turkiye, [2]İstanbul University, Faculty of Literature, Department of Psychology, Applied Psychology Division, İstanbul, Turkiye

Objective: This study investigates the often-overlooked impact of medication type (oral versus injectable) on adherence, illness perception, and beliefs about medication in osteoporosis patients.
Material and Methods: A total of 272 osteoporosis patients, already using either 'weekly oral treatment' (n=105) or 'biannual injection' (n=167), were included in the study. Statistical analyses were conducted to evaluate differences in medication adherence, illness perception, and beliefs about medicines between these groups. All participants completed the Clinical Information Form, the Medication Adherence Report Scale, the Brief Illness Perception Questionnaire, and the Beliefs about Medicines Questionnaire. Statistical analyses were performed using Statistical Package for the Social Sciences (SPSS) Version 23.
Results: Independent samples t-test revealed no significant overall differences between the groups. A borderline significant difference was observed for the specific-concerns scale, a subscale of the Brief Illness Perception Questionnaire (t[270]=1.966, p=0.050), supported by Mann-Whitney U test results (U=7563, p=0.056). The biannual injection group (M=16.98, SD=4.23) scored higher than the weekly oral medication group (M=15.93, SD=4.34).
Conclusion: These findings suggest that the type of medication does not significantly affect patients' adherence, illness perception, or beliefs about the necessity of medication. However, medication type seems to influence specific concerns related to treatment. These results emphasize the importance of considering medication type in osteoporosis treatment planning and developing patient-centered strategies to improve outcomes. This approach not only enhances patient satisfaction but also positively impacts the overall effectiveness of healthcare services.

P426

INTERRELATION OF SARCOPENIA, OSTEOPOROSIS, AND OSTEOARTHRITIS: CLINICAL IMPACT AND MULTIDISCIPLINARY MANAGEMENT

D. Taran[1], L. Taran[2], O. Bujor[2], L. Groppa[1]

[1]"Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau mun., Moldova, [2],,Timofei Mosneaga" Republican Clinical Hospital, Chisinau mun., Moldova

Background Sarcopenia, osteoporosis, and osteoarthritis often coexist in older adults, exacerbating functional decline, fall risk, and reduced quality of life. Sarcopenia leads to muscle loss and weakness, increasing vulnerability to osteoporosis-related fractures and osteoarthritis-associated joint degeneration. A comprehensive understanding of these interrelated conditions is crucial for improving patient outcomes.
Objectives To evaluate the prevalence, clinical impact, and interrelationship of sarcopenia, osteoporosis, and osteoarthritis in patients, emphasizing their combined effect on physical performance and quality of life.
Methods A cross-sectional study was conducted involving 46 patients (mean age: 67.3 ± 6.8 years; 63% female). Sarcopenia was diagnosed using EWGSOP2 criteria, incorporating grip strength and appendicular lean mass. Osteoporosis was confirmed via DXA (lumbar spine and femoral neck), while osteoarthritis severity was assessed using the Kellgren-Lawrence grading system. Functional capacity and quality of life were evaluated using the Short Physical Performance Battery (SPPB) and HAQ-DI, respectively. Statistical analyses assessed correlations between these conditions and their impact on outcomes.
Results Sarcopenia was present in 43.5% of patients, with a higher prevalence among those with osteoporosis (58%) and osteoarthritis (61%). Osteoporosis was confirmed in 52.2% of patients, predominantly women, with significantly lower BMD at the lumbar spine (-2.9 ± 0.4) and femoral neck (-2.6 ± 0.5). Osteoarthritis affected 65.2% of patients, primarily the knee and hip joints, with Kellgren-Lawrence grade III or IV observed in 48.7%. Patients with overlapping conditions exhibited worse physical performance (SPPB: 6.8 ± 1.9, p<0.01) and greater functional impairment (HAQ-DI: 1.98 ± 0.4, p<0.001). Sarcopenia and osteoporosis were significantly associated with an increased fall risk, while osteoarthritis severity correlated with higher pain levels and disability.
Conclusions The coexistence of sarcopenia, osteoporosis, and osteoarthritis amplifies functional decline and reduces quality of life. These findings highlight the importance of early detection and integrated management strategies targeting muscle strength, bone health, and joint stability to mitigate the impact of these conditions. Multidisciplinary approaches, including physical therapy, nutrition, and pharmacological interventions, are essential for optimizing care and outcomes.

P427

X-RAY CHANGES IN THE EXPERIMENT WITH INTRA-ARTICULAR INJECTION OF SODIUM MONIODOACETATE AND SYNOVIAL FLUID OF A PATIENT WITH OSTEOARTHRITIS INTO THE KNEE JOINT OF RATS

D. Y. Yankina[1], M. Chilingaryan[1], V. Smirnova[1]

[1]North-Western State Medical University named after I.I. Mechnikov, St. Petersburg, Russia

Objective: Currently, developing methods for the early diagnosis of osteoarthritis in patients is a priority. The aim: to compare the X ray changes caused by the injection of sodium monoiodoacetate (MIA) with those caused by synovial fluid of a patient with stage II osteoarthritis of the knee in an animal model. Material and Methods: 20 Wistar rats were divided into 4 groups. The control group (C) received 10 µl of sterile 0.9% NaCl solution (saline) in both knee joints. In group S, 10 µl of synovial fluid from a patient with stage II knee osteoarthritis were injected into the right knee joint, and 10 µl of saline into the left one. In group M, 10 µl of MIA solution at a dose of 2 mg per 10 µl were injected into the right knee joint, and 10 µl of saline into the left one. Animals from group MS received 10 µl of MIA solution into the right knee joint, and synovial fluid into the left knee joint. All animals underwent X-ray and histopathomorphological examination on days 10, 26, and 46. Results: The knee joint tissue in the control group remained intact according to X-ray data. The greatest changes were founded in the joints of rats administered MIA, with a noticeable progression of inflammatory and destructive processes from the 26th to the 46th day. Meanwhile, in rats administered synovial fluid, inflammatory changes were minimal on the 10th day. From the 26th day, edema appeared, narrowing of the joint space without changes in the subchondral bone. By the 46th day, the changes worsened and were comparable to those in rats administered MIA, but did not affect the subchondral bone. Conclusion: The maximum changes were observed in the tissues of the knee joints of rats with administration of MIA. Changes in the joints after the introduction of synovial fluid, developing by the end of the 4th week, lag behind in time and severity of those in the joints with the introduction of MIA. Further research is necessary to determine the nature of cellular infiltration and inflammatory reaction when introducing synovial fluid and MIA. Immunohistochemical and pathomorphological studies are currently underway.

P428

THE EFFECT OF ANTICONVULSANTS ON THE BONE SYSTEM

D. Yusupova[1], F. Muratov[1]

[1]Tashkent medical academy, Tashkent, Uzbekistan

Introduction. There have been several reports that chronic antiepileptic therapy is associated with abnormal bone and calcium metabolism, osteoporosis/osteomalacia, and increased fracture risk. Adverse bone effects of long-term antiepileptic therapy have been reported for more than four decades, but the exact molecular mechanism is still lacking. Several mechanisms have been proposed regarding the loss of bone mass induced by antiepileptic drugs: hypovitaminosis D, hyperparathyroidism, estrogen deficiency, and calcitonin deficiency.
Purpose: To study the effect of anticonvulsant drugs on bone density and women with epilepsy.
Methods: This study was performed at the multidisciplinary clinic of Tashkent Medical Academy in the period of 2021-2023. Thirty women of fertile age with epilepsy and 30 healthy control subjects participated in the study. Calcium, phosphorus, vitamin D, parathormone and alkaline phosphatase levels in blood serum were determined. Dual-energy X-ray absorptiometric scanning (DEXA) was also performed.
Results of the study: serum calcium, phosphorus and vitamin D levels were significantly lower, whereas serum parathormone and alkaline phosphatase levels were significantly higher in women with epilepsy compared to the control group. The data are summarized in Table 1. Bone mineral density (BMD) disorders were detected in 22 patients (73.4%). A statistically significant difference in DEXA scan measurements in different regions was found between patients with epilepsy and controls. Patients with epilepsy treated with antiepileptic enzyme inducer drugs (PEPs) had significantly lower serum values (calcium, phosphorus and vitamin D) and lower MPCT values compared to those treated with anticonvulsant liver enzyme inhibitor drugs. The MPCT results were positively correlated with serum calcium, phosphorus, and vitamin D, but negatively correlated with serum alkaline phosphatase and duration of therapy.
Conclusions: The results of our study showed that there are closely related and mechanisms between anticonvulsant drugs and bone density. These abnormalities may be mainly related to prolonged use of PEPs, especially liver enzyme inducers.

P429

THE INVERTED J-SHAPED RELATIONSHIP BETWEEN SERUM URIC ACID LEVEL AND ABDOMINAL MUSCLE MASS IN KOREAN MALE POPULATION: A SINGLE-CENTER STUDY OF 5114 CASES

D.-H. Lim[1]

[1]Department of Internal Medicine/Ulsan University Hospital/University of Ulsan College of Medicine, Ulsan, South Korea

Objective:
Sarcopenia, the age-related decline in muscle mass and strength, is influenced by oxidative stress and molecular inflammation, which disrupt the balance between protein synthesis and breakdown. Uric acid (UA), a compound with both antioxidant and pro-oxidant properties, may play a role in sarcopenia. However, previous studies examining the relationship between serum UA levels and sarcopenia have yielded inconsistent results. This study aimed to investigate the association between serum UA levels and abdominal muscle mass in Korean adult men.

Methods:
We analyzed data from 5114 men aged over 20 years who underwent laboratory tests and abdominopelvic computed tomography (apCT) as part of general health examinations from May 2014 to June 2019. Participants were divided into quartiles based on serum UA levels. Abdominal muscle areas, including low-attenuation muscle area (LAMA), normal-attenuation muscle area (NAMA), and total abdominal muscle area (TAMA), were quantified using cross-sectional apCT images at the L3 lumbar vertebrae. Between-group comparisons were conducted using Pearson's chi-square test for categorical variables and ANOVA for continuous variables. Trends between serum UA quartiles and abdominal muscle areas were analyzed using univariate (ANOVA) and multivariate (ANCOVA) models, adjusting for potential confounders.

Results:
The mean age of the participants was 52.5 ± 9.37 years, with a mean body mass index (BMI) of 24.6 ± 2.92 kg/m². In the univariate analysis, LAMA, NAMA and TAMA consistently increased across serum UA quartiles. However, after adjusting for potential confounding factors such as age, BMI, smoking status, hypertension, diabetes, dyslipidemia, glomerular filtration rate, and C-reactive protein, an inverted J-shaped relationship was observed. Specifically, NAMA and TAMA values peaked in the second quartile and gradually declined in the higher quartiles, while LAMA continued to increase across all quartiles (**Table**).

Conclusion:
These findings highlight that a specific range of serum uric acid levels may be linked to optimal abdominal muscle mass in Korean adult men. This inverted J-shaped relationship suggests that moderate uric acid levels could be protective, while both lower and higher levels may adversely affect muscle mass.

Table. Adjusted mean value of abdominal muscle mass by serum uric acid quartiles

variables	Uric acid				
	quartile 1 < 5.00 mg/dl (n = 1228)	**quartile 2 5.01 ~ 5.80 mg/dl (n = 1328)**	**quartile 3 5.81 ~ 6.70 mg/dl (n = 1251)**	**quartile 4 > 6.70 mg/dl (n = 1247)**	p-value
LAMA, cm^2	26.7 (26.285-27.200) [a]	26.7 (26.285-27.200) [b]	27.1 (26.654-27.557)	27.9 (27.441-28.372) [a,b]	0.003

A PILOT STUDY ON NEUROTRANSMITTERS AND SARCOPENIA

K.-V. Chang[1], W.-T. Wu[1], Y.-L. Lin[2], D.-S. Han[3]

[1]National Taiwan University Hospital Beihu Branch, Taipei, Taiwan, [2]China Medical University, Taichung, Taiwan, [3]National Taiwan University Hospital, BeiHu Branch, Taipei, Taiwan

Background
Sarcopenia may affect neurotransmitter and hormone levels through central and peripheral nervous system. However, the relationship between sarcopenia and these markers has been scarcely studied. This study delineated the neurochemical changes and their response to therapeutic interventions in sarcopenic elders.

Method
This is a post-hoc analysis of a randomized controlled trial. We recruited 57 sarcopenic and 57 non-sarcopenic participants receiving health checkup from a district hospital in Taipei, Taiwan. Grip strength, walking speed and body composition were obtained to diagnose sarcopenia. The participants received a 12-week intervention involving resistance exercise and supplementation with branched-chain amino acids, calcium, and vitamin D3. Plasma adrenaline, noradrenaline, dopamine, serotonin, and cortisol were assessed using enzyme-linked immunosorbent assay (ELISA).

Results
Sarcopenic participants showed significantly lower levels of serotonin (p=0.002), adrenaline (p<0.001), and noradrenaline (p<0.001), with a trend toward reduced dopamine (p=0.053). Cortisol levels were similar between groups (p=0.503). Generalized estimating equations, adjusted for age and gender, showed sarcopenia was linked to reduced serotonin, adrenaline, and noradrenaline, while the intervention raised noradrenaline levels (p=0.001).

Conclusion
Lower plasma serotonin, adrenaline, and noradrenaline levels were noted in elders having sarcopenia, compared with sex and age matched non-sarcopenic controls. Exercise and nutritional interventions increased noradrenaline in sarcopenic elders. Future studies are needed to evaluate the causal relationship between plasma neurotransmitters and sarcopenia.

P431

COMPARISON OF THE CLINICAL PICTURE OF HIP JOINT DAMAGE WITH THE RESULTS OF RADIOGRAPHIC EXAMINATION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

E. Agafonova[1], T. Dubinina[1], S. Erdes[1], A. Demina[1]

[1]V. A. Nasonova Research Institute of Rheumatology,, Moscow, Russia

Introduction. Inflammatory lesion of the hip joints (HJ) (coxitis) is one of the main factors of early disability of patients with axial spondylitis (axSpA). Objective. To compare the dynamics of clinical manifestations of coxitis with X-ray data of the HJ in patients with axSpA. Material and methods. The analysis included 62 patients diagnosed with axSpA (according to the ASAS 2009 criterion), observed for at least 2 years. The diagnosis of coxitis was established on the basis of clinical signs such as pain in the groin area and / or limitation of movement in the HJ. The average age of 62 patients was 29.2 ± 6.4 years with an average duration of the disease of 23.8 ± 16.2 months, 92% of patients were positive for HLA-B27. Results: Clinical signs of coxitis were detected at the beginning of the observation in 35 (56%) of 62, and after 2 years of active observation - in 13 (21%). At inclusion in the study, out of 62 patients, radiographic coxitis was detected in 1 (2%) patient (BASRI hip ³2). During the observation period, the number of patients with radiographic coxitis was 13 (21%), and radiographic progression in the hip joint was detected in 23 (37%) patients. Initially, out of 35 patients who noted pain in the hip joint, radiographic progression of coxitis was detected in 16 over 24 months, and after a year of observation, pain in the hip joint persisted in only 7, and after 24 months, pain was noted in only 4 of them. Of the 27 patients who did not experience pain in the hip joint at the time of inclusion, development and progression of coxitis was radiographically detected in 7. Conclusion: Clinical signs of hip joint damage are detected in 50% of patients with early axSpA. Pain syndrome in the hip joint in axSpA is accompanied by radiographic progression only in half of the cases, and in 12% it was asymptomatic.

P432

EFFECTIVENESS AND SATISFACTION OF AN EXERCISE-BASED TELEREHABILITATION PROGRAMME: PILOT TESTING ACROSS WOMEN WITH DIASTASIS RECTUS ABDOMINIS

M. Antoniou[1], A. Skoura[1], D. Koumoundourou[2], M. Tsekoura[1], E. Trachani[1], E. Billis[1]

[1]University of Patras, Patras, Greece, [2]University Hospital of Rio, Patras, Greece

Objective. Exercise-based telerehabilitation is suggested as an alternative means of rehabilitation when face-to-face interventions are deemed difficult. However, its effectiveness remains questionable. This pilot's objective investigated the effectiveness, satisfaction and compliance of implementing an exercise-based program via telerehabilitation in postpartum women with diastasis rectus abdominis (DRA), representing a group with barriers in attending face-to-face interventions.
Materials and Methods. Sample comprised 18-50 year-old women with established postpartum DRA (>6 months) and familiarity in using electronic media. Telerehabilitation included a 12-week exercise program, delivered 3-times weekly via two synchronous teleconference sessions (monitoring-supervision in real time by a physiotherapist) and one asynchronous one (electronic platfom-based video recorded sessions). Program comprised progressive retraining exercises of deep abdominals (core), pelvic floor muscles, trunk strengthening and combinations with progressive load functional retraining exercises. Outcomes (assessed pre- and post-intervention), included a) patient satisfaction, using the Telehealth Usability Questionnaire (TUQ_Greek), b) inter-recti distance (IRD), the distance/width between the rectus abdominis muscles assessed by real-time 2D diagnostic ultrasound, c) trunk muscle endurance tests (plank and McGill's trunk flexor endurance), d) body image assessed with Body Image States Scale (BISS_Greek) and e) patient compliance assessed through a detailed exercise diary. Analysis was performed with SPSS.
Results. Thirteen DRA women (37.54±5.49 years) enrolled and completed the pilot. Telerehabilitation appeared satisfactory for 84.62% of women. Overall mean score in TUQ_Greek was high (6.28±0.60), particularly due to the ease of use of the system, women's satisfaction on its usefulness, quality of interface and satisfactory therapist interaction (synchronous mode). IRD yielded statistically significant decreases at 3-months ($p<0.05$). Post-intervention, front plank tests had non-statistically significant improvements, whereas, significant improvements in side plank ($p=0.028$-0.029) and McGill's trunk flexor endurance tests ($p=0.023$) were observed. Body image improved at 3 months ($p = 0.023$), whistle exercise compliance was highly maintained (70.51%).
Conclusions: The 12-week exercise-based telerehabilitation program for DRA was considered effective and satisfactory, demonstrating high compliance. Significant improvements were also recorded in clinical measures; IRD decreased, core endurance increased and body image improved. Overall, telerehabilitation

appears to be a promising approach to be integrated into clinical practice, particularly across patient samples with difficulties for in-person attendances.

P433

FRACTURE RISK ASSESSMENT (FRAX) VARIATIONS IN ELDERLY WOMEN BASED ON TIME-UP-AND-GO TEST PERFORMANCE

E. Bischoff[1], S. Vladeva[2], P. Kinov[3], F. Bischoff[4]

[1]Faculty of Global Health and Health Care, University "Prof Dr Assen Zlatarov", 8010 Burgas, Bulgaria, Burgas, Bulgaria, [2]Department of Health Care, Faculty of Medicine, Trakia University, 6007 Stara Zagora, Bulgaria, Stara Zagora, Bulgaria, [3]Medical University of Sofia, Department of Orthopedics and traumatology, Sofia, Bulgaria, [4]IPSMP Rheumatology, 6000 Stara Zagora, Bulgaria, Stara Zagora, Bulgaria

Objective: Fracture Risk Assessment Tool (FRAX) is commonly used to estimate the probability of fractures. Functional mobility, as assessed by the Time-Up-and-Go (TUG) test, has been closely associated with fall risk. This study aims to investigate the relationship between TUG test performance and FRAX-calculated fracture risk.

Material and Methods: The study assessed the relationship between TUG test performance and FRAX-calculated fracture risk in 70 women aged 60 years or older. Participants were categorized into four groups based on TUG performance recorded in seconds (s): TUG < 10 s, TUG = 11–20 s, TUG = 21–29 s, and TUG ≥ 30 s. FRAX scores, estimating 10-year probabilities of major osteoporotic fractures (MOF) and hip fractures (HF) were calculated for each participant. Data collection and transfer from the electronic health record was performed with an innovative JAVA tool, developed by Kirilov et al. (1,2)

Results: Out of 70 participants, 32 women (45.7%) had TUG < 10 s, 24 women (34.3%) had TUG = 11–20 s, 9 women (12.9%) had TUG = 21–29 s and 5 women (7.1%) had TUG ≥ 30 s. The mean age of the participants was 70 ± 7.1 years, and the mean BMI was 29.6 ± 5.6 kg/m². FRAX scores for MOF differed significantly ($p < .001$) across TUG groups. Participants with the poorest TUG performance had the highest mean FRAX score for MOF (24.96%), compared to those with the best performance (14.75%). Similarly, FRAX scores for HF also showed significant differences ($p < .001$) among TUG groups. Women with the poorest TUG performance had the highest mean FRAX score for HF (11.83%) compared to those with the best performance (3.42%).

Conclusion: These findings underscore the importance of incorporating functional mobility assessments into fracture risk evaluations, as reduced mobility is strongly associated with higher fracture susceptibility.

FREQUENTLY REPORTED BLOOD BIOMARKERS IN SARCOPENIA CLINICAL TRIALS: A SYSTEMATIC REVIEW AND META-ANALYSIS

E. Calluy[1], E. Boretti[2], S. van Heden[1], Y. Malrechauffé[2], E. Cavalier[3], A. Ladang[4], D. Sanchez-Rodriguez[5], J.-M. Dogné[2], J. Douxfils[2], C. Beaudart[1]

[1]Public Health Aging Research & Epidemiology (PHARE) Group, Research Unit in Clinical Pharmacology and Toxicology (URPC), NAmur Research Institute for LIfe Sciences (NARILIS), Department of Biomedical Sciences- Faculty of Medicine, University of Namur, Namur, Belgium, [2]Research Unit in Clinical Pharmacology and Toxicology (URPC), NAmur Research Institute for LIfe Sciences (NARILIS), Department of Pharmacy- Faculty of Medicine, University of Namur, Namur, Belgium, [3]Department of Clinical Chemistry, Centre Hospitalier Universitaire de Liège, University of Liège, Liège, Belgium, [4]Department of Clinical Chemistry, Centre Hospitalier Universitaire de Liège, Liège, Belgium, [5]Geriatrics Department, Brugmann University Hospital, Université Libre de Bruxelles. Geriatrics Department, Rehabilitation Research Group, Hospital Del Mar Research Institute, Barcelona, Spain, Bruxelles, Belgium

Objectives: This systematic review and meta-analysis aims to identify most frequently reported blood-based biomarkers (BB) in randomised clinical trials (RCTs) addressing sarcopenia management, as well as to evaluate the effects of sarcopenia-specific interventions on their concentrations.

Material and Methods: Electronic databases were searched via Ovid (MEDLINE, Embase and Cochrane Central Register of Controlled Trials) to retrieve RCTs published until October 2024 with any type of intervention (dietary, physical, pharmacological and combined or other) on sarcopenic participants. Only studies including participants aged ≥ 60 years old (or mean age ≥ 60 years old) with sarcopenia defined by a measurement of at least two key parameters of sarcopenia (e.g., muscle/lean mass and muscle strength or physical function) and reporting BB values pre- and post-intervention were included. Study selection and data extraction were performed by two independent reviewers. Meta-analyses were performed for BB reported in minimum 2 RCTs using a random effect model with a standardised mean difference (SMD) and a 95% confidence interval (CI) as effect size.

Results: On the 3985 references identified by the literature search, 21 RCTs measuring BB in individuals with sarcopenia matched the inclusion criteria and were selected. The most frequently reported BB were CRP (8/21 RCTs), IL6 (7/21 RCTs), TNFα (6/21 RCTs), 25-OH-Vitamine D (6/21 RCTs), IGF-1 and Albumin (5/21 RCTs) with ≥5 RCTs measuring these biomarkers. ALAT, Cholesterol, Creatinine, IL-10 (3/21 RCTs each) and fasting blood glucose (4 RCTs) were reported in 3 to 4 RCTs. Finally, ASAT, Calcium, Follistatin, GDF-15, GDF-8, HDL, LDL, IL1Ra, IL-8, Insulin, Triglycerides and CAF were assessed in 2 RCTs. Among the most frequently re-

ported BB, only IGF-1 (SMD=0.43, CI= [0.05; 0.80]) and 25-OH-Vitamin D (SMD=0.92, CI= [0.27; 1.57]) were significantly impacted by the studied interventions.
Conclusion: Despite the large heterogeneity of BB measured in sarcopenia-specific RCTs, only a limited number of them are muscle-specific. In addition, few BB seemed impacted by the proposed interventions. Therefore, there is an urgent need to use available recommendations on biomarkers specific to sarcopenia and to develop a Core Outcome Set for sarcopenia intervention studies aiming at a better standardisation of the management of this disease.

P435

CHARACTERIZATION OF TRIVALENTLY CROSSLINKED C-TERMINAL TELOPEPTIDE OF TYPE I COLLAGEN (CTX) SPECIES IN HUMAN PLASMA AND SERUM USING HIGH-RESOLUTION MASS SPECTROMETRY

J. Demeuse[1], W. Determe[2], E. Grifnée[2], A. Mackowiak[1], P. Massonnet[2], M. Schoumacher[1], L. Huyghebaert[2], T. Dubrowski[2], S. Peeters[2], C. Le Goff[2], E. Cavalier[1]

[1]University of Liège, Liège, Belgium, [2]University Hospital of Liege, Liège, Belgium

Objectives : With an aging population, the increased interest in the monitoring of skeletal diseases such as osteoporosis led to significant progress in the discovery and measurement of bone turnover biomarkers since the 2000s. Multiple markers derived from type I collagen, such as CTX, NTX, PINP, and ICTP, have been developed. Extensive efforts have been devoted to characterizing these molecules; however, their complex crosslinked structures have posed significant analytical challenges, and to date, these biomarkers remain poorly characterized. In this work, we aimed at characterizing circulating CTX.
Material and method : We extracted and characterized type I collagen peptides directly from human plasma and serum using a proteomics workflow that integrates preparative LC, affinity chromatography, and HR-MS.
Results : Thanks to this workflow, 44 species of CTX were extracted and characterized.
Conclusion : We successfully characterized plasma CTX species.

P436

COMPARATIVE ANALYSIS OF BALP MEASUREMENT: IMMUNOASSAY AND ELECTROPHORESIS

A. Mackowiak[1], E. Cavalier[2]

[1]University of Liège / Department of Clinical Chemistry, Liège, Belgium, [2]University hospital of Liège/ Department of Clinical Chemistry, Liège, Belgium

Objectives: Bone alkaline phosphatase (BALP) is one of the recommended biomarker for assessing bone fragility in Chronic Kidney Disease (CKD) patients[1]. This study aims to compare immunoassay and electrophoresis techniques for the quantification of BALP.
Materiel and Methods: Remnants clinical samples were collected from 78 dialysis patients. Serum BALP was measured using TECO Diagnostic immunoenzymatic (ELISA) technology (Anaheim, US) and by electrophoresis. Agreement between the methods was assessed using Passing-Bablok regression and Spearman's correlation coefficient. Proportional and constant biases were evaluated respectively from the regression slopes and Bland-Altman analysis.
Results: Median (IQR) BALP concentration was 48.1 U/L (37.0–74.8) using the TECO Diagnostics kit and 32.5 U/L (21.9–52.2) with electrophoresis. A significant correlation was found between the two methods (Spearman's r=0.85, p<0.0001), but analysis revealed a significant negative constant bias (-41.9%) and a non-significant positive proportional bias (+28%). Passing-Bablok regression is shown in **Figure 1**.
Conclusion: Although the correlation between the two methods was statistically significant, the observed biases indicate that the methods are not clinically interchangeable. These findings underscore the need for careful consideration when interpreting BALP concentrations obtained using different analytical approaches and pave the way for further comparisons of electrophoresis with other immunoassays.

EXPRESSION OF BONE REMODELING MARKERS IN RA PATIENTS

E. Deseatnicova[1], L. Andries[1], E. Russu[1], M. Curchi[1], L. Groppa[1]

[1]State Medical and Pharcameutical University Nicolae Testemitanu, Chisinau, Moldova

Background: Rheumatoid arthritis (RA) is a chronic systemic disorder characterized by progressive destructive arthritis and other organ involvement. Secondary osteoporosis and high risk of fragility fractures are common for RA patients. This phenomenon is still being studied especially the role of inflammation as a mediator of bone resorption.
Objectives: To evaluate the concentration of some bone metabolism markers as a function of the level of RA disease activity.
Material and methods: 81 females with RA, confirmed according to ACR-EULAR 2010 criteria, aged from 28 to 83 years were included into the study. Patients received no more than 4 mg/per day of methylprednisolone during last year and were naive to biological treatment. We calculated disease activity score by DAS-28 CRP, evaluated RA laboratory immunological markers (FR, anti-CCP), levels of selected bone metabolism markers (osteocalcin, sRANKL, osteoprotegerine).
Results: All the patients were divided into 3 groups as a function of DAS28 CRP low, medium and high disease activity (LDA, MDA, HDA) (<3,2, 3,2 -5,1, >5,1). Osteocalcin levels were significantly higher in the LDA group compared to the MDA and HDA groups (12,3 ± 1,12 pg/mL vs. 4,66 ± 0,25 pg/mL and vs 2,52 ± 0,29 pg/mL, p<0,001 and p<0,05, respectively). A statistically significant difference was also observed between the levels of sRANKL and OPG in the groups. For sRANKL the level in LDA group constituted 682,3 ±438,3 pmol/L, for MDA 892,4 ±658,7 pmol/L and for HAD 1062,4 ±846,8 pmol/L, p<0,05 and p<0,001, respectively). LDA was associated with higher OPG level, 121,2±83,3 pg/mL vs 111,4±82,7 pg/mL. A correlational analysis showed a strong positive correlation of sRANKL level and high RA activity, (r=0,48, p<0,001) and well its moderate positive correlation with antiCCP level, (r=0,32, p<0,05).
Conclusions: Patients with RA have significant changes in bone metabolism. A high-level inflammatory process favors the increase of markers of bone resorption and decrease of markers of bone formation in RA patients. Reduced levels of osteocalcin in higher disease activity groups may show a low bone formation due to chronic high-level inflammation and strong immune response.

P439

BONE REMODELING MARKERS AND CAROTID ATHEROSCLEROSIS IN RA PATIENTS

E. Deseatnicova[1], L. Andries[1], M. Carpova[1], N. Ciobanu[2], A. Nistor[1], L. Groppa[1]

[1]State Medical and Pharcameutical University Nicolae Testemitanu, Chisinau, Moldova, [2]Institute of Cardiology, Chisinau, Moldova

Background: RA patients have an accelerated progression of atherosclerosis as well as the risk of secondary osteoporosis, associated with changes in bone turnover.
Objectives: To evaluate intima/media thickness at a. carotis in correlation with the concentration of some bone metabolism markers in RA patients.
Materials and methods: We examined 81 women with RA and 55 women without RA, as a control group, compatible by age and exclusion criteria. Anamnestic and clinical data were collected according to the questionnaire developed for the study, which includes the history of the disease, life, objective data. Patients with type 2 diabetes mellitus, oncological pathology, other inflammatory diseases, decompensated somatic, pregnant, treated with statins or biological preparations were excluded. DAS-28-CRP (C-reactive protein), rheumatoid factor, anti-CCP antibodies, selected bone metabolism markers (osteocalcin, sRANKL, osteoprotegerine) and IMT index on the carotid artery were evaluated.
Results: The mean age of the patients included in the study was 58.12±5.43 years with a mean disease duration of 10.8±3.4 years. Methylprednisolone of 4 mg per day during last year was accepted. Significant differences were identified compared to the control group for the mean IMT value (0.97±0.13 mm vs 0.85±0.09 mm, p<0.05). Mean osteocalcin level for RA group made 6.49 ±0.92 vs 11.4±1.05 pg/ml in controls, p<0.001. Mean sRANKL level in RA patients was 1028.4±1236.3 pmol/l and OPG level was 108.6±78.4 pg/ml with significant difference with control group. Increased carotid artery IMT correlated with RA duration (r=0.48, p<0.001), disease activity measured by DAS28-CRP (r=0.52, p<0.001), anti-CCP antibody levels (r=0.31, p<0.05). We found a moderate positive correlation of sRANKL level with IMT in studied group of patients (r=0.32, p<0.05) and sRANKL and DAS28-CRP (r=0.34, p<0.05).
Conclusions: In women with RA, a significant increase in carotid artery IMT was found. Increase in IMT correlated positively with increase in bone resorption markers, disease duration and activity and the presence of anti-CCP antibodies. This shows common pathogenetic background of atherosclerosis and bone resorption with management possibilities.

P440

THE ECONOMIC IMPACT OF PERIPROSTHETIC KNEE FRACTURES

E. Durá[1], N. Aranda[1], H. Marquina[1], A. Sánchez[1], M. Montero[1], C. Ferrándiz[1], A. Lozano[1], A. Devís[1]

[1]Torrevieja University Hospital, Torrevieja, Spain

Objective
The purpose of this study is to describe the inpatient costs of periprosthetic fractures of the knee in a Spanish hospital system.
Material and Methods
We conducted a retrospective study of periprosthetic fractures of the knee that were admitted to a single trauma unit between 2017 and 2022. All patients with a periprosthetic knee fracture involving the distal femur who underwent surgery were included. Data from the hospital inpatient database and finance department was utilized for cost analysis. Demographics, length of stay, laboratory and radiology tests, hospital stay and surgical implants cost were collated. An analysis of direct inpatient costs was performed.
Results
34 patients met the inclusion criteria for review. The mean age was 77 years and 94% were female. 28 patients underwent osteosynthesis surgery and 6 patients had revision arthroplasty, with a mean length of stay of 9.92 days and 10.33 days, respectively. The mean direct inpatient cost was €5.800. The mean cost for a full revision arthroplasty treatment was over €10.600 compared to €4.500 for osteosynthesis treatment. Variables with highest economic impact were surgical implants (52%) and hospital length of stay (36%).
Conclusion
Periprosthetic knee fractures create a significant economic burden on healthcare systems. The prolonged length of stay associated with fractures requiring revision implants leads to increased costs to the healthcare service. As we can expect an increasing incidence of periprosthetic fractures presenting in the coming years, it is paramount that we establish fracture prevention protocols and minimize time until surgery and postoperative recovery stay to reduce the economic impact.

P441

XANTHINE OXIDOREDUCTASE ACTIVITY IN BLOOD: DISCOID LUPUS ERYTHEMATOSUS VERSUS SYSTEMIC LUPUS ERYTHEMATOSUS

E. E. Mozgovaya[1], S. A. Bedina[1], A. S. Trofimenko[1], S. S. Spitsina[1], M. A. Mamus[1], I. A. Zborovskaya[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Background. Discoid lupus erythematosus (DLE) is the most common type of chronic cutaneous LE. Unlike systemic lupus erythematosus (SLE), the disease is characterized by the absence of internal organs damages and antinuclear antibodies in most patients. Oxidative stress is involved in the development of both diseases. Xanthine oxidoreductase (XOR) enzyme system is an important source of reactive oxygen and nitrogen species.
Objective: to reveal the features of two forms of XOR (xanthine dehydrogenase (XDG; EC 1.17.1.4) and xanthine oxidase (XO; EC 1.17.3.2)) in plasma and lysed RBC of DLE and SLE patients.
Methods. 56 patients with verified SLE, 31 patients with verified DLE and 35 apparently healthy volunteers were analyzed in the study. The SLEDAI 2K index was used to assess SLE activity. The enzymes activities were determined by previously described methods [1].
Results. In contrast to the control, XO activity was higher and XDG activity was lower in plasma of DLE patients. Activities of both XOR forms in lysed RBC did not differ from the norm in this group. Activity of XO was lower in plasma from DLE patients in comparison with the subgroups with low, moderate and high SLE activity. XDG activity in plasma and XO activity in lysed RBC of DLE patients were lower than in low activity SLE, but higher than in the subgroups with moderate and high disease activity. XDG activity of lysed RBC in DLE was higher than in patients with low and moderate SLE activities, but lower than in patients with high diseases activity. The increase in SLE activity was accompanied by the decrease in the ratio of XO/XDG levels in RBC lysates.
Conclusion. SLE differs from DLE by a more pronounced imbalance of oxidase and dehydrogenase activities of blood XOR. These metabolic changes contribute to the development of pathology.
SLE and DLE are characterized by some common changes in XO and XDG activities. At the same time, XOR blood profiles have distinctive features, which are characteristic for each nosology.

P442

FEATURES OF BLOOD XANTHINE OXIDOREDUCTASE ACTIVITY PROFILES IN SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

E. E. Mozgovaya[1], S. A. Bedina[2], A. S. Trofimenko[1], M. A. Mamus[1], S. S. Spitsina[2], I. A. Zborovskaya[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical Univ., Volgograd, Russia

Objective: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are belonged to a large group of rheumatic diseases. According to modern concepts, the pathogenesis of these diseases is based on both immunopathological mechanisms and metabolic disorders developing at the cellular and subcellular levels. We aimed to evaluate the changes in xanthin oxidoreductase (XOR) interconvertible forms (xanthine oxidase ((XO), EC 1.17.3.2) and xanthine dehydrogenase ((XDG), EC 1.17.1.4)) activities in plasma and lysed blood cells (WBC and RBC) of SLE and RA patients.

Methods: Diagnosis of SLE was verified using the SLICC criteria (2012), RA – ACR/EULAR criteria (2010). Activities of XO and XDG were measured by spectrophotometric methods [1]. The enzymatic activities were expressed as nmol/min/ml and normalized to 1×10^7 cells/ml in WBC, to 1×10^9 cells/ml in RBC. Statistical comparison tests were selected in according to common guidelines. Differences were considered significant when $p<0.05$.

Results: 56 adult SLE patients, 77 adult RA patients and 35 healthy individuals (control group) were enrolled in the study. In contrast to control, increased XO_{pl} activity and decreased activities of XO_{WBC}, XDG_{pl}, XDG_{WBC}, XDG_{RBC} ($p<0.001$ for all enzymes) were observed in SLE and RA. XO_{RBC} activity was increased in RA ($p<0.001$) and did not differ from the norm in SLE. XO_{RBG} and XDG_{pl} activities were higher ($p<0.001$ and $p=0.012$, respectively), XO_{WBC} and XDG_{RBC} activities were lower ($p<0.001$ for both enzymes) in RA compared to SLE. The XO_{WBC}/XDG_{WBC} coefficient with SLE was higher than with RA ($p<0.05$). The XO_{RBC}/XDG_{RBC} coefficient with SLE was lower than with RA ($p<0.05$). The XO_{pl}/XDG_{pl} coefficient was higher in SLE and RA than in healthy individuals ($p<0.05$).

Conclusion: SLE and RA are characterized by unidirectional changes in the activities of the oxidase and dehydrogenase XOR forms in plasma, lysed WBC and RBC. The balance of XO_{pl} and XDG_{pl} indicates an intensification of free radical oxidation reactions in both diseases. Free radicals formed as a result of XOR activities can probably have a damaging effect and participate in processes that determine the duration of blood cells life.

COULD A BODY SHAPE INDEX (ABSI) PREDICT OSTEOPOROSIS IN OLDER ADULTS LIVING WITH OBESITY?

E. Gecegelen[1], M. Üçdal[2], D. Karaduman[1], C. Atbaş[1], Y. Polat Özer[1], K. Yurtsever[2], M. Eşme[1], C. Balcı[1], M. Gülhan Halil[1], M. Cankurtaran[1], B. B. Doğu[1]

[1]Department of Internal Medicine, Division of Geriatric Medicine, Hacettepe University, Ankara, Turkiye, [2]Department of Internal Medicine, Hacettepe University, Ankara, Turkiye

Objective: Osteoporosis is a disease characterized by decreased bone mineral density and increased risk of fractures in older adults. While previous studies have used traditional anthropometric measurements for risk assessment, newer indices such as A Body Shape Index (ABSI) may provide additional information. In our study, we aimed to investigate the relationship between ABSI and osteoporosis in older adults living with obesity.

Material and Methods: 203 patients were enrolled to this study who admitted to the geriatric outpatient clinic of a university hospital, and all of them underwent comprehensive geriatric evaluation. Anthropometric measurements, assessment of physical performance were performed and all patients included in the study were obese with a body mass index (BMI) $\geq$ 30 kg/m^2. ABSI was calculated by dividing waist circumference(WC) by BMI $^{2/3}$ × height $^{1/2}$ (WC/height $^{1/2}$x BMI $^{2/3}$). Patients were divided into two groups as those with and without osteoporosis and evaluated for osteoporosis by dual-energy X-ray absorptiometry (DEXA) with BMD measurement and T-scores; and for fractures, by simultaneous frontal and lateral thoracolumbar radiography. Patients with a T score $\leq$ -2.5 and/or a vertebral fracture on radiography were diagnosed with osteoporosis.

Results: Demographic and clinical characteristics revealed strong gender-specific patterns, with females showing significantly higher osteoporosis ($p<0.001$) in **Table-1**. Waist-hip ratio (WHR) measurements showed significant differences between groups (0.84 vs 0.81, $p=0.043$), suggesting a potential relationship between body fat distribution and osteoporosis. ABSI showed positive correlation with WHR (r=0,577) and negative correlation with BMI (r=-0.307). The mean ABSI values were lower in the osteoporotic group (0.08403) compared to the non-osteoporotic group (0.08468) in **Figure-1**. Independent T-test analysis confirmed these differences were statistically significant (p=0.029). According to ROC analysis, the cut-off value for ABSI was 0.80755. This value was found to increase the risk of osteoporosis by 2.4 times when adjusted for gender and diabetes (p=0.015, 95% CI: 1,188-5.011).

Conclusion: The results suggest that high ABSI may potentially be associated with a higher risk of developing osteoporosis. This highlights the importance of assessing body fat distribution in preventing osteoporosis and may suggest the use of ABSI as a valuable marker for early intervention.

MULTICENTRIC CARPAL-TARSAL OSTEOLYSIS (MCTO)

E. Hosszu[1], A. Ponyi[1], S. Meszaros[2], T. Leel-Össy[2], E. Csupor[3], C. Horvath[2]

[1]Department of Pediatrics, Semmelweis University, Budapest, Hungary, [2]Department of Internal Medicine and Oncology, Semmelweis University, Budapest, Hungary, [3]Endocrin Unit, Budavar Health Centre, Budapest, Budapest, Hungary

Introduction:MCTO is rare syndrome characterized by progressive bone loss, usually in the carpal and tarsal bones, resulting in deformity and disability. In many cases they associate with chronic renal failure, intellectual deficits and facial abnormalities.
Case description:Our patient developed normally until the age of 2 ys. His illness began with pain and swelling in hand and wrist, and a year later in the hip joint, which soon led to camptodactyly and limited movement. Against nonsteroid, steroid and MTX treatment, the disease continued to progress, affecting the elbow join. Laboratory tests, virus serology, immunology, HLAB27 tests gave normal results. Cardiologic and ophthalmologic findings didn't detect deviations. Joint US images showed inflammatory abnormalities (tenosynovitis). On X-ray, the development of the bones was 5 years younger than chronological age, they were porotic, the cortical bones were sharply defined, and the epiphysis nuclei were irregular. ODM described reduced bone mineral content, bone markers confirmed increased bone turnover. The first initial genetic examination ruled out metabolic disease or mucopolysaccharidosis, and juvenile rheumatoid arthritis was suspected. An extended genetic examination gave the diagnosis of Multicentric Carpal-Tarsal Osteolysis (MCTO). This disease is the mutation of the MAFB gene, which is a negative regulator of the receptor activator of the nuclear factor-KB ligand (RANKL). Due to progression, a biological therapy has been initiated. The use of denosumab, an inhibitor of the RANKL, provides the possibility of treating the cause.
Conclusion:MCTO is a particularly rare disease, the symptoms of which correspond to inflammatory joint disease. For diseases that do not or barely respond to treatment, genetic testing can provide the diagnosis and direction of treatment. Recently, genetic advances have led to a better understanding of the biological basis of rare bone diseases and a new therapeutic perspective.

P445

AXIAL SPONDYLOARTHRITIS IN MEN AND WOMEN

E. Ilinykh[1], A. Sablina[1], E. Agafonova[1], K. Sakharova[1], S. Glukhova[1], A. Demina[1], I. Andrianova[1], S. H. Erdes[1], T. Dubinina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To optimize therapy in pts we have studied a gender differences in disease activity in pts with axial spondyloarthritis (axSpA).
Material and methods: A total of 108 pts who met the ASAS (2009) or modified New York criteria (1984) were included. There were 62 men (57.4%) and 46 women (42.6%).
Results: Ankylosing spondylitis was diagnosed in 67.2% of women and 88.5% of men. The remaining pts were diagnosed with non-radiographic axSpA. HLA B27 was detected in 78.3% women and 88.7% men. Women were more often diagnosed with arthritis than men (80.4% vs 62.9%, p=0.05) and dactylitis (32.6% vs12.9%, p=0.01), respectively. The results concerning the assessment of axSpA activity are presented in a Table.

Table. Disease activity assessment

Manifestation	Women, Me(Q1;Q3)	Men, Me(Q1;Q3)	p
BASDAI	5.3(3.7;6.6)	3.9(2.8;5.6)	0.02
ASDAS CRP	2.42 (1.7;3.6)	2.2(1.4;3.1)	0.6
BASFI	1.3(0.4;6.4)	1.9(0.2;4.7)	0.5
Numeric pain rating scale	5.5(4.0;7.0)	4.0(1.8;7.0)	0.01
Night back pain	6.0(3.0;7.25)	3.0(1.0;5.0)	0.1
Back pain during the day	5.0(3.3;6.0)	4.0(1.0;6.0)	0.04
Global assessment of general well-being	5.0(4.0;7.0)	4.0(3.0;5.8)	0.002
ESR according to Westergren, mm/h	16(8.0;30.0)	8.0(2.0;28.8)	0.06
CRP, mg/l	2.7(0.8;5.4)	4.6(1.2;10.0)	0.03
BASDAI components			
Fatigue	6.0(3.0;7.2)	4.0(3.0;7.0)	0.08
Back pain	6.5(4.0;8.0)	5.0(3.0;7.0)	0.02
Joint pain	3.0(1.0;6.0)	3.0(0.0;0.5)	0.1
Enthesis pain	4.0(2.0;7.0)	3.0(1.0;5.0)	0.03
Morning stiffness severity	5.0(3.0;8.0)	4.0(2.0;7.0)	0.1
Duration of morning stiffness	4.0(1.0;6.0)	3.0(2.0; 6.0)	0.7

According to the HADS, women had a higher anxiety level than men - 9(6;10) and 5(2;8) (p=0.01), respectively. Depression rates did not differ between the groups.
Conclusions: Arthritis and dactylitis was observed in women more often than in men. Men were more often positivity for HLA B27 and laboratory activity was also higher. But the BASDAI, the numerical pain rating scale, back pain during the day and a global assessment of general well-being in women were higher. Women also had significantly higher indicators of the hospital anxiety assessment scale, which may affect the perception and assessment of pain. A gender-based approach to assessing disease activity in clinical practice may contribute to the development of personalized treatment for pts.

P446

DO MODERN GLUCOSE MEASUREMENT AND INSULIN DELIVERY METHODS PRESERVE BONE HEALTH IN PATIENTS WITH TYPE 1 DIABETES?

E. Kardalas[1], V. Antonopoulou[1], D. Mpaikousi[1], M. Tzanela[1]

[1]Evangelismos General Hospital of Athens, Athens, Greece

Objective: Type 1 diabetes (T1D) can negatively affect bone metabolism and lead to deteriorated bonequality and architecture. This study evaluated bone metabolism in adult T1D patients on different insulin delivery and glucose measurement modalities.
Materials and Methods: 170 adult patients with T1D, who were either on multiple daily insulin regimens (MDIR) or on continuous subcutaneous insulin infusion (CSII) systems were retrospectively studied. Bone mass density (BMD) at femur neck (FN) and lumbar spine (LS) and trabecular bone score (TBS) were estimated. Medical therapy affecting bone metabolism was exclusion criteria.
Results: 94 patients were on MDIR and 76 were being treated with CSII systems. No differences were observed for mean age and BMI among the 2 groups. CSII patients needed markedly lower total daily insulin doses (41.1
Objective: Type 1 diabetes (T1D) can negatively affect bone metabolism and lead to deteriorated bonequality and architecture. This study evaluated bone metabolism in adult T1D patients on different insulin delivery and glucose measurement modalities.
Materials and Methods: 170 adult patients with T1D, who were either on multiple daily insulin regimens (MDIR) or on continuous subcutaneous insulin infusion (CSII) systems were retrospectively studied. Bone mass density (BMD) at femur neck (FN) and lumbar spine (LS) and trabecular bone score (TBS) were estimated. Medical therapy affecting bone metabolism was exclusion criteria.
Results: 94 patients were on MDIR and 76 were being treated with CSII systems. No differences were observed for mean age and BMI among the 2 groups. CSII patients needed markedly lower total daily insulin doses (41.1±13.6 vs 46.3±13.3 IU, p= 0.006) and achieved significantly
lower mean HbA1c levels (7.55 ± 0.71 vs 7.82 ±0.76%, p= 0.019) in comparison to the MDIR ones. Furthermore, patients with CSII presented with higher mean BMD (0.89 ± 0.14 vs 0.87 ±0.15, p= 0.011) and T-Score values (-0.88 ± 1.1 vs -0.93 ± 0.92, p < 0.01) at FN compared to the MDIR patients. The same observation occurred for both BMD (0.97 ±0.14 vs 0.93 ±0.17, p= 0.004) and T-Score (- 0.95 ± 1.0 vs -0.99 ±1.3, p < 0.01) at LS. Moreover, TBS was markedly higher in the CSII group (1.38 ± 0.16 vs 1.33 ±0.11, p= 0.002). Finally, in both groups, HbA1c was a negative and BMI and age were positive prognostic factors for TBS.
Conclusions Bone mineral density, architecture and strength of patients with T1D could potentially profit from the implementation of modern technology regarding glucose measurement and insulin delivery.
13.6 vs 46.3 13.3 IU, p= 0.006) and achieved significantly
lower mean HbA1c levels (7.55 ± 0.71 vs 7.82 ±0.76%, p= 0.019) in comparison to the MDIR ones. Furthermore, patients with CSII presented with higher mean BMD (0.89 ± 0.14 vs 0.87 ±0.15, p= 0.011) and T-Score values (-0.88 ± 1.1 vs -0.93 ± 0.92, p < 0.01) at FN compared to the MDIR patients. The same observation occurred for both BMD (0.97 ±0.14 vs 0.93 ±0.17, p= 0.004) and T-Score (- 0.95 ± 1.0 vs -0.99 ±1.3, p < 0.01) at LS. Moreover, TBS was markedly higher in the CSII group (1.38 ± 0.16 vs 1.33 ±0.11, p= 0.002). Finally, in both groups, HbA1c was a negative and BMI and age were positive prognostic factors for TBS.
Conclusions Bone mineral density, architecture and strength of patients with T1D could potentially profit from the implementation of modern technology regarding glucose measurement and insulin delivery.

YEARS OF LIFE LOST DUE TO OSTEOPOROTIC HIP FRACTURES IN ECUADORIAN OLDER ADULTS

E. Lopez Gavilanez[1], M. Navarro Grijalva[2], M. Navarro Chavez[1], N. Bautista Litardo[1], M. Hernandez Bonilla[1], A. Segura Mestanza[1], R. Cedeño German[1]

[1]AECE Research Group. The Association of Clinical Endocrinologists of Ecuador., Guayaquil, Ecuador, [2]AECE Research Group. The Association of Clinical Endocrinologists of Ecuador, Guayaquil, Ecuador

Hip fracture is an important public health challenge, worldwide: however there is no updated and comprehensive assessment of the burden of hip fracture in older adults in Latin America. The burden of hip fracture (HF) expressed as years of life lost (YLL) has not been studied in older adults in Ecuador.
Aim: To analyze years of life lost (YLLs) due to hip fracture (HF), with data from the Global Burden of Disease (GBD).
Materials and methods: In this is cross-sectional study, we examined the years of life lost due to hip fractures in older adults (60 years and older) of both sexes stratified by five-year periods. Data from patients who suffered a hip fracture (ICD-10: S720–S722) during 2019 from the hospital discharge yearbook published by the National Institute of Statistics and Census INEC, Ecuador, were used. To obtain the years of life lost, the standard life expectancy (SLE) of the Global Health Estimates (GHEs) published by the WHO was used. To calculate the crude (YLL rate) and age standardized (ASYR) rates, the world standard population published by the WHO-GBD was used.
Results: The number of deaths and years of life lost (absolute number) due to hip fractures in 2019 increased with age. The crude rate of years of life lost (YLL rate) and the age-standardized rate (ASYR) decreased in the older age groups. The main results are presented in Table 1.

Table 1. Premature mortality from hip fracture in older adults in Ecuador, 2019

Age group	Deaths	Population	SLE	YLL*	YLL rate	ASYR
60-64	0	161	30.3	0.0	0	0.00
65-69	4	224	25.5	102	45,518	1,347
70-74	7	329	20.8	145	44,191	977
75-79	12	472	16.4	197	41,771	635
80-84	23	666	12.5	288	43,203	393
85+	52	1,473	7.6	395	26,830	169
Total	98	3,325		1,127	201,513	3,521

SLE, Standard life expectancy; YLL, years of life lost (*absolute number); ASYR, Age Standard year rate.

Conclusion: The burden of years of life lost related to fragility fractures is high. Although the absolute number of deaths is greater in older individuals, the proportional impact is greater in younger individuals. Fracture prevention and risk management in younger age groups would have a significant impact on reducing the number of years of life lost and improving public health.

P448

POTENTIAL YEARS OF LIFE LOST FROM OSTEOPOROTIC FRACTURES IN ECUADOR

E. Lopez Gavilanez[1], N. Bautista Litardo[1], M. Navarro Chavez[1], M. Hernandez Bonilla[1], M. Navarro Grijalva[2], A. Segura Mestanza[1], R. Cedeño German[1]

[1]AECE Research Group. The Association of Clinical Endocrinologists of Ecuador., Guayaquil, Ecuador, [2]AECE Research Group. The Association of Clinical Endocrinologists of Ecuador, Guayaquil, Ecuador

In the world population, the number and incidence of hip fractures (HF) have increased in recent decades due to an increase in the population at risk and a change in the specific incidence in different age and sex groups. As a result, the burden of hip fracture on national health care systems is of great concern on a global scale. Potential years of life lost (PYLL) due to hip fractures have not been studied in older adults in Ecuador.
Objective: To analyze the potential years of life lost due to hip fractures at the national level.
Materials and Methods: In this cross-sectional study, we examined the potential years of life lost due to hip fractures in older adults (60 years and older) of both sexes stratified by five-year age groups. We used data on individuals who suffered a hip fracture (ICD 10: S720-S722) in 2019, from the hospital discharge yearbook published by the National Institute of Statistics and Census of Ecuador (INEC). We calculate the potential years of life lost for each age group by multiplying the number of deaths by the remaining years of life lost.
Results: The number of hip fracture deaths in 2019 increased with increasing age. Potential years of life lost increased in younger age groups, but decreased in older age groups. The main results are shown in Table 1.

Table 1. Potential years of life lost from hip fracture in Ecuador, 2019

Age group	Number of Deaths	Mean Age at Death	Remaining life expectancy	PYLL
60-64	0	62.5	22.5	0
65-69	4	67.5	17.5	70
70-74	7	72.5	12.5	88
75-79	12	77.5	7.5	90.0
80-84	23	82.5	2.5	58
Total PYLL				305

PYLL, *Potential years of life lost*

Conclusion: The number of deaths due to hip fracture increases with increasing age. If the number of hip fractures continues to increase, the total number of potential years of life lost due to hip fractures will increase. Effective prevention measures must be implemented to manage the risk of these fractures.

P449

COMPARATIVE ANALYSIS OF THE FREQUENCY OF EXACERBATIONS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS DURING METHOTREXATE DISCONNECTION

A. V. Petrov[1], E. M. Dolya[1], M. G. Nikolashin[1], S. Kulanthaivel[2], S. A. Khamidova[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India, [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Currently, there are a limited number of publications on methotrexate (MTX) discontinuation in patients with various forms of juvenile idiopathic arthritis (JIA), which makes this problem relevant. In this regard, the aim of this study is to compare the frequency of exacerbations after methotrexate discontinuation in patients with articular forms of JIA receiving MTX monotherapy and MTX in combination with genetically engineered biological drugs (GEBD), who are in remission.
Methods: The study included 117 patients aged 0 to 18 years with articular forms of JIA (diagnosed based on ILAR criteria) in remission according to C.Wallace criteria for more than 2 years. The main group included 81 (69.3%) patients with JIA receiving MTX therapy. The comparison group included 36 (30.7%) children receiving MTX and GIBP therapy. The number of girls was 52 (64.2%) and 20 (55.6%) in the main and comparison groups, respectively. The average duration of the disease was 5.8±1.6 years in the main group, 6.1±2.1 years in the comparison group. The average duration of methotrexate therapy was 3.5±1.2 years in the main group, 4.1±1.5 years in the comparison group. MTX therapy was discontinued in 32 (39.5%) patients and 23 (63.9%) in the main and comparison groups, respectively. The reasons for MTX discontinuation were: adverse events in the form of severe dyspepsia, hematological disorders in the form of persistent neutropenia, alopecia, and categorical refusal of patients to continue MTX therapy. In the main group, MTX was discontinued in 2 (6.2%) patients due to alopecia, 14 (43.8%) – dyspepsia, 16 (50%) patients categorically refused to continue MTX therapy. In the comparison group, MTX was discontinued in 2 (8.7%) patients due to persistent neutropenia, 8 (34.8%) – dyspepsia, 13 (56.5%) patients categorically refused to continue MTX therapy. Results: 12 weeks after MTX discontinuation, 3 (9.4%) patients in the main group had an exacerbation of the disease. By 24 weeks of observation after MTX discontinuation, 2 (6.3%) patients in the main group had an exacerbation. In the comparison group, 12 weeks after MTX discontinuation, an exacerbation was registered in 4 (17.4%) children, by 24 weeks - in 5 (21.7%).
Results: The frequency of exacerbations after MTX discontinuation in patients with articular forms of JIA was lower in the group of patients receiving MTX monotherapy compared to the group of patients receiving MTX and GIBP.

P450

DYNAMICS OF CLINICAL AND IMMUNOLOGICAL PARAMETERS OF EARLY RHEUMATOID ARTHRITIS ACTIVITY DURING SUBCUTANEOUS METHOTREXATE ADMINISTRATION

A. V. Petrov[1], E. M. Dolya[1], N. A. Revenko[1], E. R. Zagidullina[1], S. Kulanthaivel[2], S. A. Khamidova[3], M. G. Nikolashin[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India, [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: to analyze and evaluate the nature of changes in clinical and immunological parameters of early rheumatoid arthritis (RRA) activity following subcutaneous methotrexate (MTX) administration.
Methods: 26 patients (19 women and 7 men) with confirmed early (according to ACR/EULAR criteria, 2010) RA aged 18 to 66 years (mean age 44.5±3.8 years) were examined. Most patients with RRA (80.6%) were seropositive for IgM (rheumatoid factor) and had grade III activity (57.8%) according to the DAS28 index. All patients with RRA were prescribed methotrexate in subcutaneous form as the first basic drug at an initial dose of 7.5 mg/week with rapid escalation of the drug dose to 20-25 mg/week in order to achieve the maximum possible therapeutic effect. As a result, 2, 6, 12 and 6 patients received 10, 15, 20 and 25 mg/week of MTX subcutaneously for at least 12 months. In parallel with the introduction of MTX, all patients took NSAIDs in standard doses.
Results: After 3 months, against the background of the therapy, the majority of patients (69.1%) showed positive dynamics in relation to the reduction of clinical and laboratory parameters of disease activity (duration of morning stiffness, intensity of pain syndrome, ESR, CRP) ($p<0.05$-0.001). The significance of differences was maintained for all studied parameters of RRA activity by 12 months of observation. Additionally, the effect of monotherapy with the subcutaneous form of MTX on the level of proinflammatory cytokines (TNF-α, IL-6) and a number of indicators of humoral and cellular immunity (IgA, IgM, IgG, CD4+, CD8+) was studied. Initially, the levels of both TNF-α and IL-6 and all studied parameters in the examined patients statistically significantly ($p<0.05$-0.001) differed from the data in the control group. At the end of the study (after 12 months), against the background of MTX monotherapy, a statistically significant ($p<0.05$-0.001) decrease in the level of almost all studied immunological parameters was established in patients with RRA.
Conclusion: The obtained results and literature data show that the subcutaneous form of MTX, along with its own anti-inflammatory activity, as evidenced by a reliable decrease in clinical and laboratory parameters reflecting the activity of PPA in the first 3 months of therapy, demonstrates a pronounced immunosuppressive efficacy.

P451

MAXIMAL STRENGTH IS A STRONG DETERMINANT OF HIP GEOMETRY INDICES IN A GROUP OF OLDER SARCOPENIC MEN

E. Maliha[1], R. El Hage[1]

[1]University of Balamand/Department of Physical Education, Kelhat, El-Koura, Lebanon

Introduction: The aim of the current study was to explore the relationships between maximal strength parameters and hip geometry parameters in a group of older sarcopenic men.
Summary of facts and results: In all, 22 older sarcopenic men whose ages range from 60 to 86 (68 ± 6 years) participated in our study. Body composition and hip geometry indices (cross-sectional area (CSA) and cross-sectional moment of inertia (CSMI)) were evaluated by DXA. One-repetition maximum (1-RM) squat, 1-RM deadlift, 1-RM bench press, 1-RM military press and 1-RM seated cable row were directly measured on two non-consecutive days. All maximal strength parameters were positively correlated to CSA and CSMI. These positive correlations remained significant after controlling for age.
Conclusion: The current study shows that maximal strength is a positive determinant of CSA and CSMI in older sarcopenic men.

P452

TOE GRIP STRENGTH AND BONE MASS IN OLDER MEN

E. Maliha[1], R. El Hage[1]

[1]University of Balamand/Department of Physical Education, Kelhat, El-Koura, Lebanon

Objective: The aim of the current study was to investigate the relationship between toe grip strength and bone mass in a group of older men.
Methods: 60 Lebanese men whose ages range between 60 and 75 participated in our study. The study was granted ethical approval by the Institutional Review Board (IRB) of the University of Balamand, Lebanon. Weight and height were measured, and body mass index was calculated. Body composition and bone mass were evaluated by bioelectrical impedance analysis (BIA), and skeletal muscle mass index (SMI) was calculated. Toe grip strength was measured using a T.K.K.3365b toegrip dynamometer (Takei Scientific Instruments, Japan). Maximal strength measurements (direct one-repetition maximum (1-RM) measurements) were also assessed using valid protocols.
Results: Toe grip strength was positively correlated to lean mass ($r = 0.81$; $p < 0.001$), SMI ($r = 0.87$; $p < 0.001$), 1-RM bench press ($r = 0.68$; $p < 0.001$), 1-RM biceps curl ($r = 0.66$; $p < 0.001$), 1-RM leg extension ($r = 0.72$; $p < 0.001$), 1-RM leg curl ($r = 0.74$; $p < 0.001$) and bone mass ($r = 0.62$; $p < 0.001$). All these positive correlations remained significant after controlling for age.
Conclusion: The current study suggests that toe grip strength is a positive determinant of lean mass, muscular strength and bone mass in older adults. These results are clinically important as they suggest that toe grip measurement might predict sarcopenia and osteoporosis in the elderly.

P453

PREVALENCE OF PATIENT SELF-REPORTED FRACTURE RISK FACTORS – PRELIMINARY ANALYSIS OF A DIGITAL STUDY IN THE PRIMARY CARE SETTING (SELF-FRAX)

M. Paggiosi[1], S. Wathall[2], S. Nedungayil[3], J. Edwards[4], E. Curtis[5], A. Sturrock[6], H. Helena[7], J. Parry[8], C. Bates[8], E. McCloskey[1]

[1]University of Sheffield, Sheffield, United Kingdom, [2]University of Keele, Staffordshire, United Kingdom, [3]East Lancashire Hospitals NHS Trust, Blackburn, United Kingdom, [4]Wolstanton Medical Centre, Newcastle-under-Lyme, United Kingdom, [5]University of Southampton, Southampton, United Kingdom, [6]NHS Education for Scotland, Edinburgh, United Kingdom, [7]University of Gothenburg, Gothenburg, Sweden, [8]TPP, Leeds, United Kingdom

Fractures, particularly amongst older adults, pose a significant public health burden and place substantial pressures on NHS resources.
The SELF-FRAX study explores enhancing fracture risk assessments in primary care to ultimately improve treatment access. The aims of this observational cohort study are to investigate the prevalence of fracture risk factors in the primary care population (age ≥ 50 years) and measure the concordance between patient self-reported risk factors and those captured within their primary care electronic health record (EHR). This preliminary analysis focuses on patient self-reported risk factors.
GP practices using SystmOne EHR software from across England were approached (n=258) and recruited (n=182) through the NIHR Research Delivery Network. Men and women from consenting GP practices were screened by their surgery and eligible patients (n=500) were randomised into four equal sex/age strata (men: 50-65 and >65 years, and women: 50-65 and >65 years). Patients were invited to participate via a GP practice-generated SMS message containing a URL directing them to study information and an e-consent form. Consenting patients were invited to complete a SELF-FRAX questionnaire. Paper forms were available to patients without an active mobile phone number or by request.
Approximately 91,000 patients were approached and n=5208 questionnaire responses (99% digital) have been received to date (provisional response rate 6%). Participation is greater in women than in men, and the latter were older compared to women (see table)). Fracture risk factor prevalence was highest for previous fracture and lowest for current smoking. Some risk factors prevalences differed between the sexes (secondary osteoporosis, falls, parental hip fracture – women>men; alcohol intake, self-reported rheumatoid arthritis – men>women).
SELF-FRAX demonstrates that risk factor data collection using a digital approach is possible in the primary care setting. Further analysis will determine if a combination of patient self-reported and EHR data may permit targeted screening and intervention to

mitigate future fracture risk in primary care.

Table. Prevalence of fracture risk factors within men and women

	Male	Female	P-value
N (% of total recruited)	1876 (36.4)	3332 (64.6)	
Age, years (mean(SD), range)	67.4(9.1), 50-98	64.4(9.1), 50-98	<0.001
Previous fracture (n (%))	752 (40.2)	1292 (38.8)	ns
Secondary osteoporosis (n (%))†	130 (7.0)	674 (20.3)	<0.001
Parental hip fracture (n (%))	241 (12.8)	552 (16.6)	<0.001
Alcohol ≥3 units/day (n (%))	304 (16.3)	219 (6.6)	<0.001
Glucocorticoid use (n (%))	155 (8.3)	273 (8.2)	ns
Rheumatoid arthritis (n (%))	165 (8.8)	237 (7.2)	0.03
Current smoking (n (%))	86 (5.4)	181 (3.5)	ns
≥1 fall in the last 12 months (n (%))	235 (12.6)	593 (18.0)	<0.001
Longstanding poor mobility (n (%))	129 (6.9)	211 (6.4)	ns

† ≥1 risk factors for secondary osteoporosis including chronic kidney disease, malabsorption, premature menopause, hypogonadism, osteogenesis imperfect, type I diabetes, untreated chronic hyperthyroidism.

P454

GENOME-WIDE METHYLATION SIGNATURE OF RELATIVE TELOMERE LENGTH IN A COHORT OF SARCOPENIA AND FRAILTY PATIENTS OF LITHUANIAN ANCESTRY

E. Pranckevičienė[1], V. Ginevičienė[2], A. Urnikytė[2], L. Jurkūnaitė[2], G. Anikevičiūtė[2], R. Dadelienė[2], J. Kilaitė[3], I. E. Jamontaitė[2], A. Mastavičiūtė[2], I. Ahmetov[4], V. Alekna[2]

[1]Faculty of Medicine, Vilnius University & Faculty of Informatics, Vytautas Magnus University, Vilnius, Lithuania, [2]Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [3]Clinic of Internal Diseases and Family Medicine, Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [4]Liverpool John Moores University, Liverpool, United Kingdom

Objective. To identify and describe genome-wide methylation signature significantly associated with the relative telomere length in a cohort of Lithuanian elderly with sarcopenia and frailty.
Material and Methods. Methylation of a total of 62 subjects (43 females aged 85.5 ± 6.1 and 19 males aged 82.9 ± 8.8) diagnosed by both: sarcopenia (defined by the criteria set by EWGSOP2) and frailty (determined by Fried's criteria [weakness, low walking speed (WS), low physical activity, weight loss, exhaustion]) were profiled by Illumina Infinium EPICv2 arrays. Leucocyte relative telomere length (TL) was determined by real-time qPCR on DNA extracted from blood samples and quantified as the telomere/single-copy gene (T/S) ratio. Phenotypic data were collected via the questionnaires, scales, geriatric assessment tools (PACE, GDS and Katz ADS) and testing of anthropometric and physiological characteristics. Quality control and filtering of the raw methylation data was performed in R (4.4.2) by a package 'sesame' (v1.24.0) followed by a differential methylation analysis performed with R package 'DMRcate' (v3.2.1). Genomic locations of the differentially methylated regions (DMRs) significantly associated with the TL were analyzed in UCSC Genome browser. Trait associations with the genes, harboring identified DMRs were taken from NHGRI-EBI GWAS registry.
Results. The results showed that DNA methylation levels are not related to age or gender. The TL was associated with 49 differentially methylated CpG probes at 95% confidence level of false discovery rate (fdr <0.05). The CpG sites covered 7 genetic loci overlapping *FPGT, LRRIQ3, TNFSF9, ZDHHC14, LINC00240, MPL* and *SH3RF3* genes and regulatory ENCODE regions and *H3K27Ac* mark elements in them. These genes conjointly associated with phenotype of patients: smoking, alcohol consumption, educational attainment, mentality, depressive symptoms, body mass index (BMI), body fat mass, bone mineral density. LINC00240 associated with leucocyte TL.
Conclusions. We found significant association between the TL and methylation levels in genes associated with lifestyle traits potentially linked to the risk of developing sarcopenia and frailty in Lithuanian elderly.
This project has received funding from the Research Council of Lithuania (LMTLT), agreement No S-MIP-22-36.

P455

ANALYSIS OF PATHOLOGICAL CHANGES IN THE MAXILLARY SYSTEM IN PATIENTS WITH OSTEOPOROSIS AND RHEUMATOID ARTHRITIS

E. R. Kulieva[1], V. B. Kaliberdenko[1], V. R. Yas[2], N. G. Nikolashina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Ege University, Izmir, Turkiye

Objective: Studying the relationship of pathological changes in the dental system with damage to organs and body systems in various systemic diseases such as rheumatoid arthritis (RA) and osteoporosis (OP) is an important task of modern medicine. To date, the manifestation of RA and OP in the maxillofacial region is considered as part of a general pathological process with a peculiar clinical picture peculiar to this area and with symptoms of important diagnostic importance. However, the features of the development of diseases of the hard tissues of the teeth, parotid tissues and oral mucosa remain not fully understood.
Materials and methods. 63 patients were examined and divided into groups. Group 1 included patients with osteoporosis on the background of rheumatoid arthritis with glucocorticoid therapy and receiving antiresorptive drugs, group 2 included patients with osteoporosis on the background of rheumatoid arthritis without glucocorticoid therapy and receiving antiresorptive drugs, and group 3 included patients with primary osteoporosis receiving antiresorptive therapy.
Results. During the comparative analysis, it was revealed that in group 1, the caries index was 5.58, fillings - 6.82, extracted teeth — 8.29; in group 2, the caries index was 6.12, fillings — 5.64, extracted teeth - 7.78; in group 3, the caries index was 2.52, fillings

– 8.02, teeth removed – 2.35. The average values of caries, fillings, and extracted teeth in the groups were 6.96, 6.54, and 4.29, respectively. When assessing the hygienic condition of the mouth in patients with osteoporosis on the background of rheumatoid arthritis, an increase in the indicator was noted compared with the control group. The deterioration of oral hygiene increased as the inflammatory activity of rheumatoid arthritis increased, which indicates that as destructive changes in the joints of the hands with impaired function progress, the oral hygiene process becomes more difficult.

Conclusion. Thus, patients with RA have a high level of dental caries intensity (≈20.26) with a predominance of extracted teeth and its complications in the CPI structure; chronic generalized periodontitis is noted, the severity of which increases with increasing inflammatory activity of the underlying disease. An unsatisfactory level of oral hygiene has been established, which progresses with increasing degree of inflammatory activity of RA, functional limitations of joints and a low level of hygienic knowledge comes more difficult.

P456

LUNG LESIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. R. Kulieva[1], V. B. Kaliberdenko[1], V. R. Yas[2], N. G. Nikolashina[1], M. G. Nikolashin[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]Ege University, Izmir, Turkiye

Objective. Damage to the respiratory system is one of the most common manifestations of rheumatoid arthritis (RA). According to available data, interstitial lung disease (ILD) occurs in 28.4-29.2% of patients with RA. Respiratory complications in RA account for 20% of deaths, being the second cause of death in patients with RA.

Materials and methods. The results of CT scans and medical histories of 43 patients with RA and lung damage aged 20 to 70 years, including 31 men and 12 women, were analyzed.

Results. During the study, it was found that the greatest number of lung lesions in patients with RA is observed between the ages of 60 and 70 years, both in men and women with the same occurrence, which may be due to age-related changes in the respiratory and immune systems as a whole. In turn, among lung diseases, common interstitial pneumonia (IPR) occurred in 31 (72.0%), while the remaining 12 patients accounted for 16.2% with nonspecific interstitial pneumonia (IPR), 4.6% of patients with bronchiolitis obliterans, 2.3% of patients with thickening areas, 2.3% with lymphocytic IP and with ISL, complicated by a fungal infection, respectively. According to the outcome of the disease, 31 people (72.0%) recovered with various residual changes in the lungs, 10 (23.2%) patients were among the unfavorable cases - fatal, and only 2 patients (4.6%) had a complete recovery, without changes in the lungs. Among the characteristic symptoms of ISL on CT, the following were most common: frosted glass - 22 (51.1%), cellular lung – 29 (67.4%), consolidation – 7 (16.2%), bronchiectasis – 23 (53.4%), emphysema – 7 (16.2%), atelectasis – 2 (4.6%) focal formations – 6 (13.9%), pleural effusion – 5 (11.6%).

Conclusion: Thus, the results of the study showed that in patients with RA, AML is often found at the age of 60-70 years in men and women with the same frequency of occurrence, which may be related to functional and age-related changes in the respiratory system. Among lung pathologies, OIP and NIP were noted in 39 patients, which amounted to 90.6%. According to the study data, in patients with a history of RA and lung damage, the outcome of the disease was, as a rule, an unfavorable outcome of 23.2% or a relatively favorable 72.0%, and therefore timely diagnosis by CT scan is an integral part of modern radiology and rheumatology.

P457

CORRELATION BETWEEN SARCOPENIA AND OSTEOPOROSIS IN GERIATRIC AGES

E. Rapushi[1], T. Backa[1], A. Zoto[1], V. Salko[1], A. Kolaci[1]

[1]UHC"Mother Theresa", Tirana, Albania

Sarcopenia is the progressive age-related loss of muscle mass and strength. Sarcopenia is a type of muscle atrophy caused mainly by the natural aging process. In the geriatric age, the risk for osteoporosis increases. Osteoporosis is a major clinical problem in the geriatric age. The more the age after menopause increases, the more the risk of osteoporosis increases.

Purpose: Evaluation of the correlation between sarcopenia and osteoporosis in the geriatric age.

Material and methods: 72 patients with an average age of 67±2.3 years were taken into the study, and muscle mass was evaluated through: anthropometric measurement techniques, muscle strength and assessment of physical performance, bone density through lumbar and coxofemoral DXA scan.

Result: Bone density in the study group was -2.4±1.7 (advanced osteopoenia and osteoporosis values). The assessment of sarcopenia in the study group based on the criteria that were evaluated: muscle strength, muscle quantity or quality and physical performance resulted in moderate to severe sarcopenia for all 3 of these criteria. Statistical analysis showed that sarcopenia was significantly associated with the risk of osteoporosis (OR, 3.1; 94% CI,) and each standard deviation decrease in the relative mass of skeletal muscle was significantly associated with an increase in the risk of osteoporosis (OR, 0.72). ; 97% CI).

Conclusion: This study showed that sarcopenia and osteoporosis are highly correlated. Osteoporosis is closely related to the risk of sarcopenia.

P458

BONE MINERAL DENSITY IN HIV PATIENTS UNDER ANTIRETROVIRAL TREATMENT

E. Rapushi[1], A. Zoto[1], T. Backa[1], V. Salko[1], A. Kolaci[1]

[1]UHC"Mother Theresa", Tirana, Albania

Introduction: Osteoporosis is a bone metabolic disease that affects postmenopausal women, but is also found in many other pathologies. Patients infected with HIV present problems with bone metabolism caused by the HIV virus itself but also by antiretroviral therapy.
Aim: Evaluation of the impact of antiretroviral therapy on bone density in HIV-infected patients
Material and methods: 150 patients aged 25-40 years (male 85 patients 56.6% female 65 patients 43.3%) infected with the HIV virus, not at the AIDS stage, were taken into the study. We measure the bone density in all the patients through DXA (dual x-ray absorptiometry) in spine and hip before starting antiretroviral therapy after 12 months and 24 months. The patients were evaluated with the serum level of vitamin D, calcium, phosphorus, osteocalcin (0.7-6.5ng/mL) and CD4 level (500-1500 cells/mm^3) after 12 and 24 months.
Results: The level of DXA spine resulted: before the start of antiretroviral therapy T-score -0.5 ±0.5, after 12 months of therapy -1.1±0.65 and 24 months after therapy -1.7±0.95; the level of DXA of hip resulted: before the start of therapy -0.3±0.7, after 12 months -1.3±0.91 and after 24 months -2.1±0.97. All patients present altered values of the serum level of vitamins D, osteocalcin, phosphorus and calcium. What was seen in the study was a decrease in the level of osteocalcin in these patients in all three measurements (4.5±2.1ng/mL; 3.1±0.7ng/mL; 1.1±0.9ng/mL). The of CD4 level showed different alterations in different patients during antiretroviral treatment.
Conclusion: Antiretroviral therapy presents its impact on bone mineralization by presenting a decrease in T-score values at the spine and hip, but more at the hip with an increased risk of fractures. A direct correlation was found between the serum level of osteocalcin, T-score measured in DXA in these patients where the decrease in the serum level of osteocalcin during therapy was accompanied by a decrease in Tscore values (p≤0.05). No correlation was found between the serum levels of CD4 and the T-score value measured in DXA.

DIFFICULT TO TREAT RHEUMATOID ARTHRITIS: PREVALENCE AND RISK FACTORS

E. Razgallah[1], S. Boussaid[1], K. Zouaoui[1], M. Abbess[1], S. Rahmouni[1], S. Rekik[1], H. Sahli[1]

[1]Rheumatology department, Rabta hospital, Tunis, Tunisia

Objectives:
Our study aimed to determine the frequency of D2T RA and to define the different risk factors leading to its occurrence.
Material and methods :
We conducted a cross-sectional study among patients diagnosed with RA at a tertiary care university hospital in Tunis. Sociodemographic, clinical, biological, and follow-up characteristics were collected.
Results :
We included 120 patients diagnosed with RA. The mean age was 57 years with 83.3% of women. The mean age at diagnosis was 45.5 years, and the mean diagnostic delay was 28 months. Comorbidities including diabetes, hypertension, and dyslipidemia were noted respectively in 14.7%, 15%, and 6.7% of patients. Sixteen percent were active smokers. Only 25% have reached the secondary education level, while 36.7% were illiterate. An average of 62.5% were unemployed. Polyarticular onset pattern was seen in 81% of patients, and oligoarticular in 7.5%. At diagnosis, 18% had extraarticular manifestations, 62.5% had joint deformities, and 94% had erosive RA. Rheumatoid factor and anticitrullinated peptide antibodies were positive respectively in 95% and 80%. Coxitis and antlanto-axial instability were noted in 11.7% and 17.5% respectively. The mean C-reactive protein (CRP) level was 16 mg/L, and the disease activity score 28 (CRP) was 4.5 indicating a moderate disease activity. Seventy percent of patients were on corticosteroids with an average dose of 10mg/l in 56.6%. Combination therapy (3 concomitant csDMARDs) was noted in 36.7% of patients. Seventy-eight percent adhered to their treatment. D2T RA was detected in only 12 patients (10%).
A significant correlation was noted between the occurrence of D2T RA and female gender (p=0.005), age (p<0.001), age at diagnosis (p<0.001), a significant diagnostic delay (p<0.001), diabetes (p=0.002), smoking (p=0.004), and history of combination therapy (p<0.001).
Conclusion :
D2T RA represents a significant challenge, with a multifactorial etiology. Female gender, advanced diagnostic age, diagnostic delay, diabetes, smoking and combination therapy seems to influence the evolution to a D2T RA.

P460

PREVALENCE AND IMPACT OF OSTEOPOROSIS IN EARLY PSORIATIC ARTHRITIS: INSIGHTS INTO BONE HEALTH AND INFLAMMATORY MECHANISMS

E. Russu[1], L. Chislari[2], E. Deseatnicova[2], A. Nistor[2], O. Bujor[3], M. Homițchi[1], S. Chetruș[2], O. Chetruș[2], L. Groppa[2]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "Timofei Moșneaga" Republican Clinical Hospital, Chisinau, Moldova, [2]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Moldova, [3]"Timofei Moșneaga" Republican Clinical Hospital, Chisinau, Moldova

Background:
Psoriatic arthritis (PsA) is a systemic inflammatory disease associated with psoriasis, characterized by joint damage and functional impairment. While joint inflammation is a major focus, osteoporosis remains an underexplored comorbidity in PsA, despite its significant impact on patient outcomes. Chronic inflammation

and dysregulated cytokine activity, including TNF-α and IL-17, contribute to bone resorption and impaired bone formation, increasing the risk of fractures.

Objectives:

This study aimed to assess the prevalence of osteoporosis in early PsA, its relationship with disease activity and inflammatory markers, and to compare bone health in PsA and rheumatoid arthritis (RA) patients.

Methods:

A total of 100 patients were evaluated, including 70 PsA patients (diagnosed by CASPAR criteria) and 30 RA patients. Bone mineral density (BMD) was measured using dual-energy X-ray absorptiometry (DXA) at the lumbar spine and femoral neck. Serum levels of calcium, vitamin D, and bone turnover markers were assessed. Ultrasound (USG) imaging with Power Doppler was performed to identify synovial proliferation and enthesopathies, and correlations between inflammatory activity and bone health were analyzed.

Results:

Osteoporosis was identified in 32.9% of PsA patients, with an additional 41.4% presenting osteopenia. RA patients showed a slightly higher osteoporosis prevalence (43.3%). In PsA, high disease activity (DAS28 > 5.1) was significantly associated with lower BMD at the femoral neck ($p < 0.05$). Vitamin D deficiency was prevalent in 64.3% of PsA patients. USG detected synovial vascularization and enthesopathies in 10% of PsA patients, correlating with elevated inflammatory markers (ESR, CRP) and reduced BMD ($r = -0.61$, $p < 0.01$). Enthesopathies were linked to localized bone erosion and peri-entheseal osteopenia.

Conclusions:

Osteoporosis is a significant comorbidity in early PsA, driven by chronic inflammation and high disease activity. Early BMD assessment and proactive management, including anti-inflammatory therapies and vitamin D supplementation, are essential. USG is a valuable tool for identifying inflammatory changes impacting bone health. Addressing osteoporosis in PsA is critical for improving patient outcomes and preventing long-term disability.

P461

INTERCONNECTION BETWEEN BONE LOSS AND EARLY PSORIATIC ARTHRITIS: EMPHASIZING OSTEOPOROSIS AS A COMORBIDITY

E. Russu[1], L. Chislari[2], L. Rotaru[2], A. Nistor[2], O. Bujor[3], M. Homițchi[1], O. Chetruș[2], S. Chetruș[2], L. Groppa[2]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "Timofei Moșneaga" Republican Clinical Hospital, Chisinau, Moldova, [2]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Moldova, [3]"Timofei Moșneaga" Republican Clinical Hospital, Chisinau, Moldova

Background:

Psoriatic arthritis (PsA) is a chronic inflammatory condition frequently associated with psoriasis, marked by joint inflammation and structural damage. The interplay between PsA and bone health, particularly osteoporosis, remains underexplored, despite osteoporosis being a significant comorbidity in inflammatory diseases. Identifying early PsA manifestations and osteoporosis prevalence can improve outcomes by enabling timely interventions.

Objective:

To evaluate the prevalence and clinical implications of osteoporosis in patients with early PsA, emphasizing the need for comprehensive bone health assessment as part of PsA management strategies.

Methods:

A retrospective observational study included 103 psoriasis patients hospitalized in the Rheumatology and Arthrology departments of the Republican Clinical Hospital "Timofei Moșneaga" between 2019 and 2024. Inclusion criteria encompassed adults aged 18-70 years diagnosed with PsA per CASPAR criteria. Data collection involved mPEST screening, laboratory tests, bone mineral density (BMD) assessment, musculoskeletal ultrasonography, and MRI. Statistical analysis was performed using Statistica 9.0.

Results:

Out of 103 psoriasis patients (47 men, 56 women; mean age 44 ± 13.69 years), 61 (59.2%) were diagnosed with PsA. Early PsA (≤2 years duration) was present in 52.5% of cases. Osteoporosis or reduced BMD was identified in 42.6% of PsA patients, correlating significantly with high disease activity, prolonged inflammation, and glucocorticoid use. Imaging techniques revealed synovitis in 83% and tenosynovitis in 89.3% of cases, with 40.4% showing bone erosions on MRI. Dactylitis (65.6%), enthesitis (41%), and nail psoriasis (63.7%) were common predictors of PsA. Comorbidities, including hypertension (33%) and type II diabetes (10.7%), were prevalent.

Conclusions:

This study highlights osteoporosis as a common and underdiagnosed complication in early PsA. Chronic inflammation, systemic treatments, and altered bone metabolism exacerbate bone loss. Early PsA diagnosis, facilitated by clinical signs, imaging modalities, and bone health assessments, is essential for preventing further structural damage. Integrating osteoporosis screening and management into PsA care can enhance overall outcomes, emphasizing the interdisciplinary collaboration between rheumatologists, dermatologists, and endocrinologists.

P462

COMORBIDITIES OF OSTEOARTHRITIS, OSTEOPOROSIS, AND SARCOPENIA IN PSORIATIC ARTHRITIS: CLINICAL AND THERAPEUTIC PERSPECTIVES

L. Dutca[1], E. Russu[1], L. Groppa[1]

[1]"Nicolae Testemitanu" State University of Medicine and Pharmacy, Chişinău, Moldova

Background

Osteoarthritis (OA), osteoporosis (OP), and sarcopenia are prevalent musculoskeletal disorders, often coexisting and exacerbating each other's clinical and functional impact. These

interrelated conditions increase the risk of falls, fractures, and disability, particularly in patients with systemic inflammatory diseases such as psoriatic arthritis (PsA). Despite advances in managing these conditions independently, their overlapping pathogenetic mechanisms and cumulative burden remain underexplored.

Objectives

This study aimed to assess the prevalence and interplay of OA, OP, and sarcopenia in PsA patients, focusing on disease activity, functional outcomes, and quality of life. The study also evaluated the clinical utility of integrated diagnostic and therapeutic strategies targeting these coexisting conditions.

Methods

A cohort of 46 PsA patients was analyzed using clinical, laboratory, and imaging assessments. Disease activity was measured using DAPSA, while OA severity was evaluated through radiographic Kellgren-Lawrence (KL) grading. Bone mineral density (BMD) was assessed using dual-energy X-ray absorptiometry (DXA) to diagnose OP. Sarcopenia was identified per EWGSOP2 criteria, combining muscle strength (handgrip), muscle mass (DXA), and physical performance (gait speed). Patient-reported outcomes included HAQ-DI, FACIT-F, and SF-36. Statistical analyses explored correlations between OA, OP, sarcopenia, and clinical indices.

Results

Among the cohort, 67.4% had OA, 43.5% were diagnosed with OP, and 47.8% met criteria for sarcopenia. Patients with sarcopenia had significantly lower BMD at the hip and lumbar spine (T-score: -2.6±0.4) and worse KL grades ($p<0.01$). Multimorbidity was strongly associated with higher DAPSA scores ($r=0.732$, $p<0.001$) and poorer functional outcomes (HAQ-DI: 2.4±0.8, $p<0.01$). Sarcopenia and OP were significant predictors of reduced gait speed and increased fall risk (OR=3.2, $p=0.02$). Quality of life, assessed via SF-36, was markedly impaired in patients with combined OA, OP, and sarcopenia.

Conclusions

The coexistence of OA, OP, and sarcopenia in PsA patients represents a significant clinical challenge, contributing to disability, reduced quality of life, and increased healthcare needs. These findings highlight the importance of early detection, comprehensive assessment, and multidisciplinary management strategies targeting these interrelated conditions. Interventions that address inflammation, bone health, and muscle function concurrently can improve outcomes and reduce the cumulative burden in this high-risk population.

P463

OSTEOPOROSIS AND OCULAR INVOLVEMENT IN RHEUMATOID ARTHRITIS

R. Usatii[1], E. Russu[2], E. Deseatnicova[3], A. Pascari-Negrescu[3], L. Groppa[3]

[1]"Timofei Mosneaga" Republical and Clinical Hospital, Chisinau, Moldova, [2]"Nicolae Testemitanu" State Medical and Pharmaceutical University, "Timofei Mosneaga" Republical and Clinical Hospital, Chisinau, Moldova, [3]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Moldova

Background Rheumatoid arthritis (RA) is a systemic autoimmune disorder associated with chronic inflammation, leading to joint damage, extra-articular complications, and osteoporosis. Among these manifestations, dry eye syndrome (DES) is prevalent and correlates with systemic inflammation. This study focuses on the relationship between RA, osteoporosis, and ocular inflammation, highlighting the effects of disease-modifying antirheumatic drugs (DMARDs) on both conditions.

Objectives To assess the prevalence of osteoporosis in RA patients with DES, evaluate the impact of DMARDs on bone mineral density (BMD) and DES severity, and explore correlations between systemic inflammation, ocular health, and bone loss.

Methods Seventy-five RA patients with DES (150 eyes), aged 40–75 years, were included in this study. Participants were divided into csDMARD (40 patients) and bDMARD (35 patients) groups. Disease activity was measured using DAS28-CRP, while DES severity was evaluated with Schirmer's test, Ocular Surface Disease Index (OSDI), and tear osmolarity. BMD was assessed via dual-energy X-ray absorptiometry (DEXA) at the lumbar spine and femoral neck. Serum inflammatory markers and bone turnover markers were also analyzed pre- and post-treatment.

Results Osteoporosis was identified in 52% of patients, with higher prevalence among those on csDMARDs. After six months, bDMARD therapy significantly improved BMD (mean T-score increase of 0.3 ± 0.1, $p<0.05$), compared to 0.1 ± 0.05 in the csDMARD group. OSDI scores improved by 46.2% in the bDMARD group versus 38.2% in the csDMARD group, with better tear osmolarity and Schirmer's test results in bDMARD-treated patients. Systemic inflammation markers, including CRP and ESR, decreased significantly in both groups, correlating with improvements in BMD and DES severity.

Conclusions This study highlights the interconnected impact of systemic inflammation on osteoporosis and DES in RA patients. The superior efficacy of bDMARDs in controlling inflammation contributes to improved BMD and milder ocular symptoms, underscoring the importance of aggressive treatment strategies. Early intervention targeting both bone and ocular health is essential to optimize outcomes and enhance the quality of life in RA patients.

P464

RHEUMATOID ARTHRITIS IN CORRELATION WITH KERATOCONJUNCTIVITIS, UVEITIS AND OSTEOPOROSIS

R. Usatii[1], E. Russu[2], E. Deseatnicova[3], L. Chislari[3], A. Pascari-Negrescu[3], L. Groppa[3]

[1]"Timofei Mosneaga" Republical and Clinical Hospital, Chisinau, Moldova, [2]"Nicolae Testemitanu" State Medical and Pharmaceutical University, "Timofei Mosneaga" Republical and Clinical Hospital, Chisinau, Moldova, [3]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Moldova

Background Rheumatoid arthritis (RA) is a systemic autoimmune disorder characterized by chronic inflammation, leading to joint destruction and extra-articular complications, including ocular conditions such as keratoconjunctivitis and uveitis, as well as os-

teoporosis. The interplay between systemic inflammation, ocular health, and bone metabolism is complex, impacting both diagnostic and therapeutic approaches.

Objectives To evaluate the prevalence and interconnection of keratoconjunctivitis, uveitis, and osteoporosis in RA patients and to analyze the effects of systemic inflammation and RA treatments on these conditions.

Methods A retrospective observational study was conducted on 124 RA patients aged 35–75 years, with disease durations ranging from 1 to 20 years. Ocular manifestations were assessed using slit-lamp examination, Schirmer's test, and fundoscopy. Bone mineral density (BMD) was measured using dual-energy X-ray absorptiometry (DEXA). RA activity was evaluated with DAS28-CRP scores. Patients were stratified based on their treatment regimens: conventional synthetic DMARDs (csDMARDs) or biological DMARDs (bDMARDs). Serum levels of inflammatory markers (CRP, ESR) and bone turnover markers (osteocalcin, CTX) were analyzed.

Results Ocular manifestations were observed in 62.9% of patients: keratoconjunctivitis (47.6%) and uveitis (15.3%). Osteoporosis was present in 58% of patients, with a higher prevalence among those with severe RA activity (DAS28-CRP >5.1). Patients on bDMARDs exhibited lower rates of severe ocular inflammation and better BMD outcomes compared to those on csDMARDs. Specifically, uveitis incidence was reduced by 33%, and BMD improved by 0.4 ± 0.2 T-score units ($p<0.05$) in the bDMARD group after 12 months. Significant correlations were found between systemic inflammation markers and both ocular and bone parameters (r=0.68 for CRP vs. ocular scores, r=0.72 for ESR vs. BMD loss).

Conclusions RA-associated keratoconjunctivitis, uveitis, and osteoporosis are closely linked to systemic inflammation. bDMARDs demonstrate superior efficacy in reducing inflammatory activity, mitigating ocular complications, and preserving bone health. Early and aggressive management addressing both joint and extra-articular manifestations is essential to improve patient outcomes and quality of life.

P465

MORPHOLOGICAL TRAITS ACCORDING TO BMI OF LRP5 RS121908669 GENOTYPE CARRIERS

E. Shahrour[1], B. Al-Halabi[2], W. Al-Achkar[2], H. Yazigi[1]

[1]tishreen university, Latakia, Syria, [2]Atomic energy commssion, syria, Damascus, Syria

Objective: Descriptive diagnostics is a part of clinical diagnosis. It is not reliable, but it is prompt. Therefore, it is necessary to determine the phenotypes of the genotypes of carriers of LRP-5G171R. This study is the first of its kind worldwide.

Material and Methods: This cross-sectional study was performed on 150 premenopausal and postmenopausal women with a mean age of 40 years. Body mass index (BMI) was calculated. To determine the genotypes of LRP5 rs121908669, a PCR-RFLP assay was performed, and the results were confirmed by DNA sequencing. The likelihood test, chi-square test, binary logistic regression test, and odds ratio test were used to determine the associations between BMI and the genotype of LRP5G171R.

Results: The likelihood test confirmed the relationship between BMI and LRP5G171R ($\varkappa 2$ =15.658, p=0.048). The results indicate that there are positive correlations between obese BMI and extremely obese BMI and between obese BMI and GG ($\varkappa 2$ =23.707, 14.013 p=0.000, 0.00). There was a negative correlation between a normal BMI and GG ($\varkappa 2$ =19.675, p=0.000). There was a negative correlation between extremely obese BMI and CC ($\varkappa 2$=12.466, p= 0.000). There was a negative correlation between BMI and GC in obese individuals ($\varkappa 2$ =19.997, p=0.000).

Discussion: No previous studies have identified morphological traits in terms of BMI, but in general, studies confirm that the relationship between the LRP5 gene and metabolism and adipocyte biology is significant. This is consistent with the results of this study.

Conclusion: Finally, obesity and extreme obesity are positive factors. The carriers of the mutant LRP5G171R (GC, CC) will be protected from obesity, unlike carriers of the normal genotype (GG), which will suffer from obesity. This SNP can be added to NCBI as an SNP associated with obesity.

P466

HORMONE REPLACEMENT THERAPY AND THE RISK OF KNEE AND HIP REPLACEMENT: INSIGHTS FROM THE OSTEOLAUS COHORT STUDY

E. Shevroja[1], S. Aydogdu[2], C. Koller[2], E. Gonzalez-Rodriguez[1], D. Hans[1], O. Lamy[1], T. Hügle[2], J. Geurts[2]

[1]Lausanne University Hospital, Interdisciplinary Center for Bone Diseases, Lausanne, Switzerland, Lausanne, Switzerland, [2]Lausanne University Hospital, Rheumatology, Lausanne, Switzerland, Lausanne, Switzerland

Background: The potential benefit of hormone replacement therapy (HRT) on the risk of incident joint replacement, remains a debated topic due to mixed evidence from both interventional [1] and observational studies [2].

Objectives: In this study we assessed the association of HRT status and duration with the incidence of total knee (TKR) or hip replacement (THR) among post-menopausal women.

Methods: We conducted a population-based cohort study using data from the longitudinal OsteoLaus study [3], which included five consecutive visits conducted at regular intervals over a 10-year period between 2010 and 2022. We included participants who had a minimum follow-up duration of 7.5 years (n=1026). Incidence of TKR and THR was evaluated using DXA images obtained during each visit. Participants with joint replacement at baseline or following hip fracture were excluded (n=87). Cox proportional hazard models estimated the hazard ratio (HR) and 95% CIs of incident TKR or THR associated with the status (never, past, current) and duration of self-reported HRT use. Results were adjusted for age, BMI, femoral neck BMD, calcium use, osteoporotic drugs use, comorbidities, ΔBMI, ΔBMD as well as HRT start age and duration after baseline.

Results: Incidence rates of TKR and THR were 7.0 and 6.1 per

1000-person years, respectively. Mean follow-up durations were 5.6±2.7 years for TKR (n=63), 5.1±2.3 yrs for THR (n=55) and 9.3±1.5 yrs for controls (n=908). Participants with incident TKR were significantly older (66.4±6.2 vs. 63.1±7.2 yrs), had higher BMI (29.2±4.8 vs. 25.2±4.3 kg/m^2), and femoral neck BMD (0.76±0.10 vs. 0.73±0.11 g/cm^2) than controls at baseline. Participants with incident THR were older (66.6±5.7 yrs) and had higher femoral neck BMD (0.77±0.14g/cm^2) than controls. There were no significant differences in the proportion of past (29.1%/33.3%/29.1 %) and current (24.7%/31.7%/27.3 %) HRT users at baseline between controls, TKR and THR, respectively. Current HRT users did not significantly associate with increased risk of TKR (HR 1.46, 95%CI (0.92-2.31)) or THR (HR 1.34, 95%CI (0.67- 2.67)). HRT starting age was similar between TKR (49.6 ±4.8 yrs), THR (49.1 ±5.3 yrs) and controls (50.8 ±8.3 yrs). Duration of HRT use at baseline was significantly longer for TKR cases (13.2 ±9.0 yrs) compared with controls (9.2 ±7.8 yrs), but not THR cases (12.1 ±9.0 yrs). Longer HRT duration at baseline was associated with an increased risk of TKR (HR 1.06, 95%CI (1.01-1.11)) but not THR (HR 1.03, 95%CI (0.95-1.11)).

Conclusion: In conclusion, longer HRT duration may increase TKR risk, potentially through hormonal effects on body composition and bone remodeling. No association was found with THR, suggesting differing pathophysiological mechanisms.

PERSONALIZED 3D MORPHOMETRIC ANALYSIS OF THE MENISCUS IN MEDIAL KNEE OSTEOARTHRITIS: IMPLICATIONS FOR DIAGNOSIS AND TREATMENT

E. T. Tahir[1], Z. Z. Zhang[1], M. X. Ma[1]

[1]Department of Orthopedics, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Objective: To perform a region-specific, 3D morphometric analysis of the medial meniscus in MRI-based osteoarthritic (OA) and healthy knee models, focusing on meniscal thickness, width, and tibial coverage. **Methods:** High-resolution MRI and CT datasets from a healthy and OA knee joint were used to reconstruct 3D geometric models of the medial meniscus and tibia. The meniscus was subdivided into anterior, middle (body), and posterior regions for region-specific analysis. The meniscus was subdivided into anterior, middle (body), and posterior regions for region-specific analysis. We applied 3D spline interpolation to generate equidistant control points along the meniscal surface, ensuring a smooth representation. These control points were utilized to measure meniscal thickness and width using 3D surface analysis and geometrical metrics. Tibial coverage was calculated as the ratio of meniscal surface area to tibial plateau area. For the OA knee, medial meniscus extrusion (MME) was assessed by measuring displacement from the tibial plateau, with a threshold of ≥3 mm. **Results:** In the healthy knee, posterior meniscal width (12.96 ± 2.78 mm) was significantly greater than the middle (8.33 ± 0.44 mm) and anterior (7.67 ± 0.69 mm) regions. Similarly, in the OA knee, posterior width (8.59 ± 2.34 mm) was larger than both the middle (7.84 ± 0.59 mm) and anterior (6.54 ± 1.28 mm) regions, though to a lesser extent than in the healthy knee. Meniscal thickness was greater in the healthy knee across all regions: anterior (3.55 ± 1.30 mm), middle (4.53 ± 0.71 mm), and posterior (4.12 ± 1.47 mm), compared to the OA knee, which exhibited reduced thickness:anterior (3.34 ± 1.55 mm), middle (3.77 ± 1.65 mm), and posterior (4.03 ± 1.35 mm), indicating regional thinning in OA tissue. Tibial coverage of the medial meniscus was significantly reduced in the OA knee, with the healthy knee covering 62.1% of the medial tibial plateau, compared to only 32.1% in the OA model. Additionally, the OA knee exhibited MME of ≥ 3 mm, indicating significant displacement compared to the healthy knee. **Conclusion:** These findings highlight progressive structural changes in the medial meniscus in OA, suggesting that 3D morphometric analysis could serve as a valuable tool for early detection and personalized treatment strategies in knee osteoarthritis.

P468

TAURINE EFFECTS ON THE EXPRESSION OF TYPE II COLLAGEN AND GENES ASSOCIATED WITH ENERGY METABOLISM AND INFLAMMATION IN THE ARTICULAR CARTILAGE EXPLANTS CULTURED WITH TAURINE FROM PATIENTS WITH END-STAGE OSTEOARTHRITIS

E. Tchetina[1], M. Cherkasova[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objectives: To examine metabolic changes in the expression of genes associated with energy metabolism in the articular cartilage explants obtained from patients with end-stage osteoarthritis (OA) prior to arthroplasty and cultured with taurine.

Methods: Fourteen patients with end-stage OA (median age 58 years) were examined. Full-depth explants of human OA knee articular cartilage from arthroplasty were cultured with 50 μM taurine during 24h. Total RNA isolated from these cells was used for gene expression studies performed with quantitative real-time RT-PCR.

Results: Taurine was capable of modifying gene expression in cultured articular cartilage explants from the examined patients with OA compared with untreated counterparts. Gene expression of glycolysis –related pyruvate kinase, the Krebs cycle component succinate dehydrogenase, and electron transport chain element, uncoupling protein 1 was significantly upregulated in concert with ATP-synthase gene and AMP-activated protein kinase. Simultaneous upregulation of the autophagy-related ULK1 was

observed along with downregulation of the inflammation-related tumour necrosis factor α gene expression. Type II collagen gene expression was also upregulated. No significant changes in the expression of mammalian target of rapamycin and IL-1β genes were noted in cartilage explants from the examined patients with OA cultured with taurine compared with untreated counterparts.
Conclusion: The upregulation of genes associated with energy metabolism and type II collagen accompanied by downregulation of inflammation-related TNFα in articular cartilage explants obtained from patients with end-stage osteoarthritis from arthroplasty, indicates the involvement of whole cell metabolism in the manifestations of OA disease.

P469

METABOLIC CHANGES IN ENERGY METABOLISM AND INFLAMMATION IN THE PERIPHERAL BLOOD MONONUCLEAR CELLS CULTURED WITH TAURINE FROM PATIENTS WITH END-STAGE OSTEOARTHRITIS

E. Tchetina[1], M. Cherkasova[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objectives: To examine metabolic changes in the expression of genes associated with energy metabolism in the **peripheral blood mononuclear cells** (PBMCs) obtained from patients with end-stage osteoarthritis (OA) prior to arthroplasty and cultured with taurine.
Methods: Twenty five patients with end-stage OA (median age 58 years) were examined. PBMCs were isolated prior to arthroplasty using Ficoll density gradient and cultured with 50 μM taurine during 24h. Cell viability was monitored with 0.2% Trypan blue staining. Total RNA isolated from these cells was used for gene expression studies performed with quantitative real-time RT-PCR.
Results: Taurine was capable of modifying gene expression in cultured PBMCs from the examined patients with OA compared with untreated cells. Expression of glycolysis –related pyruvate kinase, the Krebs cycle component succinate dehydrogenase, and electron transport chain element, uncoupling protein 1 was significantly upregulated in concert with ATP-synthase gene. Simultaneous upregulation of the autophagy-related ULK1 was observed along with downregulation of the inflammation-related tumour necrosis factor α gene expression. No significant changes in the expression of IL-1β gene were noted in PBMCs from the examined patients with OA cultured with taurine compared with untreated counterparts.
Conclusion: The upregulation of genes associated with energy metabolism accompanied by downregulation of inflammation-related TNFα in PBMCs obtained from patients with end-stage osteoarthritis prior to arthroplasty, indicates the involvement of whole cell metabolism in the manifestations of OA disease.

P470

TAURINE PRODUCES CHANGES IN THE EXPRESSION OF GENES ASSOCIATED WITH ENERGY METABOLISM AND INFLAMMATION IN CULTURED PERIPHERAL BLOOD MONONUCLEAR CELLS FROM PATIENTS WITH END-STAGE RHEUMATOID ARTHRITIS

E. Tchetina[1], M. Cherkasova[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objectives: To examine metabolic changes in the expression of genes associated with energy metabolism in the peripheral blood mononuclear cells (PBMCs) obtained from patients with end-stage rheumatoid arthritis (RA) prior to arthroplasty and cultured with taurine.
Methods: Eleven patients with end-stage RA (median age 52 years) were examined. PBMCs were isolated prior to arthroplasty using Ficoll density gradient and cultured with 50 μM taurine during 24h. Cell viability was monitored with 0.2% Trypan blue staining. Total RNA isolated from these cells was used for gene expression studies performed with quantitative real-time RT-PCR.
Results: Taurine was capable of modifying gene expression in cultured PBMCs from the examined patients with RA compared with untreated cells. Expression of glycolysis –related pyruvate kinase, the Krebs cycle component succinate dehydrogenase, and electron transport chain element, uncoupling protein 1 was significantly upregulated in concert with ATP-synthase gene and downregulation of AMP-activated protein kinase. Simultaneous upregulation of the autophagy-related ULK1 was observed along with downregulation of the inflammation-related tumour necrosis factor α gene expression. No significant changes in the expression of IL-1β gene were noted in PBMCs from the examined patients with RA cultured with taurine compared with untreated counterparts.
Conclusion: The upregulation of genes associated with energy metabolism accompanied by downregulation of inflammation-related TNFα in PBMCs obtained from patients with end-stage rheumatoid arthritis prior to arthroplasty, indicates the involvement of whole cell metabolism in the manifestations of RA disease.

P472

AUGMENTED REALITY (AR) EXERGAMES IMPROVE STRENGTH AND REDUCE PAIN IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS: RESULTS FROM A CLINICAL TRIAL

E. Thuilier[1], J. J. Carey[2], B. Whelan[2], M. Fitzgerald[3], J. Dingliana[4], M. Dempsey[5], S. Biggins[6], A. Brennan[1]

[1]University of Galway, School of Computer Science, Galway, Ireland, [2]University of Galway, School of Medicine, Galway, Ireland, [3]University of Galway, College Of Medicine Nursing & Health Sc, Galway, Ireland, [4]Trinity College Dublin, School of Computer Science and Statistics, Dublin, Ireland, [5]University of Galway, School of Mechanical Engineering, Galway, Ireland, [6]University Hospital of Limerick, Department of Physiotherapy, Limerick, Ireland

Background: Osteoporosis falls often lead to fractures. While physical therapy can help reduce fall and fracture risk, patient adherence is challenging. The potential of Augmented Reality (AR) in osteoporosis remains unknown despite its use in other conditions.
Purpose: To evaluate the effectiveness of AR exergames on muscle function and pain in osteoporosis patients.
Methods: We developed 4-bespoke AR exergames using active-videogames, overlaying virtual objects on the real world to create interactive physical activity experiences. They aligned with an approved osteoporosis training programme and will be demonstrated in an oral presentation. The intervention group used an AR-headset and body-tracking camera, while the control group followed a traditional exercise programme with the same exercises. In our clinical trial, we compared flexibility, strength, and pain between groups at baseline and study-end. Pain was assessed with the Visual Analogue Scale, flexibility with the Chair-Reach test, and strength with a grip strength test. Participants completed 12 bi-weekly 20-minute sessions.
Results: Of 48 females enrolled, 41 (aged 60–86 years) completed the study. All participants improved in muscle strength, flexibility, whilst experiencing reduced pain (Table 1). The intervention group showed greater strength gains and pain relief. The control group improved more in flexibility, though the intervention group was more flexible at baseline. Composite outcomes showed a median improvement of −3.77(SD:46.84) in the intervention group versus −5.01(SD:25.61) in the control group.
Table 1. Results

Characteristic	Control(n=21)		Intervention(n=20)	
	Baseline	End	Baseline	End
Mean Age(years)	69.7y(SD=6.3)		69.8y(SD=5.3)	
Pain-score	2.33(SD=1.8)	2.19(SD=2.5)	2.47(SD=2.04)	2.05(SD=2.55)
Muscle strength	20.9(SD=6.14)	20.8(SD=5.94)	20.15(SD=5.69)	22.85(SD=5.01)
Flexibility	6(SD=8.02)	0(SD=5.78)	1(SD=4.90)	0 (SD=3.84)

Conclusions: Both groups improved in muscle strength, flexibility, and pain; the intervention group showed greater strength gains and pain relief. This suggests AR exergames are as effective as/superior to, conventional rehabilitation, providing engaging experiences that enhance outcomes and adherence for older women with osteoporosis.

P473

EFFICACY OF BUROSUMAB IN MANAGING FGF23-RELATED HYPOPHOSPHATEMIC OSTEOMALACIA: FOCUS ON TRANSITION FROM PEDIATRIC TO ADULT CARE IN 15 CASES IN JAPAN

E. Tomatsu[1], R. Morikawa[1], Y. Asada[1], Y. Yoshino[1], I. Hiratsuka[1], S. Sekiguchi-Ueda[1], M. Shibata[1], Y. Seino[1], T. Takayanagi[1], N. Hayakawa[2], A. Suzuki[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Fujita Health University School of Medicine, Toyoake, Japan, [2]Department of Clinical Pharmacotherapeutics I, Faculty of Parmacy, Meijo University, Toyoake, Japan

Objectives: FGF23-related hypophosphatemic osteomalacia has been conventionally treated with neutral phosphate supplements and active vitamin D analogs. The anti-FGF23 antibody, burosumab, has become an additional therapeutic option for treating both congenital and acquired FGF23-related hypophosphatemic ricket and osteomalacia. However, data on the long-term outcomes of such treatments are limited. We here report the clinical features of 15 cases treated at our institution and also focus on the transition from pediatric to adult care.
Subjects: The study included 15 cases (6 males and 9 females). The median age at diagnosis was 5 years (range: 1–30 years), with all but one case being childhood–onset. The median age on their first visit to our hospital was 30 years (range: 15–59 years).
Results: At the time of initial medical examination, 5 patients were asymptomatic, while 9 reported pain, 3 experienced gait disturbances, 2 had muscle weakness, and 2 showed general fatigue. The mean serum P level in the conventional therapy group was 2.1 mg/dL and the mean TmP/GFR was 1.6 mg/dL. We treated 4 cases with conventional therapy and burosumab was administered in 11 cases including 7 newly administered cases. Clinical symptoms improved in all newly burosumab administration group. There is a discrepancy between TmP/GFR levels at 2 weeks (2.5 mg/dL) and 4 weeks (2.0 mg/dL) after burosumab administration in newly administered group.
Conclusion: The maximum dose of burosumab is currently 1 mg/kg (not exceeding 90 mg per dose) every 4 weeks, but according to a report by Karl et al., even at the maximum dose, 6% of patients did not have normalised serum P levels. The administration of burosumab to adult patients with FGF23-related hypophosphatemic osteomalacia improved phosphate metabolism and clinical symptoms, but the regimen of administration still needs to be improved.
Disclosure: Suzuki A has received honoraria from Kyowa-Kirin Co. for delivering lectures.

WHAT DO WE KNOW ABOUT OSTEOARTHRITIS: DOES-IT TRANSLATE BETWEEN AFFECTED SPECIES?

E. Troncy[1], A. Delsart[2], M. Frézier[2], M. Lefort-Holguin[2], C. Otis[2], A. Castel[3], B. Lussier[1], M. Moreau[1], J. Martel-Pelletier[1], J.-P. Pelletier[1]

[1]Groupe de recherche en pharmacologie animale du Québec (GREPAQ). Osteoarthritis research unit, University of Montreal hospital research center (CRCHUM)., Saint Hyacinthe, Canada, [2]Groupe de recherche en pharmacologie animale du Québec (GREPAQ) - Université de Montréal., Saint Hyacinthe, Canada, [3]Groupe de recherche en pharmacologie animale du Québec (GREPAQ). Department of clinical sciences, Faculty of veterinary medicine, Université de Montréal, Saint Hyacinthe, Canada

Objective: To edit a narrative review comparing the osteoarthritis (OA) phenotype observed in natural models of OA in cat and dog, as well as in experimental models in rat (when justified).
Material and Methods: Data extraction in the literature and the 30y experience in studying OA in pets focused on a comparison of different aspects of OA phenotype: 1) prevalence; 2) localisation; 3) risk factors; 3) detection and diagnosis; 4) OA mechanisms from the joint to the nervous alterations. Concurrent validation of experimental OA models was conducted, when justified.
Results: Osteoarthritis is a degenerative joint disease that has been established for a certain time to be the main source of chronic pain in cats and dogs, its prevalence in Western countries being around 25% for the adult population and reaching up to 65-85% in geriatrics. It could be of primary (mostly in cats) or secondary (in dogs) origin, and risk factors include congenital articular malformations (dysplasia, *etc*.), post-trauma, sterilisation, size and weight, as well as environment (obesity, excessive activity). It affects all appendicular joints (hip, stifle, hock and elbow) as well as (lumbar) vertebral axis (cats). A trilogy of OA-associated pain is expressed in pets, including biological (functional dysfunctions), psychological (behavioural changes, cognitive dysfunction) and social (changes in human-animal and animal-animal interactions) dimensions. Originally, the focus was on the biomechanical pain associated with cartilage degeneration and articular sclerosis, which was updated with structural remodelling including neuroplasticity and particularly peripheral and central sensitisation. Chemical OA models in rat are lacking face validity whereas the MI-RAT© model associating a surgically-induced stifle instability and calibrated exercise on treadmill was validated for spinal neuropeptidomics, neuroepigenetics, structural changes and pain phenotype.
Conclusion: The translation from experimental animal pain model to natural OA models appears increasingly appropriate to better characterise and propose effective clinical treatment of chronic pain.

P475

EVIDENCE-BASED EFFICACY IN OSTEOARTHRITIS MANAGEMENT FOR COMPANION ANIMALS

E. Troncy[1], A. Delsart[2], M. Lefort-Holguin[2], C. Otis[2], A. Castel[3], B. Lussier[1], M. Moreau[1], J. Martel-Pelletier[1], J.-P. Pelletier[1]

[1]Groupe de recherche en pharmacologie animale du Québec (GREPAQ). Osteoarthritis research unit, University of Montreal hospital research center (CRCHUM)., Saint Hyacinthe, Canada, [2]Groupe de recherche en pharmacologie animale du Québec (GREPAQ) - Université de Montréal., Saint Hyacinthe, Canada, [3]Groupe de recherche en pharmacologie animale du Québec (GREPAQ). Department of clinical sciences, Faculty of veterinary medicine, Université de Montréal, Saint Hyacinthe, Canada

Objective: To complete a scoping review of osteoarthritis (OA) pharmaceutical and non-pharmacological management in dog and cat.
Material and Methods: Data were extracted in the literature and a classification of therapeutic approaches was proposed, based on their efficacy and the quality of referenced studies. The quality of each study was evaluated through its experimental design, such as randomised, blinded, prospective, placebo-controlled, and the use of objective, validated pain assessments (favoured over subjective non-validated scales), and their statistical analysis.
Results: For the past 30 years, non-steroidal anti-inflammatory drugs (NSAID) efficacy in canine, and feline, OA has been reported in 40, and 15, publications, respectively. However, several of these studies contained significant shortcomings that call into question the reliability of the results obtained. For instance, only 13, and 8, studies used objective assessment measures such as podobarometric gait analysis or actimetry, while the others relied on subjective (partially validated, if any) scales to evaluate the treatment efficacy. Side effects were well listed and remain a major constraint in NSAID use, particularly for cats. Other analgesic treatments included anti-NGF monoclonal antibody (mAb), tramadol, gabapentin, and anti-viral drug amantadine. The two latter presented poor evidence of efficacy in very few studies. Although mAb got instantaneous popularity their indications of use remain to be precise and guidelines for potential safe and efficient use (safety of drugs combination, emergence of subpopulations more sensitive to side effects) are missing. Despite 25 articles on disease-modifying OA drugs (DMOAD) in dogs, no DMOAD was attractive in terms of structural and analgesic efficacy. At the head of the efficacy evidence pyramid for non-pharmacological therapies were placed caloric restriction and omega-3 polyunsaturated fatty acids (marine oil, or green-lipped mussels) with an excellent size effect d = 0.99. Joint injection of biologics as well as physiotherapeutic modalities presented limited evidence. No publication up to now considered specifically sensitisation to treat, other therapies presented anecdotal evidence, but sensorial enrichment looks promising.
Conclusion: Pets have a richer therapeutic arsenal than humans with OA disease, but it remains imperfect.

VFX IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

E. V. Brutskaya-Stempkovskaya[1], V. V. Prybylskaya[2], N. A. Vasilyeva[3], Y. V. Dydyshko[1]

[1]Belarusian State Medical University, Minsk, Belarus, [2]Minsk Consulting Diagnostic Center, Minsk, Belarus, [3]Republic Center of Medical Reabilitation and balneotherapy, Minsk, Belarus

Background. Bone mineral density decreasing with the development of osteoporosis in rheumatoid arthritis is one of the significant complications of the disease. Osteoporotic vertebral fractures (VFx) are associated with chronic pain syndrome, decreased mobility and quality of life, and increased mortality.
Objective: to assess the impact of rheumatoid arthritis on the number of vertebral fractures in postmenopausal women.
Materials and methods. A cross-sectional controlled study was conducted. We studied 48 postmenopausal women with rheumatoid arthritis (main group), the control group - 25 postmenopausal women without rheumatoid arthritis. Exclusion criteria: age over 75 years, patients with a history of spinal injuries and musculoskeletal diseases of functional classes III - IV, a decrease in GFR less than 30 ml / min, with diseases and conditions associated with a decrease in BMD. We examined DXA, LVA, laboratory data.
Results. Patients of both groups were comparable in anthropometric and anamnestic data, did not differ in the content of total protein, cholesterol, triglycerides (p> 0.05). The average age of patients in the main group was 64.2 ± 9.77 years, the control group - 61.9 ± 5.23 years, U = 178.5, p = 0.165. When analyzing the LVA results, vertebral fractures were detected in 33.3% of patients in the main group, which is significantly higher than in the control group patients (16%, p = 0.02). The obtained data indicate a significantly increased incidence of VFx in postmenopausal women with rheumatoid arthritis compared to postmenopausal women without rheumatoid arthritis.
Conclusions. The results of the study indicate an increased incidence of vertebral fractures in postmenopausal women with rheumatoid arthritis compared to postmenopausal women without rheumatoid arthritis.

P477

AFABP IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. V. Papichev[1], L. E. Sivordova[1], Y. U. R. Akhverdyan[1], Y. U. V. Polyakova[1], B. V. Zavodovsky[1]

[1]FSBI "RICER n.a. A.B. Zborovsky", Volgograd, Russia

Aim: to study the association of adipocyte fatty acid-binding protein (AFABP) with clinical and laboratory characteristics of RA
Materials and methods: 88 women with RA were enrolled in our study. All patients fulfilled the 2010 ACR/EULAR classification criteria for RA. AFABP serum levels were determined by enzyme-linked immunosorbent assay. 76 patients (86,4%) were taking glucocorticoids to control the activity of the disease. Homeostatic Model Assessment for insulin resistance (HOMA-IR) was calculated. Statistical analysis was performed using conventional methods with a software package "Statistica 10.0".
Results. Median serum level of AFABP was 60,8 (36,5-131,7) ng/ml, which is significantly higher than the normal values, suggested by the manufacturer (19,58±16,32 ng/ml). AFABP correlated positively with serum C-reactive protein (CRP) levels (ρ=0,39; p=0,018) and median accumulated dose of glucocorticoids taken for the last 12 months (ρ=0,25; p=0,033). However, there were no statistically significant correlations between AFABP with patients' weight (ρ=-0,03; p=0,776), BMI (ρ=-0,06; p=0,595) or RA disease activity by DAS28 (ρ=-0,03; p=0,748). More than that, HOMA-IR wasn't associated with serum levels of AFABP (ρ=-0,10; p=0,334).
Conclusions. AFABP is a cytosolic lipid chaperone, expressed by adipocytes and activated macrophages. Terra X. and co. demonstrated, that serum AFABP levels correlated positively with tumor necrosis factor receptors, CRP and interleukin-6 levels in patients with obesity (1). In our study, serum AFABP levels were higher in patients with RA, compared with suggested normal values. AFABP may be associated with systemic inflammation due to its correlation with serum CRP levels. Patients with higher accumulated dose of glucocorticoids taken for the last 12 months had higher serum AFABP levels. It is supposed, that glucocorticoids intake has such a profound effect on AFABP synthesis and secretion, that this protein loses the association with metabolic flux.

P478

ASSOCIATION OF P1NP AND CTX-1 RATIO WITH BONE TURNOVER IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. V. Papichev[1], Y. U. V. Polyakova[1], Y. U. R. Akhverdyan[1], L. E. Sivordova[1], B. V. Zavodovsky[1]

[1]FSBI "RICER n.a. A.B. Zborovsky", Volgograd, Russia

Aim: to determine the clinical relevance of serum levels of P1NP and CTX-1 ratio in patients with rheumatoid arthritis.
Methods: 88 women with RA were enrolled in our study. All patients fulfilled the 2010 ACR/EULAR classification criteria for RA. P1NP and CTX-1 serum levels were determined by enzyme-linked immunosorbent assay. 76 patients (86.4%) were taking glucocorticoids to control the activity of the disease. All patients underwent DEXA on GE Lunar DPX Pro scanner. Statistical analysis was performed using conventional methods with a software package "Statistica 10.0".
Results: Median values for serum CTX-1, P1NP and P1NP/CTX-1 ratio levels were 0.62 (0.42-0.81) µg/l, 48.8 (42.2-61.3) µg/l and 84.2 (59.6-114.6) (hereinafter Me (Q1-Q3)) respectively. Patients with osteoporosis had higher P1NP (53.0 (45.9-63.8) µg/l vs. 44.1 (36.1-59.4) µg/l; U=620.5; p=0.004) and P1NP/CTX-1 ration levels (103.5 (68.6-159.9) vs. 66.5 (49.2-94.3); U=594.0; p=0.002) levels. Moreover, only P1NP/CTX-1 ratio level was statistically significant associated with osteoporotic fractures (107.0 (68.6-167.5)

in patients with fractures vs. 80.7 (57.4-108.7) in patients without fractures; U=414.0; p=0.046). More than that, only CTX-1 serum levels correlated with the dose of glucocorticoids (GCs) taken at the time of study (Spearmen's ρ=0.31; p=0.015; calculated among 60 patients). However, despite the expectations we observed negative correlation between accumulated dose of GCs with CTX-1 serum levels (Spearmen's ρ=-0.38; p=0.001) and positive – with P1NP/CTX-1 ratio levels (Spearmen's ρ=0.36; p=0,002).
Conclusions: P1NP and P1NP/CTX-1 ratio levels are higher in patients with osteoporosis. P1NP/CTX-1 ratio levels are higher in patients with osteoporotic fractures. However, GCs intake can significantly affect the results of our study, due to its correlations with CTX-1 and P1NP/CTX-1 ratio levels, which should be taken in account when conducting further research.

P479

ERYTHROMELALGIA IN SYSTEMIC LUPUS ERYTHEMATOUS: A CASE REPORT

E. Xherahu[1], T. Cico[2], A. Zoto[2]

[1]Memorial Regional Hospital, Tirana, Albania, [2]Mother Teresa University Hospital Center, Tirana, Albania

Erythromelalgia (EM) is a rare vascular condition characterised by episodes of burning pain, redness, and warmth in the extremities. While commonly idiopathic, erythromelalgia (EM) can occur secondary to systemic conditions, including autoimmune diseases such as systemic lupus erythematous (SLE). Systemic lupus erythematous is a chronic multi system autoimmune disease that can lead to vasculitis, microvascular injury, and hyper coagulability, all of which may predispose to erythromelalgia.
Case presentation: This report describes the case of a 32-year-old female with a history of 2 months with burning sensation, warm and redness in feet, exacerbated by heat and relieved by cooling measures. Erythema gets better if legs were elevated. Laboratory tests were positive for antinuclear antibody (ANA) and anti-double stranded DNA, normal complement levels (C3, C4), negative for ENA profile and ANCA, d-dimer were high. Lab test for Brucellosis were negative. Inflammatory markers, including ESR and CRP were normal. A diagnosis of secondary erythromelalgia associated with systemic lupus erythematous was made. The patient was treated with edoxaban 60 mg, topical lidocaine for symptomatic relief, hydroxychloroquine and a short course of prednisone for disease control. Over three months, the patient reported significant improvement in erythromelalgia (EM) symptoms and overall quality of life.
Conclusion: This case underscores the rare but significant association between erythromelalgia and systemic lupus erythematous. Early recognition and tailored management can improve patient outcomes and prevent complications.

P480

LONG-TERM USE OF NIMESULIDE IN PATIENTS WITH OSTEOARTHRITIS AND COMORBIDITY

E. Y. Polishchuk[1], A. E. Karateev[1], A. M. Lila[2]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, [2]V.A. Nasonova Research Institute of Rheumatology; Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Long-term therapy with non-steroidal anti-inflammatory drugs (NSAIDs) may be appropriate in patients with osteoarthritis (OA) suffering from chronic pain. However, the use of NSAIDs in patients with comorbidity in real-world clinical practice requires further study.
Aim: to evaluate the efficacy, safety and requirement for long-term administration of nimesulide in the 3-month treatment of OA.
Material and methods. The study group consisted of 282 patients, 79.4% women, age 54.5±8.9 years, with knee OA (50.0%), hip OA (12.4%) and multi-joint OA (37.6%). All patients had comorbidity, including 94.3% arterial hypertension (AH) and 22.7% type 2 diabetes mellitus. All patients had moderate to severe pain (≥4 on a numerical rating scale, NRS 0-10) for at least 3 months. All patients were prescribed nimesulide 100 mg twice daily. If pain decreased, a reduction in the dose of nimesulide to 100 mg daily or a switch to an on-demand regimen was suggested.
Results. After 1 and 3 months of therapy, 82.3% and 49.3% of patients continued to take nimesulide regularly, and 17.4% and 39.7% continued to take it 'on demand'. 11,0% of patients stopped taking the drug by 3 months, mainly because of pain control or significant pain reduction. In 1 and 3 months all patients showed significant improvement in the severity of the main symptoms of OA. Thus, pain on movement (NRS) decreased from 6.7 to 4.3 and 2.0; WOMAC pain from 11.3 to 7.3 and 3.9; impaired function (NRS) from 5.4 to 3.4 and 1.6; WOMAC function from 38.9 to 25.4 and 14.7 (for all parameters p<0.001). For all parameters, more than 75% of patients showed improvement ≥50% from baseline. 83% of patients reported an acceptable symptom state (PASS). After 3 months, no serious adverse events (AEs) were noted. Dyspepsia was noted in 3.9%, stool disturbance and gastroesophageal reflux disease in 3.2% each, hypertension in 4.6%, and hyperglycaemia in 1.1%. No withdrawal of nimesulide due to HP was noted.
Conclusion. Nimesulide is effective and relatively safe in the long-term treatment of patients with OA and chronic pain.
Keywords: Osteoarthritis, NSAIDs, nimesulide, Nise, long-term use, efficacy, safety

P481

PATIENT ACCEPTABLE SYMPTOM STATE IN RHEUMATOID ARTHRITIS ACCORDING TO SURVEY DATA

E. Y. Polishchuk[1], A. E. Karateev[1], K. R. Makhmudov[2], A. M. Lila[3]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, [2]Tajik State National University, Dushanbe, Tajikistan, [3]V.A. Nasonova Research Institute of Rheumatology; Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Patient-reported outcomes (PRO) are important parameters for assessing the health status and therapy effectiveness in patients with rheumatoid arthritis (RA); however, the time-consuming nature of most methods for determining these indicators makes it difficult to use them in real clinical practice. A simple indicator to assess treatment outcomes from the patient's perspective is the Patient Acceptable Symptom State (PASS).

Aim. To identify the PASS in patients with RA and its association with the main PRO parameters using the survey data.

Material and methods. We collected data from an online survey of 2115 patients with RA, between January 2023 and November 2024. The survey assessed demographics, PASS and PRO (joint pain severity, fatigue, anxiety, depression, daily activity limitation, severity of joint pain, fatigue, anxiety, depression, daily activity, patient global assessment (PtGA) assessed using a numerical rating scale, NRS 0-10 points). 88.3% were women, mean age 46.4±13.9 years, mean disease duration 6 [3;13] years. 80% received conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), 23.9% - biological DMARDs (bDMARD) and JAK inhibitors, 39.7% received glucocorticoids (GCs) and 67.9% received non-steroidal anti-inflammatory drugs (NSAIDs).

Результаты. According to the online survey, 45.8% of patients responded positively to PASS (PASS+). The mean PROs were: joint pain 5.6 ±2.7, fatigue 6.2±2.7, anxiety 5 [3;8], depression 5 [2;7], daily activity limitation 5 [3;7], PtGA 5.5±2.5. Negative response to PASS (PASS-), was associated with male gender, all PROs studied, and GC and NSAID intake. Therapy with bDMARD and JAK inhibitors, showed an inverse association with PASS-. Using binary logistic regression, a model was generated to predict PASS- in patients with RA. The following were included in the model: joint pain ≥4 NRS points, fatigue ≥7 points, anxiety ≥7 points, PtGA ≥4 points, treatment dissatisfaction (0 - no, 1-yes), GC and bDMARD and JAK inhibitors intake. In ROC curve analysis, the threshold value of the logistic function P was 49.7%, the area under the curve was 0.742 (95% CI: 0.721-0.764), the sensitivity of the model at the threshold value used reached 82%, and the specificity reached 60%.

Conclusion. Remote assessment has shown that in real clinical practice less than half of patients with RA are satisfied with their health status. PASS has a clear correlation with all investigated PROs (joint pain, fatigue, anxiety, depression, daily activity, PtGA) and can serve as an integral indicator of health status assessment and RA therapy effectiveness.

Keywords: rheumatoid arthritis; online survey; PASS; PRO; pain; fatigue; daily activity limitation; depression; anxiety.

P482

BONE MINERAL DENSITY AND BONE METABOLISM IN MEN WITH CHRONIC HEART FAILURE

E. Yaralieva[1], I. Skripnikova[1], V. Novikov[1], R. Myasnikov[1], O. Kulikova[1], O. Drapkina[1]

[1]Federal State Budgetary Institution National Medical Research Center for Therapy and Preventive Medicine of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Objective: To evaluate BMD and indicators of bone metabolism in men with chronic heart failure (CHF).

Methods: The case-control study included 100 men aged 20-70 years (average age 54.34±11.16). The group of patients with CHF consists of 60 men with NYHA functional class (FC) I-III and left ventricular ejection fraction ≤50%. The control group was represented by 40 patients without CHF. BMD of the lumbar spine and the proximal femur was measured using DXA. Low bone mass was defined at the Z-score ≤-2 SD in men under 50 years and at the T-score ≤-2.5 SD in men over 50 years.

Results: The low BMD was registered in 74% in men with CHF. The analysis in the group with CHF showed the independent relationship of the BMD in all measured areas with FC CHF, adjusted for age and several covariates. The chance of detecting low bone mass in patients with functional class II and III is 1.9 times higher than with functional class I (OR=1.91; 95%CI [1.14-3.21], p=0.023). Vitamin D deficiency was detected in 62% of patients with CHF and 52% control group (p=0.36), insufficiency - in 23% and 35% (p=0.32) respectively. The concentration of the bone formation marker P1NP was significantly lower in the main group compared to the control group (37 [32;54] ng/ml vs 51 [38;66] ng/ml (p=0.007)). Among the bone metabolism markers, only CTx was independently associated with clinical and echocardiographic signs of CHF, in particular, with the stage of CHF (β=0.137, p=0.001), left ventricular ejection fraction (β=-0.008, p=0.008), the level of NT-proBNP (β=0.00003, p=0.006).

Conclusion: Associations were found between the presence and severity of CHF and BMD levels. Low P1NP values in patients with CHF, in contrast to the control group, indicate a predominant suppression of bone formation during bone remodeling. An increase in the CTx level with increasing severity of CHF indicates accelerated bone loss with the progression of CHF.

P483

PRIMARY CARE REHABILITATION AFTER KNEE REPLACEMENT – A CROSS-SECTIONAL SURVEY STUDY

E. Östlind[1], M. Ljung[2], C. Ståhl[3], A. Cronström[4], T. Jönsson[5]

[1]Dalby Healthcare centre, Dalby, Sweden, [2]Department of Orthopedics, Norrköping, Sweden, [3]Department of Orthopedics, Ängelholm , Sweden, [4]Department of Health Sciences, Lund, Sweden, [5]Department of Orthopedics, Lund, Sweden

Background: Rehabilitation after knee replacement (KR) surgery is essential but high-quality guidelines are lacking. There is also a knowledge-gap regarding current rehabilitation modalities applied in primary care in Sweden. This study aimed to (I) describe physiotherapy management in primary care and (II) explore physiotherapists' perceptions of patients' challenges during rehabilitation following KR.
Methods: A cross-sectional, web-based survey was conducted among Swedish physiotherapists working in primary care. Questions were categorical or open-ended and related to current rehabilitation practices, treatment modalities, and physiotherapists' perceptions on patients' challenges in rehabilitation after KR. Data were described descriptively and open-ended answers were analysed with quantitative content analysis and categorised.
Results: In total, 202 physiotherapists answered the survey. Rehabilitation focused on home exercises with recurrent physiotherapy visits. Common treatment modalities were knee range of motion exercises, strength training, and stationary cycling. Key rehabilitation challenges included the following categories: Patients are unprepared, Challenging to find the optimal load, and Restore function and trust in the knee.
Conclusion: Rehabilitation after KR in Swedish primary care seems to be in line with previously recommended treatment modalities. According to the physiotherapists in this study, some of the key challenges that patients faced were severe pain and knee swelling, regaining function, balancing load/recovery and resuming physically demanding activities.

P484

ORGANIZATIONAL PREDICTORS OF HIGHER FRACTURE LIAISON SERVICE (FLS) PERFORMANCE IN ENGLAND AND WALES: THE RADIATE STUDY

F. A. A. Clemeno[1], M. Fielding[2], K. Whitehead[2], R. Dickinson[3], A. Johansen[4], C. Gregson[5], R. Pinedo-Villanueva[1], M. K. Javaid[1]

[1]University of Oxford, NDORMS, Oxford, United Kingdom, [2]Patient representative, Oxford, United Kingdom, [3]Royal College of Physicians, Falls and Fragility Audit Programme, London, United Kingdom, [4]Cardiff University, University Hospital of Wales and School of Medicine, Cardiff, United Kingdom, [5]University of Bristol, Musculoskeletal Research Unit, Bristol, United Kingdom

Objective:
To describe the organisational predictors of FLS performance as measured by key performance indicators (KPIs) in England and Wales.
Materials and Methods:
The submitted patient records to the FLS-DB of England and Wales from 2017 (n=52,731 patient records), 2020 (n=62,205), and 2022(n=65,844) were used to derive the KPI data were analysed to identify potential "high-performing" FLSs using K-means clustering. The optimal number of clusters was determined using the NbClust package. The organisational characteristics of the FLSs from the facilities audit (including fracture types identified, time to assessment, treatment recommendations, monitoring methods, work time by different FLS staff members per week, and the estimated caseload) were compared between the clusters by bootstrap logistic models. The organisational characteristics included the. Within cluster, associations were tested using Pearson correlations and linear regression models.
Results
61 FLSs were identified in 2017. The optimal number of clusters was two and remained relatively stable between 2017 and 2022 (Figure). The clusters differed ($p<0.002$) by KPI for DXA with 90 days, proportion recommended treatment, strength and balance testing, and follow-up measures. Of the FLS pathway parameters, monitoring by an FLS coordinator predicted higher performance, and delegating monitoring to primary care physicians predicted lower performance. Only in the higher performing cluster did FLS nurse & administrator time predict the number of patients submitted ($p<0.05$), and only administrator time significantly predict the number of patients initiating osteoporosis treatment within 16 weeks of fracture.
Conclusion
FLS performance was relatively stable before and after the COVID pandemic. How FLS delegate monitoring predicted better overall FLS KPI performance. The positive relationship between staff numbers and the number of cases submitted and initiating treatment was only seen in the higher-performing cluster, demonstrating the value of KPI in improving the efficiency of FLSs.

REMS TECHNOLOGY FOR FRACTURE RISK ASSESSMENT IN KIDNEY TRANSPLANT PATIENTS

F. A. Lombardi[1], P. Pisani[1], F. Conversano[1], C. Stomaci[2], F. R. Contaldo[2], E. Casciaro[1], G. Peluso[3], A. C. Stetco[2], R. Franchini[1], M. Di Paola[1], S. Casciaro[1]

[1]National Research Council, Institute of Clinical Physiology, Lecce, Italy, [2]University of Salento, Department of Biological and Environmental Sciences and Technologies, Lecce, Italy, [3]University of Salento, Department of Innovation Engineering, Lecce, Italy

Objective(s): Changes in bone quantity and quality are common consequences in Kidney transplant patient (KTP), who are at a significantly increased risk of fractures. A complex interplay of factors contributes to bone damage in KTPs, including immunosuppressive therapy and alterations in the parathyroid hormone-vitamin D-fibroblast growth factor 23 axis. The high fracture risk in KTPs is associated with increased morbidity, higher healthcare costs, hospitalizations, and mortality. Therefore, due to the substantial burden of this issue, assessing fracture risk and, consequently, implementing targeted early interventions and proper patient management are crucial. The aim of this study is to evaluate the 5-year fracture risk in KTP patients by using the non-invasive Radiofrequency Echographic Multi Spectrometry (REMS) technology.
Material and Methods: The 5-year fracture risk was calculated using a REMS-based algorithm that automatically combines information on both bone quantity and quality. Specifically, by combining the REMS T-score and the Fragility score (figure 1), 7 distinct risk classes are identified, each representing a different fracture risk probability. The R1 category represents the group with the lowest fracture risk probability, which increases progressively up to R7 for the category with the highest risk (figure 2).

Combining Matrix of REMS BMD and Fragility Score

REMS FRAGILITY SCORE Classification	REMS T-SCORE classification: NORMAL	OSTEOPENIA	OSTEOPOROSIS
NORMAL	R1	R3	R5
DECREASED	R2	R4	R6
LOW	R3	R5	R7

Figure 1

Total Fracture Risk at 5 years (‰)

Risk class	Risk of major osteoporotic fracture per 1000 subjects per 5 years
R1	≤ 5
R2	[5-10]
R3	[10-20]
R4	[20-35]
R5	[35-60]
R6	[60-100]
R7	> 100

Figure 2
Results: A total of 30 patients were enrolled (50-80 y; BMI 16-23 Kg/m^2, both genders). All participants underwent a lumbar spine REMS scan (L1-L4) to assess their fracture risk class. The KTPs were all classified into the high-risk categories R5-R6, indicating a 5-year fracture risk for major fractures of more than 60 ‰.
Conclusion(s): In conclusion, REMS technology enables the identification of high-risk individuals. The prevalence of R5-R6 cases in KTPs highlights the need for improved bone health monitoring and prevention strategies to reduce fractures and enhance quality of life.

P486

COMPARATIVE STUDY BETWEEN CONSERVATIVE AND EARLY KYPHOPLASTY TREATMENT FOR OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES (OVCF) IN ELDERLY PATIENTS

F. Ardura[1], M. Bragado[1], J. Crespo[1], S. Santiago[1], R. Hernández[1], G. D. J. Labrador[1], D. C. Noriega[1]

[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain

Objective.
The mean objective of this study is to analyse whether patients suffering of osteoporotic vertebral compression fractures are in need of less analgesia and show better functionality after early kyphoplasty as compared with the use of conservative therapy.
Materials and Methods.
We conducted a prospective observational study in our hospital. We included patients over 75 years old with OVCF. They were divided into 2 groups: patients that followed kyphoplasty surgical treatment within 4 weeks after vertebral fracture compared to patients treated nonoperatively. We included 50 patients per group. Demographic data, VAS, analgesic intake, ODI, were recorded. Follow up was 1 year.
Results.
100 patients were included. Most of the patients in the study were women with a mean age of 80,5 years. All vertebral fractures were acute and had imaging evidence of persistent bone edema. Mean VAS score at initial diagnosis was 8,8 in the surgical group and 8,5 in the conservative group. Three months after kyphoplasty VAS score had decreased to 2,4 while in the conservative group was 4,4 and, one year later, surgical group VAS score was 1,3 and conservative group VAS score was 1,8. Os-

westry disability Index (ODI) mean scores at initial diagnosis were 74% in the surgical group and 69,7% in the conservative group and after one year it was 15,4% and 31,6% respectively. The kyphoplasty group has a mean ASA score of 2,6, only 1 patient had to be hospitalised during 24 hours and cement leakage was detected in 4 patients without clinical repercussion.
Conclusions.
Faster pain and disability reduction was achieved with kyphoplasty treatment. At 1-year-follow up, non-surgical management group, had greater disability comparted to kyphoplasty patients. Early performance improves mobilization and decreases the complications associated to conservative treatment; therefore, it should be considered as first election treatment in very elderly patients.

P487

INFLUENCE OF PSYCHOEMOTIONAL DISORDERS ON THE OUTCOME OF SURGICAL TREATMENT OF VERTEBRAL COMPRESSION FRACTURES IN ELDERLY PATIENT

F. Ardura[1], J. Crespo[1], M. Bragado[1], S. Santiago[1], R. Hernández[1], G. D. J. Labrador[1], D. C. Noriega[1]

[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain

Objetive
The overall objective is to analyze the difference in clinical results after surgical treatment in patients with TPE and a control group, as well as to generate a rapid diagnostic method to detect TPE.
Material and methods
It is a prospective study in 55 patients (23 with diagnosis of PDE and 32 without PED) with VCF treated by balloon kyphoplasty in which Visual Analogue Scale (VAS), Oswestry Disability Index (ODI) and analgesic medication were analyzed as study variables in successive visits (pre-surgery, one month after the intervention and one year later).
Results
Patients with TPE have less reduction in pain and disability and continue with analgesic treatment one year after treatment. There are no significant differences in gender, age or the number of complications between the groups.
Conclusions
Surgical treatment using kyphoplasty improves pain and disability in all patients but with worse results in patients with TPE. In these patients the results are similar to those obtained with conservative treatment, according to published meta-analyses.

MUSCLE MASS ALTERATIONS IN PRIMARY SJÖGREN'S SYNDROME: A CROSS-SECTIONAL STUDY

S. Miladi[1], F. Ben Messaoud[1], A. El Ouni[2], Y. Makhlouf[1], H. Boussaa[1], S. Toujeni[2], Z. Meddeb[2], L. Zakraoui[1], K. Ben Abdelghani[1], A. Fazaa[1], S. Hamzaoui[2], A. Laatar[1]

[1]Mongi Slim, Rheumatology, La Marsa, Tunisia, [2]Mongi Slim, Internal medicine, La Marsa, Tunisia

Background:
Primary Sjögren's syndrome (pSS) is an autoimmune disease that can lead to changes in body composition, particularly sarcopenia. This study aimed to describe the abnormalities in muscle mass in patients with pSS and to identify factors associated with sarcopenia.
Methods:
We conducted a monocentric cross-sectional study that included patients with pSS according to the 2016 ACR/EULAR criteria and a control group of age-matched patients without autoimmune or inflammatory diseases. Clinical and biological data were collected, as well as densitometric parameters for calculating the skeletal muscle mass index (SMI). Sarcopenia was defined as an SMI ≤ 5.5 kg/m².
Results:
We included 31 patients with pSS and 31 controls. The average age of pSS patients was 59±10 years [31-75], compared to 60±12 years [28-80] in the controls. The mean SMI was 6.21±0.85 kg/m² in the pSS group, with a sarcopenia frequency of 23%, compared to 6.01±0.59 kg/m² and 16% in the control group. No significant difference was observed between the groups regarding sarcopenia (p=0.52). Among sarcopenic patients, a significant difference was noted concerning pulmonary involvement, particularly interstitial lung disease (ILD) (p=0.03). Additionally, the rheumatoid factor (RF) was negative in sarcopenic patients and positive in 36% of non-sarcopenic patients (p=0.05). Sarcopenic patients also had a higher ESSDAI score (p=0.027), with 43% showing high activity. Significant differences were observed in densitometric parameters for fat mass index (FMI) (p=0.002) and bone mineral content (BMC) parameters: total BMC (p=0.018), femoral BMC (p=0.02), femoral T-score (p=0.014), and vertebral T-score (p=0.042). Multivariate analysis revealed that fat mass and BMC parameters, the presence of ILD, and corticosteroid use were positively correlated with sarcopenia, while RF positivity was negatively correlated.
Conclusion:
Our results confirm the presence of sarcopenia in 23% of pSS patients. Regular clinical assessments and cautious prescription of corticosteroids are essential.

P489

FAT MASS IN PRIMARY SJÖGREN'S SYNDROME: BEYOND BMI

F. Ben Messaoud[1], S. Miladi[1], A. El Ouni[2], Y. Makhlouf[1], H. Boussaa[1], C. Abdelkafi[2], S. Toujeni[2], L. Zakraoui[1], K. Ben Abdelghani[1], A. Fazaa[1], S. Hamzaoui[2], A. Laatar[1]

[1]Mongi Slim, Rheumatology, La Marsa, Tunisia, [2]Mongi Slim, Internal medicine, La Marsa, Tunisia

Introduction: Primary Sjögren's syndrome (pSS) is an autoimmune disease that may lead to alterations in body composition, particularly in fat mass. This study aimed to describe fat mass abnormalities in patients with pSS.
Methods: We conducted a monocentric cross-sectional study, including patients with pSS diagnosed according to the 2016 ACR/EULAR criteria, and a control group of age-matched patients without autoimmune or inflammatory diseases. Body mass index (BMI) and fat mass densitometric parameters were collected: fat mass index (FMI), fat-free mass index (FFMI), and the android/gynoid ratio.
Results: We included 31 patients with pSS and 31 controls. The average age of pSS patients was 59±10 years [31-75], compared to 60±12 years [28-80] in the controls. The mean BMI in the pSS group was 28±5 kg/m² [17-36]. Thirty-nine percent of the patients were obese, 35% were in overweight, 23% had a normal BMI, and 3% were underweight. The mean BMI in the controls was 27±4 kg/m² [20-37]. Fifty-eight percent of the controls were overweight, 16% were obese, and 26% had a normal BMI. A significant difference was found between the groups regarding BMI (p=0.03). The study group had significantly more cases of obesity (p=0.05). Regarding densitometric parameters, the mean FMI in the pSS patients was 11.8±4.7 kg/m² vs 11.6±3.2 in the controls. The mean FFMI in the cases was 15.9±1.9 kg/m² vs 15.2±1.4 kg/m² in the controls. The android/gynoid ratio was 1±0.2 in the cases vs 1±0.2 in the controls. No significant differences were observed between the groups for FMI (p=0.85), FFMI (p=0.13), or the android/gynoid ratio (p=0.56).
Conclusion: Our results showed that the average BMI is higher in pSS patients. However, no significant differences were observed between the two groups regarding densitometric fat mass parameters. Larger studies are needed to confirm these findings and explore potential links between body composition and disease progression in pSS.

UNCOVERING BONE HEALTH IN PRIMARY SJÖGREN'S SYNDROME

S. Miladi[1], F. Ben Messaoud[1], A. El Ouni[2], Y. Makhlouf[1], H. Boussaa[1], S. Toujeni[2], C. Abdelkafi[2], L. Zakraoui[1], K. Ben Abdelghani[1], A. Fazaa[1], S. Hamzaoui[2], A. Laatar[1]

[1]Mongi Slim, Rheumatology, La Marsa, Tunisia, [2]Mongi Slim, Internal medicine, La Marsa, Tunisia

Introduction: Primary Sjögren's Syndrome (pSS) is an autoimmune disease that may lead to alterations in bone mineral content (BMC). This study aimed to investigate bone mineral density (BMD) abnormalities in patients followed for pSS.
Methods: We conducted a monocentric cross-sectional study including patients diagnosed with pSS according to the 2016 ACR/EULAR criteria, along with an age-matched control group without autoimmune or inflammatory diseases. Osteodensitometric parameters were collected for analysis.
Results: We included 31 patients with pSS and 31 controls. The mean age of the pSS patients was 59±10 years [31-75] versus 60±12 years [28-80] in the control group. Bone densitometry analysis revealed total BMC values estimated at 1.1±0.1 kg/m² in both groups (p=0.059). The total T-score was significantly higher in the pSS group (-0.1±1.3 SD) compared to the control group (-0.8±1.2 SD), with a statistically significant difference (p=0.02). No difference was observed between the groups regarding spinal BMC, which was 1±0.2 g/cm² in both groups (p=0.44). The spinal T-score was estimated at -1±1.5 SD in the pSS group and -1.6±1.4 SD in the control group, with no significant difference (p=0.40). For femoral BMC, values were 0.9±0.2 g/cm² in the pSS group and 0.9±0.1 g/cm² in the control group, with no statistically significant difference (p=0.27). The mean femoral T-score was similar between the groups, -1.2±1.2 SD and -1.4±1.2 SD, respectively, (p=0.63). Among the pSS patients, 42% were osteoporotic, and 29% presented osteopenia, while in the control group, 35% had osteoporosis and 35% had osteopenia.
Conclusion: Although significant differences were observed in total T-scores between pSS patients and controls, no significant differences were found for spinal and femoral T-scores. Further studies with larger sample sizes are needed to confirm these findings.

P491

DIFFERENCES IN THE FRACTURE RISK ASSESSED WITH FRACTURE RISK ASSESSMENT TOOL (FRAX) BETWEEN ELDERLY WOMEN WITH IMPAIRED AND UNIMPAIRED BALANCE

F. Bischoff[1], M. Kovachev[2], S. Vladeva[3], E. Bischoff[4]

[1]IPSMP Rheumatology, 6000 Stara Zagora, Bulgaria, Stara Zagora, Bulgaria, [2]Department of Orthopedics and Traumatology, University Hospital "Dr. Georgi Stranski, Medical university of Pleven, Pleven, Bulgaria, [3]Department of Health Care, Faculty of Medicine, Trakia University, 6007 Stara Zagora, Bulgaria, Stara Zagora, Bulgaria, [4]Faculty of Global Health and Health Care, University "Prof Dr Assen Zlatarov", 8010 Burgas, Bulgaria, Burgas, Bulgaria

Objective: FRAX tool used to assess fracture risk considers various clinical factors, but its relationship with balance, particularly in older women, is not well understood. This study investigates fracture risk differences, as assessed by the FRAX tool, between elderly women with impaired and unimpaired balance.
Material and Methods: Balance was assessed in 91 women using the Flamingo Test. Participants were instructed to stand on one

leg, lifting the opposite leg so that the foot was resting against the knee of the standing leg. They were required to maintain this position for 30 seconds. The test was considered successful if participants were able to complete the test without touching the ground with their lifted foot or hands. Differences in FRAX for major osteoporotic fractures (MOF) and for hip fractures (HF) were assessed in the groups with impaired and unimpaired balance. Data collection from the electronic health record was performed with an innovative JAVA tool, developed by Kirilov et al. (1,2)
Results: Out of 91 subjects, 52 women (57.1%) were with unimapaired balance and 39 women (42.9%) were with impaired balance. The mean age of the participants was 72 ± 6.1 years, and the mean BMI was 26.1 ± 5.2 kg/m². FRAX scores for MOF didn't differ significantly (p = 0.092) across balance groups. Women with impaired balance had higher mean FRAX score for MOF (18.24%), compared to those with unimapaired balance (15.92%). FRAX scores for HF showed significant differences (p = 0.004) among balance groups. Women with impaired balance had higher mean FRAX score for HF (6.22%), compared to those with unimapaired balance (4.02%).
Conclusion: Women with impaired balance had a higher risk of hip fractures (HF). These results suggest that balance impairment may be a key factor in hip fracture risk and highlight the importance of balance assessment in fracture risk evaluation.

FEASIBILITY AND ACCEPTABILITY OF A 12-WEEK VIRTUAL EXERCISE PROGRAMME FOR OLDER INFORMAL CAREGIVERS

F. Buckinx[1], S. Couclet[2], J. Charles[2], M. Moginot[2], O. Bruyère[1]

[1]University of Liège, Research Unit in Public Health, Epidemiology and Health Economics, Liège, Belgium, [2]University of Liège, Department of Physical Activity and Rehabilitation Sciences, Liège, Belgium

Objective : Older informal caregivers provide essential unpaid care but often face significant physical and mental strain. To improve their health and quality of life, a 12-week virtual exercise programme has been developed, offering flexibility via video-based sessions or printed booklets. This study aims to assess the acceptability and feasibility of the programme.
Material and Methods : In this randomised controlled trial, older informal caregivers (age ≥ 60 years) were divided into two groups: one accessed instructional videos (video group), the other used printed materials (booklet group). Each 30-minute session included a warm-up, main exercises, and a cool-down. **Acceptability** (***adherence*** and ***satisfaction*** using a 4-point Likert scale) and **feasibility** (perceived ***difficulty*** using a 4-point Likert scale and ***usability*** via the validated SUS questionnaire) were assessed post-intervention. Expected values were 80% adherence and satisfaction, SUS scores ≥ 68/100, and < 40% difficulty.
Results : Currently, 26 caregivers participated (video group: n=13; booklet group: n=13). Participants were mostly women (65.4%), with a mean age of 69.9 ± 6.01 years. The video group demonstrated higher ***adherence*** (81.5%, 10.6 ± 1.63 sessions completed) compared to the booklet group (76%, 9.13 ± 1.83 sessions, p=0.04). ***Satisfaction*** levels were similar in both groups, with all participants reporting being satisfied or highly satisfied. ***Usability*** was higher in the video group (SUS = 84.1 ± 8.19) versus the booklet group (SUS = 77.1 ± 4.91, p = 0.002). Perceived ***difficulty*** was mostly moderate or easy in both groups, but a small portion (12.5%) of the booklet group found the exercises difficult.
Conclusion : The virtual programme is feasible and acceptable for older caregivers, with video-based sessions showing slightly better adherence and usability. The study aims to increase the sample size to 82 participants and will next explore the programme's impact on physical and mental health.

PHARMACOKINETIC SIMILARITY OF CANDIDATE BIOSIMILAR AVT03 (60 MG/ML) AND REFERENCE PRODUCT DENOSUMAB

F. Bullo[1], L. Jaskiewicz[1], S. Stamatakos[1], R. Ruffieux[1], A. Sattar[1], M. Rai[1], H. Otto[1], S. Leutz[1], F. Berti[1]

[1]Alvotech Swiss AG, Zürich, Switzerland

Objective
Assess PK similarity of AVT03 (60 mg/mL), a proposed denosumab biosimilar, and reference product (RP; 60 mg/mL) in healthy adult males (NCT05126784).
Materials and Methods
A 36-week, randomized (1:1), double-blind, 2-arm, parallel-group study. Participants were randomized and received one 60 mg dose of AVT03 (n = 99) or RP (n = 107) SC on Day 1. Randomization was stratified by body weight. Primary endpoints were C_{max} and $AUC_{0\text{-}inf}$. Additional PK parameters included $AUC_{0\text{-}t}$, $AUC_{0\text{-}24}$, T_{max}, K_{el}, $t_{1/2}$, V_z/F, and CL/F.
PD parameters included $AUEC_{0\text{-}t}$ and I_{max} for sCTX-1.
Safety endpoints included incidence of treatment-emergent adverse events (TEAEs), and levels of calcium, PTH, and vitamin D. Immunogenicity endpoints included (ADAs) and neutralizing antibodies (NAbs).
Results
The 90% CIs for the geometric mean ratio for the primary PK parameters were entirely contained within the prespecified margins of 80.00% and 125.00% (C_{max} [102.231, 113.642]; $AUC_{0\text{-}inf}$ [107.169, 118.874]), supporting demonstration of PK similarity. There were no notable differences in subgroups. Additional PK parameters were comparable across treatment groups.
The $AUEC_{0\text{-}t}$ profiles for percentage change from baseline in sCTX-1 were comparable between treatment arms. Geometric mean values for sCTX-1 I_{max} were similar across treatment groups (AVT03,

91.37%; RP, 92.28%).
A similar percentage of participants reported TEAEs in both treatment arms (AVT03 75.8%; RP 73.8%). Changes over time in calcium, PTH, and vitamin D levels were comparable in both treatment arms. Immunogenicity profile was similar between treatment groups.

Conclusion

Analysis of the 90% CIs for the GMRs of the primary endpoints supports demonstration of PK similarity between 60 mg/mL AVT03 and RP. PD profiles were similar. Safety and immunogenicity profiles were comparable.

PHARMACOKINETIC SIMILARITY OF CANDIDATE BIOSIMILAR AVT03 (70 MG/ML) AND REFERENCE PRODUCT DENOSUMAB

F. Bullo[1], L. Jaskiewicz[1], S. Stamatakos[1], A. Sattar[1], H. Otto[1], M. Rai[1], S. Leutz[1], F. Berti[1]

[1]Alvotech Swiss AG, Zürich, Switzerland

Objective

Assess PK similarity of AVT03 (70 mg/mL), a proposed denosumab biosimilar, and reference product (RP; 70 mg/mL) in healthy adult males (NCT05876949).

Materials and Methods

A 28-week, randomized, double-blind, 2-arm, parallel-group study. 208 participants, including 24 (11.7%) Japanese, were randomized 1:1 to receive one 120 mg dose of AVT03 (n = 104) or RP (n = 104) subcutaneously on Day 1. Randomization was stratified by body weight and ethnicity. Primary endpoints were C_{max} and $AUC_{0\text{-}t}$. Additional PK parameters included $AUC_{0\text{-}inf}$, $AUC_{0\text{-}24}$, T_{max}, K_{el}, $t_{1/2}$, V_z/F, and CL/F.
Safety endpoints included incidence of treatment-emergent adverse events (TEAEs), and levels of calcium, PTH, and vitamin D. Immunogenicity endpoints included frequency of anti-drug antibodies (ADAs), and frequency of neutralizing antibodies (NAbs).

Results

Mean serum concentration-time profiles for AVT03 and RP were comparable over the PK sampling duration. The 90% CIs for the ratio of geometric means for the primary PK parameters were entirely contained within the prespecified margins of 80.00% and 125.00% (C_{max} [98.26, 110.00]; $AUC_{0\text{-}inf}$ [102.30, 113.60]), supporting demonstration of PK similarity. There were no notable differences in subgroups and consistency between the Japanese participants and the overall population was shown. Additional PK parameters were comparable across treatment groups.
The percentage of participants who reported TEAEs in the AVT03 group (63.5%) was similar to RP group (64.4%). Changes over time in calcium, PTH, and vitamin D levels were comparable in both treatment arms. Immunogenicity profile was similar between treatment groups.

Conclusion

Analysis of the 90% CIs for the GMRs of the primary endpoints supports demonstration of PK similarity between 70 mg/mL AVT03 and RP. AVT03 had a safety and immunogenicity profile comparable to RP.

COMPARATIVE EFFICACY AND SAFETY OF CANDIDATE BIOSIMILAR AVT03 AND REFERENCE PRODUCT DENOSUMAB

F. Bullo[1], L. Jaskiewicz[1], S. Stamatakos[1], M. Rai[1], A. Sattar[1], H. Otto[1], S. Leutz[1], F. Berti[1]

[1]Alvotech Swiss AG, Zürich, Switzerland

Objective

To demonstrate comparative efficacy of AVT03, proposed denosumab biosimilar, and reference product (RP) in postmenopausal women with osteoporosis (NCT05395091).

Material and Methods

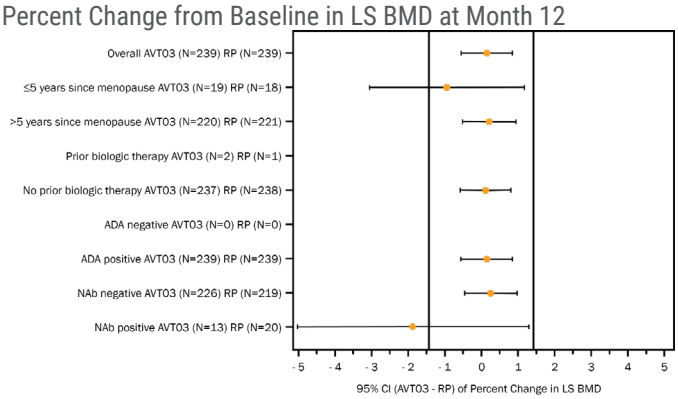
This is an 18-month, randomized, double-blind, parallel group study. Participants received AVT03 (n = 266) or RP (n = 266); 60 mg SC on Day 1 and Month 6. At Month 12, participants received a third dose of AVT03 or were re-randomized to receive a third dose of RP or switch from RP to AVT03. Randomization was stratified by years since menopause and prior biologic therapy. Primary endpoints were percent change from Baseline in LS BMD at 12 months and $AUEC_{0\text{-}6months}$ of %Cfb sCTX-1.
Safety endpoints included incidence of treatment-emergent adverse events (TEAEs). Immunogenicity endpoints included frequency of anti-drug antibodies (ADA) and neutralising antibodies (NAb).

Results

The 95% CIs of the LS means difference between treatment arms for percent change from baseline in LS BMD to Month 12 (-0.58, 0.82) were entirely contained within the prespecified margin (-1.45%, 1.45%), supporting demonstration of comparative efficacy. There were no notable differences in subgroups.
The 95% CIs of the geometric mean ratio between treatment

arms for $AUEC_{0\text{-}6months}$ of %Cfb sCTX-1 (0.97, 1.03) were entirely contained within the prespecified margin (0.80, 1.25), supporting demonstration of PD similarity.
At Month 12, a similar percentage of participants reported TEAEs in both treatment arms (AVT03 66.5%; RP 66.9%). Comparable profile persisted through Month 18. Immunogenicity profile was comparable between treatment groups to Month 12, persisting to Month 18.
Conclusion
Analysis of the primary endpoints supports a demonstration of comparative efficacy between AVT03 and RP. Safety and immunogenicity profiles were similar to Month 18, including in those who switched treatment.

Percent Change from Baseline in LS BMD at Month 12



P496

MEDICAL TREATMENT IN COMBINATION WITH OCCUPATIONAL THERAPY, EFFECTIVENESS IN PREVENTION OF FRACTURES IN ELDERLY WOMEN AFFECTED BY BREAST CANCER

F. D'Amico[1], R. D'Amico[2]

[1]Dipartimento Scienze BioMediche Università Studi Messina, Messina, Italy, [2]Unità Operativa Medicina Riabilitativa IRCCS Oasi Maria SS Troina Enna, Troina, Italy

Objective: prevention of Osteoporosis is a major objective in the management of patients treated for breast cancer with aromatase inhibitors. Denosumab proved effective in prevention of fractures in subjects whose breast cancer was treated with aromatase inhibitors. This study focused on the effectiveness of medical treament with a self sufficient occupational therapy project to be carried out at home.
Methods: 12 elderly patients affected by breast cancer were followed for 12 months. After surgery they were treated with aromatase inhibitors combined with Denosumab so to prevent fractures. From T0 to T24 the design of the study included: 1) blood tests; 2) spine and femur bone density scan DEXA; 3) lumbar dorsal spine morhometry; 4)short physical performance battery (SPPB). SPPB evaluates physical performance whose level scores between 0 and 12. In 6 patients (Group A) we evaluated the effectiveness of Denosumab treament on osteoporosis prevention, while in group B 6 more patients were treated with a combination of Denosumab and occupational therapy for effectiveness. Subjects were instructed on how to perform specific excercises on their own for 12 months following a series of increasingly demanding excercises performed three times a day for 20 minutes.
Results: Group A patients (mean age 72 ± 3 years) had an average SPPB score 7 (p 0.05) at T0. Group B patients (mean age 71±4 years) had an average SPPB score 7 (p 0.05). At T 24 group A patients average SPPB score was 9 (p 0.05) showing an improvement in gait rate. At T24 group B patients had a an average SPPB score 10 (p 0.05) showing improvement in balance & gait rates.
Conclusion: This study proved the effectiveness of combined treatment with Denosumab and occupational therapy in elderly patiens affected by breast cancer treated with aromatase inhibitors after surgery, in order to control severity markers, prevention of fracture risk and improvement of physical performance.

P497

RETROSPECTIVE ANALYSIS TO ASSESS IMPROVED IDENTIFICATION OF VERTEBRAL FRAGILITY FRACTURES ON CHEST X-RAY IN A UK CANCER HOSPITAL

F. Frost[1], S. Simpson[1], L. Berger[1], F. Wong[1], C. Barker[1]

[1]The Christie Hospital, Manchester, United Kingdom

Objective:
Vertebral fragility fracture (VFF) is the most common osteoporotic fracture with up to 70% under-reported by radiologists [1,2]. Cancer patients have an increased risk of VFF. The objective of this study was to evaluate the utility of artificial intelligence (AI) assisted interpretation for increased detection of vertebral fracture on chest X-ray (CXR).
Material and Methods:
An AI-driven computer aided detection (CAD) device (Annalise Container v2.2) was used to evaluate all CXRs performed over a 1-month period (n=1,669) at The Christie NHS Foundation . Of all studies evaluated, 955 (57%) included a lateral projection, routinely performed in our institution. The AI device flagged 100/955 (10.5%) lateral CXRs as containing a VFF. All studies flagged were reviewed by 5 reporters (reporting radiographers & consultant radiologists) who independently graded each study retrospectively for visibility of the fracture with the AI output.
Results:
There was 100% concordance with the AI classification for 76/100 studies. There were only 4/100 studies where there was 100% discordance with AI, however the confidence bars for the AI output was low for each of these studies. There was no mention in the report of fracture for 34 of the studies flagged by the AI. 23/34 (67.6%) of the studies without mention of the fracture in the report had ≥ 80% consensus with AI for presence of VFF on retrospective review of the lateral image.
Conclusion:
VFF are frequently underreported in clinical radiology. This missed opportunity can have a critical impact on patient morbidity and quality of life [2] with a significant cost-burden to the NHS.

Incorporating AI support tools when reviewing CXR studies (specifically those with a lateral projection) can enhance detection of VFF and has potential to improve/automate fracture referral pathways. Early identification of VFFs is critical to ensure patients are appropriately managed and offered preventative and cost-effective treatments where appropriate.

DIFFERENTIAL ANALYSIS OF LUMBAR SPINE BONE MINERAL DENSITY AND TRABECULAR BONE SCORE IN HYPOPHOSPHATASIA PATIENTS WITH BIALLELIC VS MONOALLELIC ALPL GENOTYPE

F. Genest[1], K. Hind[2], M. De Gruttola[3], D. Hans[3], L. Seefried[1]

[1]University Hospital Wuerzburg, Wuerzburg, Germany, [2]Faculty of Health and Medicine, Lancaster + Medimaps Group, Switzerland, Lancaster, United Kingdom, [3]Medimaps Group, Lausanne, Switzerland

Objective

Hypophosphatasia (HPP) is a genetic disorder marked by deficient Alkaline Phosphatase activity. Depending on genotype severity, this causes multiple extraskeletal manifestations and impaired bone mineralization. Dual-energy X-ray absorptiometry (DXA), which measures bone mineral density (BMD), has limitations in assessing bone quality in conditions like HPP, Trabecular bone score (TBS), derived from DXA images, enables an advanced evaluation of vertebral bone microarchitecture and mineralization homogeneity, to offer additional insights into bone quality in such conditions. This study aimed to compare lumbar spine BMD and TBS parameters in HPP patients with biallelic vs monoalleic ALPL variants.

Materials and Methods

In this retrospective, single center, matched-pairs analysis, lumbar spine DXA scans from 90 HPP patients with biallelic (n=45) vs monoallelic (n= 45) ALPL variants an no previous enzyme replacement therapy , were analyzed. Lumbar spine (L1-L4) BMD and TBS [version 3 (body mass index- adjusted) and version 4 (tissue thickness adjusted)] were assessed.

Results

Overall average values for age (49.6±14.0years), height (166.5±10.6cm), weight (74.5±17.4kg), BMI (26.9±6.0kg/m²) and tissue thickness (19.3±3.1 cm) were not significantly different between the groups.. Mean LS-BMD T-scores was normal (+0.1±2.3) but patients with biallelic variants had higher BMD (+0.88±2,22) than heterozygously affected patients (-0.70±2.06; p<0.001). Conversely, TBS T-scores were low in both cohorts 1.10 (±1.73) vs -1.48 (±1.60) for biallelic vs. monoallelic genotype, respectively (p=0.074). The more recent TBS software version 4 appeared even more sensitive to detect deterioration in both groups, with TBS T-scores of -1.40 (±1.17) vs -1.73 (±1.34) in the two groups respectively (p = 0.64).

Conclusions

In line with previous findings, this study indicates that conventional DXA-BMD may appear erroneously high in HPP patients, particularly in more severe biallelic cases where elevated BMD T-scores may mask skeletal defects. Extended analysis using TBS exhibited inferior bone microarchitecture and mineralization inhomogeneity in both, biallelic and monoallelic HPP genotypes. This underscores potential added value of TBS in evaluating skeletal involvement in HPP with the newer version 4 showing greater sensitivity.

P499

PREVALENCE OF SARCOPENIA IN CKD: INSIGHTS INTO THE ROLE OF NUTRITION AND DIALYSIS

F. Giambò[1], N. E. Foligno[1], M. Brambilla Pisoni[1], G. Vezzoli[1]

[1]IRCCS San Raffaele Hospital- Vita Salute San Raffaele University, Department of Nephrology and Dialysis, Milan, Italy

Objective

To compare the prevalence of sarcopenia, body composition, and nutritional intake between patients on dialysis and those with conservatively managed chronic kidney disease (CKD) in stages IV and V, including individuals with End-Stage Renal Disease (ESRD).

Material and Methods

A total of 92 dialysis patients (DP) were included, consisting of 65 men and 27 women, along with 36 conservatively treated CKD patients. Sarcopenia was defined using bioimpedance analysis to calculate the Appendicular Skeletal Muscle Index (ASMI, appendicular muscle mass [kg]/height^2 [m^2]). Sarcopenia was defined as ASMI values <7 kg/m² for men and <5.5 kg/m² for women. Body composition metrics such as BMI, ASMI, lean mass, and fat mass were measured, and nutritional intake was assessed using food frequency questionnaires to understand caloric and protein intake patterns.

Results

Among dialysis patients, the distribution of BMI revealed that 12% had a BMI <18.5 (underweight), 47.8% had a BMI between 18.5 and 25 (normal weight), 30.4% had a BMI between 25 and 30 (overweight), and 9.8% had a BMI >30 (obese). Concerning nutritional intake, only 53.5% of DP met the recommended caloric target of 25 kcal/kg/day, while just 17.4% achieved the ideal protein intake of 1.2 g/kg/day. These findings suggest a notable gap in the nutritional requirements of dialysis patients. Sarcopenia was significantly more prevalent in DP (78.2%) compared to conservatively treated patients (52.8%) (p=0.004), and within the DP group, it was more common in men (87.7%) than in women (55.6%) (p<0.001). Sarcopenic DP (n=72) had lower ASMI (5.83±0.8 vs. 6.68±1.1 kg/m², p=0.003), lean mass (15.9±1.6

vs. 17.2±2.3 kg/m², p=0.027), fat mass (6.9±2.7 vs. 10±3.8 kg/m², p=0.002), and BMI (22.8±3.6 vs. 26.9±5.2 kg/m², p=0.001). Sarcopenic DP had lower protein intake normalized to caloric intake compared to non-sarcopenic patients (34.4±6.4 vs. 38.8±7.2 g/1000 kcal, p=0.016), whereas carbohydrate and lipid intake did not differ.

Conclusions

Sarcopenia is more prevalent and severe in DP compared to conservatively treated CKD patients, particularly in men. It is associated with low dietary protein intake relative to caloric intake. Early screening for sarcopenia, along with targeted nutritional support, is essential to mitigate muscle loss and improve prognosis in DP.

P500

PREVALENCE AND BURDEN OF OSTEOARTHRITIS AMONGST OLDER PEOPLE IN COLOMBIA

F. Gomez[1], G. Duque[2], C. L. Curcio[1], L. Cano[1], D. Osorio[1], S. Rios[1]

[1]Research Group in Geriatrics and Gerontology, Faculty of Health Sciences, Universidad de Caldas, Manizales, Colombia, [2]Dr. Joseph Kaufmann Chair in Geriatric Medicine, Department of Medicine, McGill University. Bone, Muscle, and Geroscience Group - Research Institute of the McGill University Health Centre, Montreal, Canada

Objectives: To investigate the prevalence of osteoarthritis (OA) and to identify the inequalities in person-level risk factors among older men and women in Colombia.

Material and methods: This cross-sectional study used data from the National Survey of Health, Wellbeing and Aging in Colombia (SABE Colombia, according to its initials in Spanish), a nationwide study conducted between 2014-2016. The study included a population-based study of 23694 people aged > 60 or older (median: 70.8 years, 57.3% women) living in rural and urban communities. Logistic regression was used to determine associations between the presence of OA and a range of sociodemographic, health-related, functional, and social/environmental variables.

Results: The overall prevalence of OA was 26% (women-36.5%; men-14.9%) See table 1. Prevalence increased with age and in mestizo ethnicity placed in urban areas. On multivariable analysis, OA was significantly associated with older age, female gender, multimorbidity, fair/poor self-perceived health, higher body mass index (BMI), higher LDL-c, a greater number of physical limitations, and perceived safety/security problems in the neighborhood. In particular, there was a strong association between multimorbidity and the presence of OA (OR = 4.97 (95% CI 4.46, 5.53)).

Conclusions: OA is a common and multifaceted condition, with a comparable prevalence of self- reported OA in Colombia with similar populations elsewhere. Assessment and management should focus on potentially modifiable factors such as BMI, multimorbidity, physical limitations, mobility disabilities, and safety/security problems in the neighborhoods. More research is required to understand the complex inter- relationships between these and other risk-associated variables

Table 1. Prevalence of OA by Age SABE Colombia.

	Total		Men		Women	
Age (years)	%	CI 95%	%	CI 95%	%	CI 95%
60 – 64	19.8	(18.0 – 21.7)	10.3	(8.2 – 12.9)	29.3	(25.8 – 33.2)
65 – 69	24.7	(20.4 – 29.6)	12.1	(9.1 - 16.1)	36.5	(30.9 – 42.5)
70 – 74	26.6	(23.2 – 30.2)	17.1	(14.2 – 20.5)	36.7	(31.8 – 42.0)
75 – 79	32.8	(28.0 – 38.0)	19.6	(16.1 – 23.6)	45.2	(38.8 – 51.8)
80 – 84	34.3	(29.9 – 38.9)	20.0	(15.3 – 25.6)	46.2	(39.9 – 52.6)

EVALUATION OF THE ACCURACY OF OPERA AND OSTA FOR OSTEOPOROSIS SCREENING IN WOMEN OVER 50 YEARS IN IRAN

M. Janani[1], F. Haji-Valizadeh[1], K. Khalagi[2], N. Fahimfar[2], M. J. Mansourzadeh[2], A. Ostovar[2], H. Ghajari[3], F. Torkman Asadi[4], M. Darman[5], R. S. Mirmoeini[6], N. Fayazi[7], K. Etemad[8]

[1]Musculoskeletal Disease Department, Center for Non-Communicable Diseases Prevention and Control, Ministry of Health of Iran, Ministry of Health & Medical Education, Tehran, Iran., Tehran, Iran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran, [3]Statistical Genetics, QIMR Berghofer Medical Research Institute, Brisbane, Australia, Brisbane, Australia, [4]Deputy director of Health, University of Medical Sciences, Hamedan, Iran., Hamedan, Iran, [5]Expert of non-communicable diseases NCD management office Ministry of Health and Medical Education IR Iran., Tehran, Iran, [6]Director of Non-Communicable Diseases Department, University of Medical Sciences, Hamedan, Iran., Hamedan, Iran, [7]Non-Communicable Diseases Department, University of Medical Sciences, Hamedan, Iran., Tehran, Iran, [8]Director General for NCD, Deputy of Health - Ministry of Health and Education, Tehran, Iran., Tehran, Iran

Objective:

Identifying an appropriate screening tool for osteoporosis is essential for its integration into the health system's osteoporosis program. The aim of this study was to assess the accuracy of OPERA and OSTA in in Women Over 50 Years in Iran.

Method

This diagnostic test study was conducted in 2022 in Hamedan province in Iran. Participants included females over 50 years old who visited health centers and filled out informed consent. Before their visits, public announcements were made in communication channels to invite population to participate in this study. The OPERA and OSTA screening tools were filled for participants, and bone densitometry, considered the gold standard, was performed

to evaluate osteopenia and osteoporosis in the femoral neck, total hip, and spine. Bone mineral density (BMD) was measured using the DXA method with a GE Lunar device. Osteoporosis and osteopenia were defined as a T-score of less than -2.5 and -1, respectively, in at least one of the three mentioned regions. The sensitivity and specificity of OPERA and OSTA, in combination (a positive result in either test considered as positive), were assessed for screening osteopenia/osteoporosis and osteoporosis.
Results
In this study, a total of 998 female participants were included. The mean age and BMI of participants were 71.67 ± 6.33 years, and 26.74 ± 4.53. The sensitivity and specificity of OPERA/OSTA for detecting osteoporosis for the femoral neck were 87.27% and 38.87%, for the total hip were 90.16% and 37.85%, for the spine were 83.19% and 44.52%, and for patients with at least one site of osteoporosis were 81.41% and 45.09%, respectively.
In addition, the sensitivity and specificity of OPERA/OSTA for detecting osteopenia or osteoporosis for the femoral neck were 73.13% and 54.98%, for the total hip were 77.23% and 51.45%, for the spine were 73.76% and 58.82%, and for patients with at least one site of osteopenia or osteoporosis were 70.62% and 65.29%, respectively.
Conclusion
The combined use of OPERA and OSTA tools is more sensitive and has better performance for screening of osteopenia or osteoporosis compared to using these tools for screening of osteoporosis. However, the specificity was low in this method, and false positive effects should be considered. However, the use of these tools is appropriate for screening purposes.
Keywords: Osteoporosis, Screening Tools, Sensitivity, Specificity, OPERA, OSTA, Bone Densitometry.

TIME-EFFICIENT MRI SCORING SYSTEM FOR AXIAL SPONDYLOARTHRITIS: A PROSPECTIVE VALIDATION STUDY

F. I. Abdelrahman[1], M. A. Mortada[2], H. A. Selim[3], E. El Sayyad[4], M. A. Basha[3]

[1]Faculty of Medicine , Zagzig University , Department of Rheumatology and Rehabilitation, Zagazig, Egypt, [2]Faculty of Medicine , Zagazig University , Rheumatology and Rehabilitation Department, Zagazig, Egypt, [3]Faculty of medicine zagazig university, Zagazig, Egypt, [4]Rheumatology and Rehabilitation Department, Zagazig, Egypt

Background: Axial spondyloarthritis (axSpA) is a chronic degenerative condition that primarily affects the spine and sacroiliac joints (SIJs), leading to significant suffering. It falls under the broader category of spondyloarthritis, which presents a considerable diagnostic challenge owing to nonspecific symptoms and a notable lack of radiographic evidence in the early stages of the disease [1].
Magnetic resonance imaging (MRI) has become an indispensable diagnostic tool for evaluating axSpA that can detect both active inflammation and structural changes in the SIJs and spine, especially when inconclusive results arise from other modalities. It is the standard imaging modality recommended for the assessment of axSpA, as supported by the ankylosing spondylitis Working Group of the International Association for the Assessment of Spine Arthritis (ASAS) and Outcome Measures in Rheumatoid Arthritis Clinical Trials (OMERACT) [2]. Various MRI scoring systems are in use, with the Spondyloarthritis Research Consortium of Canada (SPARCC) score being notably sensitive in detecting subtle changes in inflammation and correlating positively with clinical measures of disease activity [3].
Despite advancements in the management of axSpA, the absence of standardized methods for routinely assessing disease activity remains a significant challenge. The current SPARCC MRI score, although valuable, is time-consuming and requires specialized training, taking between 40 min to 1 h per patient, depending on individual conditions. To address these limitations, we proposed a simple SPARCC MRI score that focuses on the three most affected slices of the SIJs and the three most affected vertebrae in the spine. This approach offers a more streamlined and time-efficient method for clinical practice.
Objective: To develop and validate a simplified Spondyloarthritis Research Consortium of Canada (SPARCC) MRI score for detecting disease activity changes in patients with axial spondyloarthritis (axSpA) undergoing biological therapy and compare its performance with the original SPARCC score.
Methods: This prospective study included 60 patients with axSpA diagnosed according to the ASAS classification criteria who were naïve to biologic DMARDs. Disease activity and physical function in axSpA patients were assessed using several indices at baseline and six months after biological therapy. Improvement was defined as either an ASDAS-Clinically Important Improvement (ASDAS-CII) (a decrease of ≥ 1.1) or ASDAS-Major Improvement (ASDAS-MI) (a decrease of ≥ 2.0).
MRI examinations of the sacroiliac joints (SIJs) and spine were performed at baseline and six months after biological therapy. The simplified SPARCC score, focusing on the three most affected slices/vertebrae instead of six, was developed and compared with the original SPARCC score. Both original and simplified SPARCC scores were correlated with clinical indices and inflammatory markers (CRP and ESR). Inter-reader agreement and diagnostic performance were evaluated to assess reliability and clinical utility.
Results: The study included 60 axSpA patients with mean age of 29.78 ± 7.28 years, with male predominance (68.3%) . Median disease duration was 4 years (0.5-10). 45% of the patients had peripheral arthritis, 15% had psoriasis, 5% had inflammatory bowel disease and 3.3% had uveitis. HLA-B27 was positive in 43.3%. By comparing various disease activity markers and clinical scales at baseline and 6 months post-therapy; all parameters showed significant improvement ($p<0.001$) (median ESR decreased from 35.0 to 12.0, CRP from 17.5 to 2.0, BASDAI from 7.0 to 2.0, BASFI from 6.0 to 2.0, and BASMI from 4.0 to 2.0). Mean ASDAS-CRP decreased from 4.02 to 1.91. ASDAS-CRP "very high" activity decreased from 73.3% to 10%, while 38.3% achieved "inactive" status. A thorough comparison between the original and simple MRI SPARCC scores at baseline and six months after biological

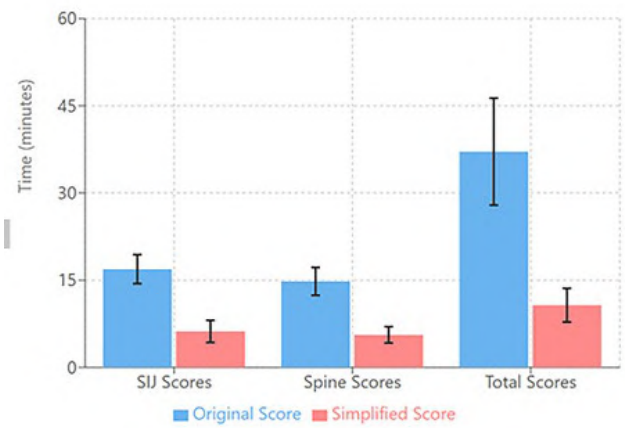
therapy is summarized in Table 1.
Table 1.

Variables	Baseline (n=60)	Follow-up (n=60)	% of improvement	P-value
Original SPARCC SIJ	22 (21.3), 4 – 56	6 (10.5), 0 – 23	73.8	<0.001
Simple SPARCC SIJ	19 (20.5), 4 – 36	6 (9.25), 0 – 21	71.4	<0.001
Original SPARCC spine	13 (16.3), 0 – 51	1.5 (10), 0 – 22	78.8	<0.001
Simple SPARCC spine	11.5 (15.25), 0 – 47	1.5 (8), 0 – 18	79	<0.001
Original SPARCC total	36.5 (36.5), 5 – 101	6 (17), 0 – 45	75.5	<0.001
Simple SPARCC total	21 (25), 0 – 69	3 (16), 0 – 30	79.1	<0.001

Both the original and simplified SPARCC scores showed significant improvement after six months of biological therapy (p<0.001). The simplified SPARCC scores demonstrated strong correlations with disease activity markers, comparable to or stronger than the original scores. BASDAI and ASDAS showed strong correlations with both systems. BASDAI correlated with original (r=0.421) and simple (r=0.413) scores at baseline. ASDAS correlated with original (r=0.419) and total scores (r=0.425). Simple SPARCC total scores had the best diagnostic accuracy for detecting the disease activity (AUC 0.810, sensitivity 76.3%, specificity 66.7% at cut-off 9.0). Original SPARCC SIJ and total scores performed similarly (AUC 0.794, sensitivity 75%, specificity 82.7% at cut-offs 12.0 and 24.0). Spine scores showed high sensitivities (87.5-89.5%) but lower specificities (67.3%).

Inter-reader agreement was substantial to almost perfect for all scores, with simplified SPARCC spine score exhibiting highest agreement (κ= 0.817 at baseline and 0.784 at follow-up) followed by simple total scores (k=0.716 baseline, k=0.744 follow-up). Simple scores consistently outperformed original SPARCC across all categories.

The simplified scoring significantly reduced assessment time (Fig. 1): SIJ scoring from 16.9 ± 2.5 to 6.2 ± 1.9 minutes, spine from 14.8 ± 2.4 to 5.6 ± 1.4 minutes, and total from 37.1 ± 9.2 to 10.7 ± 2.9 minutes (all p<0.001).



Conclusion: This study supports the construct validity of the simplified SPARCC MRI score in assessing inflammation in patients with axSpA. The simplified SPARCC MRI score demonstrates comparable efficacy to original score in assessing disease activity in axSpA patients, with advantages of improved inter-reader reliability and significantly reduced assessment time.

OPTIMIZING BONE HEALTH BEHAVIORS IN OLDER ADULTS THROUGH A PARTICIPATORY APPROACH: A FUTURE PERSPECTIVE FOR LOW- AND MIDDLE-INCOME COUNTRIES

F. Kamberi[1], S. Aderaj[2]

[1]University of Vlore "Ismail Qemali", Scientific Research Centre for Public Health, Faculty of Health, Vlora, Albania, [2]Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy

Objective: The objective was to develop educational manuals on bone health for primary healthcare services in Albania, focusing on the older population. The goal was to enhance healthcare personnel's preparedness and confidence in educating patients about bone health, particularly concerning nutrition and physical activity.

Materials and Methods: The study followed a mixed-methods approach, beginning with a literature review on bone health behaviors tailored to older adults with chronic conditions. This review served as the foundation for creating educational materials. The first phase involved developing these materials for both healthcare professionals and older patients. In the second phase, the materials were tested in a pilot group of nine older individuals with musculoskeletal diseases. A ninety-minute focus group discussion was held to evaluate the clarity of the materials, identify any ambiguities in language, and assess the patients' understanding. Based on feedback, the educational material was refined. In the third phase, a focus group of twelve healthcare professionals (doctors and nurses) discussed the revised materials. Their input, along with insights into the Albanian healthcare context, helped finalize the content, ensuring that it was culturally appropriate, easily understandable, and practical for use by both patients and healthcare providers.

Results: The manuals were highly appreciated by both patients and healthcare professionals. Patients found the materials to be clear, relevant, and easy to integrate into their daily routines. They particularly appreciated the inclusion of visual aids, which made

the content more understandable. Both patients and healthcare professionals recognized that nutrition and physical activity—key elements of bone health—were often neglected in health education. This feedback emphasized the importance of including these topics in the manual. In the end, the content of the two manuals for osteoporosis and fall risk prevention was validated, and approval for use in clinical practice was obtained.

Conclusions: The participatory approach used in developing these educational materials was found to be effective in creating content that was relevant, understandable, and useful for improving bone health behaviors in older adults. Findings highlight the need for active collaboration between healthcare providers, patients, and the community in promoting bone health, particularly for older adults.

P504

RELATIONSHIPS BETWEEN PAIN, PHYSICAL ACTIVITY AND SLEEP QUALITY AMONG INDIVIDUALS WITH RADIOGRAPHIC KNEE OSTEOARTHRITIS: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

F. Kirkham-Wilson[1], L. Westbury[1], G. Bevilacqua[1], F. Laskou[1], N. Fuggle[1], E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton , United Kingdom

Objective
The Hertfordshire Cohort Study, a cohort of community-dwelling older adults, was used to characterise the importance of physical activity in the established relationship between sleep and osteoarthritis (OA).
Materials and Methods
Participants completed a questionnaire including: the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC); the Pittsburgh Sleep Quality Index (PSQI); Longitudinal Aging Study Amsterdam Physical Activity Questionnaire (LAPAQ); and the Hospital Anxiety and Depression (HAD) Scale. Knee radiographs were taken and classified according to Kellgren and Lawrence (K&L) criteria; analyses were restricted to individuals with radiographic knee OA (K&L score ≥2 on either knee). 81 men and 88 women were included, aged 71-80.
Logistic regression was used to examine the association between the WOMAC knee pain score and poor sleep quality (PSQI>5) with adjustment for sex, age, and anxiety and depression scores; analyses were performed with and without stratification by physical activity category (bottom sex-specific tertile vs not).
Results
Knee pain prevalence (WOMAC score > 0) was 40.7% among men and 46.6% among women; 37.0% of men and 50.0% of women reported poor sleep quality (PSQI>5). Higher WOMAC knee pain scores were related to higher odds of poor sleep quality. For example, the odds ratio (95% CI) for having poor sleep quality per unit increase in WOMAC knee pain score was 1.15 (1.01,1.32), p=0.038. Relationships were similar in men and women, and across physical activity subgroups. Associations were similar in sensitivity analyses after removing those with more severe OA (K&L score ≥3).
Conclusions
In this cohort of older people with radiographic knee OA, sleep disturbance was common. We found associations between higher levels of reported knee pain and poorer sleep quality. These relationships did not differ according to physical activity level. Future work on larger populations, and among younger people who may be more physically active, is now required.

P505

A PRAGMATIC APPROACH TO DETERMINING PREVALENCE OF OSTEOARTHRITIS IN THE GAMBIA AND ZIMBABWE

F. Kirkham-Wilson[1], L. S. Gates[1], C. M. Pearse[1], T. Manyanga[2], M. K. Jallow[3], B. Cassim[4], A. Burton[5], C. Grundy[6], H. Wilson[5], F. Paruk[7], Y. Madela[4], B. Mbanjwa[7], R. A. Ferrand[6], C. L. Gregson[5], K. A. Ward[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton , United Kingdom, [2]The Health Research Unit Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, [3]MRC Unit The Gambia, London School of Hygiene and Tropical Medicine, Banjul, Gambia, [4]Department of Geriatrics, University of KwaZulu-Natal, Durban, South Africa, [5]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom, [6]MRC International Statistics and Epidemiology Group, London School of Hygiene and Tropical Medicine, London, United Kingdom, [7]Department of Rheumatology, University of KwaZulu-Natal, Durban, South Africa

Objective
To determine the prevalence of osteoarthritis (OA) in men and women in Zimbabwe and The Gambia.
Method
A population-based, cross-sectional study of community dwelling adults was conducted in urban Zimbabwe & The Gambia. Recruitment was sex- and age-stratified (40-54, 55-69, ≥70 years). The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) determined the prevalence of hip and knee pain (Stair climbing was removed as many dwellings lack stairs; so scored /16 rather than /20. Sex-stratified knee and hip pain prevalence was quantified, as WOMAC score ≥ 1. Descriptive statistics are presented as mean(SD) or median(IQR).
Results
The Gambia: 546 males(M) (mean age 60.7y (SD 13.0)) and 669 females(F) (mean age 60.7y (SD 12.7)) were recruited: mean BMI 23.6(SD 4.0)kg/m^2 in M and 28.0(SD 6.1) kg/m^2 in F. 32.9% of F and 5.7% of M were obese (BMI >30 kg/m^2). The prevalence of knee and hip pain was 57.5% and 41.6% in M and 72.3% and, 61.2% in F, respectively. The median WOMAC score for knee pain for M was 1(IQR 0-6) and for F was 3(IQR 0-7). Median WOMAC for hip pain for M was 0(IQR 0-4) and for F was 2(IQR 0-6).
Zimbabwe: 528 M (mean age 62.7y (SD 14.55)) and 560 F (mean age 62.7y (SD 13.74)) were recruited: mean BMI 23.1(SD 4.3)kg/m^2 in M and 28.7(SD 6.3)kg/m^2 in F. 37.5% of F and 6.4% of M were

obese. The prevalence of knee and hip pain was 27%, and 14.4% in M and 33.2% and 19.5% in F, respectively. The median WOMAC score for knee pain for M was 0(IQR 0-0) and for F was 3(IQR 0-7). For hip pain the median WOMAC for M and F was 0(0-0).
Conclusion
Adults in Zimbabwe and The Gambia have a significant burden of hip and knee pain. Aligning with global trends, women have more pain than men. Pain was more common in The Gambia than in high-income countries. Given the health and societal burden associated with OA and musculoskeletal pain, it will be important to determine context-specific risk factors and impact on quality of life.

P507

"INCREASING BONE DENSITY: A LONGITUDINAL STUDY IN A FRACTURE LIAISON SERVICE"

F. Magalhães[1], D. Augusto[1], S. P. Dinis[1], C. Vaz[2], N. Madeira[2], F. Cunha-Santos, J. F. Ferreira[2]

[1]rheumatology department ulsg, Guarda, Portugal, [2]Department of Medicine, Faculty of Health Sciences, University of Beira Interior; Rheumatology Department, ULSG, Guarda, Portugal

Objective: To compare bone mineral density (BMD) measurements obtained through Dual-energy X-ray absorptiometry (DXA) shortly after the initiation of pharmacological treatment, and several months after, in a Fracture Liaison Service (FLS) cohort of hip fracture patients. Additionally, to determine the effectiveness of osteoporosis treatment in improving bone density and reducing the risk of further fractures.
Methods: A prospective FLS recruited all patients with hip fractures, without dementia and able to walk post-fracture, since October 2019. Medications were prescribed according to best practices, national recommendations, and patient preferences. DXA was requested at the first appointment and again at the 24-month follow-up. The Shapiro-Wilk test assessed data normality. A paired t-test compared the BMD scores, analyzing t-values and z-values for the L1-L4 vertebrae, femoral neck, Ward's triangle, femoral trochanter, and total BMD to determine significant improvements post-medication. A p-value <0.05 was considered significant.
Results: Out of 159 patients who attended the first appointment, 92 are still in the 24-month treatment and didn't undergo the second DXA; 19 were lost to follow-up; 5 didn't adhere to the treatment and 8 died during follow up. Out of the 35 patients who had two DXA measurements, 83% were female. 83% of the patients were supplemented with a combination of vitamin D, calcium, and Denosumab every 6 months, while the remaining 17% received vitamin D, calcium, and bisphosphonates. The average interval between DXA scans was 25 months and 14 days. Analysis revealed significant improvements in T-scores and Z-scores for the lumbar vertebrae (L1-L4) post-treatment ($p < 0.05$). This also held true for the femoral trochanter Z-score and the total BMD Z-score. No statistically significant differences were observed for the remaining sites studied.
Conclusion: Our study suggests that when patients adhere to treatment, it is effective in achieving higher BMD. Treatment adherence and patients lost to follow up remain a challenge even in an FLS.

P508

IMPROVING BONE HEALTH ASSESSMENTS USING FRAX IN AN ACUTE FRAILTY UNIT

F. Maguire[1], S. Graham[1], A. Riaz[1]

[1]Countess of Chester Hospital, NHS, Chester, United Kingdom

Objective: Assessment of bone health and fracture risk is a key component of comprehensive geriatric assessment of frail adults. Our project aimed to improve the assessment of fracture risk, using the Fracture Risk Assessment (FRAX) tool, of patients attending our hospital's Acute Frailty Unit (AFU).
Materials and Methods: Admissions to AFU over a two-week period were reviewed retrospectively to determine whether bone health was considered, along with information required for FRAX calculation. Posters were displayed in AFU to encourage consideration of bone health, and clinicians were prompted to ensure FRAX scores were calculated for suitable patients. Additional data were collected over another two-week period to assess for improvement.
Results: A total of 71 patients attended AFU during the initial period, with 48 eligible for bone health assessment who had no previous osteoporosis diagnosis. Of these, three (6.3%) had a FRAX score calculated. Among patients with a history of falls, 8.6% had FRAX calculated. FRAX scores were calculated for the remaining patients, and based on national treatment guidelines, half were deemed eligible for either a bone density scan or initiation of antiresorptive treatment. After the intervention, 43 out of 75 patients were eligible for bone health assessment, and 44.2% had their FRAX scores calculated. This increased to 50% for patients with a history of falls. Seven patients had treatment initiated based on their FRAX scores, compared to just one patient during the initial review period.
Conclusions: The introduction of a poster encouraging bone health assessment in the AFU enhanced the use of the FRAX tool and led to an increased identification of patients suitable for bone density assessment and antiresorptive treatment, compared to previous practice. Identifying patients with osteoporosis risk factors enables early assessment and intervention, reducing the future risk of fragility fractures and associated complications.

P509

CORRELATION AMONG SERUM MARKERS OF MUSCLE QUALITY, BODY COMPOSITION, AND PHYSICAL PERFORMANCE IN A COHORT OF PATIENTS WITH OSTEOPENIA/OSTEOPOROSIS

F. P. Fabrazzo[1], F. Russo[1], F. D'Andrea[1], A. Scala[1], V. Sirico[1], S. Liguori[1], M. Paoletta[1], A. Moretti[1], G. Iolascon[1]

[1]Department of Medical and Surgical Specialties and Dentistry, University of Campania "Luigi Vanvitelli", Via De Crecchio n. 4, 80138 Naples, Italy., Napoli, Italy

Objectives: The study aims to analyze possible correlations between serum markers of muscle quality, body composition, physical performance, muscle strength, and physical activity levels in a cohort of osteopenic/osteoporotic patients.

Material and Methods: Patients diagnosed with osteopenia/osteoporosis underwent an evaluation protocol including anthropometric data (age, sex, body mass index - BMI), Appendicular Skeletal Muscle Mass (ASMM) using bioimpedance analysis (BIA), muscle strength with a Jamar handgrip dynamometer (Hand Grip Strength - HGS), physical performance through the Short Physical Performance Battery (SPPB) and a nutrition screening with Short Mini Nutrition Assessment (SMNA). Physical activity levels were assessed as MET (metabolic equivalent of task) using both a portable actigraph and the International Physical Activity Questionnaire (IPAQ). A blood sample was collected to measure muscle quality markers.

Results: Our analysis included 44 patients (43 F, 1 M; mean age 64.7 ± 7.3 years; BMI 24.8 ± 4.3 kg/m²). The mean serum P3NP concentration was 10.4 ± 2.6 µg/L. The mean ASMM was 17.1 ± 2.3 kg, and the BMI-adjusted ASMM was 0.699 ± 0.0985 kg/(kg/m²), slightly below the literature-reported cutoff for females. Muscle strength and physical performance assessments revealed mean HGS values of 22.2 ± 3.9 kg, weekly MET values of 12,96 ± 2,7, IPAQ scores of 4,57 ± 2,8 MET, and a median total SPPB score of 7 (IQR 4–12).
A weak inverse correlation was observed between serum P3NP levels and BMI-adjusted ASMM (r -.38 $p < 0.008$) as well as between leptin and SMNA (r -0.38 $p < 0.010$). A moderate positive correlation was noted between HGS and BMI-adjusted ASMM (r -0.49 $p < 0.01$) while a weak positive correlation was observed between sclerostin and IPAQ scores (r -0.33 $p < 0.02$)

Conclusions: The study found weak negative correlations between serum P3NP and leptin with muscle mass indicators, suggesting their potential impact on muscle composition in osteopenic/osteoporotic patients. Additionally, a weak positive link between sclerostin and physical activity levels indicates a possible connection between bone metabolism and activity. These findings highlight the complex interplay between biochemical markers, muscle mass, and physical function in this population.

P510

VITAMIN D DEFICIENCY AND FALL RISK DURING EARLY REHABILITATION AFTER TOTAL KNEE ARTHROPLASTY: A CRITICAL WINDOW FOR ACTION

F. Pegreffi[1], M. T. Di Leo[2], G. Fanzone[3], P. Mirisola[2], A. Russo[4], N. Veronese[5], M. G. Maggio[6]

[1]Department of Medicine and Surgery, School of Medicine and Surgery, University of Enna Kore - Recovery and Functional Rehabilitation Unit, Umberto I Hospital, Enna, Italy, [2]Recovery and Functional Rehabilitation Unit, Umberto I Hospital, Enna, Italy, [3]Orthopaedic and Traumatology Unit, Umberto I Hospital, Enna, Italy, [4]Department of Medicine and Surgery, School of Medicine and Surgery, University of Enna Kore - Orthopaedic and Traumatology Unit, Umberto I Hospital, Enna, Italy, [5]Saint Camillus International University of Health Sciences, Rome, Italy, [6]Department of Medicine and Surgery, University of Parma - Geriatric Clinic Unit, University Hospital of Parma, Parma, Italy

Introduction: In total knee arthroplasty (TKA) patients, muscle function is crucial for regaining strength, mobility, and balance. Vitamin D is essential for bone health and its role for muscle function and proprioception is receiving increasing attention (1,2). The latter, which is vital for fall prevention, is often impaired post-surgery due to surgical stress, prosthetic implantation, and sarcopenia (3,4). Evaluating vitamin D levels and fall risk during early rehabilitation offers valuable insights into recovery outcomes and safety.

Objective: This study evaluates the prevalence of vitamin D deficiency in TKA patients upon admission to early rehabilitation and examines the relationship between postoperative vitamin D levels, preoperative pharmacological vitamin D supplementation, and fall risk.

Material and Methods: This cross-sectional study included 40 TKA patients (age: 74±6 yrs, BMI: 24±1 kg/m²) admitted to a rehabilitation ward. Vitamin D levels and Conley Scale score, a measure of fall risk, were retrieved from records. Patients were categorized into four groups based on serum vitamin D levels: <10 ng/ml (Group 1), 10–20 ng/ml (Group 2), 20–30 ng/ml (Group 3), and >30 ng/ml (Group 3). Statistical analysis included a two-sample t-test to compare vitamin D levels between groups and Pearson's correlation to evaluate the relationship between supplementation and Conley Scale scores.

Results: Patients who received preoperative vitamin D supplementation, initiated at least one year before surgery, Group 3 and Group 4, had significantly higher serum vitamin D levels and lower fall risk during rehabilitation, with Conley scores respectively of 1.07 (20–30 ng/mL) and 0.50 (>30 ng/mL). Patients with non-history of Vitamin D supplementation exhibited lower levels of vitamin D after TKR along with higher fall risk demonstrated by Conley Scale scores (3.50, Group 1 and 2.73, Group 2). A strong negative correlation (r = -0.837) between vitamin D supplemen-

tation and Conley Scale scores confirmed the effectiveness of supplementation (Figure 1).

Discussion and Conclusion

This study highlights an often overlooked yet crucial phase of early rehabilitation after TKA, a "critical window for action" during which addressing vitamin D deficiency may play a pivotal role in mitigating fall risk and optimizing recovery outcomes. While this is not a clinical trial, the findings provide an important starting point for recognizing the potential impact of routine vitamin D assessment and early intervention.

These preliminary observational data need to be confirmed by clinical trials before their application into definitive recommendations in clinical practice.

Disclosures The authors declare no conflicts of interest.

OSTEOPOROSIS AND MULTIPLE VERTEBRAL FRACTURES. A CASE REPORT

F. Rivas Santirso[1], P. Rivas Calvo[2]

[1]Rheumatology and Rehabilitation Clinic Drs. Rivas, Segovia, Spain, [2]Rheumatology and Rehabilitation Clinic Drs. Rivas and CEU San Pablo University (Madrid)., Segovia, Spain

Introduction:

The presence of osteoporotic fractures identifies a subgroup of patients more susceptible to presenting new fractures. Hence the importance of detecting and treating fractured patients.

Case report:

A 65-year-old woman who consulted for severe, persistent and disabling back pain. Two and a half months earlier, without any effort or previous trauma, she presented acute low back pain and was diagnosed with a degenerative process. Low back pain persists and MRI [30/01/2024] (fig.1) identifies fractures D11, D12, L1, performing percutaneous vertebroplasty of L1 with poor clinical response.

The patient had not received any pharmacological treatment for osteoporosis.

In his history, he highlighted: smoking (24 packs/year), low intake of dairy products and little habitual physical activity. No history of nephrolithiasis or RA. No treatment with corticosteroids, antiepileptics, or heparin. Mother with hip fracture at age 45.

Exploration:

Low back pain radiating to the abdomen, accompanied by a significant limitation in range of motion. Dorsal hyperkyphosis with pelvis-rib index < to 2 fingers.

Complementary tests:

DEXA: CL T-score: L1-L4 of - 3.5 SD and CF: - 1.20 SD.

Dorsal and posterior lumbar MRI [04/04/2024]: fractures D7, D8, D9, D1 and D12. L1 foundation material. L2, L3 and L5 fractures, with bone edema pattern (Fig. 2).

Blood tests: ESR: 31 mm/h (<20); CRP: 24 mg/L (0-6). Serum Ca and P and 24-h urine: normal. FA: 449 U/L (88-279), 25(OH) Vit. D3: 7.69 ng/mL. TSH, PTH: normal. Monoclonal IgG Lambda peak. CTX: 1.012 ng/mL (0.104-1.008), P1NP: 103.7 ng/mL (20.3-76.3), NTX: 124.9 nM/nM (26.0-124).

Bone SPECT (Fig. 3): multiple deposits in D7, D8, D11, D12, L1, L2, L5 and 2 grouped deposits, arranged on the 7th and 8th left anterior costal arches in relation to fractures.

Hematology: confirms the existence of IgG Lambda Monoclonal Gammopathy of uncertain significance.

Treatment:

Cholecalciferol 50,000 IU weekly for 8 weeks and then zoledronic acid 5 mg intravenous infusion, cholecalciferol 50,000 IU monthly, 1,500 mg calcium carbonate + 1,000 IU cholecalciferol daily.

In the evolutionary period, there is a significant improvement in clinical manifestations, normalization of RFA and AF, with the val-

ue being 25(OH)vit. D3 of 29.6 ng/mL.

Conclusions:

The appearance of new fractures after vertebroplasty is a frequent finding. 12% of patients develop a new vertebral fracture; The highest incidence occurs one month after the procedure, and it is difficult to determine whether they correspond to new secondary fractures, their underlying pathology or are fractures induced by vertebroplasty.

The treatment of vertebral fracture requires a multidisciplinary approach and a detailed study before vertebroplasty.

P512

EROSIVE OSTEOARTHRITIS OF THE HANDS AND POLYOSTOTIC PAGET'S BONE DISEASE. A CASE REPORT

F. Rivas Santirso[1], P. Rivas Calvo[2]

[1]Rheumatology and Rehabilitation Clinic Drs. Rivas, Segovia, Spain, [2]Rheumatology and Rehabilitation Clinic Drs. Rivas and CEU San Pablo University (Madrid)., Segovia, Spain

Objective:

Rare coexistence of this association or pathology.

Introduction:

Erosive osteoarthritis (EOA) should be considered as a variant of primary nodal polyarthrosis. It is a rare, inflammatory, destructive and disabling form. It predominantly affects the DIPs and PIPs joints. Aggressive clinical course, appearance of subchondral erosions, bone and cartilage damage, which can cause ankylosis. Although males may be affected, they do so much less frequently. Joint damage in EOA is not only mediated by interleukins, but also involves other inflammatory molecules such as TNF-α and matrix metalloproteinases. These interactions between cytokines and proteases promote the degradation of articular cartilage and subchondral bone, leading to the destructive characteristics of EOA. Paget's disease of bone (PDB) is the second most common disease of bone metabolism after osteoporosis, with a marked decrease in its incidence in recent decades. It is characterized by the alteration, in one or more bone locations, of the balance between bone formation and resorption. This imbalance results in deformed areas of bone, with a disorganized pattern, increased vascularization and greater fragility despite the apparent increase in bone mineral density.

Clinical Case:

A 63-year-old caucasian man presented for acute low back pain after minimal exertion.

PA:
EOA hand disabling disease, treated with NSAIDs and hydroxychloroquine. No personal or family history of psoriasis.
Exploration: Heberden and Bouchard nodules in bilateral DIPs and PIPs, with functional limitation. Lumbar paravertebral contracture, L4-L5 apophysalgia and limitation to flexion and rotations of the right hip.
Blood tests: ESR: 27 mm/h (<20); CRP: 15 mg/L (0-6); FA: 402 U/L (88-279). FR, anti-CCP and ANA: negative.
Rx: Soft tissue augmentation in DIPs and PIPs bilaterally with subluxations, erosive and osteolytic lesions. Bilateral thumb rhizarthrosis (fig. 1). Lumbar spondyloarthrosis. Involvement of the bone trabeculae and global bone thickening in the iliopubic ramus, ischium, acetabulum and right pubis (fig.2).
Bone scintigraphy with 99 mTc-HDP (fig.: 3): Hyperuptake in MCPs of the first finger, bilateral interphalangeal and carpal, left parietal bone, right scapula, L3 vertebra and right hemipelvis.
CT scan: Bone rarefaction with hypodense areas in the left frontoparietal region. Osteoblastic lesion in the right scapula. L3 osteolysis (fig. 4). Areas of osteolysis alternating with other osteoblastic areas involving the iliac bone, acetabulum, and right ileus and ischiopubic branches.

Conclusions:

The diagnostic challenges associated with the rare coexistence of EOA and PDB, which can have a significant impact on patients' functionality and quality of life, due to the combination of joint damage and structural bone alterations.
PDB should be considered as a new addition to the large family of osteoimmunological disorders. The cytokine profiles observed in this disease are also very similar to those observed in other osteoimmunological disorders, which is why we try to better understand its pathogenesis.

RELATIONSHIP BETWEEN FOOT BIOMECHANICAL DISORDERS AND KNEE PAIN IN RHEUMATOID ARTHRITIS

D. Ben Nessib[1], F. Rouatbi[1], S. Zanned[1], L. Kharrat[1], F. Majdoub[1], H. Ferjani[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Rheumatology Department, Mohamed Kassab Institute of Orthopedics, Mannouba, Tunisia

Objective:
Rheumatoid arthritis (RA) is a disease that can lead to biomechanical abnormalities of the foot, requiring precise evaluation. This study aims to explore the associations between foot biomechanical characteristics and the presence of knee pain in patients with RA.
Material and Methods:
This was a single-center, cross-sectional study including patients diagnosed with RA based on the 2010 ACR/EULAR criteria. Sociodemographic data and RA characteristics were collected. All patients underwent a podiatric examination using a podoscanner. The significance level was set at $p < 0.05$.
Results:
Twenty-nine patients, 9 men and 20 women, with a mean age of 59.7 ± 16.1 years [18–84], were included. The mean disease duration was 7.2 ± 7 years [0.5–28]. RA was seropositive in 92% of cases and erosive in 76%. Regarding comorbidities, 14% of patients were smokers, 27% had hypertension, 11% had diabetes, and 11% had dyslipidemia. The mean body mass index (BMI) was 25.7 ± 5.2 kg/m² [16.2–34.5]. Among the patients, 52% had knee pain, 44% had metatarsalgia, and 8% had heel pain. Foot deformities were observed in 22% of patients, with synovitis present in the feet in 24%. The foot arch was abnormal in 66% of patients on the right side and 45% on the left side. Regarding foot types, 86% of patients had a square foot type on the right side and 57% on the left, compared to 14% with an Egyptian foot type on the right and 43% on the left. No statistically significant association was found between the presence of knee pain and the type of foot arch ($p=0.359$ on the right; $p=0.340$ on the left) or foot type ($p=0.353$ on the right; $p=0.340$ on the left). The mean total perimeter of the foot was 33.1 ± 4.1 cm [25.5–44.7] on the right and 37.3 ± 16.1 cm [18.1–109.8] on the left. The mean total volume was 1.1 ± 1 cm³ [0–4.2] on the right and 3 ± 2.2 cm³ [0–6.8] on the left. The presence of knee pain was significantly associated with a higher total foot volume on the left side ($p=0.048$). This association was not observed on the right side ($p=0.336$). The Postural Biomechanical Index (PBI) was abnormal in 48% of cases. No significant association was found between an abnormal PBI and the presence of knee pain ($p=0.191$), heel pain ($p=0.953$), or metatarsalgia ($p=0.165$).
Conclusion:
The results of this study did not reveal a link between knee pain and podiatric abnormalities, particularly the type of foot arch or foot type, in patients with RA.

P514

LINK BETWEEN BIOMECHANICAL DEFORMATIONS OF THE FOOT AND ANKLE SYNOVITIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

F. Rouatbi[1], D. Ben Nessib[1], S. Zanned[1], L. Kharrat[1], F. Majdoub[1], H. Ferjani[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Rheumatology Department, Mohamed Kassab Institute of Orthopedics, Mannouba, Tunisia

Objective:
Rheumatoid arthritis (RA) is often associated with structural foot deformations, which may influence the development of synovitis. Our objective was to study the impact of biomechanical factors on foot synovitis in patients with RA.
Material and Methods:
This is a monocentric cross-sectional study including patients followed for RA according to the ACR/EULAR 2010 criteria. Socio-demographic data and RA characteristics were collected. All patients underwent podiatric examination using a podoscan. The significance level was set at $p < 0.05$.
Results:
Twenty-nine patients, 9 men and 20 women, with a mean age of 59.7 ± 16.1 years [18-84], were included. The mean duration of RA was 7.2 ± 7 years [0.5-28]. Ninety-two percent of cases were immuno-positive, and 76% were erosive. Regarding comorbidities, 14% of patients were smokers, 27% had hypertension, 11% had diabetes, and 11% had dyslipidemia. The mean body mass index (BMI) was 25.7 ± 5.2 kg/m² [16.2-34.5]. Among the patients, 52% had knee pain, 44% had metatarsalgia, and 8% had heel pain. Foot deformity was noted in 22% of patients. Twenty-four percent of patients had ankle synovitis, 17% of which was bilateral and 7% only on the left. The foot arch was pathological in 66% of patients on the right side and 45% on the left, with a statistically significant association between the presence of synovitis in the right ankle and a pathological arch on the right side ($p = 0.019$). Regarding foot types, 86% of patients had a square foot type on the right side, and 57% on the left, compared to 14% with an Egyptian foot type on the right side and 43% on the left, with a significant association between foot type and the presence of synovitis in the right ankle ($p = 0.01$). Patients with an Egyptian foot type had a significantly lower probability of having synovitis in the right ankle, with an odds ratio of 0.072 (95% CI: [0.009; 0.561]). This association was not found on the left side. The Postural Biomechanical Index (PBI) was pathological in 48% of cases, with no significant association with the presence of ankle synovitis ($p = 0.590$).
Conclusion:
The results of our study highlight the importance of biomechanical foot assessment in the management of patients with RA. The majority of significant associations found in this study were on the right side, emphasizing the importance of considering patients' dominant side when analyzing their complaints and podiatric disorders.

P515

PLACE OF Z-SCORE IN THE DETECTION OF CHEMOTHERAPY-RELATED BONE LOSS IN ALGERIAN YOUNG WOMEN WITH BREAST CANCER

F. Z. Macheroum[1], M. Sididris[2], R. Hamitouche[1]

[1]HCA kouba, Kouba, Algeria, [2]HCA, Kouba, Algeria

Background

Breast cancer is the most prevalent cancer type in Algeria, with over 14,000 new cases diagnosed annually, a significant proportion of which occur in women under 40. Due to its aggressive nature, chemotherapy is commonly used as treatment, but it is associated with both immediate and long-term toxicities that can negatively impact the quality of life of cancer survivors. One of the long-term side effects of chemotherapy, particularly in premenopausal women, is hormonal disruption, leading to ovarian failure, chemotherapy-induced amenorrhea (CRA), and early menopause, all of which may contribute to bone loss. The aim of this study was to assess bone mineral density (BMD) and identify potential factors associated with bone loss in young premenopausal patients following adjuvant chemotherapy.

Methods

We included premenopausal Algerian women under 45 years old who had undergone adjuvant chemotherapy. At the time of enrollment, demographic information, cancer characteristics, and menstrual history were collected. BMD was measured at trabecular and cortical sites using dual-energy X-ray absorptiometry (DXA). Factors contributing to reduced BMD and an increased risk of fractures were analyzed.

Results

A total of 94 patients were evaluated. The median age at breast cancer diagnosis was 39 years, while the median age at the time of study entry was 42 years. The median BMDs were 0.96 g/cm² for the femoral neck (FN) and 1.01 g/cm² for the lumbar spine (LS). Of the patients, 37.2% had abnormal Z-scores (≤−2) with a specificity of 84%, and 41.3% had osteopenia or osteoporosis in either the FN or LS. Multivariate analysis identified several factors correlated with bone loss (low BMD), including low vitamin D levels (OR = 2.632 [1.124–4.527]), low BMI (OR = 2.56 [1.599–2.907]), a longer time since the last adjuvant treatment (OR for LS = 2.781 [1.102–4.631]), use of LH-RH analogues(OR [95% CI] = 2.531 [1.691–4.131]),, and the use of adjuvant tamoxifen (OR = 1.752 [1.243–3.841]).

Conclusions

This study emphasizes that bone loss is a prevalent issue among early breast cancer survivors who have undergone chemotherapy. Approximately 37.2 of these survivors experience bone loss. Identifying and addressing factors associated with bone loss is essential to prevent fractures and improve long-term health outcomes for these patients.

P516

MADELUNG'S DEFORMITY AND DYSCHONDROSTEOSIS: A CASE REPORT

F. Z. Y. Heddi[1], A. Laouti[2], Z. Lamri[2], C. Haouichat[1]

[1]Djilali Bou Naama University Hospital, Algiers, Algeria, [2]Oran University Hospital, Oran, Algeria

Objective: Madelung's deformity (MD) is a rare congenital anomaly of the wrist and constitutes about 1.7% of all developmental hand deformities [1]. It is caused by premature closure of the medial and volar aspect of the distal radial physis [2]. MD occurs predominantly in adolescent females and is often associated with Leri Weill dyschondrosteosis [3]. The objective of this case report was to describe the clinical presentation and radiographic findings of MD.

Methods: We present a case report of a girl with Leri Weill dyschondrosteosis.

Results: A 17-year-old girl, with an unremarkable medical history, was admitted to our department of rheumatology because of gross disfigurement at the wrists with pain and difficulty executing daily activities, which have progressed gradually over the last four years. There was no trauma or fall. Physical examination revealed a girl with short stature and dinner fork deformity of the wrists, there was a spontaneous palmar subluxation of the wrist with the dorsal prominence of the ulna head (Figure 1). The patient also has shortened forearms and a bilateral decreased range of motion in pronation, supination, and wrist extension. There was no evidence of deformity of any other member of the family. Radiographs of both wrists showed a shortening and curvature of the radius, a widened distal radioulnar joint, and a triangular arrangement of the carpal bones (Figure 2). The clinical presentation and X-ray findings were typical of Madelung's deformity associated with Léri-Weill dyschondrosteosis. Conservative treatment was indicated because the patient refused to accept surgical intervention.

Figure 1

Figure 2

Conclusion:

MD of the wrists is rarely encountered in clinical practice but has definite radiological appearances. MD can occur in isolation or in association with other diseases. In our case, the patient also had short stature and mesomelia consistent with Leri-Weill syndrome. Conservative treatment is important in primary management and surgical options depend on the symptoms and patient's preferences.

THE FREQUENCY OF INFECTIONS IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS TREATED WITH BIOLOGIC THERAPY

F. Z. Y. Heddi[1], Z. Mansouri[1], M. Moussa Mebarek[1], H. Rahmouni[1], R. Allat[1], C. Haouichat[1]

[1]Djilali Bou Naama University Hospital, Algiers, Algeria

Objective:

Biologic agents are widely used in juvenile idiopathic arthritis (JIA) therapy. However, in spite of their high benefits, they are associated with a risk of infections. The study objective was to describe the infectious complications occurring in JIA patients under biologic therapy.

Methods:

We performed a single-center, retrospective study including patients diagnosed with JIA according to ILAR classification criteria and treated with biologics from January 2019 to December 2024. All infectious events were identified and the date, the site, the type of pathogen, the severity, and the treatment were assessed for each infectious event.

Results:

A total of 42 patients were included, 16 males (38.1%) and 26 females (61.9%). The mean age at the diagnosis was 8.3±4.2 years and the mean age at symptom onset was 7.5±4.2 years. The predominant subtypes of JIA were the systemic form (n: 12, 28.6%) followed by the seronegative polyarticular form (n:11, 26.2%), the oligoarticular form (n: 6, 14.3%), the seropositive polyarticular form (n: 5, 11.9%), enthesitis-related arthritis (n:4, 9.5%) and juvenile psoriatic arthritis (n: 3, 7.1%). One child had undifferentiated arthritis. Patients received etanercept in 19 cases (32.8%), adalimumab in 11 (43.2%), tocilizumab in 8 (19%), and anakinra in 4 (9.5%). The mean age at first use of a biologic was 10.6±3.8 years and the mean time between diagnosis of JIA and the first use of a biologic was 2.3±2.2 years. Biological agents were used as monotherapy in 9 patients (21.4%), in combination with methotrexate in 22 (52.4%), in combination with corticosteroids in 21 (50%), and in combination with NSAIDs in 12 (28.6%). During the study period, 18 patients (42.9%) developed an infection, of whom 9 (50%) had more than one infection. The mean time between the start of a biologic and the occurrence of the infectious event was 8.1±6.8 months and the most common sites were: ENT system (72.2%), urinary and genital tracts (38.9%), respiratory tract (27.8%), the skin (23.5%) and gastrointestinal system (11.1%). The infection agent was identified in 12 cases (4 Escherichia coli, 2 Staphylococcus aureus, 2 SARS-CoV, 1 Klebsiella pneumoniae, 1 varicella zoster, 1 herpes zoster and 1 candida albicans). Infections occurred in 8 patients with systemic arthritis (44.4%), 6 polyarticular arthritis (33.3%), 2 juvenile psoriatic arthritis (11.1%), one enthesitis-related arthritis, and one undifferentiated arthritis (5.6%). One patient required hospitalization, he was treated with etanercept and methotrexate for seronegative polyarticular arthritis. The risk of infectious events with IL-6 inhibitors was significantly higher compared to TNF inhibitors and IL-1 inhibitors (p=0.02). There was no statistically significant relationship between the risk of infection development and subtypes of JIA.

Conclusion:

Our study showed a high rate of infectious events in JIA patients under biologic therapy, affecting mainly the ENT system. They are more frequent in patients treated with IL-6 inhibitors.

P519

EFFECTIVENESS OF ROMOSOZUMAB ON BONE MINERAL DENSITY SURROGATE THRESHOLD EFFECT: RESULTS FROM THE ROMOSOZUMAB EARLY EXPERIENCE IN FEMALE PATIENTS WITH SEVERE OSTEOPOROSIS (ROMEO STUDY)

G. Adami[1], M. Bartezaghi[2], F. Montanari[1], F. Pollastri[1], A. Piccinelli[1], C. Benini[1], D. Gatti[1], O. Viapiana[1], R. Fornari[2], M. Rossini[1]

[1]University of Verona, Verona, Italy, [2]UCB Pharma, Milan, Italy

Background

Romosozumab (ROMO), a sclerostin inhibitor, has been approved in Italy for treating postmenopausal osteoporosis (OP) in women at high fracture risk.

Objectives

To evaluate the effectiveness of ROMO in a cohort of Italian postmenopausal women at high fracture risk.

Methods

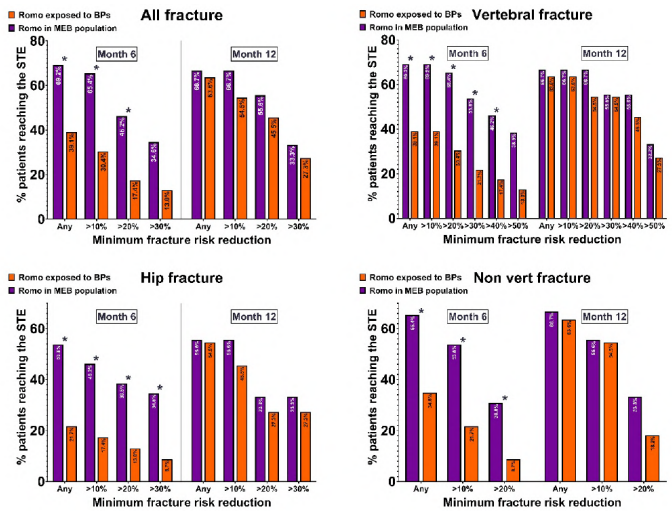
We retrospectively analyzed prospectively collected data from postmenopausal women with severe OP treated with ROMO at the Verona center. Bone mineral density (BMD) was assessed at baseline, month 6, and month 12. Bone turnover markers (BTMs) and calcium-phosphate metabolism were measured at baseline and months 3, 6, and 12. The surrogate threshold effect (STE) for BMD, defined as the change needed to predict fracture risk reduction with 95% confidence, was evaluated based on the FNIH-ASBMR SABRE Project criteria.

Results

The study included 133 postmenopausal women (mean age 72.5 ± 9.5 years). Seventy-nine patients completed 6 months of follow-up, and 39 completed 12 months. A subgroup of 91 patients had minimal prior bisphosphonate exposure (MEB). Significant BMD increases were observed at all sites at 6 and 12 months, particularly in the MEB group: femoral neck (+3.9% and +6.5%), total hip (+3.4% and +3.7%), and lumbar spine (+7.5% and +10.9%). Over 50% of patients reached the STE for fracture risk reduction by 6 months, with higher proportions in the MEB group. Among patients with baseline lumbar spine T-scores ≤-2.5, 18.2% and 32.0% reached a T-score >-2.5 at months 6 and 12, respectively. P1NP levels increased significantly at months 3 (+76.2%) and 6 (+34.6%), while CTX levels decreased (-2.6% and -26.6%). BTMs returned to normal ranges by month 12.

Conclusion

In this real-world cohort of Italian postmenopausal women at high fracture risk, over half achieved the STE for minimal fracture risk reduction, particularly those with minimal bisphosphonate exposure. Additionally, one-third reached osteopenic BMD levels after ROMO treatment.



P520

INCREASE IN SERUM DKK1 LEVELS ATTENUATES THE ANABOLIC RESPONSE TO ROMOSOZUMAB IN POSTMENOPAUSAL OSTEOPOROSIS

G. Adami[1], F. Pollastri[1], A. Fassio[1], C. Benini[1], A. Piccinelli[1], D. Gatti[1], O. Viapiana[1], M. Rossini[1]

[1]University of Verona, Verona, Italy

Background

Romosozumab exhibits strong anabolic effects in treating osteoporosis in the first 6 months of treatment, yet its efficacy diminishes beyond 6 months as bone formation markers decline. We hypothesized that increased levels of Dickkopf-1 (Dkk1), a Wnt pathway inhibitor, might contribute to this attenuation by suppressing osteoblast activity.

Methods

We did a 12-month prospective observational study on postmenopausal women with osteoporosis naive to anti-osteoporosis treatment and treated with romosozumab. Serum Dkk1, Procollagen Type I N-Terminal Propeptide (P1NP), C-terminal telopeptide of type I collagen (CTX), and sclerostin were measured at baseline (M0) and at 3 (M3), 6 (M6), and 12 months (M12). Bone mineral density (BMD) was assessed at M0, M6, and M12. Linear mixed-effects models were used to analyze associations between Dkk1 and P1NP.

Results

59 women were included. Dkk1 increased significantly from 38.9 pmol/L at baseline to 44.2 pmol/L at M12 ($p = 0.003$). P1NP increased significantly from M0 to M3 (89.4 pg/mL to 115.4 pg/mL, $p = 0.004$) before declining to 61.5 pg/mL at M12 ($p < 0.001$). CTX levels significantly decreased from 0.477 pg/mL at baseline to 0.269 pg/mL at M12 ($p < 0.001$). Sclerostin levels increased steeply from 36.3 pmol/L at baseline to over 1500 pmol/L at all time points ($p < 0.001$). BMD significantly improved across all skeletal sites. A significant association was found between Dkk1 increase and P1NP decrease between M3 and M12 (estimate -0.909, $p = 0.032$), suggesting a compensatory mechanism influencing romosozumab's effects.

Conclusions

Romosozumab improves BMD in postmenopausal osteoporosis but is associated with increased Dkk1, which may reduce its anabolic effects over time. These findings underscore the potential of dual inhibitors targeting sclerostin and Dkk1 to mitigate this limitation and enhance therapeutic outcomes.

FIRST MULTIDISCIPLINARY CLINICAL PRACTICE GUIDELINES FOR OSTEOPOROSIS IN COLOMBIA: EVIDENCE-BASED AND CONTEXT-SPECIFIC RECOMMENDATIONS

G. Altamar-Canales[1], D. Fernández-Ávila[2], M. A. González-Reyes[3], F. Linares-Restrepo[2], A. Medina-Orjuela[4], O. Rosero-Olarte[5], J. Velásquez-Mendoza[6], X. Castro-Flórez[7], E. Castro-Osorio[8], M. Chalem[9], C. Pérez-Niño[10], A. M. Sierra-Osorio[11], R. Vidal-Barragan[12], S. Martínez[13], L. Ibata[13]

[1]Family medicine deparment , Universidad del Valle, Cali, Colombia, [2]School of Medicine, Pontificia Universidad Javeriana, Bogota, Colombia, [3]Cecimin Medical Unit, Bogota, Colombia, [4]Universidad Nacional de Colombia, Bogota, Colombia, [5]Osteollanos IPS, Villavicencio, Colombia, [6]Universidad de Manizales, Manizales, Colombia, [7]Deparment of Family medicine, Universidad del Valle, Cali, Colombia, [8]SES Hospital Universidad de Caldas, Manizales, Colombia, [9]Fundación Santafé de Bogotá, Bogota, Colombia, [10]Clinical Research Department, Bogota, Colombia, [11]Deparment of endocrinology , Fundacion Universitaria Ciencias de la Salud, Bogota, Colombia, [12]Universidad del Cauca, Popayan, Colombia, [13]EpiThink Health Consulting, Bogota, Colombia

Objective: To develop Colombia's first evidence-based clinical practice guidelines (CPGs) for osteoporosis diagnosis and treatment, reflecting the country's healthcare context and resources. Material and Methods: A multidisciplinary team of endocrinologists, rheumatologists, geriatricians, family physicians, orthopedists, physiatrists, sports medicine specialists, and patient representatives developed the guidelines using GRADE methodology. Systematic reviews of the literature were conducted, and evidence was critically appraised to formulate 32 recommendations and 14 good practice points. Results: The guidelines promote early detection in primary care settings through country-specific FRAX® thresholds for fracture risk assessment in adults aged ≥50 years with risk factors. When DXA is unavailable, FRAX® intervention thresholds guide treatment decisions. Radiofrequency Echographic Multi Spectrometry (REMS), now available in Colombia, serves as an alternative diagnostic tool. Comprehensive evaluation includes TBS and vertebral fracture assessment in high-risk cases. Management recommendations embrace span lifestyle modifications, supplementation, and prescribed exercise programs. Pharmacological interventions with bisphosphonates, denosumab, or bone-forming agents are tailored to fracture risk profiles. The guidelines emphasize sequential therapy planning and systematic monitoring through DXA, imaging, and adherence assessment. Implementation through Fracture Liaison Services and orthogeriatric care models aims to enhance outcomes. Conclusions: These inaugural Colombian guidelines provide an evidence-based, nationally adapted framework for osteoporosis management. The recommendations reflect local healthcare resources while promoting standardized, high-quality care through coordinated multidisciplinary services. Disclosures: Funded by the Colombian Association of Osteoporosis and Mineral Metabolism (ACOMM). No conflicts of interest reported.

PREVALENCE AND RISK FACTORS FOR MUSCULOSKELETAL DISORDERS AMONG POSTAL SORTING CENTER EMPLOYEES

G. Ben Rejeb[1], N. Kammoun[2], S. Ernez[1], S. Haj Ali[1], H. Aoun[1], S. Fehri[1]

[1]Tunisian Occcupational Safety and Health Institute, Tunis, Tunisia, [2]Tunisian Occcupational Safety and Health Institute/ University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia

Introduction: Musculoskeletal disorders (MSDs) represent a major occupational health issue due to their high prevalence and considerable socio-economic costs. In the Tunisian context, where epidemiological data on MSDs in this sector are limited, we deemed it interesting to conduct a descriptive, cross-sectional survey among postal sorting center employees.Objective: We aimed to assess the prevalence of MSDs among workers at a Tunisian postal sorting center, and to identify the associated risk factors.Methods: A cross-sectional study was carried out on 50 employees of a postal sorting center in Tunisia, representing a participation rate of 32.8%. Data were collected using a questionnaire inspired by the Nordic questionnaire and the INRS (National Institute for Research and Safety) questionnaire for MSD screening.Results: The study conducted among 50 postal workers out of a total of 152 assigned to the Postal Sorting Center revealed a high prevalence of MSDs, affecting 80% of participants over the past 12 months. The median age of participants was 51 years [30-61]. The M/F sex ratio was 6.14, showing a clear male predominance. The median length of service was 22 years, with sorting agents being the most prevalent category (52%). Sixty-six percent of participants performed repetitive tasks, 50% regularly carried heavy loads (>30 Kg) and 38% estimated working at a

"very fast" pace. One third of postal workers reported significant stress over the past 12 months, and 24% had frequent episodes of exhaustion. Almost 30% suffered from recurrent anxiety. As for musculoskeletal disorders (MSDs), 80% of postal workers had experienced them over the past year. The most frequently affected anatomical regions were the lumbar region (56%), the cervical region (44%) and the femoro-tibial joint (40%). Upper limbs were also affected, with manifestations in wrists and hands (28%) and elbows and forearms (24%).Among them, 52% had consulted a physician for these symptoms, of whom 38% underwent medical treatment and 14% were granted medical leave.Conclusion: This study reveals an alarming prevalence of musculoskeletal disorders (MSDs) among Tunisian postal workers, underlying the urgent need for integrated prevention programs that include ergonomic, organizational and psychosocial interventions to reduce the incidence of MSDs in this sector.

P523

STRESS FRACTURE IN MALE ROYAL MARINES RECRUITS: WORKING TOWARD IDENTIFICATION OF THOSE AT HIGHEST RISK OF INJURY

G. Bevilacqua[1], L. D. Westbury[1], T. Davey[2], J. L. Fallowfield[2], K. Harrison[3], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom, [2]Institute of Naval Medicine, Alverstoke, United Kingdom, [3]Defence Statistics (Health), Ministry of Defence, Abbey Wood North, United Kingdom

Objective

Stress fractures (SF) are common among individuals engaging in intense physical activity, such as military personnel. Previous research identifies female sex as a risk factor for SFs in military settings, but SF is a significant injury burden in male recruits as well. We aimed to report the prevalence of SFs and to identify characteristics associated with fracture in male Royal Marines (RM) recruits.

Material and Methods

We studied 1,815 male RM recruits (aged 16-33 years) who started a 32-week training programme at the Commando Training Centre Royal Marines, UK, between November 2017 and March 2020. Baseline (week-1) exposures included age, weight, body mass index (BMI), waist circumference, waist-to-height ratio, smoking status, estimated maximum oxygen consumption (VO2max), and maximum counts of sit-ups, press-ups and pull-ups. Incident SFs during the training programme were determined through radiography or MRI imaging. Associations between baseline exposures and SF were examined using univariate logistic regression.

Results

The median (lower quartile, upper quartile) age at entering training was 21 (19.2, 23.3) years. Cardiorespiratory fitness levels at the start of training were high, with median VO□max of 52.2 (51.1, 54.6) mL/kg/min. Mean (SD) BMI was 24.5 (2.1) kg/m2, and 10.4% were current smokers. Most recruits (85.6%) had healthy central adiposity (waist-to-height ratio: 0.4–0.49), with none classified as high (≥0.6). 102 (5.6%) recruits sustained at least one SF, with the highest rates in those aged 16-18 years at training entry (7.2%). In univariate analyses, the highest quintiles of BMI (odds ratio 0.16, 95% CI 0.06-0.42, p<0.001), weight (0.50, 0.26-0.95, p=0.036), waist circumference (0.40, 0.19-0.83, p=0.014), and waist-to-height ratio (0.37, 0.18-0.78, p=0.009) demonstrated significantly lower odds of SF compared to respective lowest quintiles. No other associations were observed between the other exposures and incident stress fracture.

Conclusions

Stress fractures were common in Royal Marines recruits, especially those who were less skeletally mature. In this population where central adiposity was very uncommon, higher BMI appeared protective against SF risk and we hypothesise that greater BMI is likely related to reduced SF risk via greater muscle mass rather than greater adiposity. Further validation in other cohorts is planned.

P524

RISK FACTORS FOR FRACTURES IN TYPE 2 DIABETES: A RETROSPECTIVE STUDY IN AN OUTPATIENT COHORT

G. Cavati[1], F. Pirrotta[1], E. Ceccarelli[1], G. Dipasquale[1], P. Cardamone[1], D. Merlotti[1], L. Gennari[1]

[1]Department of Medicine, Surgery and Neurosciences, University of Siena, Italy, Siena, Italy

Background: Patients with type 2 diabetes (TD2) have an increased risk of fracture and common diagnostic strategies such as bone densitometry (DXA) and FRAX algorithm underestimate this risk. Recent position statements proposed the use of specific algorithms to improve fracture prediction in T2D, based on the integration of risk factors (RFs), the presence of prevalent fractures, and, where necessary, DXA and FRAX. Importantly, beside the classical RFs for fractures (i.e. age, sex, prevalent fractures), T2D duration ≥ 10 yrs, the presence of ≥ chronic T2D complications, the use of insulin or TZDs treatment, and a poor glucose control (i.e. HbA1c ≥8% for at least 1 yr) have been included in those algorithms. However, their implication in fracture risk remains to be universally confirmed.

Objectives and Methods: In this study, we assessed the predictive role of these T2D-related RFs on fracture incidence in 402 T2D patients attending the outpatient service (mean age 72±9 yrs, range 45-90) followed for 9 yrs. Subjects were followed from the baseline visit to the date of fracture event; subjects without fracture were censored at the end of follow-up.

Results: The incidence of fractures progressively increased in relation to the number of T2D-RF(no RF: 8%, 1 RF: 16%, 2RF:25%; 3RF:38%; 4RF:46%; p<0.0001) so that patients with all the 4 T2D-RF had an hazard ratio (HR) of 4.04 (95% CI, 1.3–10.68; p < .005) compared with the reference group of patients without T2D-RF. As shown in Figure 1, each of the selected T2D-RF separately contributed to fracture incidence with HRs of, respectively, 1.65 (95% CI, 1.05–2.58; p < .05), 2.49 (95% CI, 1.62–3.83; p < .001), 1.62 (95% CI, 1.07–2.43; p < .05), and 2.20 (95% CI, 1.13–4.26; p < .05) for T2D complications, uncontrolled diabetes, insulin or

TZD treatment and T2D duration ≥ 10 yrs, as compared with the reference group (no T2D-RF).
Conclusions: the use of the above-mentioned T2D-RF should be mandatory in fracture risk stratification of patients with T2D.

P526

ADHERENCE TO GUIDELINES IN THE PRESCRIPTION OF ANTI-RESORPTIVE DRUGS FOR BREAST AND PROSTATE CANCER: AN ITALIAN EXPERIENCE

G. Deinite[1], O. L. F. Ragusa[2]

[1]Rehabilitation Center Papa Giovanni XXIII, Pianezza, Italy, [2]PRM physician, Venaria Reale - TO, Italy

Introduction:
The prescribing of drugs for osteoporosis is regulated in Italy by Note 79. This Note outlines the use of the following drugs for the primary prevention of osteoporosis in women with breast cancer or men with prostate cancer treated with adjuvant hormonal blockade.
Methods:
From June 2023 to September 2024, patients belonging to the our clinics, with any access diagnosis and a history of breast or prostate cancer within the last 10 years, aged between 50 and 75, were evaluated.
Results:
150 patients (120 women and 30 men) met the inclusion criteria. Men had a mean age of 68, with an average disease duration of 6.8 years. The mean age was 64,2 years old with an average disease duration of 5.3 years. There was also a group of 25 people that went to the clinic for lymphatic drainage where they underwent treatment for lymphedema of the upper right and/or left limb 2 to 3 times per year. Out of them, 75% had undergone at least 1 densitometry in the past 5 years and, among them, at least half, especially the older ones, regularly had densitometry performed every 18 months. 65% had taken a dosage of Vit.D in the last year and were regularly treated with Cholecalciferol. In total, the women undergoing preventive treatment were 25, with a notable prevalence of the use of classic biphosphonates and a clear minority of Zoledronato (2) and Denosumab (4). Conclusion: Of the patients that potentially could have and should have had access to the treatment planned in Note 79, just a small minority, generally female, received the outlined treatment. The risk of facing bone complications increases with the patient's age at disease onset and the time passed before the beginning of the treatment. Discussion: The risks in patients that are already in difficult conditions and an increase of the costs for the problems linked to the risk of fracture from osteoporosis, but also pain associated with the progressive impoverishment of the bone structure.

P527

IS MYOSTATIN LEVEL A DETERMINANT OF FRACTURE RISK IN OSTEOSARCOPENIC PATIENTS?

G. Demir Yıldız[1], T. Emiroğlu Gedik[1], H. Peynirci[1], G. Anataca[1]

[1]Kanuni Sultan Süleyman Training and Research Hospital, İstanbul, Turkiye

Introduction and Aim: Myostatin is a molecule that has been linked to osteoporosis and sarcopenia. However, no studies investigating the relationship between myostatin and osteosarcopenia have been found in the literature. In this study, we aimed to determine the myostatin levels in osteosarcopenic patients and evaluate the relationship between myostatin levels and fracture risk assessed by FRAX.
Materials and Methods: Patients diagnosed with osteosarcopenia who admitted between October 2023 and June 2024 were included in our study. The patients were divided into two groups such as osteosarcopenic and non-osteosarcopenic individuals. Demographic data, laboratory parameters, bone mineral density (BMD) measured by DXA (Dual-energy X-ray absorptiometry), FRAX score, skeletal muscle mass index (SMI) determined by bioimpedance analysis (BIA), and myostatin levels in serum samples were examined. A myostatin cutoff value was determined. The relationship between FRAX score and myostatin levels was investigated between the two groups.
Results: Significant differences were found in terms of menopause age, education level, and monthly income. Myostatin levels were significantly higher in the osteosarcopenia group (p=0.037). Additionally, in the patient group, FRAX, SARC-F (Strength, Assistance with walking, Rise from a chair, Climb stairs, and Falls) measurements, walking speed, and sit-to-stand times were found to be significantly higher compared to the control group (p<0.001). The L1-L4 vertebra, femoral neck T-score, and handgrip strength were significantly lower in the patient group compared to the control group (p<0.001). A significant (AUC=0.636) effectiveness of the 16.72 ng/mL myostatin cutoff value was observed in distinguish-

ing the case and control groups. At this cutoff value, myostatin showed 70.7% sensitivity and 57.5% specificity. A significant correlation was found between myostatin levels and the FRAX hip and major osteoporotic fracture risk (r=0.528, p<0.001; r=0.631, p<0.001, respectively). A significant difference was found between FRAX-calculated hip fracture (HF) risk and myostatin levels in the univariate regression analysis (p=0.005).
Conclusion: Although the role of myostatin levels in the pathogenesis of osteosarcopenia has not been fully clarified, myostatin levels could be an important marker in terms of predicting diagnosis and related complications in predicting osteosarcopenia diagnosis and related complications.

P528

CHALLENGING KNEE OSTEOARTHRITIS: EFFICACY AND TOLERABILITY OF AN INNOVATIVE MEDICAL DEVICE CONTAINING A COMBINATION OF HYALURONIC ACID AND POLYPEPTIDES AS TOPICAL THERAPY

G. Doro[1], A. Colombini[2], E. Ragni[2], L. Forte[3], L. De Girolamo[2], F. Zerbinati[1]

[1]Orthopedics and Traumatology Department, Humanitas Mater Domini, Varese, Italy, [2]Laboratorio di Biotecnologie Applicate all'Ortopedia, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy, [3]Contrad Swiss SA, Lugano, Switzerland

Objective.
A new topical hydrogel (CR500®) available as a monodose vial, containing hyaluronic acid and two polypeptides, derived respectively from Fibroblast Growth Factor 9 (FGF-9) and Connective Tissue Growth Factor (CTGF), has been developed to counteract cartilage degeneration and improve symptoms in patients with non-severe knee osteoarthritis (OA). The content of the vial must be squeezed into the centre of a surgical patch and applied to the target area. The efficacy of CR500® was evaluated in a single-arm, post-market confirmatory interventional clinical trial.
Material and Methods.
A total of 38 patients with unilateral mild-moderate knee OA were enrolled. Each patient underwent a screening visit (V-1), a baseline visit (V1) and 3 follow-up visits (V2-V4) on a weekly interval, from week 2 to week 4. The primary outcome was the evaluation of the Lequesne Knee Index (LKI) after the topical knee application of CR500®, twice a week for 4 weeks. Knee injury and Osteoarthritis Outcome Score (KOOS), synovial fluid (SF) collection for cartilage-related markers quantification (C2C, CTXII, CPII, TNFα and HA) and analysis of macrophage polarization genes expression (*CD11c*/*CD206*) were also evaluated.
Results.
35 patients were included in the final analysis. The LKI total score showed a statistically significant reduction from baseline/V1 to end-of study visit/V4 by 28% (p<0.001).
The KOOS score also confirmed a significant improvement of patient condition already at V2 in comparison with baseline/V1 for all subscales (except for KOOS sport subscale which significantly improved from V3), suggesting a quick efficacy of the treatment.
A thorough SF analysis was limited by insufficient joint liquid at protocol's end. However, V1 data and KOOS pain scores suggest less pain correlates with reduced cartilage remodelling, despite a pro-inflammatory infiltrate.
Conclusions.
The treatment with CR500® showed a marked and statistically significant improvement in knee pain and function, suggesting that the device has the potential to quickly attenuate the symptomatology related to the osteoarthritic processes starting from the 2nd week of treatment (4-6 applications). Hence, CR500® resulted to be effective, safe, convenient and well tolerated.

ADVANCING TRABECULAR BONE SCORE (TBS): CLINICAL PERFORMANCE OF TBS VERSION 4.0 WITH DIRECT CORRECTION FOR SOFT TISSUE THICKNESS - THE OSTEOLAUS STUDY

G. Gatineau[1], K. Hind[2], E. Shevroja[1], E. Gonzalez-Rodriguez[1], O. Lamy[1], D. Hans[1]

[1]Interdisciplinary Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland, [2]Medimaps group SA, Plan-Les-Ouates, Switzerland

Objectives: This study aimed to compare trabecular bone score (TBS) version 4.0, which uses direct tissue thickness correction via DXA measurements, with TBS version 3, which adjusts for soft tissues using body mass index (BMI). The objective was to assess the performance of TBS v4.0 compared to v3, for bone health evaluation and fracture risk assessment across diverse body compositions.
Methods: Data from the OsteoLaus cohort were analyzed. Associations between TBS, BMI, DXA-measured tissue thickness, visceral fat (VFAT), and android fat were examined using regression and correlation analyses. Machine learning, including Random Forest (RF) and SHapley Additive exPlanations (SHAP), explored TBS changes between versions. Five-year fracture risk was assessed using FRAX adjustment, and logistic regression.
Results: TBS v3 correlated with BMI (r = 0.110, p <0 .001), VFAT mass (r = -0.162, p <0 .001) and soft tissue thickness (r=-0.165, p<0.001). TBS v4.0 demonstrated weaker correlations with BMI (r=-0.057, p>0.999), VFAT Mass (r=-0.067, p>0.779) and soft tissue thickness (r=-0.114, p=0.019). Differences between TBS versions were investigated with SHapley Additive exPlanations (SHAP) and explained by BMI, tissue thickness, VFAT, and gynoid fat. Logistic regression and Delong's test revealed no significant differences in fracture prediction between the two TBS versions (p = 0.564). FRAX adjustments were highly consistent between versions (r = 0.994, p < 0.001), with no evidence of calibration bias (p = 0.241).
Conclusion: TBS v4.0 enhances the adjustment for regional soft tissue effects and maintains comparable vertebral fracture risk

prediction to TBS v3. Explainable AI provided insights into the contributions of BMI, tissue thickness, visceral fat, and gynoid fat to the observed changes between TBS versions. Incorporating direct tissue thickness adjustment improves TBS applicability across diverse body sizes and compositions.

SURGICAL TREATMENT OF VERTEBRAL FRACTURES THROUGH KYPHOPLASTY. A CASE REPORT

G. González[1], C. Vázquez[1], R. Chiavegatti[1], C. Gómez[1], F. Dachs[1], I. Díez[1]

[1]Hospital Sagrat Cor, Barcelona, Spain

Objectives To analyze, through a clinical case, the effectiveness, outcomes, and complications associated with kyphoplasty in the treatment of vertebral fractures.

Materials and Methods A 73-year-old male patient presented with acute vertebral fractures at L2, L3, and L4 without accompanying neurological deficits. Additionally, a complementary study with Computed Tomography (CT) identified lytic lesions in the right hemipelvis, consistent with metastasis, likely related to Multiple Myeloma. After preoperative studies, the patient was deemed suitable for surgery. The surgical procedure consisted of kyphoplasty at three consecutive levels (L2, L3, L4) under general anesthesia, without intraoperative complications.

Results The patient in our case progressed favorably postoperatively, being monitored in the Intensive Care Unit and then transferred to the general ward where radiographic controls were performed, confirming the absence of complications. Postoperative pain decreased significantly, allowing for assisted ambulation and hospital discharge two days after the intervention.

Conclusions As exemplified by our case, kyphoplasty offers several advantages in the treatment of vertebral fractures, such as the restoration of vertebral height, immediate and long-term pain reduction, and functional improvement. This minimally invasive procedure carries a lower risk of complications compared to open surgery, allows for faster recovery, and enhances the patient's quality of life by reducing the disability associated with vertebral fractures.

Objective(s) We face a rising aging population, many with complex health and social needs who will live in long-term care (LTC). This is an opportunity to examine the needs of residents in LTC to preserve their health and quality of life. Yet, residents in LTC are often excluded from research, and do not receive potential treatment benefits. The objective of this analysis was to understand participation barriers facing LTC homes that were invited to participate in research.

Material and Methods Recruitment included up to four invitations to participate through an introductory telephone or email invitation sent to the Administrator and/or Director of Care of each eligible (≥70 beds) LTC home. Second and third invitations to participate were sent 2-4 weeks apart with a final invitation 6-12 weeks after the introductory invitation.

Results A total of 454 eligible LTC homes in Ontario were invited to participate. A total of 143 (31.5%) homes expressed interest in participating in the study. Of the 143 homes, 48 (33.6%) declined participation, 1 (0.7%) did not respond after expressing interest, 12 (8.4%) were ineligible, 13 (9.1%) remain interested/unscreened, 66 (46.2%) were screened, 48 (33.6%) have been enrolled, and 3 (2.1%) withdrew from the study to date. Of the 48 homes enrolled, 27 (56.2%) are for-profit and 21 (43.8%) not-for-profit. A total of 33 (68.8%) homes were not-for-profit and 15 (31.2%) were for-profit that declined participation. The main reasons for not participating included: competing priorities/proj-

ects (22 (45.8%)), insufficient or changes to staff/organizational leadership (10 (20.8%)), duplication of current practice (4 (8.3%)), unknown (5 (10.4%)), or other (7 (14.6%)).
Conclusion(s) Many LTC homes continue to face challenges post-pandemic, including new legislation, increased oversight, staffing pressures, and negative portrayals. Despite these obstacles, LTC homes have the potential to improve residents' quality of life, particularly in areas like osteoporosis management and fracture prevention, by engaging staff in research. Overcoming these barriers will require a multifaceted approach, addressing institutional challenges (e.g., legal), fostering a research culture to mitigate biases, and building partnerships between researchers and LTC homes.

P532

ROLE TERIPARATIDE VS CALCITONIN ON TRANSFORAMINAL LUMBAR INTERBODY FUSION IN LUMBAR DEGENERATIVE DISEASE PATIENTS WITH OSTEOPOROSIS

G. Kakadiya[1], P. Gadhiya[1]

[1]ASHIRWAD SPINE HOSPITAL, SURAT, India

Introduction: Osteoporosis is a progressive metabolic bone disease that is characterized by a decrease in bone mass and density. TLIF is biomechanically a better technique for the treatment of degenerative lumbar disease. Teriparatide (rPTH) is the only anabolic agent that has been approved for the treatment of osteoporosis. The study aim was to evaluate the efficacy of teriparatide for TLIF in osteoporotic women.
Methods: 94-osteoporotic patients underwent TLIF surgery for degenerative lumbar spine disease. Patients were divided into two groups. The calcitonin group (n = 48) was administered nasal calcitonin (200 IU) for 2-months. The teriparatide group (n=46) was injected subcutaneously with teriparatide (20 ug/daily) for 3-month cycles. Serial plain x-rays, computed tomography, and bone mineral densitometry (BMD) evaluations were performed. Fusion rate, bony fusion duration, and T-score changes were evaluated. VAS and ODI were evaluated.
Results: The teriparatide group showed earlier fusion than the calcitonin group. The mean bone fusion period was 5.8±4.7 months in the teriparatide group but 9.4±5.2 months in the calcitonin group. The bone fusion rate in the teriparatide group was higher than that in the calcitonin group at 5-months; however, there was no difference after 12 and 24 months surgery. Pain scores and ODI were not significantly different between groups. BMD scores in the teriparatide group were significantly improved compared with the calcitonin group 2 years after surgery.
Conclusions: There was no significant improvement in overall fusion rate and clinical outcome in our patients after injection of teriparatide, but the teriparatide group showed early bony union and highly improved BMD scores.

P533

EFFECTIVENESS OF VERTEBROPLASTY WITH SHORT SEGMENT FIXATION VERSUS LONG FIXATION IN OSTEOPOROTIC VERTEBRAL FRACTURE

G. Kakadiya[1], P. Gadhiya[1]

[1]ASHIRWAD SPINE HOSPITAL, SURAT, India

Introduction: The thoracolumbar region is susceptible to injury because of its location between the stiff thoracic kyphotic and mobile lumbar lordotic. The OVCFs can lead to delayed union or non-union and lead to progressive collapse that can result in kyphosis with the possibility of neurological deficit. There is controversy regarding the ideal treatment for OVCFs. The study aim was to compare the safety and efficacy of vertebroplasty with short-segmented cement-augmented pedicle screws fixation and long-segment fixation for osteoporotic vertebral compression fractures (OVCF) in elderly patients.
Methods: A retrospective study of 182 single-level OVCF. 88 patients were treated by vertebroplasty and short-segment PMMA cement augmented pedicle screws fixation, and 94 patients were operated with long-segment posterior fixation. Local Kyphosis angle, vertebral height, VAS, ODI and neurological state were compared and analysed.
Results: 48.35% patients had short segment and 51.65% had long segment Spine fixation. Significant improvement was noted in VAS, ODI and neurological status in both groups. Mean kyphosis angle was corrected significantly from 19.08±4.9° preoperative to 6.49±2.59° immediate post-operative, and 8.62±2.60° at one year follow-up in short segment group In long segment group mean kyphosis was also corrected significantly from 23.20° ± 5.90° to 5.30°±3.9°immediate postop, and 8.60° ± 4.60° at one year follow-up. Anterior vertebral height was restored from 56.10±8.9 % to 85.9±11.2% postoperative in short segment group. In long-segment, it was restored from 55.80±11.9 to 87.6±13.1. Four case of cement leakage in short-segment group. In short-segment group, one patients had proximal junction failure, two had implant failure and it was four and six in long-segment group respectively.
Conclusions:
Both Short-segment and long-segment fixation can restore local kyphosis for osteoporotic vertebral fracture with lower complication and faster pain relief. A short-segment stabilization has faster relief of pain, lesser tissue destruction, minimise blood loss, shorter surgical duration with less stress risers at the junctional area.

P534

COMPUTED TOMOGRAPHY SCANS AS AN OPPORTUNISTIC SCREENING FOR OSTEOPOROSIS AND ITS COMPARISON WITH DEXA SCAN

G. Kakadiya[1], P. Gadhiya[1]

[1]ASHIRWAD SPINE HOSPITAL, SURAT, India

Introduction: Osteoporosis is a prevalent condition leading to an increased risk of bone fractures. Osteoporosis poses a worldwide public health concern, impacting over 200 million individuals and resulting in a staggering 1.66 million hip fractures each year. Opportunistic osteoporosis screening can be employed during CT scans to assess bone mineral density (BMD) through Hounsfield units (HU) without the need for additional imaging, radiation exposure, or appointments. This study aimed to investigate a CT scan's diagnostic value in the opportunistic osteoporosis screening through L1 vertebra densitometry and compare it with dual energy x-ray absorptiometry (DEXA) findings.
Methods: The cross-sectional study. A 298 patients with an average age of 67.71 ± 10.92 years were included in the study. An individual who underwent densitometry using the DEXA method between 2022 and 2023 and subsequently received CT scans within a 90-day window before or after were identified and had their radiology records reviewed. Individuals were categorized into three groups based on the T-score obtained through the DEXA method.
Results: The age of osteoporotic patients was significantly higher than osteopenia ($p = 0.001$) and normal individuals ($p < 0.001$). The HU of osteoporotic patients was found to be significantly lower compared to both osteopenia ($p = 0.023$) and normal individuals ($p < 0.001$). According to the ROC curve for osteoporosis prediction using the HU (AUC = 0.793 and $p < 0.001$), with a cut-off of 103 HU, the CT scan had a sensitivity of 69% and a specificity of 74% for the diagnosis of osteoporosis.
Conclusion: Individuals with osteoporosis exhibit a significantly lower average HU compared to both osteopenia and healthy individuals. A CT scan can serve as an effective predictor of osteoporosis in patients. The CT images obtained for reasons unrelated to osteoporosis diagnosis can be employed to discern patients with osteoporosis without incurring the added cost or radiation exposure.

P535

BONE MINERAL DENSITY AND TRIGLYCERIDES

G. Kavaja[1], B. Kavaja[2], D. Gjeliani[1]

[1]Durres Regional Hospital, Durres, Albania, [2]Faculty of Medicine, Tirane, Albania

Objective: Osteoporosis, a condition characterized by the weakening of bones and increased fracture risk, presents a significant public health concern, particularly among the aging population. This disorder results from various factors, including hormonal changes, nutritional deficiencies, and lifestyle choices. Elevated triglyceride levels have been associated with an increased risk of osteoporosis, prompting investigations into the underlying mechanisms by which lipid metabolism may influence bone density and strength. Understanding this relationship is crucial, as it could lead to novel preventive and therapeutic strategies for individuals at risk.
Methods: The study included 225 patients who presented to the rheumatology clinic with complaints of degenerative joint pathology who had alterations in calcium and vitamin D levels. These patients were with no pathology or treatment that could affect bone or lipid metabolism. These patients were evaluated for serum lipid profile (in particular triglycerides values) and osteoporosis. Lumbar region, femoral neck and total hip BMD were measured by DXA; osteoporosis was defined as Tscore ≤ -2.5. Multivariable logistic regression models were used to test the associations of TG with osteoporosis.
Results: From 225 patients included, 71.8% of them were female. The mean age of patients was 66.4 years (SD = 7.6 years). The prevalence of osteoporosis was 11.2% in men and 42.1% in postmenopausal women. Each standard deviation (SD) increase in TG (OR: 1.74; 95 % CI: 1.28 – 2.48) was associated with increased risk of osteoporosis.
Conclusions: These results indicate that levels of TG were correlated with the risk of osteoporosis.

P536

BONE MANIFESTATIONS IN SYSTEMIC MASTOCYTOSIS: CASE REPORTS OF ARGENTINIAN PATIENTS

M. C. Pereyra[1], L. Cuello[2], C. A. Martinez[3], A. E. Aberastain[2], J. M. López[2], M. Echegoyen[2], G. Maspero[1], E. Cohen[1], D. Sirolli[3], J. M. Farias[3], G. Kluwak[4], O. D. Messina[5]

[1]Clínica Universitaria Reina Fabiola, Cordoba, Argentina, [2]Hospital El Carmen, OSEP, Mendoza, Argentina, [3]Sanatorio Güemes, Buenos Aires, Argentina, [4]COT- Centro de Ortopedia y Traumatología, Rosario, Argentina, [5]IRO Medical Center, Buenos Aires, Argentina

Introduction: systemic mastocytosis (SM) is defined by the pathological proliferation and activation of mast cells. At the bone level, it can manifest as osteoporosis, osteosclerosis, or mixed focal lesions. The release of cytokines and inflammatory mediators promotes increased bone remodeling, typically characterized by a predominance of resorption over formation, leading to significant bone loss, osteoporosis and vertebral fractures.
Objective: emphasize the importance of bone involvement in SM through the presentation of three clinical cases.
Case 1. A 25-year-old male debuted with skin lesions. At 29 years, DXA L1-L4 showed a Z-score of -3.5 and triptase levels of 30 ng/ml. Bone marrow biopsy (BMB) confirmed a diagnosis of well-differentiated SM associated with low bone mass. He began daily imatinib and 4 mg zolendronic acid (ZOL) every 60 days, resulting in improved bone mass and no new fractures.
Case 2. A 30-year-old male with skin lesions and no gastrointestinal symptoms. At 42 years, develops bone pain and an atraumatic L2 fracture. At 44 years, DXA reveals low bone mass and L3 fracture. At 46 years, bone pain increases, and he suffers multiple

acute vertebral fractures (D1, D4, D8-D10, D12, L4, L5). Triptase level is 65 ng/ml. BMB confirms aggressive SM with cKit D816V+. Treatment with 4 mg ZOL/month for 12 months and midostaurin is initiated.

Case 3. A 40-year-old male presents an acute atraumatic L3 fracture, associated with a 10 kg weight loss, anemia, and an ESR of 92, with 5 months of evolution. Diagnosed with SM with bone involvement. Lytic lesions are observed in the axial and appendicular skeleton, along with splenomegaly. BMB reveals aggressive SM with cKit+. Treatment with cladribine is initiated, later switched to midostaurin due to disease progression. The patient develops sepsis and finally died.

Conclusions: Bone involvement is present at the time of diagnosis in 28-34% of cases and in 90% throughout the course of SM. These lesions, whether focal or diffuse, can be lytic, sclerotic, or mixed. Three cases of advanced SM in young adult males with severe bone involvement are presented, highlighting its impact on prognosis and quality of life for the patients.

P537

OLDER NASA ASTRONAUTS HAVE ELEVATED CORONARY ARTERY CALCIUM

G. L. Klein[1], D. C. Jupiter[2]

[1]University of Texas Medical Branch/Department of Orthopaedic Surgery and Rehabilitation, Galveston, United States, [2]University of Texas Medical Branch/Department of Orthopaedic Surgery and Rehabilitation/Department of Biostatistics and Data Science, Galveston, United States

Objective: Older adults retain calcium and phosphate in the circulation (1,2), although the age at which this occurs is not determined. Since astronauts are known to lose bone during space flight, we asked if older astronauts are more prone to develop higher coronary artery calcium (CAC) scores and if these could be related to bone loss due to microgravity.

Method: We obtained from the National Aeronautics and Space Administration (NASA) a de-identified dataset on all NASA astronauts who flew missions to the International Space Station (ISS). Data included CAC Agatston scores from chest computed tomography at approximately 5 yr intervals, with an ISS space mission at some time within the interval but not individually disclosed in the de-identified data. The dataset also included changes in bone mineral density (BMD) of total hip, femoral neck and lumbar spine within 1 yr of space mission (pre-flight) and at 10d and 1 yr post-flight. Statistical analyses included unpaired and paired t-tests, Shapiro-Wilk normality of data distribution, non-parametric Spearman correlation coefficients, and inter-quartile distribution as appropriate.

Results: 52 astronauts spent a mean of 6 months in the ISS. CAC scores rose in 19 of the 52 (36.5%). These astronauts were significantly older than the remaining 33, 50.2 +/- 1yr vs 45.4 +/- 5yr, p=0.0057. CAC scores rose a median of 30 Agatston units in the older group. From ages 40-49 to 50-59, CAC rises a mean of 5.6 units/yr in people without cardiovascular disease (3). 7 of the 19 (37%) older astronauts had CAC rises from 6.8-21.3 units/yr. The rise in post-flight CAC did not correlate with the degree of bone loss.

Conclusions: Due to disparate sampling times, we could not correlate changes in CAC and bone density. However, the 37% CAC rise in older astronauts sparks concern about the risks of developing cardiovascular disease during prolonged space missions.

WHICH THRESHOLD VALUES OF CROSSLAPS TO TARGET TO PREVENT BONE LOSS AT 1 AND 2 YEARS AFTER DENOSUMAB DISCONTINUATION. THE REOLAUS STUDY

G. Liebich[1], E. Gonzalez-Rodriguez[2], O. Lamy[3]

[1]Faculty of Biology and Medicine, University of Lausanne and Service of Internal Medicine, Lausanne University Hospital, Lausanne, Switzerland, [2]Interdisciplinary Center for Bone Diseases, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland, [3]Interdisciplinary Center for Bone Diseases and Service of Internal Medicine, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland

Objective

After denosumab discontinuation (DD) elevated serum crosslaps (sCTX) is associated to bone mineral density (BMD) loss over a two-year period. Bisphosphonates reduce this rebound effect, especially if sCTX remain low. The objective was to define an sCTX threshold below which BMD gained on denosumab is maintained.

Material and Methods

Postmenopausal women receiving ≥2 consecutive denosumab doses and followed ≥2 years after DD with regular BMD and several sCTX measurements were included retrospectively. Lumbar spine (LS) T-score loss ≥0.2 SD defined the losers group. Linear regression analysis and ROC curves were performed to define sCTX threshold (in %ULN, upper limit of the norm; 573ng/l in our laboratory) preventing 1- and 2-year LS BMD loss.

Results

161 women received 8.0±2.9 injections; 50% were defined as losers 2 years after DD. Losers received more denosumab injections (9.0±2.8 versus 7.3±2.9, p=0.002). BMD at DD were similar at all sites in stable and losers groups. LS T-score decreased in losers after 1 (-0.38±0.40 versus -0.09±0.36 SD, p<0.001), and 2 years (-0.49±0.31 versus +0.09±0.25 SD, p<0.001). After 2 years, losers had lower LS T-score (-2.26±1.30 versus -1.75±1.10 SD, p=0.025). Two years after DD, BMD loss was highly correlated with sCTX increase during the first and during the two years on linear regression models (p<0.001). The best sCTX threshold sensitivity-specificity relationship to avoid LS BMD loss at 1 year and over 2 years was 69.3 (397.1ng/l) and 63.8 (365.6ng/l) %ULN, respectively; 32.2 (184.5ng/l) and 35.5 (203.4ng/l) %ULN respectively for a 100% sensitivity (ROC AUC 0.686 and 0.678). sCTX threshold during the first year to avoid LS BMD loss at 2 years was 49.1

(281.3ng/L) and 22.5 (128.9ng/L) %ULN for a 100% sensitivity (ROC AUC 0.674). More patients received ≥3 zoledronate infusions in the losers group (28% vs 7%, p=0.006).

Conclusions

sCTX level during the first year after DD predict 1- and 2-year BMD loss at LS. Strategy to maintain low sCTX level during this first year and regular sCTX monitoring are needed to avoid BMD loss. Maintaining sCTX below 49.1 %ULN during the first year prevent LS BMD loss at 2 years. Shorter denosumab treatments are encouraged. Despite high doses of bisphosphonates, it is not always possible to reach this target.

P539

IMPACT OF VITAMIN D DEFICIENCY ON MORTALITY IN PATIENTS WITH HIP FRACTURE: A META-ANALYSIS

R. Llombart-Blanco[1], G. Mariscal[2], C. Barrios[2], R. Llombart-Ais[2]

[1]Orthopedic Surgery Department, University Clinic of Navarra, Pamplona, Spain, [2]Institute for Research on Musculoskeletal Disorders, School of Medicine, Valencia Catholic University, Valencia, Spain

Objective: To assess the impact of different levels of vitamin D deficiency on mortality in patients with hip fractures and examine the influence of potential confounding factors.

Material and Methods: A systematic search of PubMed, EMBASE, Scopus, and Cochrane Collaboration Library was conducted, resulting in nine eligible cohort studies (n=4409). Patients with hip fractures were categorized based on their vitamin D levels as severe, moderate, or insufficient. Mortality was the primary outcome measure in this study. Subgroup analyses were performed according to the follow-up time. Odds ratios (OR) with 95% confidence intervals (CI) were calculated using a random-effects model in Review Manager 5.4.

Results: Nine studies, with a pool of 4,409 patients, were included. Vitamin D insufficiency was significantly associated with increased mortality (OR 1.24, 95% CI 1.05 to 1.46; I2 = 4%). Severe deficiency also led to a significant increase in mortality (OR 2.08, 95% CI 1.09 to 3.97; I2 = 42%), while moderate deficiency did not show a significant effect (OR 1.06, 95% CI 0.79 to 1.44; I2 = 0%). Subgroup analysis revealed significant associations between vitamin D insufficiency and increased mortality at one-year (OR 1.37, 95% CI 1.06 to 1.77) and two-year follow-up (OR 1.78, 95% CI 1.01 to 3.15). After adjusting for potential confounders, no significant increase in the mortality rate was observed.

Conclusion: This meta-analysis suggests that vitamin D insufficiency and severe deficiency are associated with increased mortality in patients with hip fracture. However, after adjusting for confounding factors, this association was not statistically significant. Further research is necessary to understand the role of vitamin D deficiency in this population.

P540

DOES VITAMIN D DEFICIENCY AFFECT FUNCTIONAL OUTCOMES IN HIP FRACTURE PATIENTS? A META-ANALYSIS OF COHORT STUDIES

R. Llombart-Blanco[1], G. Mariscal[2], C. Barrios[2], R. Llombart-Ais[2]

[1]Orthopedic Surgery Department, University Clinic of Navarra, Pamplona, Spain, [2]Institute for Research on Musculoskeletal Disorders, School of Medicine, Valencia Catholic University, Valencia, Spain

Objective: This study aimed to conduct a meta-analysis to quantify the effects of vitamin D deficiency on physical function and quality of life after hip fractures.

Methods: The PubMed, EMBASE, Scopus, and Cochrane Library databases were searched for relevant studies. The inclusion criteria were hip fracture, comparison between vitamin D deficiency and normal vitamin D levels in patients with hip fracture, and functional outcome as the primary outcome. The exclusion criteria were case reports, reviews, duplicates, studies with a high risk of bias, and non-comparable or missing data. Two independent reviewers selected studies, extracted data, assessed bias, and performed meta-analyses using the Review Manager. Heterogeneity and publication bias were also assessed. Two independent reviewers selected the studies, extracted data, and assessed the risk of bias. We performed a meta-analysis using Review Manager and assessed heterogeneity and publication bias.

Results: Seven studies with 1,972 patients were included. Vitamin D deficiency was defined as a 25(OH)D level <20 ng/mL. There were no significant differences in the ability to walk (OR 0.68, 95% CI 0.31-1.53, I2=69%) or length of hospital stay (MD 2.27 days, 95% CI -2.47 to 7.01, I2=93%) between patients with and without vitamin D deficiency. However, patients with vitamin D deficiency had significantly worse functional ability and quality of life (SMD -1.50, 95% CI -2.88 to -0.12, I2=96%).

Conclusions: Despite the limitations of this study, such as small sample size, heterogeneous outcome assessments, and variable vitamin D measurement techniques, the results demonstrated that screening for vitamin D status and optimizing levels through supplementation could facilitate rehabilitation, promote lifestyle changes, aid in the recovery of independence, and help reduce long-term burdens.

P541

SURVIVAL IMPACT OF PATHOLOGICAL FRACTURES IN METASTATIC CANCER: A COMPREHENSIVE META-ANALYSIS

J. M. Lamo-Espinosa[1], G. Mariscal[2], J. Gómez-Álvarez[3], M. San-Julián[3]

[1]Vithas 9 de Octubre Hospital. Tumor and Hip Surgery Unit, Valencia, Spain, [2]Institute for Research on Musculoskeletal Disorders, School of Medicine, Valencia Catholic University, Valencia, Spain, [3]Hip, Tumors and Pediatric Orthopedic Unit, University Clinic of Navarra, Navarra, Spain

Objective: The aim of this study was to evaluate the survival of metastatic cancer patients with pathological fractures (PF).
Material and Methods: This study adhered to PRISMA guidelines and employed the PICOS strategy for inclusion criteria. A comprehensive search was conducted across multiple databases. The primary focus was on survival outcomes. Statistical analysis employed Review Manager 5.4.1, calculating mean differences for continuous variables and generic inverse variances for hazard ratios. Heterogeneity was assessed using Chi2 and I2 tests.
Results: A total of seven studies with 14,011 patients were included. Unadjusted hazard ratios (HRs) showed that PF increased the risk of mortality1.31 (95% CI 1.08 to 1.57). Adjusted HRs confirmed significant increase in mortality risk for PF HR 1.31 (95% CI 1.08 to 1.57). The PF group had significant lower mean survival (MD -14.50, 95% CI -22.95 to -6.05). PF increased mortality risk in studies including solid tumors overall (HR 1.32, 95% CI 1.12 to 1.56) and in leiomyosarcoma (HR 5.40, 95% CI 1.80 to 16.2).
Conclusion: PF increases the mortality risk and reduces the mean survival of patients with metastatic cancer.

P542

INCIDENCE OF VITAMIN D DEFICIENCY IN ADOLESCENT IDIOPATHIC SCOLIOSIS: A META-ANALYSIS

C. I. Llopis-Ibor[1], G. Mariscal[1], J. E. De la Rubia Ortı[1], C. Barrios[1]

[1]Institute for Research on Musculoskeletal Disorders, School of Medicine, Valencia Catholic University, Valencia, Spain

Objective: This study aimed to investigate the incidence of vitamin D deficiency in patients with adolescent idiopathic scoliosis through a meta-analysis and to analyze trends and risk factors.
Material and Methods: Potentially relevant studies were searched using the terms "Vitamin D AND scoliosis." Data on the incidence and risk factors, such as race, curve magnitude, and sex, were extracted from the selected studies. Review Manager 5.4 software was used for data analysis. Six studies with a total of 1,428 patients met the inclusion criteria.
Results: The incidence of vitamin D insufficiency in patients with idiopathic scoliosis was 36.19% (95% CI [21.93 to 50.46]). In contrast, the incidence of vitamin D deficiency was 41.43% (95% CI [16.62 to 66.23]). Vitamin D levels were compared between Caucasian and African patients, and it was concluded that Caucasian patients had a lower risk of vitamin D deficiency (RR 0.15, 95% CI [0.03 to 0.82]; P = 0.03). There was also an association between patients with idiopathic scoliosis and lower vitamin D levels (-5.58, 95% CI [-7.10, -4.06]). Finally, no significant differences were observed in terms of curve magnitude assessed with the Cobb angle (mean difference [MD] 4.45, 95% CI [-0.55, 9.44]) or sex with lower-than-normal levels of vitamin D (OR 0.96, 95% CI [0.58 to 1.60]).
Conclusion: The incidence rates of vitamin D insufficiency and deficiency in patients with adolescent idiopathic scoliosis were 36.19% and 41.43%, respectively. The Caucasian race was associated with a lower risk of vitamin D deficiency compared to the African race. Vitamin D deficiency was not related to curve magnitude or sex.

RADIOLOGICAL FEATURES OF VERTEBRAL FRACTURES IN MAJOR BETA-THALASSEMIA: IMPACT ON BONE INTEGRITY AND SPINAL INSTABILITY

G. Muscatella[1], M. Montatore[1], F. Masino[1], B. Balbino[1], A. Sciacqua[1], R. Gifuni[1], G. Guglielmi[1]

[1]University of Foggia, Foggia, Italy

Purpose or Learning Objective
The objective of this study is to explore the radiological behavior of vertebral fractures in patients with major beta-thalassemia, focusing on the impact of the disease on bone integrity and the resulting spinal instability. The study aims to highlight how thalassemia affects bone quality, fracture healing, and the clinical implications for vertebral fractures, particularly in the context of reduced bone density and structural abnormalities.
Methods or Background
Beta-thalassemia major is a genetic hematological disorder characterized by defective hemoglobin production, leading to chronic anemia and compensatory mechanisms such as increased bone marrow activity. Over time, this can result in significant skeletal abnormalities, including reduced bone density, trabecular bone loss, and bone fragility. Imaging modalities such as MRI and CT are essential for assessing the effects of thalassemia on bone architecture and the response to fractures. These imaging techniques offer detailed views of bone density, fracture patterns, and instability, which are critical in understanding how the disease affects bone metabolism and fracture risk.
Results or Findings
Radiological findings in patients with major beta-thalassemia typically show reduced bone mineral density and altered trabecular structure, making the vertebrae more prone to fractures, even under low-impact trauma. MRI and CT scans often reveal vertebral fractures with significant instability, deformity, and displacement. In addition, the affected bones may show evidence of cortical thinning and irregularity, which further compromises their structural integrity. Despite the bone fragility, soft tissue involvement

is usually minimal, and nerve compression is uncommon.

Conclusion

In patients with major beta-thalassemia, the combination of low bone mineral density, altered trabecular architecture, and reduced bone healing capacity leads to an increased risk of vertebral fractures with spinal instability. Radiological imaging plays a crucial role in the early detection and management of these fractures. The findings suggest that thalassemia-induced bone changes require careful consideration in treatment planning, emphasizing the need for bone-strengthening therapies and careful monitoring to prevent further skeletal complications.

Limitations

No limitations were identified

Onlus), Florence, Italy, [2]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy, [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy

Objectives: The endocannabinoid system (ES) has recently been recognized to be present in bone, playing a role in bone remodeling processes. The principal aim of this study was to investigate and demonstrate not only how the ES is involved in the osteoblastogenesis process but also to investigate how phytocannabinoids contained in Cannabis sativa could influence this process. **Materials and Methods:** Our experiments were conducted on a pool of four mesenchymal stem cell lines derived from adipose tissue, signed as PA Mix. To study the effects/role of ES on the osteoblastogenesis we have evaluated the in vitro effects of a range (i.e., 1nM-10nM-100nM-1μM-10μM) of anandamide (AEA), the principal endocannabinoid, of two phytocannabinoids (i.e., cannabidiol (CBD) and cannabigerol (CBG)) on osteogenic differentiation. Through TaqMan technology we have evaluated the expression levels of the osteogenic markers genes during osteogenic differentiation. Alkaline phosphatase (ALP) activity and hydroxyapatite (HA) deposits were evaluated through fluorometric and cytochemical assays. **Results:** AEA, CBD and CBG showed to induce a significant increase in ALP activity as well as an equal increase in the production of HA deposits during in vitro osteogenic differentiation of PA Mix line. Gene expression analyses revealed that AEA, CBD and CBG induced an early increase in the expression levels of osteogenic markers genes, too. Studies regarding the modulation of the components of the ES during the osteogenic differentiation process are now ongoing. **Conclusions:** Thanks to the established bioassay of PA Mix our findings indicate that the ES is really involved in the osteoblastogenesis and that can enhance this process. Our preliminary results seem really demonstrate that phytocannabinoids contained in Cannabis sativa could be really represent a future treatment of the bone loss and a treatment of all those pathologies which are characterized by an altered bone mineralization process. **Acknowledgements:** Supported by Fondazione Ente Cassa di Risparmio di Firenze

PHYTOCANNABINOIDS AND THE ENDOCANNABINOID SYSTEM IN THE TREATMENT OF OSTEOSARCOMA

G. Palmini[1], F. Giusti[2], S. Donati[2], F. Marini[1], I. Falsetti[2], C. Aurilia[2], G. Galli[2], R. Zonefrati[1], L. Margheriti[3], T. Iantomasi[2], A. Franchi[4], A. Moro[3], M. L. Brandi[1]

[1]Fondazione Italiana Ricerca sulle Malattie dell' Osso (F.I.R.M.O. Onlus), Florence, Italy, [2]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy, [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy, [4]Department of Translational Research and of New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Objectives: Several studies have recently shown that the endocannabinoid system (ES) plays an important role in neoplastic progression by promoting apoptosis and inhibiting cell proliferation in several tumors, among which we find primary bone tumors such as osteosarcoma. A bone tumor for which to date, despite multidisciplinary treatment, the survival rate five years after diagnosis is still very low. In light of the above, the development of specific in vitro bioassay for studying the role of ES in the physiology of osteosarcoma represents an important starting point both for understanding the role of ES in osteosarcoma progression and for understanding the effects of phytocannabinoids contained in Cannabis sativa on osteosarcoma progression. **Materials and Methods:** First, we have established a primary cell line from conventional osteosarcoma, from small cell osteosarcoma, and from telangiectatic osteosarcoma, respectively. All the cell lines have been established from bioptic samples collected at the "Unit Ortopedia Oncologica and Ricostruttiva", AOUC Careggi, Florence, previous signed informed consent approved by the local Ethical Committee. Through Taqman technology, we have evaluated the expression levels of the components of the ES in each established cell line. After, we have evaluated the effects of anandamide (AEA), the principle endocannabinoid, and of cannabidiol (CBD) on the proliferative activity of all the established cell lines. **Results:** The presence of the ES has been confirmed in all the established cell lines. The data obtained showed also that AEA and CBD are both able to reduce the proliferation rate of all tested cell lines. Studies regarding the possible role of AEA and of CBD on the metastatic potential of these three types of osteosarcoma are now ongoing.

Conclusions: Thanks to these established bioassays, one for each type of high-grade osteosarcoma, we confirmed, for the first time, the presence of the ES in osteosarcoma. We have also demonstrated for the first time a possible antineoplastic role of phytocannabinoids in high grade osteosarcoma progression, paving the way to find in phytocannabinoids new molecules to develop new therapeutic treatments based on the use of Cannabis sativa against osteosarcoma.

P546

ROUTINE HOME CARE DATA AS A TOOL FOR OSTEOARTHRITIS RESEARCH: ASSESSING FUNCTIONAL DECLINE, COMORBIDITIES AND MEDICATION PATTERNS

G. Prando[1], T. Heger[1], N. Windle[1]

[1]Cera Care, London, United Kingdom

Objective
The study aims to investigate if data collected via professional carers in a home care setting for service users with osteoarthritis match clinical experience, thus providing a set of frequently collected patient reported outcomes from elderly people.
Material and Methods
A retrospective analysis was conducted on data from digital care plans for 1196 osteoarthritic service users and a control group of 54764 service users. Care plans, compiled by professional carers with inputs from service users, are reviewed twice per year and contain demographics, comorbidities, medication regimens, and assessments of daily living activities (ADLs). For the study, the widely used WOMAC index was approximated by translating assessments of ADLs into an equivalent WOMAC score.
Results
Most of the study population was over 65 y.o.: 91% in the osteoarthritis cohort and 85% in the control group. 71% of osteoarthritic service users were women, only 37% in the control group.
Hypertension (35%), diabetes (26%) and chronic kidney disease (20%) were the most prevalent comorbidities observed with osteoarthritis.
The medication analysis showed that paracetamol, ibuprofen, aspirin and codeine were respectively prescribed for 20%, 5%, 6%, 3% of the osteoarthritis cohort and to less than 0.5% of the control group.
The approximate WOMAC score included 10 of the original WOMAC sections (see Table 1). 96% of the osteoarthritis cohort scored a total estimated WOMAC greater than 0, indicative of functional limitations, compared to 27% of the control group. Longitudinal analysis showed an increased approximate WOMAC score over time for 9% of the osteoarthritis cohort, compared to 5% in the control group.
Conclusion
The study demonstrates the feasibility of using real world data collected in a home care setting to investigate osteoarthritis in the elderly population. The findings, which align with established clinical knowledge, support the use of this approach to assess patient outcomes and disease progression, both in retrospective and prospective studies.

Table 1

WOMAC section	% of subjects with score > 0	
	Osteoarthritis cohort	Control group
Stiffness	17	7
Localised pain	23	8
Rising from sitting	13	8
Walking	41	26
Lying/rising from bed	24	16
Standing	34	22
In/out of bath	26	16
On/off toilet	20	13
Descending/ ascending stairs	12	7
In/out of car	5	2

THE ASSOCIATION BETWEEN GUT MICROBIOTA AND SARCOPENIA AMONG THE ELDERLY: BIRJAND LONGITUDINAL AGING STUDY (BLAS)

G. Shafiee[1], H. S. Ejtahed[2], F. Ramezani[2], S. Najafi[1], F. Ettehad Marvasti[3], F. Sharifi[4], R. Heshmat[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran, [2]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran, [4]Elderly Health Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Background: Sarcopenia, a condition marked by age-related loss of muscle mass, strength, and physical ability, is a growing public health issue. It's linked to higher rates of illness and death, making it a significant concern, especially for older adults. Recent studies suggest that the gut microbiome might influence muscle health through what's known as the gut-muscle axis. This study explores the connection between gut bacteria and sarcopenia in older adults participating in the Birjand Longitudinal Aging Study (BLAS).
Methods: The study included 293 participants aged 60 and older from the BLAS cohort. Sarcopenia was diagnosed using the Asian Working Group for Sarcopenia (AWGS) 2019 criteria, which take into account muscle mass, handgrip strength, and walking speed. The researchers analyzed the composition of gut bacteria by sequencing the 16S rRNA gene from stool samples. They used

statistical models to examine the relationship between specific types of gut bacteria and sarcopenia, while adjusting for factors like age, diet, and overall health.
Results: Sarcopenia was found in 38.2% of the participants. Two types of bacteria, *Akkermansia* and *Lactobacillus*, were linked to a higher risk of sarcopenia. For every increase in their levels, the odds of having sarcopenia went up by 7% and 8%, respectively. On the other hand, *Roseburia* was associated with a lower risk of sarcopenia, with each increase in its levels reducing the odds by 11.5%. *Akkermansia* was also linked to lower muscle mass, weaker handgrip strength, and slower walking speed. In contrast, higher levels of *Roseburia* were tied to better physical performance.
Conclusion: This study suggests that gut bacteria may play a role in sarcopenia, with specific types like *Akkermansia*, *Lactobacillus*, and *Roseburia* showing strong connections to muscle health. These findings open up the possibility of using gut microbiome-targeted treatments, such as probiotics or prebiotics, to help prevent or reduce sarcopenia in older adults. However, more research is needed to confirm these links and explore how these treatments might work in practice.

THE EFFECT OF WHOLE-BODY VIBRATION ON MUSCLE PARAMETERS, BIOMECHANICAL AND METABOLIC FACTORS IN DIABETIC SARCOPENIA: STUDY PROTOCOL OF A RANDOMIZED CONTROLLED CLINICAL TRIAL

M. Ababaf Behbahani[1], G. Shafiee[2], S. Boozari[1], F. Bahrpeyma[1], M. R. Mohajeri-Tehrani[3], R. Heshmat[2]

[1]Department of Physiotherapy, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, Tehran, Iran, [2]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran

Background: Sarcopenia, characterized by a reduction in muscle mass and strength, can coexist with type Ⅱ diabetes, diabetic sarcopenia, leading to exacerbated muscle degeneration and blood factors dysfunction. Whole Body Vibration (WBV) as a physical therapy intervention has emerged as a promising intervention with potential benefits in muscle strength, balance, and blood factors. This study aims to evaluate the effects of WBV on muscle parameters, biomechanical and metabolic factors in older adults with diabetic sarcopenia through a randomized controlled trial protocol.
Methods: This study is a randomized controlled trial will enroll 60 individuals with diabetic sarcopenia. Participants will be randomly assigned to a WBV intervention group or a control group. The WBV group will undergo 36 treatment sessions over 12 weeks. While the control group will be recommended to receive standard care. Primary Outcomes include muscle mass and strength, biomechanical parameters, physical function, inflammatory biomarkers, and quality of life.
Results: Data will be collected and analyzed at baseline and post-intervention. A paired samples t -test will be used to compare within-group differences. An ANCOVA will be used to compare between-group differences. A two-sided P <0.05 will be considered statistically significant.
Conclusions: This trial will provide comprehensive data on the efficacy of WBV in managing diabetic sarcopenia, potentially offering a viable and practical intervention to improve muscle mass, muscle strength, and metabolic health, biomechanic parameters in walking and balance in this vulnerable population.

P549

MUSCULOSKELETAL DISORDERS IN THE TREATMENT OF OBESITY: A NARRATIVE REVIEW

G. Shafiee[1], R. Heshmat[1], S. Maleki Birjandi[1], A. R. Heshmat[1], M. P. Maleki Birjandi[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran

Obesity is a chronic condition that often comes with a range of complications, including musculoskeletal disorders (MSDs). Managing obesity typically involves weight loss through lifestyle changes, medications, or bariatric surgery. However, losing a significant amount of weight can sometimes have unintended effects, such as the loss of fat-free mass (FFM), which includes muscle and bone. This can worsen musculoskeletal health issues. This review explores how obesity treatments affect muscle and bone health and discusses ways to minimize these negative impacts.
To gather insights, we reviewed various studies that looked at how weight loss methods—like medications (e.g., GLP-1 receptor agonists) and bariatric surgery—affect muscle and bone health. We also examined research on sarcopenia, sarcopenic obesity, and changes in bone mineral density (BMD) after weight loss. The findings show that weight loss interventions, especially bariatric surgery and certain medications, often lead to a significant reduction in fat-free mass, including muscle. This can result in sarcopenia, reduced physical ability, and a higher risk of fractures due to weaker bones. In some cases, up to 25% of the total weight lost can come from muscle and bone, with older adults being particularly at risk. To combat this, it's important to focus on proper nutrition, especially getting enough protein, and incorporating strength training exercises to help maintain muscle and bone mass during weight loss.
While losing weight is crucial for managing obesity and its related health issues, it's equally important to address the potential risks to musculoskeletal health. A well-rounded approach that includes nutritional support and regular physical activity is key to preserving muscle and bone health, ensuring better long-term outcomes for obesity treatment. More research is needed to improve these strategies and develop new ways to protect musculoskeletal health during weight loss.

10 YEAR TREND OF THE PREVALENCE OF KNEE OSTEOARTHRITIS IN JAPAN USING THE ROAD COHORT DATA

G. Tanegashima[1], T. Iidaka[2], N. Yoshimura[2]

[1]Department of Orthopaedic Surgery, Sensory and Motor System Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Department of Prevention Medicine for Locomotive Organ Disorders, 22nd Century Medical and Research Center, The University of Tokyo, Tokyo, Japan

[Objective]To unveil the long-term trend of prevalence in knee osteoarthritis in Japan.
[Material and Methods] In Japan, little is known about the prevalence of knee OA. To investigate the prevalence of Japanese population, we have initiated a large-scale nationwide cohort study known as Research on Osteoarthritis / Osteoporosis Against Disability (ROAD). In 2005-2007, we have recruited 3,040 participants (1,061 men, 1,979 women; mean age 70.3 years) over three diverse communities and set up a baseline survey. The Xray of knee joints was performed and we evaluated osteoarthritis (OA) of the knee joints by using Kellgren-Lawrence grading system. KL>=2 was diagnosed as knee OA. 10 years later, at the same three communities, we have conducted the fourth survey with 2,893 participants (895 men, 1,998 women; mean age 70.7 years), and compared the prevalence of knee OA between the baseline and the fourth survey.
[Results]We have already reported the prevalence of knee OA was 54.6% (men 42.0%, women 61.5%) at the baseline period. 10 years later, at the fourth survey, however, the prevalence of knee OA in 2,893 participants was 39.3% (men 26.9%, women 44.9%), which indicated prevalence of knee OA had gradually lowered in the 10 years (p<0.001). After the logistic regression analysis adjustment for age, sex, and area, the same tendency remained (p<0.0001).
[Conclusion]From the long-term observation results of the community-based cohort, it became evident that the prevalence of knee osteoarthritis (OA) is decreasing. We have already reported from the observation of the ROAD study that the prevalence of osteoporosis and degenerative hip OA is lower in the current generation compared to the same age group ten years ago. Similarly, in the long-term trend of knee OA, we observed a similar tendency. When combined with these results, it suggests that the bone and joint health of Japanese people is improving over the 10 years.

P551

FUNCTIONAL OUTCOMES AFTER ARTHROPLASTY USING THE "BIKINI" INCISION FOR HIP SUBCAPITAL FRACTURES

G. Tsounaka[1], S. Maragos[2], K. Vardakastanis[3], S. Xergia[1]

[1]Department of Physiotherapy, School of Health Rehabilitation Sciences, University of Patras, Patras, Achaia, Greece, [2]Orthopaedic Departement, General Hospital of Lefkada, Lefkada, Greece, [3]Medical Advisor, Patras, Greece

Objectives
In recent years, more surgeons have opted for the anterior approach for hip replacement, a variation of which is the "Bikini" incision. This method is usually not only for arthroplasties after osteoarthritis, but also for hip fractures -although rarely. This study aims to document short-term outcomes in terms of functional recovery and complications in hip subcapital fractures after arthroplasty using the "Bikini» method.
Materials and Methods
This study included 31 patients with an average age of 81.32+-9.74 years and an average Body Mass Index (BMI) of 28.46+-6.25, who underwent total or partial hip arthroplasty after a subcapital hip fracture using the "Bikini" method. Postoperative complications and length of hospital stay were also recorded. The pain levels, the hip function, the balance, and the quality of life were evaluated using the Visual Analog Scale (VAS), the Harris Hip Score (HHS)(3), The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), the Time Up and Go (TUG) test, and the 36-Item Short Form Survey (SF-36) respectively. The evaluations were conducted preoperatively and postoperatively at 1,3, and 6 weeks and at 3 and 6 months. The Statistical Package for the Social Sciences (SPSS28.0) was used for the statistical analysis, which included tests for normality and the appropriate correlations between the variables at the assessed time points.
Results
Postoperative pain level was low on the VAS, with statistically significant differences in the 3rd week. The hip function and the walking speed showed improvement with statistically significant differences in the TUG test and WOMAC (p=0,004 and p=0,002 respectively) in the 6th week, while SF-36 values were high in every sub-category studied. Four postoperative complications were recorded: one of which was a delayed wound healing, a second was a seroma and two more were periprosthetic fractures.
Conclusions
The "Bikini" incision approach for treating hip fractures is recommended as safe and appears to shorten the hospital stay, reduce complication frequency, and promote recovery of the patients. Moreover, the low postoperative pain level rapid functional recovery, and patient independence, make it increasingly preferred for hip surgeries.

MONITORING THE STATE OF THE MUSCULOSKELETAL SYSTEM IN UNIVERSITY STUDENTS AS A PREDICTOR OF THE RISKS OF DEVELOPING ITS DISEASES

E. E. Ibragimova[1], G. V. Reshetnik[1], V. B. Kaliberdenko[1], G. V. Nikolashin[2], M. Nikolashin[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, [2]St. Luka Multidisciplinary Clinical Hospital of V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: Musculoskeletal disorders (MSD) are common among university students. This necessitates monitoring to identify MSD disorders in students in order to prevent the development of serious disorders in the future.
Methods: MSD disorders were monitored using the somatoscopic method, postural disorders were diagnosed by calculating the shoulder index according to V.K. Asymmetry was determined by measuring the distance from C7 (7th cervical vertebra) to the left - S1 and right - S2 scapula. Flat feet were determined by calculating the podometric index using the Friedland method. The reliability of the data obtained was assessed using Student's t-test. The closeness of the relationship between the obtained indicators was determined based on the Spearman rank correlation coefficient.
Results: During the somatoscopic examination of 83 students, 31.32% of the subjects had musculoskeletal disorders, 34.94% had flat feet of varying degrees, and 36.14% had asymmetry. Statistically significant ($p < 0.001$) gender differences in the studied parameters were found: 10.25% of boys had posture disorders, while 47.72% of girls had them. It was found that girls had more pronounced axial skeletal disorders with left-sided deformation. 5.13% of the examined boys had asymmetry: the difference in the distance from the C7 cervical vertebra to the shoulder blades varied from 1.5 to 2 cm. In 72.72% of girls, asymmetry varied from 0.5 to 2 cm. The incidence of flat feet in girls was 2.32 times higher than in boys. Calculation of the Spearman correlation coefficient (girls - $r = 0.311$; boys - $r = 0.4$) allowed us to identify a direct statistically significant ($p < 0.05$) relationship between the studied indicators (the value of the brachial index and the podometric index), the strength of the relationship according to the Chaddock scale is moderate. Statistically significant gender differences in the frequency of occurrence of combined disorders, which were 4.87 times ($p < 0.001$) more common in girls than in boys, may indicate the presence of physiological characteristics caused by complex hormonal changes in their bodies.
Conclusion: The results obtained indicate the need to monitor the state of the musculoskeletal system of students in order to identify functional disorders to prevent negative changes in the functioning of the body in the future.

P553

EFFECT OF TIBOLONE ON CORTICAL AND TRABECULAR BONE IN POSTMENOPAUSAL WOMEN COMPARED WITH ESTROGEN THERAPY

G.-A. Cruz-Priego[1], P. Clark[1], M.-A. Guagnelli[1], L. Humbert[2], S. Ortiz-Santiago[1], L. Castrejón-Delgado[3], M. A. Sánchez-Rodriguez[3]

[1]Hospital Infantil de México-Universidad Nacional Autónoma de México, Mexico City, Mexico, [2]3D-Shaper Medical, Spain, Spain, [3]Facultad de Estudios Superiores Zaragoza UNAM, Mexico City, Mexico

Objective: To evaluate the effects of 2.5 mg/day of tibolone compared to 0.625 mg/day of estrogen and placebo on cortical and trabecular bone in postmenopausal women at 6 and 12 months of treatment.
Material and Methods: A randomized controlled trial was conducted in postmenopausal women from Mexico City. Participants were divided into three groups: A) Tibolone 2.5 mg/day, B) Conjugated estrogens 0.625 mg/day with medroxyprogesterone 5 mg/10 days, and C) Placebo.
Hip aBMD was assessed at 6 and 12 months. Cortical and trabecular bone measurements were obtained using 3D modeling from DXA scans (3D-SHAPER v2.10.1, Galgo Medical, Spain). Parameters included cortical vBMD, cortical thickness, cortical surface BMD, and trabecular vBMD. Comparisons between groups were performed for these measurements.
Results: There were 22 participants in the tibolone group, 27 in the estrogen group, and 22 in the placebo group. At 6 months, hip aBMD increased by 0.34% in the tibolone group but decreased by 0.47% and 0.31% in the estrogen and placebo groups, respectively. Comprehensive vBMD increased by 0.77% in the tibolone group and 0.11% in the estrogen group, while it decreased by 1.04% in the placebo group. Trabecular vBMD increased by 1.51% and 0.65% in the tibolone and estrogen groups, respectively, but decreased by 1.5% in the placebo group. Cortical thickness increased by 1.69% in the tibolone group but decreased by 2.17% and 2.75% in the estrogen and placebo groups, respectively. 3D modeling provided valuable insights into whether changes in DXA aBMD were driven by trabecular or cortical compartments, highlighting more pronounced improvements in the tibolone group.
Conclusions: Tibolone therapy demonstrated a trend toward improvement in all parameters, with increases of up to 2% at the 6-month mark. These findings suggest tibolone could be a viable alternative to hormonal therapy, offering similar BMD benefits with fewer adverse effects. Greater improvements are expected with continued treatment at 12 months.

ASSOCIATION BETWEEN VERTEBRAL COMPRESSION FRACTURES AND LIFESTYLE HABITS

H. Ayano[1], K. Miwa[1], N. Makiko[1], M. Tatsuro[1], N. Kei[1], K. Mayo[1], Y. Naoya[1], Y. Toshiyuki[2], F. Kentaro[2], T. Yuki[1]

[1]Kawasaki Orthopedics and Rheumatology Clinic, Kawasaki, Kanagawa, Japan, [2]Saiseikai Yokohamashi Tobu Hospital, Yokohama, Kanagawa, Japan

[Objective] Japan is becoming a super-aged society, and the number of osteoporosis patients is increasing. It is known that vertebral compression fractures caused by osteoporosis have a significant impact on life prognosis as well as on the decline in activity. Lifestyle and nutritional intake, especially calcium intake, are also considered important in the prevention of osteoporosis. The purpose of this study was to evaluate and compare the relationship between vertebral compression fractures and lifestyle habits and calcium intake status.
[Subjects and Methods] This study included 477 female patients aged 50 years or older who underwent bone mineral density measured by dual-energy X-ray absorptiometry and completed a questionnaire at our clinic between November 2023 and October 2024. We used a medical questionnaire to investigating fracture risk factors (fracture history, symptoms, medical history, glucocorticoid use, etc.), lifestyle habits (walking duration, sun exposure, regular exercise, childhood exercise, dieting experience, smoking, alcohol consumption, etc.), dietary preferences, and calcium intake. We evaluated the relationship between vertebral compression fractures and the items in the medical questionnaire, extracted significant factors as explanatory variables, and performed logistic multivariate analysis (P<0.05).
[Results] Multivariate analysis identified the following factors as significantly associated with vertebral compression fractures: age (p=0.009), BMD T-score (p=0.018), history of respiratory disease (p=0.017), lack of childhood exercise experience (p=0.009), and low milk consumption frequency during elementary and middle school (p=0.031).
[Discussion] The present study suggests that increased age, low bone mineral density, history of respiratory disease, no childhood exercise experience, and low frequency of milk intake during elementary and middle school may be associated with the occurrence of vertebral compression fractures. These results reaffirm the importance of past and present lifestyle optimization and nutritional management in the prevention of osteoporosis. Further studies with a larger number of cases and multifaceted investigations that take other relevant factors into account are needed in the future.

BISPHOSPHONATES AND ORAL HEALTH: BRIDGING KNOWLEDGE GAPS AMONG DENTISTS

M. Dhifallah[1], H. Bettaieb[1], S. Jemli[2], A. Mtiri[2], M. Boudokhane[1], M. H. Doggui[1], S. Belakhel[1]

[1]Internal medicine, Internal Security Forces Hospital, La Marsa, Tunisia, [2]Dentistry, Regional hopital of Ben Arous, Ben Arous, Tunisia

Background/Aims: Bisphosphonates (BPs), powerful pharmacological agents that inhibit bone resorption, are frequently used in rheumatology. Dentists play a crucial role in educating patients treated with these drugs, particularly regarding the risk of osteonecrosis of the jaw (ONJ). Our objective was to assess dentists' knowledge and practices concerning BPs. **Methods:** This was an observational, cross-sectional study conducted among dentists. They were invited to complete an anonymous, self-administered questionnaire distributed via Google Forms. The questionnaire covered the demographic characteristics of the practitioners, their knowledge, and their practices regarding the oral health management of patients on BPs. **Results:** A total of 46 dentists (41 women and 5 men) responded to the questionnaire. The average age was 32.5 ± 4.78 years, and the average duration of practice was 6.17 ± 4.43 [1-21] years. Fifty-seven percent (55.3%) of practitioners worked in a public setting. Forty participants (87%) reported seeing fewer than five patients on BPs per month, 10.9% (n=5) saw between five and ten patients, and 2.2% (n=1) saw more than ten. Seventeen percent of them had observed at least one case of BP-induced ONJ. According to the participants, the indications for BP use were as follows: osteoporosis (according to 89.1%), bone metastases (according to 80.4%), multiple myeloma (according to 45.7%), Paget's disease (according to 39.1%), and primary hyperparathyroidism (according to 2.2%). Three participants did not know any indications for BPs. Regarding associated adverse effects, all participants recognized ONJ, but only 56.5% mentioned atypical fractures, and 23.9% noted gastrointestinal issues. The risk factors for ONJ identified included the injectable

form of BPs (n=35), recent tooth extraction (n=33), the malignant nature of the underlying disease (n=18), corticosteroid use (n=14), and untreated periodontitis (n=13). Half of the dentists (n=53) believed that tooth extraction should be performed before starting BP therapy. Additionally, 59.4% felt that mucosal healing time is essential, while 43.4% considered that bone healing is desirable. Among the participants, 53.8% felt that their level of knowledge was sufficient, while 29.2% reported lacking knowledge. Only 17.9% had attended specific training on BPs. Furthermore, 95.3% (n=101) of them recommended the development of national guidelines in collaboration with various specialists. Conclusion: This study reveals that while Tunisian dentists are generally aware of the risks associated with BPs, particularly ONJ, gaps remain in their knowledge of other adverse effects and in the management of patients on these treatments. Enhancing continuous education and establishing appropriate protocols will help improve the quality of oral care for at-risk patients.

PREVALENCE AND ASSOCIATED FACTORS OF FIBROMYALGIA IN PATIENTS WITH DIABETES MELLITUS

H. Bettaieb[1], D. Zghal[1], M. Boudokhane[1], W. Helali[1], R. Bourguiba[1], C. Besrour[1], M. H. Douggui[1], S. Bellakhel[1]

[1]Department of internal medicine , Internal Security Forces Hospital, Tunis, Tunisia

Objective:
The aim of this study is to evaluate the prevalence of fibromyalgia (FM) among patients with diabetes mellitus (DM) and to explore possible contributing factors.
Material and methods:
This is a cross-sectional study collecting data from patients with DM. Demographic characteristics, hemoglobin A1c (HbA1c) levels, type of diabetes (DM1 or DM2) and complications related to disease were collected. Patients with diabetic neuropathy or musculoskeletal disorders were excluded. All participants completed the Fibromyalgia Rapid Screening Tool (FiRST) questionnaire. A diagnosis of fibromyalgia was considered if a score of at least 5 out of 6 is achieved. Statistical analysis was performed using SPSS software, with a significance threshold set at $p<0.05$.
Results:
One hundred patients (61 men and 39 women), with a mean age of 57.6 ± 13.5 years, were included. Of these, 94% had DM2 and 6% had DM1. The median disease duration was 8.5 [0-37] years. Thirteen patients (13%) had microvascular complications: diabetic retinopathy (n=5) and diabetic nephropathy (n=14). Fifty-four patients (54%) were insulin-dependent. The disease was poorly controlled in 40% of patients with a median HbA1c level of 8.6 [4.7-18.9] %.
According to the FIRST, 46% of patients had FM with a mean FiRST score of 3.08 ± 2.04. In the analytical study, FM was significantly associated with the following parameters: older age ($p=0.001$), female sex ($p<0.0001$), longer disease duration ($p<0.0001$) and higher HbA1c level ($p=0.04$). A significant positive correlation was noted between the FiRST score and age ($r=0.344$; $p<0.001$) as well as the duration of the disease ($r=0.49$; $p<0.001$). However, no association was found between the occurrence of FM and these parameters: type of DM ($p=0.68$), insulin therapy ($p=0.67$), the presence of diabetic retinopathy ($p=0.62$) or nephropathy ($p=0.38$).
Conclusion:
Our study shows a high prevalence of concomitant FM in patients with diabetes mellitus. Optimal disease control and regular screening of FM—particularly in patients with risk factors—are mandatory to improve clinical outcomes.

ANNOUNCING JUVENILE IDIOPATHIC ARTHRITIS: CHALLENGES ENCOUNTERED BY TUNISIAN RHEUMATOLOGISTS

H. Bettaieb[1], I. Weslaty[1], M. Boudokhane[1], M. H. Douggui[1], S. Bellakhel[1]

[1]Department of internal medicine , Internal Security Forces Hospital, Tunis, Tunisia

Objectives: The aim of this study was to assess the perception of Tunisian rheumatologists when faced with the need to announce the diagnosis of Juvenile idiopathic arthritis (JIA).
Material and Methods: We conducted a cross-sectional descriptive study among Tunisian rheumatologists. Participants were invited to answer an anonymous web-based questionnaire. The data were analyzed with descriptive statistics using the SPSS statistical package.
Results: A total of 34 rheumatologists (30 women and 2 men) responded to the questionnaire. The mean age was 31.5 [26-43] years. They were as follows: 44.1% residents (n=15), 41.2% (n=14) rheumatologists in the public sector and 14.7% (n=5) rheumatologists in the private sector. Overall, 64.7% (n=22) of participants provide care for paediatric patients. Only 5.9 % of them report receiving courses in the field of announcing the diagnosis of JIA. Physicians assessed their general self-efficacy in communication skills as follows: 17.6 % (n=6) good, 55.9% (n=19) satisfactory and 26.5% (n=9) poor.
At JIA announcement, 44.1% (n=15) of participants claim that they always explain the disease to the parents and 44.1% (n=15) of them assert that they do so frequently. Furthermore, 20.6% (n=7) of rheumatologists consistently involve the children, while 76.5% (n=26) adapt their approach depending on the age of the child. Only 47.1% (n=16) of physicians use resources when announcing JIA: therapeutic patient education sessions (39.4%), explanatory brochures (18.2%), videos (6.1%) and continuing professional training courses (3%).
The dominant reported feelings when announcing the diagnosis were as follows: empathy (n=27), anxiety (n=11), apprehension (n=4), and confidence (n=9). According to participants, the main challenges include: effectively managing the patient's emotions (n=27), answering family questions (n=25), tailoring information to the child's age (n=24), offering sufficient emotional support (n=19) and empathizing with the child (n=16).

Conclusion: This study illustrates the challenges faced by Tunisian rheumatologists when announcing JIA. Many of them report not being properly trained to cope with this situation. These findings underscore the need to target the training gaps in communication skills among these physicians within this field.
